Keywords: exosomes, proteomics, nLC-MS/MS

Introduction:

Exosomes are cell-derived nanovesicles that are secreted from all types of cells and are present in all body fluids. Tumor derived exosomes contain molecules derived from the tumor, and thus represent an opportunity for health monitoring and diagnosis[1].

Here an exosome proteome purification procedure has been developed with the aim to purify exosomes from low sample amount and to study the correlation between exosome cargo and cancer progression.

Methods:

Exosomes were purified from 100 ul serum. Serum was previously depleted from bigger vesicles.

Exosomes were then isolated by precipitation and the resulting pellet was ultra-filtrated on 3kDa spin filters, vesicles were lysed, and proteins concentrated. After protein digestion, peptides were analyzed by bottom-up-LC-MS/MS. To reduce the serum proteins level size exclusion chromatography(SEC)has been investigated as an additional purification step.

Results:

350 protein groups were identified, and which included 14 of the top 25 frequently identified exosomal proteins defined by the ExoCarta database. Functional enrichment analysis of the proteomics data was performed for cellular component geneontology. Gene ontology analysis performed by STRING reported the presence of exosomal proteins (194 proteins in GO:0070062, FDR: 1.87e-122), PANTHER reported vesicles as the main category present in the sample (135 proteins). Serum albumin, immunoglobulins and protein of the complement system were also identified in the EVs-UF-precipitated samples, indicating that the samples also contained soluble proteins as impurity. Serum exosomes purified by SEC reported lower level of albumin, immunoglobulins and complement system proteins showing the ability of the columns to further purify exosomes from contaminants.

Conclusions:

Our exosomes purification procedure will be applied to purify exosomes from cancer patient serum with the aim to study the role of these vesicles in inter-cellular communication and to study the correlation of exosome cargo and tumor progression. Further scaling down of the procedure will be evaluated so as to be able to analyze an even lower amount of starting sample.

Novel Aspect:

This procedure enable the in depth proteome analysis of vesicle cargo starting from very low amount of sample. Proteomics analysis of exosomes by bottom-up-LC-MS/MS have been overwhelmingly performed on exosomes purified by ultracentrifugation, but which requires a lot of sample volume available and thus is not feasible on the serum from individual mice (circa 100ul available from a single mouse) for studying cancer mouse models [2]. The exosomes purification method reported here enables the analysis of exosomes from individual mice.

Mass spectrometry based proteomics and metabolomics are fast growing and powerful technologies, with the potential to revolutionize health care and precision medicine. However, separation technologies has so far limited throughput and robustness and thereby prevented omics technologies from being fully integrated and routinely used in a clinical setting. Here we describe a conceptually novel low-flow chromatography system that delivers the robustness and throughput required for clinical applications while maintaining the sensitivity of current nano-flow LC instrumentation. The new system uses four low-pressure pumps in parallel to elute samples from a disposable trap column while simultaneously creating a final but offset chromatographic gradient with embedded analytes.

Initially, two low-pressure pumps form a primary gradient that flows through a disposable trap column thereby eluting analytes of interest while two additional low-pressure pumps positioned right after the trap column are modifying the eluent to create an "offset" that increases the retention of the now embedded analytes at the separation column. The offset gradient with the embedded analytes are removed into a long, narrow holding loop that subsequently is switched in-line with a single high-pressure pump and a separation column. Thus elution from the disposable trap column and gradient formation become de-coupled from the high-pressure separation.

We have characterized the performance of the new system regarding cross contaminations (<0.05%, total TIC), retention time shifts and peak widths (<8.5 sec) in over 1,500 HeLa runs. The extremely short overhead time of approximately 3 min/gradient allowed us to measure 60 samples per day (21 min gradient, 3 min overhead time) compared to 40 samples with a standard nano-LC systems (22 min gradient, 15 min overhead time). To benchmark reproducibility, we measured 100 human plasma samples in 40 hours and each resulted in several hundred quantified plasma proteins, including more than 50 FDA-approved biomarkers. Assured of a high reproducibility, we then aimed to find significant biological information in the human plasma proteome. For this purpose, we analyzed a longitudinal weight loss study that included a total of 319 plasma samples, where we found strongest effects on proteins of the lipid metabolism and inflammation system.

1149 - CLUSTER-ASSEMBLED SMART SURFACES FOR ON-TARGET PROCESSING OF BIOLOGICAL SAMPLES IN MALDI-MS ANALYSIS

Emanuele Barborini (1) - Simone Vinati (1) - Giacomo Bertolini (1) - Marc Baumann (2)

Tethis SpA, R&D, Milan (1) - University of Helsinki, Clinical Proteomics Unit, Helsinki (2)

Keywords: MALDI target, Imaging, processing, film, nanoparticles

Introduction

Matrix-assisted laser desorption/ionization mass spectrometry (MALDI-MS) is a powerful analytical tool endowed with the capability to analyze biological samples ranging from biomolecules to micro-organisms, up to whole histological sections. Due to the complexity of such analytes, there is the need for ad-hoc sample pre-processing (e.g. washing, reduction/alkylation, enzymatic cleavage), which can be performed on-target, through the use of smart surfaces.

Methods

Cluster Beam Deposition [1,2] was adopted to deposit patterned functional films made of ultrafine TiO₂ nanoparticles, either on polymeric, metallic and glass slides at room temperature. Peculiar nanoporosity and bio-affinity of this material play a synergic role in sample capturing. TiO₂ super-hydrophilicity by UV irradiation [3] provides uniform spreading of liquid samples and optimal adhesion of histological sections onto the patterned functional areas.

Results

Hydrophobic barrier at the border of the super-hydrophilic functional areas acts as an effective droplet confinement structure, which allows easy and reliable on-target processing of liquid-phase samples. In comparison with standard in-vial approach, on-target processing of protein samples (including secondary cleaning and Trypsin digestion) avoids the loss of sample fractions, due to cleaning, as well as of peptide fractions due to their capture on vial plastic walls. Regarding histological samples, improved adhesion avoids detachment, tearing and shrinking, during tissue processing (e.g. dehydration, delipidation, fixation). Improved adhesion can also benefit pharmaco-kinetic studies, where any tissue treatment should a-priori be excluded [4]. Tissue stability permits matrix removal after MALDI Imaging, in order to carry out immunohistochemical analysis on the very same section. In general, nanoscale surface roughness offers distributed nucleation points favoring uniform and homogeneous crystallization of MALDI matrix.

Conclusions

Advanced surface engineering concepts have been adopted to develop innovative MALDI targets aiming to reliable on-target sample processing. Advantages were thoroughly demonstrated with protein samples, subjected to secondary cleaning and Trypsin digestion, and with histological samples subjected to harsh chemical treatments prior MALDI Imaging. Benefits are also expected in pathogen analysis as well as in robotic sample processing for clinical diagnostics.

Novel Aspect

Improved on-target sample processing in MALDI-MS through the use of nanoporous bio-affine films made of ultrafine TiO₂ nanoparticles deposited on any kind of a substrate.

Keywords: clinical proteomics, label-free, EvoSep, bronchioalveolar lavage, iron cobalt oxide nanoparticles

Introduction:

Magnetic nanoparticles are of great interest in biomedicine (e.g. magnetic resonance imaging, targeted tumor therapy), however, their biocompatibility is an ongoing concern and large-scale *in vivo* toxicology studies are mostly lacking. Here we examined the effects of magnetic iron and cobalt oxide nanoparticles on the lung in mice using label-free quantitative proteomics. The new EvoSep LC system, specifically developed for clinical proteomics, was evaluated.

Methods:

Toxicity of iron cobalt oxide nanoparticles was examined *in vivo* by intratracheal instillation in mice. Bronchioalveolar lavage fluid (BALF) samples were collected at day 1 and 3 post exposure. Nanoparticles with different iron cobalt composition were included (Fe Co: 1:0, 3:1, 1:1, 1:3, 0:1) testing two doses (54 µg, 162 µg). The BALF proteome of 168 mice was profiled by label-free LC-MS/MS (EvoSep coupled to Orbitrap Fusion Lumos, Thermo) using 21 min gradients.

Results:

Performance of EvoSep was evaluated. Average Pearson correlation coefficient of 0.99 was determined among 16 technical replicates demonstrating very high reproducibility. To increase identification and quantification a mix of representative samples was separated by high pH fractionation and measured in parallel. Biological replicates (168 BALF samples) were run as single shot injections using 21 min gradients. A total of 1400 proteins were quantified with average of 400 proteins per biological replicate (min: 269, max: 602). Statistical analysis was performed by empirical Bayes moderate T test incorporated in the Limma package. Differentially expressed proteins were clustered and enrichment analysis was performed. Highly enriched were proteins associated with extracellular vesicles, stress and immune response, as well as glutathione metabolism, response to metal ion and reactive oxygen species. To assist pathway identification in-depth BALF library from high pH fractionation was included in the bioinformatic analysis.

Conclusions:

We present here a proteomic toxicity screening testing simultaneously 6 different nanoparticle types (magnetic iron cobalt oxide nanoparticles with Fe Co ratio: 1:0, 3:1, 1:1, 1:3, 0:1; carbon black as control), after pulmonary inhalation at two time points and two concentrations. As demonstrated EvoSep combined with short LC gradients and high-resolution mass spectrometry enables high-throughput proteome profiling of clinical samples such as BALF or plasma.

Novel Aspect:

The EvoSep LC system designed for clinical proteomics allowing for high throughput and robust measurement was tested on real-life samples.

209 - A NOVEL MASS SPECTROMETRY BASED ASSAY FOR THE DIAGNOSIS AND TYPING OF SYSTEMIC AMYLOIDOSIS

Paul Boersema (1) - Ting Huang (2) - Johan Bijzet (3) - Christian Zimmerli (4) - Olga Vitek (2) - Bouke Hazenberg (3) - Paola Picotti (5)

ETH Zurich, Institute of Molecular Systems Biology, Zuerich (1) - Northeastern University, College of Computer and Information Science, Boston (2) - University Medical Center Groningen, Rheumatology, Groningen (3) - ETH Zurich, Institute of Molecular Systems Biology, Zurich (4) - ETH Zurich, Institute of Molecular and Systems Biology, Zurich (5)

Keywords: systemic amyloidosis, SRM, diagnosis, fat tissue aspirates, clinical

Introduction:

In systemic amyloidoses (SA) different precursor proteins misfold, aggregate as amyloid fibrils and are deposited in various tissues. Correct identification of the precursor amyloid protein is key for successful clinical treatment. However, current diagnostic approaches are lacking. We developed an LC-MS method that assays in one analysis the major specific systemic amyloidosis proteins, their mutations and additional proteins as generic indicators of SA.

Methods:

We developed an SRM-MS assay targeting 13 major SA proteins and often-occurring mutations plus 20 additional proteins. To improve peptide detectability and allow for intra-sample and batch normalization, we spiked in heavy isotope labeled synthetic peptide analogs for all targeted peptides and iRT peptides. The final assay, containing 289 precursors and 1134 transitions, was condensed to a single, 35 minute LC-SRM-MS analysis method.

Results:

A 1- μ g fraction of the trypsin digested tissue is enough to perform the developed SRM-assay. After target peptide and transition selection and optimization together with retention time scheduling, we could quantitatively measure more than 1000 transitions in a 35 minute LC gradient.

Three sets of in total 226 samples consisting of control samples and patient samples with varying levels of the SA types ATTR, AA, AL-L and AL-K were measured with the SRM-assay. One set was used to create a prediction model based on amyloid protein intensities. The two other sets were used to test and validate the prediction model. The amyloidogenic precursor protein was correctly detected with >80% specificity and sensitivity. The correctness of diagnosis increased with increasing disease severity. Potentially present mutations could be detected simultaneously with the assay.

Conclusions:

An amyloid signature of 20 proteins was developed to diagnose the presence of amyloid fibrils in fat tissue aspirates from systemic amyloidosis patients regardless of type and to gauge SA severity.

The high specificity and sensitivity of the assay combined with its relative straightforwardness make it an interesting alternative to the contemporary SA diagnosis pipeline.

Novel Aspect:

Single, 35-minute LC-SRM assay simultaneously diagnoses, types and grades 13 different SA types including their potential mutations.

1317 - ANALYSIS AND CHARACTERIZATION OF GASTROINTESTINAL METABOLISM OF MAJOR SOY ALLERGENS GLYCININ AND B-CONGLYCININ IN AN IN-VITRO MODEL BY LC-MS/MS

Julia Bräcker (1) - Natalie Lok (2) - Jens Brockmeyer (1)

University of Stuttgart, Food Chemistry, Stuttgart, Germany (1) - University of Hohenheim, Institute of Food Chemistry, Stuttgart, Germany (2)

Keywords: food allergens, in-vitro digestion model, LC-MS/MS, label free quantification, proteomics

Introduction:

Soy is one of the eight major allergenic foods, that can cause severe reactions. But little is known so far about the fate of allergenic soy proteins during gastrointestinal digestion. Beside already published potential epitopic regions of different soy allergens with the ability to bind Immunoglobulin E and cause an allergic reaction, there is still no profound knowledge about kinetics of allergen degradation and characterization of degradation products [1].

Methods:

The three phases of human gastrointestinal digestion of dried soy beans were simulated with a standardized in-vitro digestion model [2]. While time dependent degradation of intact soy proteins was analyzed by SDS-PAGE, the identification of the highly complex set of degradation products was performed by micro-LC-MS/MS on a Q-TOF instrument in a software assisted proteomics approach. Degradation rates were estimated by label-free quantification for each phase.

Results:

For major soy allergens β -Conglycinin (Gly m 5) and Glycinin (Gly m 6) degradation was observed during gastrointestinal digestion. Gly m 5 β -subunit showed the highest stability during gastric digestion whereas α -subunits of Gly m 5 and Gly m 6 subunits were largely degraded during 30 minutes of gastric digestion. For both phases highly complex mixtures of low-molecular products (Gly m 5: 121 peptides, Gly m 6: 405 peptides) could be identified. Gastrointestinal digestion seems to follow a multi-step mechanism in repetitive patterns regarding time dependent formation and degradation kinetics of peptides with different length. Investigation of digestion kinetics by label-free quantification verifies that some proteins are degraded into larger peptides at an early digestion state, whereas others are degraded as late as in the end of gastric phase. Regions in the amino acid sequence overlapping with previously identified epitopes could be determined, suggesting that these peptides can trigger allergic reactions after intestinal absorption.

Conclusions:

By Simulation of gastrointestinal digestion of soy in an in-vitro model time dependent degradation of major soy allergens β -Conglycinin und Glycinin could be determined as well as differences in formation kinetics of degradation products. Additionally, degradation products of both allergens with intact epitopic regions could be identified, keeping the ability of IgE-binding to potentially cause an allergic reaction after absorption by the intestinal mucosa.

Novel Aspect:

Time dependent degradation of allergens and formation of potential allergenic products could be observed by simulated gastrointestinal digestion in an in-vitro model.

⁴ Department of Sciences and Technological Innovation, University of Piemonte Orientale, Alessandria, Italy

Keywords: Mesenchymal stromal cells, Extracellular vesicles, Shotgun Proteomics

Introduction:

Mesenchymal stromal cells (MSCs) are adult multipotent stem cells used for regenerative medicine and immunomodulation [1]. Extracellular vesicles (EVs) released by MSCs act as their paracrine effectors by delivering transcription factors, oncogenes, mRNA, microRNA, and proteins to target cells [2]. In this study, we have investigated the immunomodulatory capabilities of EVs derived from primed-MSCs (pEVs) compared to control (cEVs), through a SWATH-MS approach.

Methods:

Shotgun mass spectrometry (MS) analysis has been performed on pEVs and cEVs in order to characterize and compare their proteomic profile. Proteins differentially expressed were evaluated in silico using different bioinformatic prediction tools. Multivariate pattern recognition methods like Principal Component Analysis (PCA) and Partial Least Squares Discriminant Analysis (PLS-DA) were also employed. Selected proteins and pathways were validated using Western Blot and flow cytometry analysis respectively.

Results:

Shotgun proteomic analysis revealed in pEVs, a strong modulation of proteins involved in many processes related to immune response. The results obtained through SWATH-MS analysis, were validated through western blotting, by selection of four candidate proteins according to their immunomodulatory potential. Proteins differentially expressed in p-EVs compared to c-EVs were mapped to terms in the GO database. Biological process classification showed enriched terms categories such as “leukocyte migration”, and “leukocyte cell-cell adhesion” suggesting a possible involvement of pEVs in modulating immune effector cells activity. Enrichment analysis of pEVs downregulated proteins revealed that the top four identified pathways are: “PI3K-AKT signalling pathway”, “regulation of actin cytoskeleton”, “focal adhesion” and “leukocyte trans-endothelial migration”. The expression and phosphorylation profile of different components of PI3K-AKT signalling pathway was evaluated by flow cytometry in activated B lymphocytes. Our results showed that, the treatment with pEVs, induced a significant down regulation of the pathway compared to cEVs.

Conclusions:

The molecular characterization at protein level of pEVs derived from MSCs, and the consequent functional validation of candidate pathways in activated B lymphocytes, will suggest novel therapeutic perspectives for the treatment of inflammatory and autoimmune diseases.

740 - CONCURRENT QUANTIFICATION OF SYNAPTOTAGMIN-1 AND SNAP-25 IN CLINICALLY RELEVANT VOLUMES OF CSF BY IMMUNOAFFINITY LC-MS/MS

Ann Brinkmalm (1) - Annika Öhrfelt (1) - Lutz Frölich (2) - Lucrezia Hausner (2) - Henrik Zetterberg (1) - Kaj Blennow (1)

The Sahlgrenska Academy at University of Gothenburg, Institute of Neuroscience and Physiology, Department of Psychiatry and Neurochemistry, Mölndal (1) - University of Heidelberg, Department of Geriatric Psychiatry, Central Institute for Mental Health Mannheim, Mannheim (2)

Keywords: PRM-MS, immunoprecipitation, cerebrospinal fluid, synaptic proteins

Introduction:

Reduction of synaptic activity is an early event in several neurodegenerative diseases. In two earlier studies we have used affinity purification combined with PRM-MS to demonstrate increased CSF levels of the synaptic proteins synaptotagmin-1 and SNAP-25 in patients with Alzheimer's disease compared with controls(1, 2). In this study the strategy was further developed to concurrently measure levels of both proteins in individual patient CSF samples.

Methods:

The immunoprecipitation was performed on a KingFisher™ Flex System which uses magnetic rods to move particles through the various binding, mixing, washing and elution phases in a 96 well plate format. HR-PRM analyses were performed on a Q Exactive™ Hybrid Quadrupole-Orbitrap™ MS coupled to an Ultimate 3000 standard liquid chromatography system. The instrument was set to acquire scheduled pairs of PRM scans in profile mode.

Results:

In this study, we developed and validated a high-throughput assay for concurrent quantification of synaptotagmin-1 and SNAP-25 in clinically relevant volumes of CSF. The assay was utilized to compare the levels of synaptotagmin-1 and SNAP-25 in a clinical cohort with CSF samples from patients diagnosed with early AD, prodromal AD, mild cognitive impairment, late AD, mixed AD, and non-demented controls. The increased CSF levels of both synaptotagmin-1 and SNAP-25 in AD patients compared to controls are in agreement with the results from two previous studies where CSF synaptotagmin-1 and SNAP-25 were quantified separately.

Conclusions

We have shown that automated immunoprecipitation combined with PRM-MS is robust and sensitive enough to concurrently measure two synaptic proteins in CSF from individual patients.

Novel Aspect:

This platform will make it feasible to perform larger and diagnostic diversified studies as well as adding other biomarkers mirroring other pathologies.

Keywords:

Introduction:

Comprehensive, robust, high-throughput analysis of the plasma proteome has the potential to enable analysis of the health state. Up to now, analysis of the plasma proteome was achieved using delicate nano-flow setups. To reduce this limitation, we established a robust capillary-flow LC-MS-DIA setup capable of measuring 32 plasma proteomes a day. Using this setup, we acquired the samples of a large-scale weight loss and maintenance plasma sample study (DiOGenes).

Methods:

Plasma samples were randomized and prepared with an optimized in-solution digestion protocol and spiked with Biognosys' PlasmaDeepDive. The samples were acquired on a Thermo Scientific Orbitrap Fusion Lumos connected to a Waters M-class UPLC and a 300µm*150cm Waters CSH 1.7µm column. DDA runs were performed using HPRP fractionation. DIA was done in a 45 min injection-to-injection mode. Analysis of DIA runs was performed using Spectronaut Pulsar.

Results:

After testing several combinations, we obtained optimized conditions using a 300 µm inner diameter column. This setup has the advantage of offering increased flow rates (5 µl/min) resulting in small injection-to-injection overhead times (i.e., 5 min). A gradient of 40 min was determined as an optimal gradient length, resulting in 90% of the maximally achieved identifications with longer gradients. Further characterization of the system showed precise quantification of 47 FDA approved plasma biomarkers (CVs below 20%).

We successfully used this capillary LS-MS DIA setup to acquire 1,508 (plus 66 control pools) samples of the DiOGenes project. We identified in average 450 proteins per samples and achieved a dataset completeness of 77% at the protein level. Proteins of the inflammation system were the most variable and proteins involved in blood coagulation were the least variable protein groups. Unsupervised clustering showed that the weight loss was most severe intervention accompanied with significant protein changes in plasma.

Conclusions

Differential abundance analysis identified proteins to be significantly differential between all of the time points revealing biology. Non-enzymatic addition of glucose to proteins (i.e., glycation) was detected and could be followed over the time course of the study. The PlasmaDeepDive kit could be used to perform extrapolation to all identified proteins enabled label-free absolute quantification of 490 additional proteins in of 1,472 plasma samples.

Novel Aspect:

High-throughput capillary-flow DIA of 1,574 human plasma proteomes with label-free absolute quantification and unbiased determination of glycation sites.

853 - IDENTIFICATION OF COMPLETE POOL OF BIO ACTIVE PEPTIDES IN MOUSE BRAIN STRIATUM INCLUDING SEPS, A NOVEL CLASS OF NON-CLASSICAL BIO ACTIVE PEPTIDES

Harshavardhan Budamgunta (1)

Center for proteomics, University of Antwerp/Biology, Antwerp (1)

Keywords:

short Open Reading Frame (sORF), Mass spectrometry, Bio active peptides, Peptidomics, sORF encoded polypeptides (SEPs).

Introduction:

Bio active peptides are involved in the regulation of major physiological processes that occur in an organism [1]. Classical bio active peptides are cleaved from their precursor and are directed towards the secretory pathway [2]. Recently, another novel class of bioactive peptides often termed as SEPs (sORF encoding polypeptides) alias micro peptides alias non-classical bio active peptides were discovered [3]. These are called non-classical because they are translated directly from small ORFs [3]. Therefore, they lack a signaling sequence and are released into the cytoplasm, not directed through the secretory pathway [3]. Despite their unconventional expression, some of these peptides are found to play critical functional roles [4-10]. The first SEP was discovered in *c.elegans* in 1996 [11]. From then, many sORFs were discovered in plants such as Polaris gene (*Arabidopsis thaliana*), ROTUNDIFOLIA4, Brick, Zm401 and Zm908p1 [12-16]. Recently, with the advent of ribosome profiling (an RNA sequencing technique), millions of sORFs potentially translated to peptides were discovered in *Saccharomyces cerevisiae*, *Drosophila melanogaster*, *Mus musculus*, *Danio rerio* and *Homo sapiens* by various research groups [17-18]. Although ribosome profiling experiments predicted SEPs that are being translated, proving their actual bio chemical existence is quite challenging. In 2012, with the aid of mass spectrometry 90 SEPs were identified in a human cell line [19]. This was followed by the identification of 237 SEPs in humans in 2017 [20]. Since their discovery, millions of SEPs were predicted through ribosome profiling data but only few (hundreds) SEPs were biochemically identified. Four challenges hamper these identifications. The peptides are thought to be in Low abundance (1) – In general natural peptides are less abundant than cytosolic proteins; 2) Narrow mass range – The mass range of SEPs is between 0 -10 KDa which is often missed in the regular proteomic analysis, therefore they are absent in most proteomic data repositories. In addition they often lack of cleavage site for the proteases; 3) Difficulties in data analysis – Search engines are typically not good to identify long peptides with multiple charges; 4) False positives – (During the database search) The databases that are typically used are concatenated ones that contains both known large proteins and predicted SEPs. Due to (up to) a 100 fold larger number of the predicted SEPs (millions) in the database when compared to known uniprot entries, false discoveries are likely to aggregate more in the SEP database. In present study, we performed an extensive analysis on mouse brain striatum sample with an intention to identify SEPs. In order to do so, we developed a protocol to overcome the challenges that arise during the process of identifying these peptides with a high confidence.

Methods:

The mouse brain peptides were extracted using a mixture of methanol:water:acetic acid (90:9:1). The peptides were fractionated into 20 fractions in reverse phase liquid chromatography. All the fractions are analyzed in nanoLC QExactive plus orbitrap mass spectrometer, 60 min linear gradient for each fraction. Two replicates for each fraction were run.

Peptide identification: A concatenated database was used: “mouse uniprot reviewed proteome downloaded on 2017-03-01 + predicted SEPs from mouse ribosome profiling data (sorfs.org) + contaminant database [2017-03-01]”.

The database searching is performed in three methods:

PEAKS (version 7.0, Bioinformatics Solutions Inc.) was used as the first strategy for the database search. Variable modifications used in the settings are: oxidation of methionine, C-terminal amidation of peptides, N-terminal acetylation of proteins, pyro-glu formation from glutamine and glutamic acid at N-terminus, acetylation of lysine, phosphorylation of tyrosine, threonine and serine.

The peptides are searched with Mascot (Version 2.1, Matrix science Pvt Ltd) and Sequest HT (University of Washington, USA) with no enzyme selected. The spectra from precursors with mass range from 500 to 10000 Daltons were selected for the identification process. The database search was conducted on deconvoluted data that was exported from PEAKS. The precursor mass tolerance was set to 10 ppm and the fragment ion mass tolerance was set to 0.02 Daltons. Only high confident peptides (1% False Discovery Rate) were chosen in this analysis.

Dynamic modifications including N-terminal acetylation of protein, N-terminal pyro-glutamic acid formation from glutamine, C-terminal amidation of peptide and oxidation of methionine were set as variable modifications. A global false discovery rate (FDR) for peptide and protein identification was set to 1%.

The third approach is similar to the second approach but without using a deconvolution step.

Peptide validation: After identifying peptides with high confidence. The resulting peptides were validated through four steps.

Manual verification of the fragmentation spectrum for the ion series match.

BLASTp analysis for the novelty of the identified SEPs. In this section, the fragment that is matched with the in-silico generated ion series was only searched through BLASTp but not the whole identified sequence.

MS2PIP based validation: MS2PIP is a tool that generate predicted ion peak signal intensities based on artificial neural network. The experimentally identified fragmentation spectra was be matched to the MS2PIP generated fragment intensities [21].

The sORF attributes such as ORF score, FLOSS score, Ribosome occupancy, conservation, and in frame coverage of the identified SEPs will be checked [18,22].

Only those peptides passing all validation steps, are considered confident. Finally experimental fragmentation spectra of the identified peptides were compared to that obtained from a synthetic equivalent.

Results:

In total 5650 unique peptides were identified combining both the replicates. Using charge state deconvolution of peptides, we observed 36% increase in unique peptide identifications and we identified longer peptides ranging from 0-85 AA long. Classical bio active peptides: 926 peptides originating from 37 neuropeptide precursors were identified. Non classical bio active peptides: 12 peptides originating from 4 SEPs were identified.

Prior to the validation steps, 53 putative SEPs were identified with 1% FDR (this number can be comparable to the previous studies identifying 90 SEPs). Out of the 53, 49 identifications passed through the first filter (manual sequence verification). Out of 49, only 11 identifications passed through the second filter (BLASTp based verification). Out of 11, 6 identifications survived the third filter (MS2PIP based validation). Out of 6, 4 SEPs passed through the fourth filter (sORF attributes cross check).

Conclusions:

A protocol to identify a complete set of natural bioactive peptides is created. Using this approach we identified 926 peptides originating from 37 neuropeptide precursors. To our knowledge, using peptidomics approach, this is the highest number of peptides derived from neuropeptide precursors identified in mouse brain in any study so far. Using a four step validation approach we effectively reduce the chances for eliminated false positive identifications and confidently identified 4 SEPs, out of which 3 SEPs are novel.

Novel aspect:

First, identification of 926 peptides originating from 37 neuropeptide precursors through peptidomics approach in mouse brain striatum is the highest number of unique peptide identifications reported till date.

Second, the concept of SEPs is relatively novel which originated in 1996. There are studies proving the functional importance of the SEPs. These SEPs can be a heavy interest for the pharmaceutical companies. Most importantly, we observed false positive identifications in the data where few studies claim to identify SEPs. In this study we proposed a method to eliminate the false positives and result with confidently identified SEPs. In our study we confidently identified 4 SEPS, out of which 3 SEPS are novel and not reported previously.

1301 - DIFFERENTIATION OF HYPERTENSIVE DISORDERS DURING PREGNANCY BASED ON URINE PEPTIDOME PROFILING BY HIGH RESOLUTION MASS SPECTROMETRY

Anna Bugrova (1) - Alexey Kononikhin (2) - Victoria Sergeeva (1) - Maria Indeykina (1) - Igor Popov (2) - Natalia Starodubtseva (3) - Vladimir Frankevich (3) - Evgeniy Nikolaev (4)

Emanuel Institute for Biochemical Physics, Russian Academy of Sciences, Moscow, Russian Federation (1) - Moscow Institute of Physics and Technology, Dolgoprudny, Moscow, Russian Federation (2) - V. Keywords: peptidomics, urine, preeclampsia

Introduction:

Accurate differential diagnosis of hypertensive disorders is important during pregnancy, because it affects the outcome for the mother and fetus. The high potential of urine peptidomics has been demonstrated for clinical purposes. Several MS based approaches have been successfully applied for urine peptidome analysis and potential biomarker search. Herein we apply LC MS to identify a peptide panel for differentiation of hypertensive disorders during pregnancy.

Methods:

A case-control study was designed for 64 women from 4 groups: preeclampsia (PE), superimposed PE, chronic hypertension, and healthy pregnant individuals. The urine peptidome fraction was separated using ultracentrifugation, purified by gel-filtration, and analyzed with nano-HPLC coupled to a high resolution 7T LTQ-FT Ultra (Thermo) mass-spectrometer and semiquantitative label free analysis was performed.

Results:

Analysis of the LC-MSMS data from different groups of patients showed that 36 peptides were common for them all. 22 belonged to alpha-1-chain of collagen I, 9 were from alpha-1-chain of collagen III, 2 from alpha-2-chain of collagen I, 1 from alpha-1/2-chain of collagen I, 1 from alpha-1-chain of collagen I/XVIII and one from uromodulin. Patients with hypertensive disorders had 34 common peptides: 12 from alpha-1-chain of collagen I, 10 from fibrinogen alpha-chain, 8 from alpha-1-chain of collagen III, and 4 per other types of collagen. The most important is a group of 16 peptides common for PE and superimposed PE cases. It consists of peptides from alpha-1-chain of collagen I, alpha-2-HS-glycoprotein, apolipoprotein A-I – one per each and the rest 13 belong to alpha-1-antitrypsin. Fibrinogen peptides in the urine point to inflammation processes and those of alpha-1-antitrypsin – to changes in metabolic ways of protein degradation.

Conclusions

Fragments of alpha-1-antitrypsin confirmed their importance as markers of pre-eclampsia suggested earlier. Statistical data analysis by non-parametric Kruskal-Wallis and Mann-Whitney tests showed the presence of 12 peptides differentiating at least one pair of groups.

Novel Aspect:

Comparative analysis revealed 12 peptides, which could be used as a diagnostic panel for confident discrimination of various hypertensive disorders.

834 - PROTEOMIC CHARACTERIZATION OF HUMAN PLATELET LYSATE BY LABEL-FREE NLC-MS/MS: TOWARDS THE EFFECTORS OF ITS BENEFICIAL EFFECT IN REGENERATIVE MEDICINE

Keywords: Regenerative medicine, Proteomics, platelet lysate, scaffold, MALDI imaging

Introduction:

Hydrogel-forming polymeric scaffolds (HyPS) provides a favourable 3D biomimetic and biodegradable environment for Human Mesenchymal Stromal Cells (hMSCs) [1]. Recently, in HyPS engineered with hMSCs, human platelet lysate (hPL) has been shown as highly effective to stimulate the hMSCs cell-growth and osteo-chondral differentiation [2-4]. The proteins responsible for its beneficial effect have been not yet clarified and will be herein investigated by MS.

Methods:

Quali-quantitative evaluation of hPL (n=4) compared to Platelets Poor Plasma (PPP)(n=4) was achieved by label-free shotgun proteomics. IgG and albumin depleted and not depleted samples were trypsinized [5] and analysed by nLC-UHRTOF. Data was submitted to PEAKS studio and Mascot.

Proteomic images of chondrogenic differentiated hMSCs from bone marrow (BM) and adipose tissue (AT), grown in HyPS for 21 days with hPL, were obtained by RapifleX MALDI TissueTyper™ [6].

Results:

About 450 and 570 protein IDs were identified in not depleted and depleted hPL and PPP, respectively. 59 of them resulted specific of hPL and not present in PPP independently from depletion, representing a possible panel of factors involved in cell stimulating effect of this supplement. Relative quantification highlighted 7 and 43 proteins significantly altered in their abundances comparing hPL vs PPP in not depleted and in depleted samples (fold change >1.5; p < 0.05; ≥ 2 unique peptides). 3 of these differences were in common, including a critical proliferation regulator. The functions and networks of the proteins of interest were investigated and compared. In situ proteome evaluation of AT-hMSCs and BM-hMSCs grown in HyPS in vitro models for 21 days in presence of hPL and chondrogenic medium was also provided. Histology evaluation was also performed with H&E. The molecular images of trypsinized samples were co-registered with the stained counterparts and co-localization of specific peptide signals with differentiated cells were enlightened.

Conclusions:

Shotgun analysis and label-free quantification of hPL and PPP allowed to 'proteomically' characterize the supplement and to highlight possible candidates responsible for the beneficial effect onto the proliferation and differentiation of in vitro models.

MS imaging analysis of seeded scaffold permitted also to recognize proteomic profiles specific of chondrogenic differentiated cells for in situ monitoring cell expansion and maturation.

Novel Aspect:

Proteomic characterization of hPL and MS imaging analysis give important information to clarify and monitor the hMSCs chondrogenic differentiation in in vitro HyPS 3D model.

Keywords: Elderly yoga, Healthy plasma, Comparative glycoproteomics, Lectin affinity chromatography

Introduction:

As the elderly population grows, yoga gets more popular as one of the exercises to improve the quality of life and health of the elderly. Glycoproteins in human plasma are known to be associated with multiple diseases, cell differentiation, aging, and etc. This study intends to examine the efficacy of yoga by identifying and comparing the glycoproteins in human plasma from elderly yoga groups before and after participation in a fall-prevention yoga program.

Methods:

Human plasma were collected from both Advanced level group and Beginner level group before and after participation in a fall-prevention yoga program. The plasma were pooled and affinity-selected using self-packed LEL columns. The captured glycoproteins from each plasma were then trypsin digested and deglycosylated with PNGase F. After that, proteins were identified with nLC-MS/MS and database searches in both groups.

Results:

Plasma glycoproteins were identified from both Beginner level group and Advanced level group before and after 4-month of yoga practice. The average age and sex ratio were equally matched in each group for the same experimental conditions.

The results show that the number of plasma glycoproteins in Advanced level group is less than that of Beginner's group, demonstrating an inverse correlation between number of plasma glycoproteins and yoga experience.

Conclusions

As the result of 4-Month yoga Program, the numbers of glycoproteins in the blood plasma tend to decrease for yoga participants. The longer the participants have enrolled in the program, the greater the change in the number of detected glycoproteins for the same 4-Month of yoga Program. Glycoprotein compositions of healthy elderly people have been obtained as reference data for future related studies.

Novel Aspect:

This is a comparative plasma glycoproteomics between elderly healthy yoga groups to see the efficacy of yoga programs with lectin affinity selection.

Keywords: Synovial fluid, periprosthetic joints infections, alpha defensin, liquid chromatography-mass spectrometry

Introduction:

Synovial fluid Alpha defensin is regarded as a potential biomarker for rapid identification of periprosthetic joints infections (PJI). The availability of a method not prone to interferences, with high sensitivity and specificity, could be of great help to clinicians, to make treatment decisions. LC-MS technology is widely used to measure new biomarkers, due to high selectivity and high sensitivity. We developed and validated a LC-MS method to perform synovial fluid alfa-defensin quantification.

Methods:

Synovial fluids (SF) samples were sample left over obtained from Patients referring to a large Italian private hospital. A pre-analytical step was performed based on chemical protocol to obtain a peptide from trypsin digestion of protein. The quantification of peptide are carried out by blank synovial fluid (spike solution) and simulant of synovial fluid (simulant [1]) in range from 0.1 to 100 µg/ml. To develop the LC-MS method, two different platforms (LC-QTOF and LC-MS/MS) were used.

Results.

The isolation and identification of the marker peptide from alpha defensin was achieved by LC-QTOF analysis by Auto-MS acquisition of data, after tryptic digestion of synovial fluid sample, positive for the presence of alpha defensin (Positive in according to MSIS criteria). The raw data were elaborated with Spectrum Mill Software, to verify the uniqueness of marker peptide of alpha defensin: the peptide LWAFCC is identify as a specific marker for the presence of alpha defensin. To evaluate the method performance, LOD and LOQ are calculated with 60 replicates of negative samples, in accordance to CLSI EP17-A2:20012 [2]: the best results are 0.09 µg/ml for LOD and 0.29 µg/ml for LOD performed by negative matix spike and LC-QTOF analysis. For December 2016 to November 2017, 119 synovial fluid samples are tested (from 119 patients, 92 aseptic and 27 positive by MSIS criteria): the results are cut-off value of 1.0 µg/ml, AUC 0.992 (95% C.I. 0.98-1.0), sensitivity 100%, specificity 96.3%, PPV 90% and NPV 100%.

Conclusions:

Presently, Alfa defensin measure in SF is performed either by laboratory based alpha- defensin immunoassay or by Synovasure "quick test" (lateral flow test kit). Both methods claim high degree of accuracy in the diagnosis of PJI [3]. LC-MS offers the potential to be an alternative to immunoassays and offers the highest sensitivity and precision for the identification and detection of analytes, although it still requires high skilled professionals and may need a long TAT.

Novel Aspect.

The results of the LC-MS assay validation show a robust method for qualitative and quantitative research of alpha defensin in synovial fluid.

Keywords: Mass spectrometry, hepatocellular carcinoma, multiomics, biomarkers, cancer.

Introduction:

One of the prominent obstacles in hepatocellular carcinoma (HCC) is the diagnosis in advanced stages when patients have several liver dysfunctions, limiting treatment options and life expectancy. A specific molecular signature is “a must” to be established to complex diseases, as HCC, to better monitor the development and progression of those pathological stages [1,2]. Cancer multiomics approach could reveal global signature under different biological scenarios, especially for redundant alterations as those seen in HCC [3].

Methods:

Nine patients with HCC, submitted to orthotopic liver transplant, and nine non-pathological patients (donors, negative control) were evaluated. Label-free LC-MS/MS-based proteomics (350 to 1.800 m/z, positive mode) and MALDI-TOF/MS-based lipidomics (600 to 1.200 m/z, positive mode) analysis were performed associated with statistical analysis (Progenesis QI®) and chemometric approach (MetaboAnalyst®) to compare plasma global protein and lipid profiles. The present study was approved by the Research Ethics Committee of the Federal University of Ceara (COMPEPE 026/98).

Results:

The results displayed two distinct proteomic and lipidomic profiles within pathological conditions versus control. The criteria for protein classification for biomarkers prospecting study used the highest fold change variation (≥ 5), the highest VIP score (1.9–1.4) after PLS-DA (PLS-DA imp, $p < 0.05$) performance and GO annotation analysis. In total, seventeen proteins were highly indicated for future validation. Cofilin-1 and Ig heavy chain variable region highly contribute to pathological phenotype when compare to control group under PLS-DA analysis. In patients with HCC, the major variations on fold change were detected at up-regulated Immunoglobulin kappa variable 4-1 (fold change 1716.93) and down-regulated Procollagen C-endopeptidase enhancer 1 (fold change 221.49) proteins. The criteria for lipid identification by important features of relative concentrations used the highest VIP score (2.5–1.0) after PLS-DA (PLS-DA imp, $p < 0.05$) analysis. The most abundant lipid in control patients is phosphatidylcholine (PC), with four ions contribution under PLS-DA analysis. In contrast, in HCC patients there was a shift on lipid profile, with phosphatidylethanolamine (PE) contributing as equally as PC, under PLS-DA analysis. Glycerophospholipids highly contribute to pathological phenotype when compare to control group.

Conclusions:

In this research, variations on fold change and VIP score display aberrant expression and contribution of several proteins, allowing the screening of 17 biomarkers candidates for future validation. Alteration in ratio between PC and PE revealed glycerophospholipids imbalance as potential diagnostic biomarkers pathway in a non-invasive method for HCC, as well for other liver diseases. Lipidomics and proteomics analysis, assessed individually or together, revealed possible candidates for diagnostic markers in a non-invasive method for HCC, as well for other liver diseases.

Novel Aspect:

Applying mass spectrometry to clinical questions under a translational-multiomic approach provides deeper understanding on advanced HCC and possible biomarkers candidates [3,4].

Keywords: sepsis, plasma, S100A8/S100A9, biomarker, PRM

Introduction:

Sepsis causes one death every 5.2 seconds worldwide [1]. To achieve rapid patient care, prognostic markers are needed. Predictive value of S100A8/9 complex was recently highlighted with an ELISA [2]. However, antibody affinity to particular isoform is questionable. Our study has assessed the prognostic value of plasmatic S100A8 and S100A9 by combining intact protein mass spectrometry for isoform characterization and bottom-up quantification of total isoforms.

Methods:

Proteoform characterization includes immunoprecipitation using specific antibodies coated on magnetic beads, acidic elution and intact protein analysis on a Q-Exactive instrument operated in full MS mode.

Bottom-up assay: the antibody-free assay consists in a simple pellet and tryptic digestion protocol using 10 μ L of plasma. The Q-Exactive was operated in the PRM mode and four specific peptides were monitored with labeled peptides for quantification.

Results:

Intact protein analyses following immunoprecipitation were used to characterize the circulating proteoforms of S100A8 and S100A9. In plasma of septic patients, truncated, acetylated and oxidized isoforms were detected.

Peptides common to all detected proteoforms were selected to quantify the total forms. A simple antibody-free sample preparation was developed for targeted analysis of S100A8 and S100A9 signature peptides. Application to clinical cohort analysis requires robust and quantitative assays. Validation in plasma of septic patients demonstrated good reproducibility, linearity and peptide stability.

A cohort of 45 plasma of septic patients was analyzed with the present assay, in parallel to an ELISA [3]. Remarkably, we found a significant difference in S100A8 and S100A9 concentration between survivor and non-survivor patients ($p = 0.009$). Additionally, excellent correlations between MS analysis and ELISA were observed ($r = 0.97$), thus demonstrated similar performance for both assays.

Conclusions:

Intact mass spectrometry allowed identification of S100A8 and S100A9 isoforms in patients with sepsis and all isoforms were then quantified by a simple antibody-free bottom-up assay. The present method demonstrated high reproducibility and accuracy, in agreement with the latest bioanalytical recommendations [4]. It should help harmonization of S100A8 and S100A9 quantification across laboratories, with the objective of reaching a better sepsis prognosis.

Novel Aspect:

Novel validated LC/MS assay for S100A8 and S100A9 quantification in a cohort of patients with sepsis, provide new significant variables for prognosis in sepsis.

Keywords: infertility, preimplantation factor, LC-MS/MS, affinity chromatography, proteomics

Introduction:

Nowadays infertility affects a significant number of couples and for many of them ART procedures provide a unique opportunity of achieving pregnancy. The major factor limiting the success of IVF procedures is embryo implantation. Studies showed that PIF peptide can be responsible for tolerances of the immune system of the mother [1]. The aim of the project is to understand the protein interactions of the PIF peptide in human serum to understand molecular mechanisms responsible for implantation.

Methods:

For binding proteins from human serum to PIF peptide we used affinity chromatography. PIF peptide was immobilized on solid support and then human serum was applied to microcolumn with immobilized peptide. The eluted proteins were subjected to bottom up analysis by liquid chromatography tandem mass spectrometry. Fragmentation spectra obtained in connection with available bases of amino acid sequences enabled to create a list of proteins that bind to PIF peptide.

Results:

The PIF peptide consisting of the 15 aminoacids residues (H-MVRIKPGSANKPSDD-OH) was chemically synthesized with the variants containing cysteinpentaglycine. These variants enable to prepare affinity column for binding proteins. The bottom up analysis with trypsin as a digestion enzyme enable to identify more proteins in a sample. Fragmentation spectra obtained from LC-MS/MS analysis in connection with SwissProt databes enabled to identify several proteins which bind to PIF peptide. These proteins have potential impact on trophoblast invasion, eventually affecting placental development in the peri-implantation period.

Conclusions:

Performed methods of affinity chromatography and LC-MS/MS technique are good tools for analysis of PIF interactome in human serum and other fluids. Presented method reveals that PIF peptide interacts with proteins which are responsible for implantation of the embryo and immune tolerance of the mother. However, holistic approach should be performed to understand whole mechanism of the implantation.

Novel Aspect:

The information obtained in this project can be used to develop diagnostic and therapeutic methods for monitoring the development of pregnancy and maintaining endangered pregnancies.

Keywords: chronic pain, microdialysis, MD-LC-MS/MS, fibromyalgia, intervention

Introduction

Fibromyalgia (FM) (prevalence of 2-4%) is a multifaceted chronic pain condition. The pathophysiological mechanisms behind FM involve both central and peripheral sensitization. Validated objective markers for involved pathophysiological processes in FM are crucial for diagnosis, but are today unfortunately lacking. The aim of this study were to investigate the interstitium muscle proteome in FM and healthy subjects to identify activated molecular pathways before and after progressive resistance exercise.

Methods

30 FM patients and 30 healthy subjects were included. Microdialysis (MD) was performed in the vastus lateralis muscle using commercial catheter (100 kDa). Dialysate samples were collected every 20 minutes during a four hours session at a flow rate of 5 μ L/min. The proteome was analyzed by nLC-MS/MS on LTQ OrbitrapVelos Pro (Thermo). Multivariate statistical analysis and bioinformatics were used to compare and describe the proteome profile between the FM and controls.

Results

The proteome fingerprinting analysis of the interstitial muscle identified proteins involved in inflammatory responses, stress response, immune system processes, muscle contraction and nociception. The insertion of MD catheter causes an acute tissue trauma and nociception. The equilibration period for the muscle was two hours. To investigate if the myalgic muscle reacts differently to the insertion of MD catheter compared to healthy muscle, dialysate samples from the trauma period (20-120 minutes) were analyzed. There was a significantly altered protein pattern in FM during the acute tissue trauma compared to the healthy controls. Important proteins whose levels were lower in FM during the tissue trauma were proteins involved in muscle contraction. The expression levels of proteins involved in inflammation, gluconeogenesis and stress responses were higher in FM compared to healthy subjects. Statistical analysis on the effect of the exercise regime on the proteome profile are ongoing.

Conclusions

This study shows that the nociceptive reaction of the muscle due to the MD catheter insertion in FM is different compared to healthy pain free subjects. The findings in this study together with the findings in plasma from the same cohort contribute to increased knowledge about peripheral and systemic molecular mechanisms involved in the nociceptive mechanisms in FM. Taken together our results can contribute to a better understanding of how to improve outcomes of treatments.

Novel Aspect

MD-LC-MS/MS is a promising tool to provide new insights into the interstitial proteome of muscle and to finding altered molecular pathways in fibromyalgia.

314 - DEEP PROTEOMICS OF SAW-SCALED VIPER (ECHIS CARINATUS SOCHUREKI) VENOM BY INTEGRATED TOP-DOWN AND BOTTOM-UP MASS SPECTROMETRIC APPROACHES

Parviz Ghezellou (1) - Vannuruswamy Garikapati (1) - Seyed Mahdi Kazemi (2) - Kerstin Strupat (3) - Alireza Ghassempour (2) - Bernhard Spengler (1)

Justus Liebig Giessen University, Institute of Inorganic and Analytical Chemistry, Giessen (1) - Shahid Beheshti University, Medicinal Plants and Drugs Research Institute, Tehran (2) - Thermo Fisher Scientific (Bremen) GmbH, Thermo Fisher Scientific (Bremen) GmbH, Bremen (3)

Keywords: top-down proteomics, bottom-up proteomics, snake venom

Introduction:

Venoms produced by viper snakes contain medically significant toxins that play a key role in the pathophysiology of snakebites disease. The most widely used techniques for venom analysis is LC-MS/MS based bottom-up (BU) proteomics [1]. On the contrary, intact protein measurement with top-down (TD) MS strategies, offers the richest data, covering the almost complete protein sequence and the ability to identify proteoforms and to localize modulations [2-3].

Methods:

Snake specimens were captured and milked in their localities around three different geographical regions of Iran. Size-exclusion chromatography (Bio-Rad NGCQuest Plus) was used for protein fractionation prior to LC-MS/MS. Mixed and fractionated venom samples were subjected to TD and BU proteomics analysis using Ultimate 3000 RP-UHPLC coupled to a Fourier transform orbital trapping mass spectrometry (Q Exactive HF-X, Thermo Scientific GmbH, Bremen, Germany).

Results:

The venom toxin composition of three geographically different saw-scaled viper samples were primarily measured as a venom mix through both, direct TD and BU strategies. The results of these approaches provide an initial overview of the venom toxin family on the protein level. The venom mix measurement illustrated that the venom proteomes were dominated by PLA2 and SVMP. Considering the proteome complexity of snake venoms, pre-fractionation is an essential part of venomics prior to MS analysis. We therefore de-complexed the venom of three populations by size-exclusion chromatography into 6 fractions for each sample. The fractions were then applied to LC-MS/MS in reduced and non-reduced form (TD) and also digested in solution (BU) for proteomics measurements. The data indicated sequence similarities to more than 300 proteins, belonging to 20 protein and peptide families.

Conclusions:

Accurate understanding of venom proteome contents can greatly help to improve the treatment of this neglected tropical disease and also drug discovery. Venom research is constantly developing, based on advanced analytical technology. Implementation of multi-dimensional separation techniques and TD proteomics using high-performance mass spectrometry accelerates the identification and characterization of venom components.

Novel Aspect:

First comprehensive qualitative and quantitative proteomics study of saw-scaled viper (*Echiscarinatus sochureki*) venom from three different geographical regions of Iran

1306 - SERUM PROTEIN CLASSIFIERS OF ALS FOR DISEASE ETIOLOGY AND PROGRESSION

Szymon Filip (1) - Tori Sosnowski (2) - Ina Dervishi (3) - Young Ah Goo (4) - Pembe Hande Ozdinler (5)

Northwestern University, Proteomics Center of Excellence, Chicago, United States (1) - Northwestern University, Proteomics Center of Excellence, Chicago, United States (2) - Northwestern University, Neurology, Chicago, United States (3) - Northwestern University, Proteomics Center of Excellence, Chicago, United States (4) - Northwestern University, Neurology, Chicago, United States (5)

Introduction:

Amyotrophic Lateral Sclerosis (ALS) is a progressive neurodegenerative disease that affects motor neurons in the brain and the spinal cord. The progressive motor neuron degeneration eventually leads to death usually within 5 years of diagnosis[1]. ALS can be often mistaken for primary lateral sclerosis (PLS), which progresses more slowly[2]. In addition, comorbidities in ALS patients further complicates diagnosis, treatment and proper care[3, 4].

Methods:

In an effort to investigate protein biomarkers for better diagnosis and disease progression, serum samples from a longitudinal cohort of 48 subjects, including ALS, re-classified from PLS to ALS, and age- and sex-matched healthy controls, were investigated. Highly abundant serum proteins were depleted and subjected to LC-MS/MS analysis. For label-free protein quantification and data analysis, MaxQuant, Perseus and R software were employed.

Results:

Thirty-nine differentially expressed proteins between ALS patients (including subjects re-classified from PLS to ALS) compared to healthy controls were identified. These proteins include complement factor H, complement C2 and apolipoprotein A1, suggesting abnormality or impairment in the regulation of complement cascade and cholesterol metabolism pathways. These findings were in agreement with the previous published studies[5, 6]. Only six proteins were common between the ALS and reclassified ALS when they were compared to the healthy control. This could be due to human heterogeneity or may actually representing different molecular mechanisms affecting disease progression, which warrant further investigation. Analysis of the longitudinal patient samples revealed a number of proteins potentially involved in disease progression. The role of candidate proteins in ALS pathophysiology and progression will be further evaluated.

Conclusions:

Our study revealed the presence of a distinct set of proteins in the serum of ALS patients that can potentially be used for tracking disease progression and diagnosis. A better understanding of the pathological features characterizing ALS will shed light onto the common and unique cellular events shared among disorders of similar etiology. This will ultimately help to develop effective diagnostic tools and will potentially identify novel treatment strategies.

Novel Aspect:

Identification of diagnostic protein markers for ALS disease stratification from disorders of similar etiology and for tracking ALS disease progression.

1160 - DIFFERENTIAL PROTEOME ANALYSIS OF HUMAN NEUROBLASTOMA XENOGRAFT PRIMARY TUMORS AND MATCHED SPONTANEOUS DISTANT METASTASES

Lorena Haenel (1) - Hartmut Schlüter (1) - Laura Heikau (1) - Tobias Lange (2)

University Medical Center Hamburg-Eppendorf, Institute of Clinical Chemistry and Laboratory Medicine, Hamburg (1)
- University Medical Center Hamburg-Eppendorf, Institute of Anatomy and Experimental Medicine, Hamburg (2)

Keywords: spontaneous metastasis, bioluminescence imaging, infrared laser ablation, proteome analysis

Introduction:

Metastasis formation is the major cause for cancer-related deaths and the underlying mechanisms remain poorly understood. In this study we describe spontaneous metastasis xenograft mouse models of human neuroblastoma used for unbiased identification of metastasis-related proteins by applying an infrared laser (IR) for sampling primary tumor (PT) and metastatic tissues, followed by mass spectrometric proteome analysis.

Methods:

IR aerosol samples were obtained from ovarian and liver metastases, which were indicated by bioluminescence imaging (BLI), and matched subcutaneous primary tumors. Tissue ablation products were tryptically digested using a filter aided sample preparation protocol [1].

Results:

Corresponding histology proved the human origin of metastatic lesions. Ovarian metastases were commonly larger than liver metastases indicating differential outgrowth capacities.

Among ~1,700 proteins identified at each of the three sites, 89 proteins were differentially regulated in ovarian metastases while 290 proteins were regulated in liver metastases. There was an overlap of 26 and 10 proteins up- and downregulated at both metastatic sites, respectively, most of which were so far not related to metastasis such as LYPLA2, ACTL8, EIF4B, LGALS7, GFAP, and ELAVL4. Moreover, we established in vitro sublines from PT and metastases and demonstrate differences in cellular protrusions, migratory/invasive potential and glycosylation.

Conclusions

Our study demonstrates that BLI-guided collection in the LAN-1 neuroblastoma model is suitable to identify novel candidate proteins that contribute to spontaneous metastasis formation in vivo. The number of regulated proteins (showing differential expression levels in PT vs. metastatic sites) decreases in advanced metastases. The derived sublines maintain pro-metastatic features in vitro making them highly attractive tools for future functional studies.

Novel Aspect:

Summarized, this study identified potential novel putative drivers of metastasis formation and provides novel sublines of metastatic neuroblastoma.

Keywords: Amyloid-beta, Alzheimer's disease, blood, proteomics, peptidomics

Introduction:

Alzheimer's disease is a fatal neurodegenerative disorder of the elderly, characterized by slow onset of memory loss, impaired consciousness and other brain functions, which are not detected until severe and possibly irreversible signs appear. Study of proteome changes during all stages of pathology— normal aging, mild cognitive impairment and dementia— may allow to obtain understanding on the mechanisms of disease onset or approaches to monitor progression.

Methods:

Comparative analysis of blood plasma proteins, peptides and their post-translational modifications was carried out for three groups of patients at different stages of the disorder. Proteome and peptidome fractions were extracted by a combined set of preparative procedures and analyzed by HPLC MS/MS analysis on an Agilent 1100 HPLC system coupled to a 7T FT ICR LTQ FT Ultra mass-spectrometer in DDA mode.

Results:

Label-free analysis of obtained data allowed to show potential protein markers specific for different levels of cognitive disorders. Over 300 proteins were identified in total. Among the common 76 coreproteins, 15 proteins were shown to reliably change in the MCI group in comparison with the controls. Of them 8 proteins were associated with various neurological diseases. A similar approach was used to find the significantly changing proteins for the AD group. A significantly less pronounced difference was observed between the AD and MCI conditions. In addition, a search for significant differences in the post-translational modifications of plasma proteins was carried out with a special attention to oxidative modifications known to be one of the early and valid tissue damage indicators, especially, for brain tissues. Significant changes in levels of PTMs such as deamidation of glutamine residues, oxidation of methionine and N-terminal residues and glutathione binding were observed.

Conclusions:

The found difference in the proteomes between groups of healthy individuals and patients with MCI and a less significant variation between mild and heavy disease states allow to hope for a possibility to develop methods of diagnosis at the earlier and potentially more treatable stages of the disease progression.

Novel Aspect:

The obtained protein panel can be potentially used for validation of biomarkers for screening of significant cognitive function changes and AD onset in particular

Thomas O. Joos (1)

University of Tübingen Reutlingen (1)

Keywords: Biomarker, Immunoassays, Safety biomarkers, Signaling

Introduction:

Array-based assay systems allow the analysis of hundreds of molecular parameters in a single experiment. Within the last decade multiplexed protein analytical assays achieved robust analytical performance and enable to screen for a multitude of parameters using minimal amounts of sample material. There are a variety of technologies and methods available to address assay requirements in terms of covering analyte concentration, sample variety and sample origin.

Methods:

Two assay formats addressing unmet needs in biomarker discovery developed at NMI will be presented.

Our DigiWest assay format transfers the western blot to a bead-based microarray platform extending traditional western blotting to enable the rapid quantification of hundreds of specific proteins and protein modifications in complex samples (1).

The second assay format combines sensitive and selective immunoprecipitation coupled with mass spectrometric readout. The use of peptide group-specific antibodies called MS-based immunoassays employing such terminal specific antibodies are established for several applications, including a number of cross-species drug induced organ injury assays that represent truly translational biomarker assays. (2)

Results:

The DigiWest high-throughput western blot approach allowed us to identify alterations in cellular signal transduction that occur during the development of resistance to the kinase inhibitor Lapatinib. A total of 185 western blot equivalents were performed. Differential phosphorylation was observed for a variety of proteins; a substantial increase in phosphorylated Aurora A, p27 and IRAK4 was detected; for other proteins a decrease in phosphorylation was observed (e.g. MEK1, Src, Erk1/2, different sites in EGFR). (1)

For our immunoaffinity mass spectrometry assays the quantification of drug induced kidney biomarker candidates in canine and monkey urine samples will be presented. The expression profiles of osteopontin, retinol binding protein 4, clusterin and KIM-1 in urine samples correlates with histopathology and conventional clinical pathology parameters when compared to tissue samples from the same animal. The biomarker assays are more sensitive than blood urea nitrogen (BUN) and serum creatinine (sCr) to detect early drug induced kidney injury. (4)

Conclusions:

Biomarker discovery and subsequent validation require robust technologies and assays combined with an excellent study design to include appropriate sample sets. This is a prerequisite for any biomarker qualification process. Our new assay formats enable the generation of such relevant data sets and can be implemented into a generic qualification strategy. Such new biomarkers will allow early identification, assessment and management of drug-induced injuries throughout R&D as well as biomarkers relevant for precision medicine.

125 - BIOMARKER CANDIDATES FOR ACUTE MYOCARDIAL INFARCTION IN HUMAN SERUM

Min-Jung Kang (1) - Yunseo Seong (2)

Korea Institute of Science and Technology, Molecular Recognition Research Center, Seoul (1) - KIST, Molecular Recognition Research Center, Seoul (2)

Keywords: Low abundance proteins; AMI biomarker candidates; Quantitative analysis; UHPLC-LTQ-Orbitrap; ELISA

Introduction:

Acute myocardial infarction (AMI) is a chronic disease and major cause of mortality worldwide, together with cancer. AMI is currently diagnosed based on an electrocardiogram and elevated levels of protein biomarkers such as troponin I, troponin T, myoglobin, creatine kinase, and CK-MB [1]. Once a heart attack occurs, surgery should be done within a short period of time, and the prognosis is very poor. If a novel biomarker in early stage is discovered, then it will help to reduce the burden of life for heart disease patients. We used a mixed non-targeted and targeted approach to discover novel biomarker candidates for AMI from the comparison of healthy and patient serum using quantitative analysis.

Methods:

Serum samples of healthy controls (n = 22) and AMI patients (n = 14) were pretreated using an albumin and immunoglobulin G depletion kit before trypsin digestion, and desalting. UHPLC-LTQ-Orbitrap analysis was achieved by data dependent analysis followed by a Mascot search. Comparative and shotgun proteomics developed were modified to discover biomarker candidates [2, 3]. Multi reaction monitoring by UPLC-LTQ-Orbitrap and ELISA were used for the quantitative analysis of biomarker candidates from serum samples for validation.

Results:

Thirty four peptide biomarker candidates were screened. Multi reaction monitoring showed that alpha-1-acid glycoprotein 1 level was significantly decreased ($P < 0.05$) and those of antithrombin III, clusterin, obscurin, and titin were significantly increased ($P < 0.001$) in AMI patient samples compared to levels in healthy controls. Four significantly decreased peptides, which were unidentified in Mascot Search, were also discovered ($P < 0.05$) as AMI diagnostic biomarker candidates. We quantified the biomarker candidates further using commercial ELISA kits. ANOVA showed that obscurin and titin concentrations were significantly elevated in AMI patients compared to levels in healthy controls, together with that of troponin I. Obscurin and titin showed the highest decision performance, with sensitivities of 86% and 85%, specificities of 100% and 94%, and diagnostic criteria of 11.4 ng/ml and 36.1 ng/ml, respectively.

Conclusions

A modified comparative proteomics approach provided excellent results in the search for novel biomarker candidates of AMI. A combination of obscurin and titin could be used for the diagnosis of AMI with high diagnostic performance.

Novel Aspect:

Combination of new technology, abundant protein depletion; UHPLC-LTQ-Orbitrap; data dependent analysis; Mascot search, was applied to discover AMI biomarker candidates by comparative proteomics. Obscurin and titin are novel biomarker candidates for AMI patient in early stage.

737 - RHEUMATOID FACTOR-CORRELATED PROTEINS IS COMPLEMENTARY BIOMARKER OF RHEUMATOID ARTHRITIS

Hee-Gyoo Kang (1) - Sora Mun (1) - Arum Park (1) - AeEun Seok (1) - You-Rim Lee (1) - Hyo-Jin Kim (1) - Yoo-Jin Lee (1)

Department of Senior Healthcare, BK21 Plus Program, Graduate School, Eulji University, Daejeon (1)

Keywords: Biomarker, Proteomics, Rheumatoid factor, Rheumatoid arthritis

Introduction:

Rheumatoid factor (RF) is auto-antibody that is involved in autoimmune such as rheumatoid arthritis. RF is diagnostic biomarker of rheumatoid arthritis. However, single RF factor is not sufficient to reflect all of the state of rheumatoid arthritis. To increase efficacy of diagnosis of rheumatoid arthritis, our aim is to discovery RF-correlated proteins that can be used complementarily with RF.

Methods:

For proteomics approach, Serums were classified into RF-low (RF<18 IU/ml), RF-intermediate (18<RF<54 IU/ml), and RF-high (RF>54 IU/ml). Nano-liquid chromatography-tandem mass spectrometry is used to identify and quantify global proteins in RF-low and RF-high subjects. Candidate biomarker proteins were validated using Enzyme-linked immunosorbent assay (ELISA) in RF-low, RF-intermediate and RF-high.

Results:

Among identified proteins by nano-liquid chromatography-tandem mass spectrometry, 4 proteins, including cholinesterase, histidine-rich glycoprotein (HRG), lipopolysaccharide-binding protein (LBP) and C-reactive protein, were more than 2-fold differentially expressed with statistically significance ($p<0.05$). Of these 4 proteins, the ELISA results of HRG and LBP was consistent with the results of nano-liquid chromatography-tandem mass spectrometry. Areas under the ROC curve of HRG and LBP were 0.861 and 0.828, respectively. The correlation between RF and HRG was statistically significant ($p = 0.003$), and that with LBP was also statistically significant ($p = 0.044$).

Conclusions:

As a results, HRG and LBP are altered in RF-high serum, which is suggested that HRG and LBP can be complementarily used with RF. In validation discovery set, the efficacy of HRG and LBP proved in patients with rheumatoid arthritis by ELISA.

Novel Aspect:

We propose that HRG and LBP can be useful screening markers for rheumatoid arthritis with RF.

Keywords: extracellular vesicles, plasma, biomarker, colorectal cancer

Introduction:

Targeted proteomics using SRM has been proved to be highly sensitive and quantitatively accurate. However, it is expensive and time-consuming to perform large-scale SRM analysis. We introduce a systematic and scalable SRM workflow for discovery and validation of novel biomarkers in plasma extracellular vesicles (EVs) targeting more than 400 proteins effectively.

Methods:

We developed a three step strategy for selecting biomarker candidates (BCs). Step 1: Primary BCs were selected from three sources; experimental data, literature data and database. Step 2: Targeted proteomics was performed for selecting secondary BCs from primary BCs. Isolated plasma EVs obtained from patients with colorectal cancer (n=59) and healthy volunteers (n=59) were analyzed in Step 1/2. Step 3: We evaluated the performance of secondary BCs in another sample set.

Results:

Step 1; 1,300 proteins were identified from plasma EVs as experimental data. 900 and 5400 proteins were extracted from PubMed literature search and ExoCarta database respectively. From these sources, 450 proteins were selected as primary BCs. Step 2; More than 1,000 stable isotope-labeled peptides were synthesized by our original peptide synthesis method, MS-based Quantification By isotope-labeled Cell-free products (MS-QBiC)[1]. We performed SRM analysis by using synthetic peptides to confirm their retention time and select top 5 highest intensity transitions. Next, spike-in plasma EVs isolated from pooled plasma were analyzed to select measurable peptides. Optimized SRM analysis was performed for selecting secondary BCs in individual plasma EVs. Step 2/3 is now still in the investigation stage.

Conclusions

Although the selection of final BCs is still on going, Step 1 / 2 are supported by each unique logical method to choose candidates which is the best for purpose. Our three step strategy would be innovative and practical approach for novel biomarker discovery.

Novel Aspect:

We proved the feasibility of targeted proteomics using more than 1,000 stable isotope-labeled synthetic peptides for clinical samples.

275 - QUANTITATIVE PROTEOMIC ANALYSIS OF CERVICOVAGINAL FLUID PROTEOME USING A 2D-NLC-ESI-MS/MS FOR EARLY DETECTION OF PRETERM BIRTH

Young Eun Kim (1) - Kwonseong Kim (1) - Dukjin Kang (1)

Center of Bioanalysis, Korea Research Institute of Standards and Science, Daejeon (1)

Keywords: cervicovaginal fluid; preterm birth; quantitative proteomics; biomarkers

Introduction

Preterm birth (PTB) before 37 weeks of pregnancy is one of major causes of perinatal mortality and neonatal morbidity. Despite of previous studies in developing biomarker(s) of PTB [1-3], unfortunately, the valuable protein maker for the early detection of PTB has not been unveiled. In this study, we performed quantitative profiling of cervicovaginal fluid (CVF) proteome for discovery of PTB-specific marker(s) via online 2D-nLC-ESI-MS/MS with isobaric labeling.

Methods

Comparative proteomic analysis of CVF proteome from PTB and control (its normal counterpart) was carried out using online two dimensional nanoflow liquid chromatography-electrospray ionization-tandem mass spectrometry (2D-nLC-ESI-MS/MS) with Isobaric tags for relative and absolute quantitation (iTRAQ)-based labeling.

Results

From 2D-nLC-ESI-MS/MS experiments, a total of 1346 proteins were identified in both CVF proteome from PTB and control and resulted in identifying 30/72 (up-/down-regulated by 1.5-fold change) proteins that were differently expressed in PTB compared to control. Bases on Gene Ontology (GO) enrichment analysis, it revealed that these significantly changed proteins were functionally involved in structural constituent of epidermis and cytoskeleton, serine-type endopeptidase inhibitor activity and oxygen carrier activity. We further evaluated the PTB biomarker candidates in five PTB individuals and seven control individuals, resulting in 55 proteins showed statistically significant difference between PTB and control. Among these, two proteins (transaldolase and junction plakoglobin) have been previously proposed as candidate PTB biomarkers [3] and other proteins are novel PTB biomarker candidates.

Conclusions

In summary, we analyzed the proteomic difference of human CVF between PTB and control group, which allowed the identification of novel CVF protein biomarkers for diagnosis of PTB. Further investigations will focus on the assessment of these biomarkers (specificity and selectivity) in a large cohort of subjects.

Novel Aspect

This study provided novel CVF protein biomarkers that have the potential to be applied in clinical diagnosis of PTB employing quantitative proteomics.

468 - ANTIBODY-FREE LC-MS METHODS FOR LOW TO SUB NG/ML QUANTIFICATION OF THE SOLUBLE RECEPTOR OF ADVANCED GLYCATION END-PRODUCTS IN SERUM

Frank Klont (1) - Marrit Hadderingh (1) - Marc Joosten (1) - Nick H.T. ten Hacken (2) - Péter Horvatovich (1) - Rainer Bischoff (1)

University of Groningen, Department of Analytical Biochemistry, Groningen (1) - University Medical Center Groningen, Department of Pulmonary Diseases, Groningen (2)

Keywords: Biomarker, Immunoaffinity enrichment, Ion-exchange, LC-MS, Quantification

Introduction:

The soluble Receptor of Advanced Glycation End-products (sRAGE) is a decoy receptor moderating pro-inflammatory signals in the lungs. For COPD, sRAGE is considered to be a promising biomarker candidate based on data obtained using antibody-based assays. Here we describe two antibody-free approaches for LC-MS-based sRAGE quantification, one using affimers and one using strong cation exchange (SCX).

Methods:

A UPLC-MRM/MS method using affimers, a novel class of affinity ligands, and a method employing SCX solid-phase extraction (SPE) were developed to enable sRAGE quantification in the range of 0.2-10 ng/mL using 50 μ L of serum. Both methods were validated according to EMA and FDA guidelines and were compared with a previously developed antibody-based LC-MS method for sRAGE.[1]

Results:

Efforts to establish an affimer-based sRAGE method led to an easily automatable workflow, which is capable of analyzing hundreds of samples per week thus having considerable potential for clinical applications. SCX-based sample cleanup at pH 10 enabled sRAGE enrichment with good precision owing to the protein's bipolar charge distribution, despite of having an average pI of 7.8. Compared to the antibody-based assay, our affimer method showed good correlation (R-squared of 0.9) and a bias around -25%, whereas the SCX assay showed moderate correlation (R-squared of 0.5) and reported on average 20% higher results. Plausible explanations for the observed differences include different subsets of sRAGE proteoforms being quantified and varying impacts of sRAGE ligands on the enrichment of this protein.

Conclusions:

We developed and validated two antibody-free LC-MS methods for sRAGE quantification. Levels reported by these assays are different from each other as well as from those reported by antibody-based assays. Thereby, these results indicate that sRAGE assays should be critically evaluated and adequately characterized in order for this protein to become useful as a biomarker.

Novel Aspect:

We present the unique applications of affimers, a novel class of affinity ligands, and strong cation exchange for low abundant protein enrichment.

387 - PROTEOME ANALYSIS OF HUMAN NEUROMELANIN GRANULES AND NEURONS IN THE CONTEXT OF DEMENTIA WITH LEWY BODIES

Steffen Kösters (1) - Sarah Plum (1) - Caroline May (1) - Kathrin Marcus (1)

Medizinisches Proteom-Center, Ruhr-University Bochum, Bochum (1)

Keywords:

Dementia with Lewy bodies (DLB), Neuromelanin (NM) granules, laser microdissection, LC-MS/MS, proteomic study

Introduction:

Neuromelanin is a dark insoluble pigment, which forms so called NM granules with lipids and proteins in the substantia nigra¹. It is widely debated if those granules are neuroprotective or neurodegenerative^{2,3}. For example, there is a loss of dopaminergic neurons containing NM during the course of DLB⁴. A proteome analysis of NM granules and neurons could allow deeper insight into the function of these granules in the pathogenesis of neurological disorders like DLB.

Methods:

NM granules were enriched from fresh frozen DLB and control tissue by laser microdissection. A tryptic digestion was performed afterwards. The samples were analyzed by liquid chromatography tandem mass spectrometry (LC-MS/MS). MaxQuant was used for the evaluation of the MS/MS spectra. A data synchronization was conducted with Gene Ontology for further analysis.

Results:

Mass spectrometric analysis and subsequent evaluation of the data in this pilot study of four DLB and five control samples led to the identification of around 660 proteins. A significant differential study were performed to give a statement about over- and underrepresented proteins. 116 significantly (t-test <0.05) differential proteins were identified: 72 proteins overrepresented and 44 proteins underrepresented in NM granules from DLB cases. Analysis revealed that lysosomal associated proteins are significantly overrepresented and mitochondrial associated proteins are underrepresented in NM granules of DLB compared to healthy control cases. To affirm these results and increase the statistical significance, the study will be extended by 18 DLB and 20 control cases. Additionally, a simultaneously enrichment and comparison of NM granules and neurons will be performed. This could give deeper insight in the function of NM granules in the pathogenesis of DLB.

Conclusions:

The results of this pilot study support the hypothesis of the NM granules formation as described in the literature that NM granules are probably lysosome related organelle species. NM forms in the cytoplasm at physiological temperature and pH as a side product of dopamine synthesis and is incorporated by endosomes or lysosomes⁵. Furthermore, 536 proteins were identified in all cases, which can be considered as biochemical essential composition of the NM granules.

Novel Aspect:

For the first time a protein biochemical characterization of NM granules in the context of DLB was performed.

1094 - PROTEOMIC PROFILING OF MELANOMA CELL LINES AND TISSUE USING DATA INDEPENDENT ACQUISITION MASS SPECTROMETRY TO PREDICT TREATMENT RESPONSE AND PATIENT SURVIVAL

Christoph Krisp (1) - Robert Parker (1) - Dana Pascovici (1) - Nicholas K. Hayward (2) - James S. Wilmott (3) - Richard A. Scolyer (3) - Mark P. Molloy (1)

Australian Proteome Analysis Facility, Macquarie University, Sydney (1) - Oncogenomics Laboratory, QIMR Berghofer Medical Research Institute, Brisbane (2) - Melanoma Institute Australia, The University of Sydney, Sydney (3)

Keywords: Melanoma, SWATH-MS, Targeted Therapy, Inhibitor Resistance, Survival Prediction

Introduction:

Melanoma is the most frequent cause of skin cancer-related deaths and is the most common lethal malignancy in young people (<40yrs). Inhibition of crucial survival pathways, such as the MAPK pathway, has become a routine in melanoma, however, response rates vary and responders cannot be reliably predicted by genotype alone. We conducted mass spectrometric screening to detect cellular processes that might predict MEK inhibition (MEKi) response.

Methods:

Ten subcutaneous lymph node metastatic melanoma derived cell lines with known MAPK status and 32 fresh frozen NRASmut or BRAFmut regional lymph node metastatic melanoma specimens were obtained. Lysed cells and tissues were digested and analyzed by Data-Independent Acquisition (SWATH-MS) using a TripleTOF 5600/6600 mass spectrometer. Cell line viability over ten days in presence of 2 μ M of the MEK inhibitor Selumetinib was determined by a PrestoBlue assay.

Results:

Across all cell lines, about 2500 proteins were quantifiable. Principal component analysis segregated melanomas based on in vitro MEKi sensitivity, whereas genotype alone did not. In total, 63 proteins were highly correlative with MEKi response. Survival analysis demonstrated significantly better survival ($p=0.01$) for patients with MEKi sensitive (>7.5 years) versus patients with MEKi resistant cell lines (<1.7 years).

About 2000 proteins were quantifiable in the tissue cohort. The MEKi proteome phenotype was also a dominant signal in tissues, however, neither this phenotype nor genotype correlated directly with survival. Dividing patients into active and low or inactive melanogenic tumors and combining it with expression level of two plasma membrane proteins, allowed for accurate segregation between patients with good and poor post-biopsy survival. The three marker panel was further validated on a data set retrieved from a publically accessible data base containing RNA sequencing information of 460 melanoma specimen.

Conclusions:

Mass spectrometric profiling of patient derived melanoma cell lines using SWATH-MS led to the identification of predictive markers for MEKi therapy response. In a validation cohort using 32 melanoma tissues, SWATH-MS identified the MEKi response as a major driver of patient segregation. Additionally, a three protein marker panel was identified in the tissue cohort predictive for patient post-biopsy survival independent of genotype and MEKi response phenotype.

Novel Aspect:

SWATH-MS profiling demonstrated MEKi phenotypes in cell lines and fresh frozen metastatic melanoma and identified a marker panel predicting patient post-biopsy survival.

Keywords: Proteomics; Mass spectrometry; *Aeromonas salmonicida*; Subcellular fractionation; Outer membrane vesicles

Introduction:

Aquaculture is one of the most rapidly growing food sectors globally [1]. Still, high economic losses occur due to infections, for example by the gram negative bacterium *Aeromonas salmonicida* as this organism causes a septicemic disease called furunculosis in freshwater fish [2]. In this study we utilized mass spectrometry based proteomics to study the physiology of this pathogen with special interest in the outer membrane vesicles that may interact with the host.

Methods:

The *A. salmonicida* strain JF2267 was grown in lysogeny broth liquid medium. The bacteria were harvested in the logarithmic and stationary growth phase. Cytoplasmic, inner membrane, outer membrane and extracellular proteins as well as proteins of outer membrane vesicles were enriched by subcellular fractionation and subsequently analyzed in a mass spectrometer. The resulting data were processed with the MaxQuant [3] and Perseus [4] software.

Results:

Overall, app. 50 % of the proteins predicted for this *A. salmonicida* strain were identified, indicating a high proteome coverage. For validation of the applied fractionation protocol the predicted cellular location (according to PSORTb [5]) and the subcellular fraction in which the proteins were identified, were compared. This comparison showed a clear enrichment of the proteins according to their prediction. Further, clear alteration between the logarithmic and stationary phase could be observed on proteome level. The changes in the fraction of the outer membrane vesicles are particularly interesting, as more than twice as many proteins were identified in the vesicles of the stationary phase compared to the logarithmic phase.

Conclusions:

In summary, in this study a very good proteome coverage could be achieved by application of a subcellular fractionation for *A. salmonicida*. Moreover, as expected, significant alterations were observed in the comparison of the proteome of the logarithmic and stationary phase. Interestingly, the most striking changes were detected in the vesicle fraction. Therefore, in future experiments, we will have a deeper look into the physiological role of the vesicles.

Novel Aspect:

For the first time the protein composition of the outer membrane vesicles of *Aeromonas salmonicida* was determined.

Keywords: Proteomics, UHPLC, 2DRP/RPLC, NCFC, High-throughput LC

Introduction

Proteomics aims to complete profiling of the protein contents and their modifications in cells, tissues, and biofluids and to quantitatively determine changes in their abundances. This information reveals cellular processes and signaling pathways and serves to identify candidate protein biomarkers and/or therapeutic targets. Therefore, analysis should be comprehensive and efficient.

Methods

A novel online two-dimensional reversephase/ reverse-phase liquid chromatography separation platform, using six switching valves based on a newly developed online non-contiguous fractionating and concatenating device (NCFC device)

Results

In bottom-up proteomics analyses of a complex proteome, this system provided significantly improved exploitation of the separation space of the two RPs, resulting in a considerable increase in the numbers of peptides identified compared to a conventional contiguous 2D-RP/RPLC method.

Conclusions

The fully automated online 2D-NCFC-RP/RPLC system bypassed a number of labor-intensive manual processes (offline fractionations, pooling, clean-up, drying/reconstitution, and autosampler injection) required with previously described offline 2D-NCFC-RP/RPLC method, offering minimal sample loss and highly reproducible 2D-RP/RPLC experiment

Novel Aspect

The developed system was the first online 2D RP/RPLC system that NCFC technology was applied. This system allowed comprehensive proteome profiling using small amount of sample without loss of sample and their information.

1080 - QUANTITATION OF MONOCLONAL ANTIBODY INFlixIMAB IN HUMAN PLASMA BY LC-MS/MS USING FAB-SELECTIVE LIMITED PROTEOLYSIS nSMOL TECHNOLOGY

Neil Loftus (1) - Alan Barnes (1) - Aurore Jaffuel (2)

Shimadzu, MS/BU, Manchester (1) - Shimadzu France, MS, Paris (2)

Keywords: mAb, nSMOL, LC-MS/MS, infliximab, plasma

Introduction

Infliximab is a chimeric IgG1 kappa monoclonal antibody, used in the treatment of inflammatory diseases targeting tumor necrosis factor-alpha (TNF). However, studies have identified a substantial proportion of patients (between 30-40%) who fail to respond to anti-TNF therapy. In this study, we describe the use of nSMOL (nano-surface and molecular-orientation limited) proteolysis to selectively target the Fab CDR region of the mAb and LC-MS/MS detection.

Methods

Plasma samples (5µL) were initially captured using FG beads and digested with trypsin to selectively target the Fab CDR region of the mAb, followed by LC-MS/MS detection using reversed phase UHPLC separation (Nexera LC, Shimadzu Corporation using a Shimpack GISS 1.9µm 50x2.1mm C18).

Results

A novel method was developed that performed selective proteolysis of the Fab region of mAbs using nano-surface and molecular-orientation limited (nSMOL) proteolysis (Iwamoto et al. 2014). The approach decreases sample complexity through mAb protein enrichment from plasma and uses proteotypic peptide sequence specificity for quantitative LC-MS/MS analysis. By restricting digestion, tryptic fragments are limited to the Fab region, allowing a selective quantification of target mAb peptides with higher efficiency and selectivity in combination with MRM measurement. Skyline software (MacCoss Lab, University of Washington) was used to perform in-silico protein digestion and predict candidate peptides and MRM transitions. SINSATHYAESVK, YASEMSGIPSR and DILLTQSPAILSVPGER were selected based on response, linearity and accuracy.

Conclusions

Quantitation of the mAb infliximab in plasma was implemented using standard sample preparation and generic peptide chromatographic conditions. Method development using Shimpack GISS column achieved a cycle time of 8 minutes per sample. nSMOL technology in combination with LC-MS/MS can offer a rapid alternative to mAb quantitation by ELISA. Inclusion of an internal standard in nSMOL& LC-MS/MS increases accuracy and robustness not available in ELISA type assays.

Novel Aspect

Using a Fab CDR restricted trypsin digestion method, infliximab was quantified in plasma by LC-MS/MS resulting in an alternative technique compared to ELISA.

857 - TOP DOWN MASS SPECTROMETRY WITH MULTIPLE MS/MS STRATEGIES TO IDENTIFY AGE-RELATED PROTEOFORM CHANGES IN TEAR FLUID.

daniel Lopez-Ferrer (1) - Romain Huguet (2) - David Horn (2) - Peter PM Raus (3) - Vlad Zabrouskov (2) - Andreas Huhmer (4) - Peter DEM Verhaert (5)

thermo fisher scientific, Vertical Marketing, San Jose (1) - Thermo Fisher Scientific, Product Management, San Jose (2) - Miro Center, Clinic, Geel (3) - Thermo Fisher Scientific, Vertical Marketing, San Jose (4) - ProteoFormiX, R&D, Beerse (5)

Keywords: biofluids, precision-medicine, top-down proteomics, UVPD, Orbitrap

Introduction:

Tear fluid is of key importance to maintain the health of the front of the eye and provide clear vision. In addition, it represents a promising body fluid that can help in the diagnosis and prognosis of various eye diseases. Here we explore the use of top-down proteomics to map the proteoform diversity in the tear fluid. The proposed work flow includes an array of top-down fragmentation techniques on a chromatographic time scale that allows for identification of over 50 proteoforms simultaneously in less than 1 hour. We then applied this workflow to a cohort of sixteen individuals with ages ranging from 18 up to 70 years old to identify molecular changes due to age

Methods:

Tear samples were purchased from Lee Biosolutions. Extracted proteins were directly transferred to an injection vial and analyzed by LC-MS using an Orbitrap Fusion Tribrid Instrument modified with UVPD. MS/MS acquisition was performed using ETD, EThcD, HCD and UVPD fragmentations at a resolution of 120,000 at m/z 200. Data analysis was performed using Thermo Scientific Deconvolution 4.0 and ProSight PD nodes in the Proteome Discoverer 2.2 software. Label free analysis was done using Biopharma Finder 3.0. Statistical analysis to identify differentially expressed or processed proteoforms was done using R.

Results:

Tear fluid functions as lubrication of the eye surface, contains a cocktail of antimicrobials to prevent bacterial infections, washes away foreign matter that is deposited in the eye during our daytime activities, and keeps the eye surface clean and smooth. Tears have the potential to be a source of biomarkers for diagnosing eye-related diseases. First, it is a fluid that can easily be obtained in a non-invasive manner. Second, it is localized to the organ of interest to the ophthalmologist (the eye) and not prone to the same dilution problems associated with biomarker fluids like plasma. Third, tear fluid composition changes with the health of the eye (as well as with age).

In this work, we have coupled high sensitivity top-down mass spectrometry to enable the characterization of tear proteoforms in less than 1 h with an elegant combination of bioinformatics algorithms. Our approach consists of a simplified two-step workflow. First, samples are then analyzed over a 30 min LC gradient by MS and MS/MS using various fragmentation mechanisms. And then, MSMS are searched against a protein database. Label free quantitation is performed by aligning the raw files in the chromatographic dimension and extracting the areas under the curve for each of the identified molecular species. Intensities were then normalized and a t-test was performed to identify differential events. PCA analysis shows that samples within the age groups are more similar. And among the significant proteins in the dataset, lacritin is the one that changes most with age. This protein is involved in the promotion of basal tearing and which low levels are associated with dry eye syndrome. Overall, this strategy offers a powerful option for discovery and characterization of potential tear biomarkers that could be used for the screening of diseases, both eye related or other.

Conclusions

From our analyses, we have proven that tear fluid could be of great interest for understanding eye related diseases and stratifying individuals. In addition, this work also proves that top-down proteomics in clinical research presents a great opportunity to inform about the actual changes that are happening, because it enables to correlate exact proteoforms to a given phenotype. And opens the door for the development of proteoform specific assays in the clinical setting.

Novel Aspect:

Tear proteoform biomarker discovery in hours using label free proteomics and an Orbitrap Fusion Lumos.

Keywords: thyroid lesions; Fine needle aspiration biopsies, proteomics, cytological sample stability, mass spectra similarity index.

Introduction: Thyroid nodule lesions are one of the diseases diagnosed using liquid-based cytology [1]. Such samples are collected via fine-needle aspiration biopsy (FNAB) and deposited into preservative solutions in order to maintain their morphological integrity. However, the proteomic stability of these preserved samples is yet to be investigated and must be ascertained in order for them to be reliably employed in proteomic studies aimed at biomarker discovery.

Methods: Thyroid FNABs were collected from 14 patients (San Gerardo Hospital, Monza, Italy) and transferred into CytoLyt solution, centrifuged and re-suspended in PreservCyt solution. Cytospin spots have been positioned onto ITO-conductive slides and MALDI-MSI intact proteins analysis was performed using an ultrafleXtreme MALDI-TOF/TOF (Bruker Daltonik). Spectra pre-processing and data analysis were performed using the open-source R software v.3.4.3.

Results: Each FNAB was split into several samples in order to investigate the experimental repeatability (intra-day and inter-day) of the proteomics analysis and the cytological samples stability after 7, 14 days and 2 months in PreservCyt and after 7 days in CytoLyt at 4°C. All samples were compared with the one prepared at t₀. Mass spectra similarity was evaluated by using two score systems. The score S₃, derived from a previous study [2], was the sum of three components (fit, retrofit and Spearman's correlation). The second score system (S₄) ranges 0–4 and includes a fourth feature that measures the overlap, which takes into account the whole shape of the two spectra. Intra-day and inter-day CV were very low within ranges of 8.64%–12.03% for S₃ and of 7.37%–10.43% for S₄, respectively. The results suggest no substantial deviations from t₀ when the cytological samples were stored in PreservCyt until 14 days and in CytoLyt until 7 days. However, longer storage time (2 months) in PreservCyt does not preserve the specimens, and the spectra overlap with t₀ was only 50%.

Conclusions: This study represents a step forward towards the implementation of MALDI-MSI, combined with a trustworthy and robust sample preparation methodology, into the cytopathology routine, integrating the morphology with the proteomics data to improve the diagnosis. Moreover, this protocol allows simple sample collection and shipment to be used not only for the proteomic MALDI-MSI analysis of thyroid FNABs but also for other biological liquid based specimens.

Novel Aspect: A new similarity score was introduced to equally take into account the number of signals (fit and retrofit) and their intensities (Spearman's correlation and spectra overlap).

1139 - QUANTIFICATION OF ENDOGENOUS VEGFA LEVELS FROM HUMAN PLASMA USING NANOLC/HIGH RESOLUTION MASS SPECTROMETRY COMBINED WITH IMMUNOCAPTURE ENRICHMENT

Sina Pleiner (1) - Karen Koehler (1) - Joachim Hoke (1) - Sascha Keller (1)

Boehringer Ingelheim Pharma GmbH & Co. KG, DMPK, Biberach a. d. Riss (1)

Keywords: VEGFA, biomarker, immunoprecipitation, LC-HR/MS

Introduction: VEGFA as biomarker for blood vessel formation and tumor progression

Tumor progression is often accompanied by `aberrant angiogenesis`, a process of blood vessel formation with a special permeable structure. Such structures lead to an adequate supply of the tumor with oxygen and nutrients [1]. Vascular endothelial growth factor A (VEGFA) is an angiogenesis stimulating factor and can therefore serve as a prognostic biomarker for several types of cancer [2, 3].

Methods: VEGFA enrichment and analysis by LC-HR/MS

Human plasma samples were mixed with isotopically labelled VEGFA protein as internal standard. Unlabeled, recombinant VEGFA was used to create a calibration curve. Samples were denatured and digested before VEGFA peptides were enriched by an immunocapture step using the KingFisherTM Flex platform. After further SPE clean up, samples were analyzed in the fullscan mode of a Q ExactiveTM HF system connected to a nanoLC system (all Thermo Fisher Scientific).

Results: Quantification of endogenous VEGFA levels from human plasma with high precision

We were able to set up and validate a robust LC-MS method for the quantification of VEGFA as a biomarker from human plasma down to 0.7 ng eq/mL (~ 1.8 fmol absolute per sample) with a CV < 10%. Since the method is based on an immunoprecipitation approach using a polyclonal antibody as capturing agent, antibody lot-to-lot variance was examined as well and found to be negligible.

Conclusions: Approach can be applied to patient samples

The newly developed LC-MS approach can be used to analyze endogenous VEGFA levels and drug treatment profiles of patient samples. As the method is semi-automated, up to 96 samples can be processed in one run.

Novel Aspect: Development of a LC-MS method for VEGFA

To our knowledge it was the first time that VEGFA was quantified from a complex plasma sample by an LC-MS assay.

Keywords: eIF6; mitochondrial proteome; shotgun proteomics; multivariate statistical analysis; biomarker identification

Introduction:

Eukaryotic Initiation Factor 6 (eIF6) binds 60S ribosomal subunits, has with an anti-association property, and rate limiting for tumour onset and progression. eIF6 haploinsufficient cells are normal, but not efficiently transformed in vitro. Some lines of evidence have shown that alterations in mitochondria (the main compartments of energy production) contribute to the development of metabolic syndrome.

Methods:

The mitochondrial proteome of AML-12 (non-tumourigenic murine liver hepatocytes) cell line, with eIF6 down-regulated by shRNA, and of liver tissues from wild type and +/- mice for eIF6 has been analysed by uHPLC-QTOF-MS/MS exploiting the SWATH-MS acquisition, which is a high throughput label-free method for protein quantitation combining shotgun proteomics with the quantitative accuracy and reproducibility of selected reaction monitoring (SRM).

Results:

The data collected were further processed by multivariate statistical tools to identify the effects of eIF6 depletion. Partial least squares-discriminant analysis (PLS-DA) coupled to a variable selection procedure in cross-validation was applied to this purpose, in order to identify the most relevant panel of markers with the best predictive ability. The analysis allowed the identification of panels of markers with a very good predictive ability. Bioinformatic tools applied to the identified markers allowed the identification of deranged pathways.

Conclusions

We found that depletion of eIF6 by shRNA induces profound and varied impact on mitochondrial proteome, impairing the energy production, steering the metabolism toward the up-regulation of aerobic glycolysis and the inhibition of oxidative phosphorylation.

Novel Aspect:

We identified interesting deranged pathways in the mitochondrial proteome after eIF6 depletion.

800 - IDENTIFICATION OF PROTEOMIC AND LIPIDOMIC MARKERS IN INFLAMMATORY BOWEL DISEASES BY MS-BASED TECHNIQUES AND MULTIVARIATE STATISTICAL ANALYSIS

Keywords: Inflammatory bowel diseases; proteomics; lipidomics; multivariate statistical analysis; biomarkers identification

Introduction:

The causes of Inflammatory Bowel Diseases (IBDs) are still little known, the prevailing hypothesis being an immunologic reaction towards antigens. The diagnosis of IBDs is usually carried out by quite invasive instrumental techniques; some plasma biomarkers have been proposed but much can be done to clarify the etiology of the pathology and identify reliable biomarkers with predictive ability.

Methods:

Plasma proteins and fatty acids from controls and patients affected by Chron's disease (CD) and Ulcerative Colitis (UC) were analysed using mass spectrometry-based techniques. Low-abundant plasma proteins were quantified after depletion of the 14 most abundant and tryptic digestion, followed by uHPLC-QTOF-MS/MS. Several fatty acids were simultaneously analysed by Gas Chromatography Mass Spectrometry (GC-MS), after derivatization.

Results:

uHPLC-QTOF-MS/MS was applied exploiting the SWATH-MS acquisition, a high throughput label-free method for protein quantitation combining shotgun proteomics with the quantitative accuracy and reproducibility of selected reaction monitoring (SRM). The data collected were further processed by multivariate statistical tools to identify markers of CD and UC but also identify markers able to discriminate UC vs CD samples. Partial least squares-discriminant analysis (PLS-DA) coupled to a variable selection procedure in cross-validation was applied to this purpose, in order to identify the most relevant panel of markers with the best predictive ability. Proteomic and lipidomic data were also integrated to provide new combined biomarkers including both proteomic and lipidomic markers. The analysis allowed the identification of panels of markers with a very good predictive ability and pointed out the importance of including fatty acids.

Conclusions

The combination of proteomic and lipidomic data allowed to obtain panels of biomarkers with improved predictive ability, pointing out the importance of fatty acids, combined with proteins, in the identification of IBDs. Bioinformatic tools applied to the panels of identified markers allowed the identification of deranged pathways (up and/or down regulated).

Novel Aspect:

The combination of proteomic and lipidomic data provided panels of markers with improved predictive ability with respect to the only proteomic analysis.

876 - SHEDDING NEW LIGHT ON SPINAL CORD INJURY

Michel Salzet (1) - Jusal Quanico (2) - Melodie Anne Karnoub (2) - Celine Meriaux (2) - Zahra Laouby (2) - Franck Rodet (3) - Dasa Cizkova (4) - Isabelle Fournier (2) - Richard Assaker (2)

Keywords: Spinal Cord Injury, Spatio temporal Proteomic, Tempotally 3D MALDI MSI, Antibody DependantNeuritogenesis Modulation, Stem Cells

Introduction:

Spinal cord injury (SCI) belongs to currently incurable disorders of the CNS and is accompanied by permanent health consequences-disability. In order to mimic a SCI, a balloon-compressive technique was used at thoracic Th8-9 spinal level in adult rat.

Methods:

4D MALDI Imaging, lipidomics,Saptiotempral tissue microproteomics were undertaken combined with confocal imaging. Exosomes from Stem Cells, functionalized biomaterial, Rho A inhibitor have been tested in pre-clinical way to develop a smart biomaterial.

Results: (

We determined the spatio-temporal events occurring in acute phase after SCI. Caudal segment has clearly been detected as the therapeutic target [1,2]. We then assessed in a rat SCI model the in vivo impact of a sustained RhoA inhibitor administered in situ via functionalized-alginate scaffold [3,4] . In order to decipher the underlying molecular mechanisms involved in such a process, an in vitro neuroproteomic-systems biology platform was developed in which the pan-proteomic profile of the dorsal root ganglia (DRG) cell line ND7/23 DRG was assessed in a large array of culture conditions using RhoAi and/or conditioned media obtained from SCI ex-vivo derived spinal cord slices. A fine mapping of the spatio-temporal molecular events of the RhoAi treatment in SCI was performed. The data obtained allow a better understanding of regeneration induced above and below the lesion site.

Conclusions

Results notably showed a time-dependent alteration of the transcription factors profile along with the synthesis of growth cone-related factors (receptors, ligands, and signaling pathways) in RhoAi treated DRG cells and involvement of IgG by binding to their receptors on the DRG cells

Novel Aspect:

We established a novel origin of IgG, their role in neurites outgrowth modulation, and developed a smart biomaterial for treating SCI.

Keywords: ccRCC, Urinary Exosomes, Proteomics, Label-free, Biomarkers

Introduction:

RCC represents 2-3% of all cancers and its incidence is increasing [1]. Clear cell RCC (cc-RCC) is the most frequent type. Although ccRCC are diagnosed at early stages, their aggressiveness and clinical outcomes result heterogeneous within each staging group; thus, novel predictors are needed. A non-invasive test using urine will have a significant impact on patient management. Urinary Exosomes (UE) are proposed as a useful biomarkers source for ccRCC.

Methods:

The aim of this study is to highlight a characteristic UE protein profile of RCC progression. UE pools obtained from patients with cc-RCC classified as pT1 (n=6) and pT3 (n=6), and from age- and sex-matched healthy subjects (n=6) were isolated by ultracentrifugation. The corresponding proteome of each sample was digested using the FASP-based method and analysed by label-free nLC-ESI MS/MS.

Results:

The UE proteome of patients with ccRCC (low- and high-stage) was investigated by mass spectrometric approach following correlation of the data with clinical features (TNM) [2]. The MS analysis allowed the identification and quantification of about 500 proteins. Considering only the protein identification, the data show that the UE protein composition remained rather constant in the three groups (pT1, pT3 and CTRLs). However, by evaluating the protein abundance, 230 had a statistically significant variation. The pathway network elaboration revealed that many typical urinary system proteins changed their levels in UE. Furthermore, the results shown that some proteins involved in signaling pathways change their abundance, increasing disease stage. This finding suggests a possible relationship of these quantitative variations with the process of tumour dedifferentiation and spread. Finally, a panel of proteins were selected in order to validate their differential content between ccRCC and Ctrl UE, through immunoblotting.

Conclusions:

UE comparative proteomics could represent a promising starting point for the identification of ccRCC biomarkers for prognostic purposes. The data obtained may be a useful finding for the future investigation of the molecular mechanism of ccRCC progression. More important, with the prospective validation in a larger cohort, information derived from this study may lead to the development of ccRCC candidate biomarkers.

Novel Aspect:

In this work, for the first time, the proteomic characterization of UE in patients affected by ccRCC at different stages is approached.

Keywords: timsTOF Pro, PASEF, Evosep One High throughput, Clinical Research

Introduction:

The achievable depth in high throughput proteomics analyses is most often limited by the sequencing speed of mass spectrometers, while the nano-LC turnover rate limits the sample throughput. Here we combine a trapped ion mobility spectrometry (TIMS) QTOF capable of Parallel Accumulation Serial Fragmentation (PASEF) acquisition to a front end allowing efficient use of short gradients, the Evosep One to achieve, high depth at high throughput analysis.

Methods:

50ng of a peptide digest of a HeLa cell line were separated on an Evosep One (Evosep) and analyzed on a timsTOF Pro instrument (Bruker Daltonics). PASEF acquisition allowed for very high sequencing speed at high sensitivity. HeLa digests were separated on very short gradients of 11.5 and 5.6 min corresponding to 100 and 200 samples/day, respectively. Data were analyzed using PEAKS studio (Bioinformatics Solution Inc.) and MaxQuant (Max-Planck-Institute of Biochemistry).

Results:

The use of short nano-LC gradients reinforces the need of a fast MS instrument to guarantee reasonable analytical depth. TIMS provides a further dimension of separation in addition to the retention time and m/z ratio that increases peak capacity, and it releases the ions from the TIMS cell as concentrated ion packets. By applying the PASEF scan mode on those packets we obtain almost 100% duty cycle, increased sequencing speed ($> 100\text{Hz}$) and high sensitivity leading to a deep coverage of the proteome over 4 orders of magnitude dynamic range. To test if we can profit from the high speed and sensitivity of PASEF we set up very short gradients on the Evosep system with a total runtime of 14.0 min (11.5 min gradient) and 7.1min (5.6 min gradient), resulting in 100 samples/day and 200 samples/day, respectively. Evotips were loaded with only 50 ng of HeLa tryptic digest and analyzed. Using the 200 sample per day turnover we found more than 1200 protein families and 8000 peptide matches.

Conclusions

Our results demonstrate that PASEF on the timsTOF Pro coupled to the Evosep One enables fast and robust analysis of large sample numbers with potential applications for high throughput screening and clinical research.

Novel Aspect:

High Depth, High Throughput Label-free proteomics for clinical research.

168 - TARGETED QUANTITATION OF PROTEINS FOR DISCRIMINATING OBESE FROM NORMAL-WEIGHT ADOLESCENTS BY LIQUID CHROMATOGRAPHY-MASS SPECTROMETRY

Hyunsuk Shin (1) - Kisoan Dan (1) - Sanghoon Song (2) - Dohyun Han (1)

Seoul National University Hospital, Biomedical Research Institute, Seoul (1) - Seoul National University Hospital, Laboratory Medicine, Seoul (2)

Keywords: protein quantification, stable isotope-labeled (SIL) peptide, LC-MS/MS, protein biomarker, multiple reaction monitoring (MRM)

Introduction:

Targeted quantitation of proteins based on isotope-labeled synthetic peptides with multiple reaction monitoring (MRM) LC-MS/MS has been reported as one of the important technique. The aim of the present study was to select unique peptides of target proteins and to determine the concentration of the target peptides with LC-MS/MS in human plasma to compare between obese and non-obese subjects.

Methods:

The process began with a list of target proteins that identified by Tandem mass tag (TMT) strategy in the discovery phase. The next step was to select tryptic peptides and transitions of peptides after collision energy optimization using isotope-labeled peptides with Skyline software. Then, peptides were to analyze the samples by MRM LC-MS/MS method and to integrate and to evaluate the data.

Results:

Using detectability test of the endogenous peptides, we selected 100 representative target peptides from the 39 proteins. Stable isotope labeled internal standard peptides for 39 proteins have been synthesized. The concentration of the internal standards for each peptides was spiked to the sample was obtained by level of the unlabeled peptides in the plasma and randomized samples (n=60) were analyzed in triplicate by MRM LC-MS/MS. Relative quantitation of the peptides was carried out by monitoring the ratio of heavy-to-light peptide. Intra-day and inter-day precision of stable isotope-labeled peptides showed less than 15.62%. P value and AUC of the peptides were calculated with Medcal software and AUC of 12 peptides (9 proteins) that represented below 0.05 is showed below 0.0417.

Conclusions

100 Target peptides for the 39 proteins that distinguishing between obese and non-obese subjects were quantified and assessed by MRM LC-MS/MS in human plasma. This method is sensitive, robust and fit for purpose to verification of peptides. Finally, 60 human samples with obese or non-obese were successfully analyzed using our MRM method.

Novel Aspect:

Fully integrated MRM LC-MS/MS quantitation approach of targeted proteins to compare obese and non-obese subjects.

Keywords: pancreatic cancer, biomarkers, serum, TMT, early detection

Introduction:

Pancreatic ductal adenocarcinoma (PDAC) accounts for 85–90% of all pancreatic tumours. The median survival of all PDAC patients is less than 6 months, and the 5-year-survival rate is 3–5%[1]. One of the most crucial reasons for the poor prognosis is the lack of early diagnostic markers for PDAC. To overcome this and improve the outcomes of patients with PDAC, there is an urgent need to identify highly sensitive and specific markers for early detection.

In the present study, we employed the TMT method to generate comparative protein profiles of sera samples obtained from pre- and postoperative PDAC patients. Furthermore, we compared the serum levels of candidate proteins to evaluate the ability to discriminate between PDAC and healthy controls. Serum CA19-9 cannot discriminate the PDAC from other diseases such as pancreatitis and major gastroenterological cancers including biliary tract cancer (BTC).

Methods:

Using tandem mass tag labelling and LC-MS/MS, we performed comparative analyses of pre- and postoperative sera from PDAC patients to identify specific serum biomarkers for PDAC. In validation studies, we evaluated the discriminatory power of candidate proteins.

Results:

Among the 302 proteins analysed, 20 were identified as potential biomarkers, with C4b-binding protein α -chain (C4BPA) and polymeric immunoglobulin receptor (PIGR) being selected for further analysis. The sera levels of C4BPA and PIGR were significantly higher in the preoperative PDAC patients than in the postoperative ones ($P < 0.008$, $P < 0.036$, respectively). In addition, serum C4BPA levels, but not PIGR, in patients with PDAC were significantly higher than those in healthy controls as well as in patients with pancreatitis and other malignancies including biliary tract cancers (BTC) ($P < 0.001$). The respective area under the receiver operator characteristics (ROC) curve (AUC) was 0.860 for C4BPA, 0.846 for CA19-9 and 0.930 for the combination of C4BPA and CA19-9 in PDAC vs non-cancer individuals. The respective AUC was 0.912 for C4BPA, 0.737 for CA19-9 in Stages I and II of PDAC, 0.854 for C4BPA and 0.264 for CA19-9 in PDAC vs BTC.

Conclusions:

We have demonstrated that C4BPA is a novel serum biomarker for detecting early stage PDAC, as well as for distinguishing PDAC from other gastroenterological cancers. Further analysis in large cohort studies will warrant C4BPA as a promising biomarker of PDAC in clinical use.

Novel Aspect:

C4BPA is a novel serum biomarker for detecting early stage PDAC.

877 - USE OF THE MALDI BIOTYPER SYSTEM WITH MALDI-TOF MS FOR RAPID IDENTIFICATION OF MICROORGANISMS CAUSING BACTERIAL URINARY TRACT INFECTION FROM URINE SAMPLES

Maho Yano (1) - Kazuyuki Sogawa (1) - Hiroto Maeda (2)

Azabu University, Biochemistry, Kanagawa (1) - Maeda Veterinary Hospital, Surgery, Hokkaido (2)

Keywords: direct identification, LUTD, MALDI-TOF MS, rapid BACpro, urine

Introduction:

With the increasing number of cats maintained as pets, the opportunities to treat cats with lower urinary tract disease have recently increased in the clinical veterinary field. Several studies have reported urinary tract infection of felines with LUTD accounting for 2–10% of cases [1]. We performed direct identification of bacteria in urine using pretreatment kits for the direct application of positive blood culture bottles to MALDI-TOF MS, aiming to improve the low identification rates of *E. faecalis* and 2-morphology colony types.

Methods:

Urine samples collected from 50 cats with bacterial cystitis brought to Maeda Veterinary Hospital between August 10, 2015 and March 31, 2017 were used in the study. Sample preparation of the urine was performed using the MALDI Sepsityper kit and rapid BACpro. To identify the isolates, MALDI-TOF MS was performed on the AutoFlex TOF/TOF mass spectrometer.

Results:

MALDI-TOF MS seems to require high bacterial counts to be able to provide reliable scores. Experimental inocula with at least 1.0×10^5 CFU/mL were required to obtain reliable scores for *E. coli* by MALDI Sepsityper Kit and rapid BACpro, and the required inocula were even higher for *E. faecalis* by MALDI Sepsityper Kit (5.0×10^6 CFU/mL) and BACpro (1.0×10^5 CFU/mL).

Of the 50 urine specimens, the growth of colonies was observed in 37 specimens: 29 specimens with single colony morphology, 8 specimens with two colony morphology. Thirteen specimens did not grow in culture, and MALDI-TOF MS did not identify any significant protein profile in any of these cases.

Single colony morphology correctly identified 25 isolates (86.2%) using the MALDI Sepsityper Kit and 25 isolates (86.2%) with the rapid BACpro. In 4 cases in which identification was not possible, the bacterial count was 1.0×10^5 CFU/mL or lower, which was below the detection limit of sensitivity. In the specimens with two-colony morphology, the MALDI Sepsityper Kit identified only one species (*Citrobacter freundii*, *Enterobacter cloacae*, *Klebsiella pneumoniae*). The rapid BACpro was capable of identifying 2 species in 7 urine specimens. It was not able to identify any bacterium in one case, in which *E. faecalis* and *E. cloacae* were present, and the *E. cloacae* count was 1.0×10^5 CFU/mL, which was below the detection sensitivity.

Conclusions:

The MALDI-TOF MS method employing the rapid BACpro for pretreatment is a quick and reliable method for the identification of bacteria from infected urines, whose shortened analysis time enables an earlier and more accurate selection of antibiotics for feline LUTD treatment.

Novel Aspect:

The identification of bacteria by the MALDI-TOF MS method using the rapid BACpro for pretreatment is possible when the bacterial level is 1.0×10^5 CFU/mL or higher.

Keywords: adipose tissue inflammation, oxylipins, imaging mass spectrometry, targeted MRM

Introduction

Adipose tissue inflammation is a well-observed consequence of obesity and a prologue of the metabolic syndrome. It may result from infiltrating immunoinflammatory cells in adipose tissue, which disturbs metabolic homeostasis and initiates low-grade systemic inflammation. Obesity-induced lipid spillover in adipocytes provokes an aberrant adipokine secretory profile, resulting in the release of increased pro-inflammatory mediators such as cytokines and signaling lipid derivatives. Arachidonic acid is the main source of lipid derivatives (i.e. prostaglandins, thromboxanes, leukotrienes, resolvins, protectins and epoxyeicosatrienoic acids), that mediate inflammation. Different enzymatic conversions downstream of arachidonic acid, i.e. cyclooxygenase (COX), lipoxygenases (LOX) and cytochrome P450 epoxygenases (P450), yield specific lipid derivatives. The correlation between adipose tissue levels of these lipid derivatives and the metabolic healthy or unhealthy phenotype of the obese subjects is not clear [1]. Moreover, it is unclear to what extent circulating lipids reflect the inflammatory state of the diseased adipose tissue [2]. We hypothesize that we can determine the diagnostic value of these molecular lipids as biomarker for adipose tissue inflammation through the identification of aberrant local lipid expressions in diseased adipose tissue and subsequently connecting these to circulating lipid levels. Therefore, this project aims to analyze circulating pro-inflammatory lipids and oxylipins that reflect adipose tissue inflammation. The topological distribution of the molecular lipid profile in adipose tissue will be analyzed with mass spectrometry imaging (MSI), whereas circulating lipids in matched patient plasma samples will be analyzed with LC-multiple reaction monitoring-(MRM) MS.

Methods

Matched adipose tissue and plasma samples of 10 lean- and 10 obese metabolic healthy subjects were included in this study. For MSI experiments, fresh frozen adipose tissue biopsies were cryosectioned at 10 μm thickness slides. Each cryosectioned biopsy was split into three different slides randomly to minimize batch bias effects. A primary MALDI-MSI analysis on human adipose tissue was performed on a Rapiflex MALDI TissueTyper system (Bruker Daltonik GmbH, Bremen, Germany) in both positive and negative ionization mode. Representative tissue sections with aberrant lipid expression profiles from the primary screening were subsequently analyzed with high mass resolution imaging on an Orbitrap Elite mass spectrometer (Thermo Fisher Scientific, Bremen, Germany). Data analysis was performed as described previously [3].

A UPLC-ESI-MRM targeted mass spectrometry assay for oxylipins was developed on a Xevo TQ-S triple quadrupole, in negative ESI mode, coupled to an ACQUITY UPLC system using a Waters ACQUITY HSS PFP, 2.1x100 mm, 1.8 μm as analytical column (Waters Corporation, Milford, Massachusetts, USA). COX metabolites were obtained from Cayman Chemicals (Ann Arbor, Michigan, USA) to assess the method's performance, sensitivity and specificity by plasma spike-in assays with mixed mode solid-phase extraction (SPE) using Oasis MAX $\mu\text{Elution}$ plates (Waters Corporation, Milford, Massachusetts, USA). Heavy labeled COX metabolites were used as reference standards in patient samples. Sample preparation and SPE conditions were performed as described previously [4]. Data analysis was performed with TargetLynx V.4.1 (Waters Corporation, Milford, Massachusetts, USA).

Results

Lean and obese subjects were well defined based on anthropometric parameters (e.g. BMI and total body fat mass), biochemical analysis (e.g. plasma glucose, insulin and C-reactive protein) and markers of adipose tissue inflammation (e.g. IL-6, IL-8, number of macrophages and crown-like structures). Topological distribution of the COX-, LOX- and P450 metabolites in adipose tissue is being determined. Subsequently, aberrant lipid profiles in adipose tissue will be analyzed with existing metadata of individual subjects to infer the biological relevance of these metabolites. This holistic approach will indicate those relevant oxylipin profiles that are related to adipose tissue inflammation, which are then selected for targeted oxylipin MRM approach in circulating plasma samples.

MRM methods using specific transitions were developed for analysis of fourteen COX metabolites individually (i.e. 6 keto-Prostaglandin F1 α , Thromboxane B₂, 11 β -Prostaglandin F₂ α , Prostaglandin F₂ α , 11 β -13,14-dihydro-15-keto PGF₂ α , Prostaglandin E₂, Prostaglandin D₂, 13,14-dihydro-15-keto Prostaglandin E₂, 13,14-dihydro-15-keto Prostaglandin D₂, 15-keto Prostaglandin E₂, Prostaglandin J₂, 15-deoxy- Δ 12,14-PGD₂, 15-deoxy- Δ 12,14-Prostaglandin J₂ and Arachidonic Acid). MRM methods show good linearity across at least two magnitudes of standard (R² >0.97). Purification by SPE was further optimized to extract spiked COX metabolites standards (unlabeled and heavy labeled) in human plasma.

We currently perform assay validation of the MRM assay prior to analysis of patient samples. This pilot study of 10 lean and 10 obese subjects will be evaluated first prior to analysis of all lean (n=35) and obese (n=37) subjects and type 2 diabetic (T2D) patients (n=33). The T2D patients will be included as the metabolic unhealthy subjects.

Conclusions

This approach will allow to identify aberrant lipid expressions in diseased tissue and its connection to circulating lipid levels, which indicates the diagnostic value of these molecular lipid profiles as biomarker for adipose tissue inflammation.

Novel Aspect

The unique availability of matched patients samples (viz. adipose tissue biopsies and plasma) enables biomarker research for adipose tissue inflammation. This holistic approach that combines complementary mass spectrometry approaches will strengthen personalized biomarker research. This is the first study that combines MALDI-MSI with LC-MRM-MS to analyze molecular characteristics and location of lipid profiles in the adipose tissue and how this relates to the circulating lipid profiles per individual.

Keywords: glioblastoma, interferon signaling, oncolytic viruses, LC-MS/MS-based proteomics, label free quantitation

Introduction:

Therapy of glioblastoma multiforme (GBM) is challenging due to specific property of glioblastoma stem cells (GSC) to penetrate far from the tumor localization, thus, avoiding therapeutic actions. However, experimental therapy using oncolytic viruses have demonstrated ability to kill GSC and cause stable remissions. In this work, we studied specific defects in GBM antiviral mechanisms, enabling success of virus therapy.

Methods:

8 GBM cell cultures treated with interferon α, β were analyzed using Orbitrap Fusion Lumos mass spectrometer coupled with UltiMate 3000 nanoflow LC (Thermo Scientific). Protein identification, post-search validation and label free quantification were performed using X!Tandem [1] and MPscore [2], respectively. Statistical analyses of differential protein regulation followed by GO analysis were implemented using python-based libraries and GOrilla [3].

Results:

Tests for GBM cells sensitivity to vesicular stomatitis virus Indiana strain (VSV) have revealed 5 GBM cultures developing resistance to virus infection due to pre-treatment with interferon α or β (IFN α , IFN β). Other GBM cultures have either developed resistance after pre-treatment with IFN α or kept sensitivity to the virus regardless of IFN α and IFN β treatment. Based on these results, 5 GBM cultures were combined into the group with intact type I IFN signaling, while the other 3 cultures were defined as cultures with broken (at least partially) type I IFN signaling. Proteomics-based analysis of untreated and IFN treated GBM cells followed by analyses of differentially regulated protein products of IFN stimulated genes (ISGs) and biological process enrichments have revealed that GBM cells with intact IFN signaling respond to IFN α and IFN β treatment by enhanced production of ISGs proteins with antiviral properties. The number of ISGs proteins is considerably less in the group with broken type I IFN signaling.

Conclusions

Results of proteomic analysis of GBM cell responses to IFN α and IFN β treatment supported the results of VSV sensitivity tests. In our data, a molecular signature of significantly upregulated IFIT1/2/3, OAS1/2/3/L, MX1/2 proteins was a marker of developed resistance to VSV infection. We assume inactivation of STAT1 and STAT2, the key components of IFN signaling; can be responsible for the broken antiviral defense in GBM cells.

Novel Aspect:

The interactions between GBM cells, GSC and oncolytic viruses as well as the role of IFN signaling for virus therapy are the studies of primary interest, promising novel and effective therapy against glioblastoma.

Keywords: VC1-RAGE, glycosylated human serum albumin, affinity-mass spectrometry, epitope identification, surface plasmon resonance

Introduction

In the pathogenesis of diabetic complications, the interaction between the receptor for advanced glycation end products (RAGE) and its ligands AGEs is evident: however AGE structural properties and the interaction mode is still unknown [1]. Aimed at clarifying AGE structural requirements, the study intended to characterize the binding of VC1 (RAGE ectodomain) and commercial glycosylated human serum albumin (HSAgly) to gain new insights on AGE-RAGE interaction.

Methods

HSAgly and HSA were covalently immobilized onto carboxymethyl dextran surface and the binding with recombinant VC1 was investigated by means of surface plasmon resonance (SPR) [2]. Then, an affinity column was prepared by immobilizing VC1 on CNBr-activated sepharose beads for VC1-HSAgly interaction studies by MALDI-ToF mass spectrometry (MS). Epitope extraction MS[3] on HSAgly tryptic digestion was performed to identify HSAgly peptides involved in the binding.

Results:

Two surfaces of HSAgly and HSA were prepared via amine coupling chemistry and a SPR-based assay was used to verify the selectivity of the binding between VC1 and HSAgly in comparison with the unglycosylated isoform. VC1-HSAgly affinity analyses were carried out and a 1:1 binding model was used to extrapolate the equilibrium dissociation constant of the complex (KD). The binding constant ($KD = 4.9 \mu M$) showed a moderate affinity of VC1 for HSAgly and allowed to make some consideration on the strength of such interaction.

Furthermore, a VC1-based affinity column was prepared and VC1-HSAgly interaction was confirmed by MALDI-ToF MS. HSAgly was tryptic digested and analyzed by ESI-Q-ToF and MALDI-ToF MS in order to characterize the glycation sites on the protein scaffold. Epitopes extraction method allowed the isolation and the characterization of HSAgly peptides involved in the interaction. The analysis of the model structure showed that they belong to discontinuous epitope included in domain I and sub-domain IIA of the protein.

Conclusions

The results of this study enabled the assessment of VC1-HSAgly interaction by affinity-MS. VC1 showed to well discriminate between glycosylated and unglycosylated HSA confirming that HSAgly acts as VC1 binder. The determination of the affinity binding constant and the structural identification of epitope involved in such interaction provided a reliable characterization of commercial HSAgly as marker for AGE-RAGE interaction studies.

Novel Aspect

The affinity-MS approach for identification of epitopes and affinity quantification of the complex provided key information on the glycation sites involved in RAGE binding.

495 - THE MOLECULAR PATTERN OF PLASMA PROTEINS AND THEIR CORRELATION TO PAIN INTENSITY AND SENSITIVITY IN WOMEN WITH FIBROMYALGIA – A MULTI-CENTER STUDY

Karin Wåhlén (1) - Björn Gerdle (1) - Kaisa Mannerkorpi (2) - Eva Kosek (3) - Malin Ernberg (4) - Bijar Ghafouri (1)

Linköping University, Department of Medical and Health Sciences, Linköping (1) - University of Gothenburg, Department of Health and Rehabilitation/Physiotherapy, Gothenburg (2) - Karolinska Institutet, Department of Clinical Neuroscience, Stockholm (3) - Karolinska Institutet, Department of Dental Medicine, Stockholm (4)

Keywords: Proteomics, chronic pain, plasma, multivariate statistics, fibromyalgia

Introduction:

The complete knowledge of the molecular mechanisms behind fibromyalgia (FM) is still lacking and few studies have analyzed the peripheral molecular pattern in women with FM. The primary aim of this study was to investigate and compare the plasma proteome profile between women with FM and healthy controls (CON). Secondly, to investigate the correlation between plasma protein patterns and pain intensity (Visual analogue scale, VAS) and pressure pain thresholds (PPT).

Methods:

Clinical variables and background data were collected and PPTs were recorded using an electronic algometer. Plasma proteome profile from women with FM (n=30) and CON (n=32) was analyzed by 2-DE combined with MS. The 2-DE results were analyzed with Principal Component Analysis (PCA) and Orthogonal Partial Least Squares – Discriminant Analysis (OPLS-DA) models. Correlation between plasma proteins and pain intensity, pain sensitivity was analyzed in FM using OPLS.

Results:

As expected significant differences were found between FM and CON in the clinical variables Fibromyalgia impact questionnaire (FIQ), VAS, PPT, hospital and anxiety depression scale (HADS) and pain catastrophizing scale (PCS). The OPLS-DA model, identified 27 plasma proteins as being important for the group separation between FM and CON. In the OPLS model of pain intensity, 12 proteins were multivariately correlated with pain intensity in the FM group; eight of 12 proteins were associated with higher pain intensity score (VAS > 50 mm). In the OPLS model of pain sensitivity in FM, 11 proteins multivariately correlated with PPT; three out of 11 proteins were associated with very low pain sensitivity score (< 200 kPa).

Conclusions:

In this cohort prominent differences exist in plasma protein patterns between FM and CON. Several plasma proteins correlated with pain intensity and sensitivity and these proteins need to be further identified to confirm their role in FM. Combining clinical and proteomic data with multivariate statistics, potential biomarkers could be identified that can lead to improved clinical assessments, treatments and eventually new pharmacological therapies for FM.

Novel Aspect:

Plasma proteomic generate large data set, which in combination with multivariate statistics, is an important tool for identifying potential biomarkers associated with FM.

133 - THERAPEUTIC PROTEINS IN SPORTS DRUG TESTING: DETECTION OF DIFFERENT ACTRII INHIBITORS IN SERUM BY MEANS OF (IMMUNO-)AFFINITY PURIFICATION, TRYPTIC DIGESTION, AND LC-HRMS

Katja Walpurgis (1) - Andreas Thomas (1) - Christian Reichel (2) - Frank Dellanna (3) - Mario Thevis (1)

German Sport University Cologne, Institute of Biochemistry/Center for Preventive Doping Research, Cologne (1) - AIT Seibersdorf Laboratories, Doping Control Laboratory, Seibersdorf (2) - Fresenius University of Applied Sciences, Fresenius University of Applied Sciences, Cologne (3)

Keywords: Doping, ActRII-Fc fusion proteins, Therapeutic antibodies, Affinity purification, LC-HRMS

Introduction:

Therapeutic proteins represent an emerging class of pharmaceuticals comprising several drug candidates with potential performance-enhancing properties. Especially inhibitors of the ActRII signaling pathways possess the potential for being misused as doping agent in sports as they were found to have positive effects on muscle mass, bone formation, and red blood cell production[1, 2].

Methods:

Ammonium sulfate precipitation, (immuno-)affinity purification, tryptic digestion, and LC-HRMS were employed to develop targeted detection assays for the therapeutic antibody Bimagrumab and the ActRII-Fc fusion proteins Sotatercept (ActRIIA-Fc) and Luspatercept (modified ActRIIB-Fc) in doping control serum samples.

Results:

Three complementary assays for the detection of different ActRII inhibitors were successfully developed by using different proteomic techniques [3, 4]. The methods were comprehensively characterized and found to be fit for purpose for doping control routine analysis. In addition to LC-HRMS, ion mobility was employed to facilitate the unambiguous identification of the target peptides. For Bimagrumab, clinical samples were analyzed to demonstrate the applicability of the approach to authentic serum specimens.

Conclusions:

Mass spectrometric assays for the detection of emerging protein drugs are of great value for both the pharmaceutical industry and preventive doping research. The presented assays will expand the range of available tests and can readily be modified to include other therapeutic fusion proteins and antibody-based drugs.

Novel Aspect:

Although no ActRII inhibitors have obtained clinical approval yet, LC-HRMS detection methods for three candidates were proactively developed.

265 - A NOVEL HIGH-THROUGHPUT ANTIBODY-FREE LC-MS/MS ASSAY TO QUANTITATE CHROMOGRANIN-A IN SERUM

Darren Weber (1) - Scott Goldman (1) - Michael McPhaul (2) - Michael Caulfield (2) - Nigel Clarke (1)

Quest Diagnostics, R&D Mass Spectrometry, San Juan Capistrano (1) - Quest Diagnostics, Quest Diagnostics Nichols Institute, San Juan Capistrano (2)

Keywords: Tumor biomarker; diagnostics; clinical mass spectrometry; proteomics

Introduction:

Chromogranin-A (CgA) is a protein produced in the secretory granules of neuroendocrine tissue, with increased plasma levels being indicative of neuroendocrine tumors (NET)[1]. Currently, CgA is measured using various immunoassays [2]. However, limitations arising from non-specific binding and a reduced dynamic range pose hurdles in implementing such tests in clinical laboratories. Here we describe a novel, antibody-free LC-MS/MS assay to quantitate CgA in serum.

Methods:

Exploiting the acidic properties of CgA, 100 μ L of serum is extracted using an anion exchange solid-phase extraction plate followed by addition of internal standard (IS). The extracted sample is concentrated, enzymatically digested, and a unique peptide to CgA is chromatographically resolved and analyzed by SRM on a Sciex 6500+ QTrap mass spectrometer. The ratio of the analyte peak area to the isotopically labeled IS peak area is used to achieve quantitation.

Results:

Chromogranin-A showed linearity across a wide range (50-50,000 ng/mL, $R^2=0.99$), as well as inter- and intra-assay reproducibility (CV 5.2-15.7%). Analytical sensitivity and limit of quantitation were determined to be 35.5 and 50 ng/mL, respectively. This method has no cross reactivity with interfering substances, and shows sample stability up to 5 days at room temperature, up to 14 days at 4C, and up to 31 days at -20C. Samples from 308 patients were analyzed to compare CgA serum values measured by the Cisbio CGA-ELISA-US immunoassay with values from our LC-MS/MS assay. After natural logarithm-transformation of the measurements, a normal distribution was seen in the 308 patients. A paired t-test was performed on these data and the concordance between the assays was measured by the Pearson correlation coefficient and Passing & Bablok curve fitting ($R^2=0.76$; $-0.25 + 1.03x$).

Conclusions:

We have developed and validated a fully automated LC-MS/MS assay for quantitating chromogranin-A out of serum. Unlike immunoassays, our workflow is not dependent on capture and detection antibodies, and therefore structural changes in CgA due to denaturation, aggregation, or post-translational processing will have no impact on detection.

Novel Aspect:

This is a first-of-its-kind LC-MS/MS assay to detect and quantitate chromogranin-A out of serum.

516 - OPTIMIZATION OF BIOTIN ENRICHMENT PROTOCOL AND ITS APPLICATION FOR THE ANALYSIS OF ORGANELLE-ENRICHED PROTEINS BY LC-MS/MS

Shiva Ahmadi (1) - Dominic Winter (1)

Institute of Biochemistry and Molecular Biology, University of Bonn, Bonn (1)

Keywords: BioID, Affinity Enrichment, Organelle, MS

Introduction:

The strong interaction of biotin and avidin is widely used for the enrichment of proteins from complex mixtures. The recovery of biotinylated proteins and the discrimination between unspecific binding and specifically enriched proteins remain major challenges. We compared different strategies for the purification of biotin-enriched proteins followed by MS analysis and applied them to the analysis of organelle proteomes.

Methods:

Equal amounts of heavy control and light stably BioID [1] transfected SILAC cells were combined, lysed and processed with 4 methods (three replicates): 1,2: Binding to beads followed by digestion and off-gel fractionation using 2 sets of washing buffers [2]; 3. Digestion prior to biotin capture [3]; and 4. Elution from the beads and in-gel digestion [4]. Organelle proteomes were enriched using different BioID constructs. Samples were analyzed using LC-MS/MS.

Results:

Using unbiotinylated 3plex SILAC labeled HEK cells (in two replicates), a significance threshold for biotinylation (95% of proteins) was calculated. Peptides with experiment/control ratios above this threshold were considered to be specifically enriched and therefore biotinylated. On bead digestion followed by offgel fractionation resulted in identification of 3165 and 3006 proteins on average for 2 different sets of washing buffers (82.3% and 81.6% biotinylated). Incubation of peptides with beads yielded on average in 173 proteins identifications (64% biotinylated) while elution of biotinylated proteins followed by in gel digestion resulted on average in 711 proteins (81.3% biotinylation). Using method 1, cells transiently transfected with 4 different BioID constructs (three replicates) located at the cytoplasm, endoplasmic reticulum, nucleus, and mitochondria were analyzed, resulting in distinct subcellular proteomes.

Conclusions:

Except digestion of proteins prior to on bead biotin capture, all approaches resulted in similar enrichment efficiencies for biotinylated proteins. On bead digestion resulted in the highest number of identifications being in our hands the best method for the analysis of affinity captured biotinylated proteins. It was possible to identify subcellular proteomes using different BioID constructs.

Novel Aspect:

Comparison of methods for avidin affinity capture of biotinylated proteins for MS analysis and analysis organelle proteomes using BioID constructs.

1285 - GLOBAL ANALYSIS OF PROTEIN COMPLEXES IN TRYPANOSOMA BRUCEI USING CROSS-LINKING MASS SPECTROMETRY

Fernando Almeida (1) - Michele Tinti (1) - Michael Ferguson (1)

The University of Dundee, Biological Chemistry and Drug Discovery, Dundee, United Kingdom (1)

Keywords: protein correlation profiling; Trypanosoma brucei; cross-linking; size exclusion chromatography; cryomilling

Introduction

Trypanosoma brucei is a protozoan parasite and the causative agent of sleeping sickness in humans. Approximately 9100 protein coding genes have been identified by whole genome sequencing[1], yet 4900 of these lack classifiable homology to known proteins in other organisms. To further ascribe functional classification to these “hypothetical” proteins [2,3], we performed a protein correlation profiling (PCP) based on a cross-linking mass spectrometry approach.

Methods

Cells were cryomilled and the lysate powder was reacted with the cross-linking reagent DTSSP. After, the cross-linked protein samples were submitted to size exclusion chromatography (SEC) followed by their fractionation. Each fraction was submitted to nanoLC-MSMS analyses and their PCP analysis was performed based on label free quantification (LFQ) intensities processed by MaxQuant.

Results

PCP identifies co-fractionating proteins to enable a global characterization of functionally related proteins via “guilt by association”, as many intracellular biological processes are dependent on the stable physical association between two or more proteins. We utilised cryomilling to maintain *in vivo* protein associations, whilst using chemical crosslinking to stabilise such interactions during further sample processing.

In order to optimise DTSSP mediated crosslinking conditions, α -tubulin was monitored as a reference protein by Western blotting with anti- α tubulin. The established reaction condition of 4 mM DTSSP for 30 mins was sufficient to induce crosslinking. As a next step, the SEC was performed, and the eluted protein complexes were collected in 12 fractions. The PCP results revealed protein complexes that were not seen in the previous study carried out using native conditions[4]. Moreover, we have found hypothetical proteins associated with annotated proteins, that might help to accredit their shared function.

Conclusions

We established a crosslinking approach with DTSSP on cryomilled *Trypanosoma brucei* cell lysates, followed by their proteins separation on SEC and fractionation. Using a small number of fractions, PCP preliminary data have shown the capability to reveal not only protein complexes that were not seen in the previous study, but also the protein associations between annotated and hypothetical proteins.

Novel Aspect

The novel aspect of this approach relies on the combination of cryomilled cell lysates, the covalent protein association using crosslinking, SEC and PCP.

1008 - SAMPLE MULTIPLEXING BY ISOELECTRIC FOCUSING (PI-CODING) FOR ISOBARIC LABELING AND LABEL-FRANTIFICATION

Juan Astorga-Wells (1) - Christian Beusch (2) - Thorleif Lavold (3) - Roman A. Zubarev (2)

--, Karolinska Institutet, Medical Biochemistry and Biophysics, -- (1) - --, Karolinska Institutet, Medical Biochemistry and Biophysics, Stockholm (2) - Biomotif AB, --, Stockholm (3)

Keywords: Multiplexing, Isoelectric Focusing, Isobaric Labeling

Introduction:

Sample multiplexing is an important tool for improving the throughput of MS analysis. Herein, we introduce the concept of Isoelectric Point Coding (pI-Coding) for an additional x2 or x3 level-multiplexing power of isobaric labeled samples. An in-solution isoelectric focusing device for fast pI-Coding is described, especially suitable for combining biological-replicates into a single sample. The utilization of pI-Coding for LFQ and TMT samples is demonstrated.

Methods:

Steps for pI-Code multiplexing:

1. Separation. Isolation of non-overlapping pI windows from each sample; Sample 1: peptides with pI < 5.0, Sample 2: peptides pI between 5.2-7.5, and Sample 3: peptides with pI > 7.8.
2. Pooling of all isolated pI ranges into one sample, followed by its LC MS/MS analysis.
3. Signal deconvolution: theoretical pI calculation of every peptide & assignment according to: pI < 5 to Sample 1, pI between 5.2 and 7.5 to Sample 2, pI > 7.8 to Sample 3.

Results:

In isobaric labelling, the sample number information is encoded into a chemical tag, which is later decoded by MS [1]. Similarly, the isoelectric point value can be used as an information tag, since its value can be easily calculated, and because each protein produces tryptic peptides having pI values from acidic to neutral to basic, with empty valleys between them. In fact, it has been shown full human proteome coverage using peptides with pI ranges between 2.5 - 4.7 [2].

pI-Coding was developed as followed:

In-silico modelling. Several isoelectric focusing ranges were studied for optimum multiplexing. The results showed that two to three pI-channels provide at least 3 peptides for each protein.

pI-Coding. An isoelectric focusing device was developed for optimum collection of 3 pI areas in a way compatible with automation.

Validation. The results showed that pI-coding could be used for x2 or x3 multiplexing for the analysis of thousands of proteins in a highly parallelized manner for iTRAQ/TMT-based or label-free quantification.

Conclusions:

The pI-Coding works with LFQ and TMT-reagents to double or triple their throughput. In LFQ, pI-coding is especially suitable for combining 3 biological replicates into a single sample (using 3 pI-Code channels). In the case of TMT-labeled samples, pI-Coding allows up to 20-30 sample multiplexing. In-silico modelling suggest that pI-Coding could be applied to different organisms. To our knowledge this is the highest level of multiplexing described in the literature.

Novel Aspect:

pI-Coding works with LFQ and TMT-labeling to double or triple their throughput. In TMT-labeled samples, it allows up to 20-30 sample multiplexing.

1203 - DIFFERENTIAL PROTEOMIC ANALYSIS OF ACTINIC KERATOSIS, BOWEN'S DISEASE AND CUTANEOUS SQUAMOUS CELL CARCINOMA BY SEQUENTIAL WINDOW ACQUISITION OF ALL THEORETICAL MASS SPECTRA (SWATH-MS)

Ali Azimi (1) - Marina Ali (1) - Kimberley Kaufman (2) - Pengyi Yang (3) - Graham Mann (4) - Pablo Fernandez-Penas (1)

Centre for Translational Skin Research, The University of Sydney, Westmead, Australia (1) - School of Life and Environmental Science, The University of Sydney, Camperdown, Australia (2) - School of Mathematics and Statistics, The University of Sydney, Camperdown, Australia (3) - Centre for Cancer Research, The University of Sydney, Westmead, Australia (4)

Keywords: Differential Proteomic Analysis of Actinic Keratosis, Bowen's Disease and Cutaneous Squamous Cell Carcinoma by Sequential Window Acquisition of All Theoretical Mass Spectra (SWATH-MS)

Introduction:

Actinic keratosis (AK), Bowen's disease (BD) and cutaneous squamous cell carcinoma (cSCC) are heterogeneous skin tumours with high prevalence rates globally. This study reports comprehensive protein biomarkers with discriminatory capabilities towards these lesions.

Methods:

Proteolytically digested peptides from formalin-fixed and paraffin embedded (FFPE) samples of normal skin, AK, BD, well differentiated cSCC (n=14), moderately differentiated cSCC (n=15) and poorly differentiated cSCC (n=15) were analysed in TripleTOF® 6600 using sequential window acquisition of all theoretical mass spectra (SWATH-MS) workflow. Peptide peaks were extracted using Skyline followed by their differential abundance analysis and bioinformatics analysis.

Results:

We reliably identified and quantified 3574 proteins across 93 samples. Differential abundance analysis revealed that 15, 26 and 403 proteins were exclusively changed in cSCC, BD and AK samples compared to the normal skin, respectively. Also, 16 and 225 proteins were differentially abundant exclusively in BD and cSCC compared to AK samples, respectively. Ten proteins were differentially abundant in cSCC compared to BD samples. In addition, a total of 118 proteins were commonly changed in moderately-differentiated and poorly-differentiated cSCC samples compared to well-differentiated cSCC subtype while 55 and 809 proteins were differentially abundant exclusively in moderately and poorly differentiated cSCCs compared to well-differentiated cSCC samples, respectively. Majority of these proteins were involved in pathways associated with cell proliferation, apoptosis and DNA damage response which are crucial in carcinogenesis.

Conclusions:

To our knowledge, this is the most comprehensive and complete SWATH-MS proteomic study in cSCC and its premalignant lesions. The identification of differentially abundant proteins and potentially important molecular pathways in this study form a rich resource for biomarker discovery in the future.

Novel Aspect:

For the first time we successfully applied SWATH proteomics on FFPE skin samples. Our methodology opens invaluable opportunities to explore proteome of other skin conditions.

1144 - TAPE STRIPPED STRATUM CORNEUM SAMPLES PROVE TO BE SUITABLE FOR COMPREHENSIVE PROTEOMIC INVESTIGATION OF ACTINIC KERATOSIS

Ali Azimi (1) - Marina Ali (2) - Kimberley Kaufman (3) - Graham Mann (4) - Pablo Fernandez-Penas (2)

Centre for Translational Skin Research, The University of Sydney, Westmead, Australia (1) - Centre for Translational Skin Research, The University of Sydney, Westmead (2) - School of Life and Environmental Science, The University of Sydney, Camperdown (3) - Centre for Cancer Research, The University of Sydney, Westmead (4)

Keywords: tape stripping, mass-spectrometry based proteomics, actinic keratosis, noninvasive skin biopsy

Introduction:

Actinic keratoses (AK) are frequent premalignant tumors that can be clinically difficult to differentiate from skin cancer. To definitely confirm or rule out the diagnosis, a biopsy is needed, but this is an invasive procedure that leads to increased morbidity. An easy, quick and reliable non-invasive alternative to biopsy is needed to definitively confirm the clinical diagnoses. In this paper, we evaluate Tape Stripping (TS) of stratum corneum (SC) for biomarker analysis of AK.

Methods:

Lesional and non-lesional human SC samples were obtained by application of stripping tapes on the skin of five AK patients. Following sample preparation, protein digests were analyzed by liquid chromatography tandem mass-spectrometry (LC-MS/MS). Bioinformatics analysis were performed using Funrich, Ingenuity Pathway Analysis (IPA) and Oncomine bioinformatics and analytical tools.

Results:

Of the total 613 unique proteins identified, 477 overlapped with proteins identified in our proteomic analysis of formalin-fixed and paraffin-embedded (FFPE) AK samples. Additionally, 32 proteins were significantly increased, and four proteins decreased in AK samples compared to the normal skin ($p < 0.05$). In line with proteomic analysis of FFPE samples, IPA and Funrich analysis showed that differentially abundant proteins in the TS AK samples are implicated in PI3K/AKT and EGF signaling pathways. These findings were confirmed at the transcript level.

Conclusions:

Tape stripped AK sample is suitable for biomarker analysis using mass spectrometry.

Novel Aspect:

The application of this technique further could revolutionize management of keratinocytic skin tumors by reducing the need for traditional invasive biopsy.

1196 - DRUG EFFECTS ON PROTEIN HOMEOSTASIS

Marcus Bantscheff (1)

GlaxoSmithKline, GSK Cellzome GmbH, Heidelberg (1)

Keywords: protein turnover, drug effects, protein homeostasis, targeted degraders

Introduction:

Protein degradation plays important roles in biological processes and is tightly regulated. Further, targeted proteolysis is an emerging research tool and therapeutic strategy. However, proteome-wide technologies to investigate the causes and consequences of protein degradation in biological systems are lacking.

Methods:

mPDP enables the sensitive and comprehensive relative quantification of cellular mature and nascent protein pools across a range of different treatment conditions in biological duplicates and in a single mass spectrometric experiment by combining dynamic SILAC with chemical labeling using neutron-encoded tandem mass tags (TMT).

Results:

We developed 'multiplexed proteome dynamics profiling', mPDP [1], a mass spectrometry-based approach combining dynamic-SILAC labelling with isobaric mass tagging for multiplexed analysis of protein degradation and synthesis. When applied combination with other quantitative proteomics approaches such as chemoproteomics and thermal protein profiling, mPDP provides unique insights in drug mechanism-of-action. The method was applied in three proof-of-concept studies, and uncovered different responses induced by the bromodomain inhibitor JQ1 versus a JQ1-proteolysis targeting chimera. Further, we elucidated distinct modes-of-action of estrogen receptor modulators, and we comprehensively classified HSP90 clients based on their requirement for HSP90 constitutively or during synthesis demonstrating that constitutive HSP90 clients have lower thermal stability than non-clients, higher affinity for the chaperone, vary between cell types and change upon external stimuli.

Conclusions:

We have established multiplexed proteome dynamics profiling a powerful means to elucidate the mechanism of action of bioactive molecules, thus complementing current proteome-wide target identification strategies. mPDP identifies targets of protein degraders and more generally enables the discovery of regulatory degradation mechanisms in biological systems.

Novel Aspect:

PROTAC target identification and detection of regulated degradation events.

1037 - A HIGH-RESOLUTION ORGANELLAR PROTEOMICS APPROACH TO STUDY PROTEIN SUBCELLULAR DISTRIBUTION AND DYNAMICS IN CELLS

Clara Steinbrueck (1) - Johannes Jordan (1) - Maciej Kocylowski (1) - Astrid Kollwe (1) - Wolfgang Bildl (1) - Alexander Haupt (1) - Bernd Fakler (1) - Uwe Schulte (1)

Institute of Physiology, Faculty of Medicine, University of Freiburg, Freiburg (1)

Keywords: organellar proteomics, subcellular fractionation, relative quantification, hierarchical clustering, protein complexes

Introduction:

In previous studies we have presented comprehensive interactome analysis using multi-epitope AP-MS ([1], [2]) and stoichiometric complexome analysis by csBN-MS ([3]) for membrane proteins. Notwithstanding, these techniques do not provide information on biogenesis of assemblies, subcellular distribution or spatiotemporal dynamics. We, therefore, took on extending/refining organellar proteomics workflows ([4], [5], [6], [7]).

Methods:

Primary epithelial cells (RPTEC) were used as a model for endosomal recycling. After isotonic homogenization, hypotonic lysis and disruptive sonication multidimensional protein fractionation was applied. Fractions were analyzed by nano-LC-MS/MS. After label-free quantification, Euclidian-distance based hierarchical clustering and dimensionality reduction by t-distributed stochastic neighbor embedding (t-SNE) data were visualized in two dimensions.

Results:

Key elements of the approach are subcellular fractionation (which is inherently limited), comprehensive and quantitative MS profiling, and unsupervised cluster analysis. High reproducibility and accuracy are required for optimal results. The higher the number of non-redundant fractions, the higher the precision of quantification. Nano-LC-MS/MS analysis of 80 trypsin-digested RPTEC samples (40 sub-fractions, each divided into an upper and a lower molecular weight range sample by SDS-PAGE) with an LTQ Orbitrap XL instrument yielded more than 3700 quantitative protein distribution profiles. Hierarchical clustering revealed more than 20 distinct entities representing classical cellular organelles or organelle substructures, populations of trafficking vesicles, multiprotein machineries and cytoskeletal networks as shown by successful mapping of 1074 prequalified marker proteins and validated functional annotations from UniProtKB/Swiss-Prot.

Conclusions:

Organellar proteomics is a powerful method for comprehensive, robust and quantitative assessment of the subcellular localization of proteins with a broad range of applications: Identification and verification of subcellular markers, classification of interactomes, unbiased definition of subcellular proteomes, analysis of spatial dynamics of proteins and localization determinants, etc.

Novel Aspect:

With multidimensional fractionation and advanced quantification, cluster analysis and visualization tools protein clusters were resolved with unprecedented resolution.

1269 - ABUNDANT PROTEIN DEPLETION OF HUMAN PLASMA SAMPLES – SAMPLE PREPARATION APPROACHES FOR QUANTITATIVE COMPARISON STUDIES

Ryan Bomgarden (1) - Sergei Snovida (1) - Katherine Herting (1) - Ramesh Ganapathy (1) - Barbara Kaboord (2) - John Rogers (1)

Thermo Fisher Scientific, R&D, Rockford, United States (1) - Thermo Fisher Scientific, R&D, Rockford, United States (2)

Keywords: plasma, depletion, TMT, sample preparation

Introduction:

Depletion of abundant plasma proteins is required to identify and measure changes in prognostic or diagnostic proteins [1]. We have developed new top2 and top12 abundant protein depletion resins and evaluated them for depletion specificity, efficiency, and reproducibility. We also combined our abundant protein depletion resins with a streamlined Tandem Mass Tag (TMT) sample preparation procedure.

Methods:

Commercially-obtained pooled human plasma samples were used to assess depletion resins by SDS gel, ELSIA, and LC-MS. HighpHreversed-phase fractionation was performed on TMT-labeled samples before LC-MS analysis. All samples were analyzed on Thermo Scientific Orbitrap Fusion Tribrid mass spectrometer and processed using Thermo Scientific Proteome Discoverer 2.2 software [2].

Results:

After optimization of the antibody ligand conjugation chemistries and resin blending protocols, we achieved >97-99% depletion efficiency of twelve high abundance protein targets in human plasma samples. Abundant protein depletion from plasma enabled detection of 34% more peptides and 25% more proteins compared to undepleted samples. Assessment of depletion capacity of the new resins showed high reproducibility for samples ranging from 10-100ul. These depletion resins were also used in combination with a new sample preparation workflow for TMT-reagent labeling which minimizes sample handling and the number of steps. Using this workflow, we identified and quantified nearly 1100 proteins in normal and lung cancer patient plasma samples.

Conclusions:

Abundant protein depletion from plasma enables detection of more peptides and proteins for better detection and quantitation of relevant biomarkers. Combining abundant protein depletion with a streamlined TMT reagent sample preparation workflow and high pH reversed phase fractionation resulted in quantification of nearly 1100 proteins in normal and lung cancer patient plasma samples.

Novel Aspect:

Development and comprehensive analysis of new top2 and top12 depletion resins for abundant human plasma proteins for quantitative comparison studies.

342 - EVALUATION OF PROTEOMICS QUANTITATIVE METHODS ON A RECONSTRUCTED SKIN MODEL

Sylvie Bourassa (1) - Clarisse Gotti (1) - Marie-Pier Scott-Boyer (2) - Judith Marcoux (1) - Isabelle Kelly (1) - Arnaud Droit (3)

CHU Proteomics Platform, Laval University, Quebec (1) - CHU Bioinformatics Platform, Laval University, Quebec (2) - CHU Proteomics and Bioinformatics Platform, Laval University/Molecular Medicine, Quebec (3)

Keywords: proteomics quantification methods comparison softwares

Introduction: (Limit of 400 characters)

No consensus have been made whether label or label free proteomics quantitative methods are better for the quantitative analysis of complex mixtures. We have analyzed human reconstructed skin samples of 4 donors at different time using 10-plex TMT labeling, label free quantitation, DIA (Data Independent Acquisition) and SRM for a comprehensive analysis of the phenomena of skin reconstruction and comparison of proteomics quantitative techniques and softwares.

Methods: (Limit of 400 characters)

Epidermal skin reconstruction of 4 donors at 10 times (0 to 28 days) were used for the comparison. Peptides were labeled with 10-plex TMT and injected on the orbitrap fusion. The label-free experiment was injected on the orbitrap fusion and analysed by MaxQuant and Proteome Discoverer 2.2.60 selected proteins were targeted by SRM on the 6500 QTRAP and analyzed by Skyline. DIA experiments were performed on the orbitrap fusion and analysed by Scaffold DIA or Skyline.

Results: (Limit 900 characters)

4338 proteins were identified by using 5 different 10-plex TMT experiments (14 fractions of 2 hours) with a common reference pool. 1821 quantifiable proteins were common between the 5 experiments and 48 variant proteins were obtained. For the Label-Free experiment, individual samples were run for 5 hours identifying 3619 proteins, from which 2749 were quantifiable. 393 proteins were considered variant with MaxQuant and the results will be compared with PD 2.2 software. 55 of the selected proteins for the SRM experiment were quantifiable and 13 proteins were variants. DIA experiments (50 windows of 10 amu) using Scaffold DIA and Skyline will be compared with the 3 other Methods: 11 proteins were commonly statistically variants between the 4 different techniques at specific time points and 8 of them behave exactly the same along the time course for the quantitative techniques tested.

Conclusions (Limit of 400 characters)

For this project, TMT gave the highest number of protein identifications, Label-Free analysis gave the highest number of quantifiable proteins and DIA gave the best results for the reproducibility. Label free analysis using precursor intensity was the most valuable method despite the longest time of analysis. We found that the use of Scaffold DIA is promising for the analysis of DIA data.

Novel Aspect: (Limit of 150 characters)

Different quantitative proteomics methods and the use of a new released software for DIA allows better understanding and confidence in the mechanism of skin reconstruction.

436 - NEW PHARMACOLOGICAL TARGETS FOR CYSTIC FIBROSIS TREATMENT FROM EXTENSIVE PROTEOMIC PROFILING OF Δ F508-CFTR EXPRESSING CELLS.

Clarissa Braccia (1) - Valeria Tomati (2) - Nicoletta Pedemonte (2) - Andrea Armirotti (3)

Fondazione Istituto Italiano di Tecnologia, D3Pharmacemistry, Genova (1) - Istituto Giannina Gaslini, U.O.C. Genetica Medica, Genova (2) - Fondazione Istituto Italiano di Tecnologia, Analytical Chemistry Facility, Genova (3)

Keywords: Cystic Fibrosis; bronchial epithelial cells; SWATH ion library

Introduction:

Cystic fibrosis (CF) is a genetic disorder, caused by mutations in the CFTR gene [1]. Deletion of phenylalanine 508 (F508del) is the most frequent mutation. Dr. Pedemonte's group has selected molecules with a role in F508del-CFTR processing and degradation. After their silencing, an increase of CFTR at the cell membrane was measured [2], [3]. Using SWATH workflow [4], it is possible to analyze changes at proteome level. The first step is the creation of an ion library.

Methods:

We characterized the proteome of CFBE410-, the in-vitro model for cystic fibrosis pharmacological research [5]. CFBE410- cells were cultured and transfected as already described [2]. From cell lysates, we performed both an in-gel digestion and an in-solution digestion. The in-solution digestion was performed on both Proteominer [6] wash and eluted fractions and the resulting peptides were then fractionated offline (8 fractions) with a high pH/low pH strategy [7].

Results:

Raw data were analyzed with ProteinPilot software using the Paragon algorithm [8]. Spectra were searched against the Homo sapiens reference proteome, reporting 71599 proteins. Search was performed against both target and decoy databases. Carbamidomethylation of cysteine (CAM) was set as fixed modification and only four variable modifications were allowed, maximum one per peptide (methionine oxidation, asparagine and glutamine deamidation and conversion of glutamine and glutamate to pyroglutamic acid). This search, done using the FDR calculation protocol described by Tang in 2008 [9], returned 5935 proteins and 72031 distinct peptides at a FDR of 1%.

To ensure high quality to our library, we imported in the library builder only MRM data of proteins with a maximum global FDR of 1%. Moreover, we removed the peptides shared by more than one protein.

After these filtering steps, we produced an ion library with the spectral information on 5627 proteins.

Conclusions:

Thanks to this ion library, we were able to quantify more than 2000 proteins in a total lysate from a single 2 hours LC-MS/MS run.

The ion library we generated will enable us to detect changes at protein level in response to the silencing of molecules known to be involved in CFTR processing.

Novel Aspect:

We built the first SWATH ion library dedicated to the most used cell model for CF research. Unlike the pan-human ion library [10], our library contains CFTR and some of CFTR interactors.

489 - STRAIGHT FORWARD PHOSPHOPROTEOMIC ANALYSIS PIPELINE IN CHO CELLS AS MAMMALIAN NON-MODEL ORGANISM

Louise Brachtvogel (1) - Antonia Pries (1) - Stefan Walter (2) - Thomas Noll (1) - Raimund Hoffrogge (1)

Cell Culture Technology, Bielefeld University, Bielefeld (1) - Faculty of Biology, University of Osnabrück, Osnabrück (2)

Keywords: CHO, MaxQuant, LFQ, SILAC, Signaling

Introduction:

Quantitative (phospho)proteomics is often used to elucidate cellular responses on media supplements [1]. Especially for non-model species, certain aspects besides LC-MS set up, like sample preparation, databases and evaluation workflow strongly impact the outcome of signaling studies. Adapted workflows then lead to impacted phosphorylation sites and signaling pathways. Here we outline critical steps based on our experience with chinese hamster ovary (CHO) cell analysis.

Methods:

CHO cells were cultivated in chemically defined media. For SILAC experiments, media are supplemented with either lLys/lArg or hLys/hArg. After protein digestion, phosphopeptides were enriched with different strategies. Measurements were performed by nLC-ESI Orbitrap MS and data was evaluated utilizing two different pipelines based on MaxQuant/Perseus and Proteome Discoverer (PD). The obtained SILAC data was also quantified by LFQ for cell line comparison.

Results:

Sample preparation workflow

An optimized lysis buffer solubilizes membrane proteins and allows a direct digest. The resulting new 6-step workflow decreases the variation of identified phosphorylation sites between techn. replicates.

Database searches

Combination of two databases (well annotated mouse; incomplete *C. griseus* for CHO) leads to the highest identification rate compared to individual DB. However, the mix of identifiers for both species complicates software evaluation. Merging of data fore.g. pathway mapping hence is to great extend manually. An intermediate step was necessary for mapping different protein identifiers to homologous ones.

Quantification methods

The SILAC-based data analysis yields in substantially more identification of modified peptides than LFQ-based approaches, where only 75 % were identified. However, LFQ offers to describe cell-specific ground phosphorylation status and protein expression comparisons. As the current version of PD supports LFQ, we summarize pros and cons in comparison to MaxQuant.

Conclusions

Several aspects besides the LC-MS set up showed to have strong impact on signaling analysis of non-model organisms such as CHO. We highlight the importance and limitations of sample preparation steps, referred protein databases and quantification methods and propose applicable solutions.

With this improvements, based on complementary LFQ + SILAC phosphoproteomic data, a comprehensive view on CHO cell signaling in dependence on media supplements was possible.

Novel Aspect:

Optimized procedures allowed us to reach a high coverage of less-abundant phosphoproteins in CHO cells, which results in a full view on signaling events in this non-model organism.

Keywords: shotgun proteomics, comparative proteomics, *S. cerevisiae*, alcohol stress

Introduction:

Distilled spirits production using *S. cerevisiae* requires understanding the mechanisms of yeast cell resistance to alcohols. Mutations in genes of ubiquitin-proteasome proteolytic system, such as RPN4, may result in appearance of the strains exhibiting hyperresistance [1]. Indeed, RPN4 controls expression of proteolytic genes involved in metabolic pathways [2]. In this work we elucidate the RPN4-dependent mechanisms of yeast cell resistance to alcohol.

Methods:

Three *S. cerevisiae* strains: wild-type (WT) BY4742, RPN4-Δ (with RPN4 deletion), and YPL mutant with decreased proteasome activity, were grown up to log phase in stressed (7% ethanol) and normal conditions. Samples were subjected to LC-MS/MS analysis followed by protein identification, quantification (X!Tandem/MPscore), statistical evaluation of changes in protein expression, and pathways analysis (STRING).

Results:

PCA results have shown the protein grouping according to strains, biological and technical replicates. No technical bias was found for analyzed data. Next, protein levels were compared in pairs: no stress vs. ethanol stressed for each strain (WT, YPL, RPN4-Δ). Proteins that passed the corrected (Benjamini-Hochberg FDR) t-test's p-value of 0.05 were defined as differentially expressed. We found the following pathways affected significantly by the ethanol effect on the cells: protein folding and unfolding, rRNA modification, as well as carbohydrate and nucleotide metabolism. Thus, the ethanol elicits complex cellular response that involves known players like chaperones and metabolic enzymes, as well as the new ones like enzymes of nucleotide metabolism and rRNA modification. Some of these genes are RPN4-dependent. Detailed analysis of differentially expressed proteins allowed identifying the candidates that determine the phenotype of the cells' alcohol resistance.

Conclusions:

Comparative proteome analysis of three different strains of *S. cerevisiae* revealed differences in yeast response to ethanol at proteome level and suggested gene candidates that are potentially responsible for developing alcohol resistance in the cells. These genes can be targets for further studies using methods of molecular genetics.

Novel Aspect:

The importance of RPN4-regulated non-proteasomal genes as novel factors involved in cellular response to ethanol was revealed for the first time using LC-MS/MS.

The work was supported by the Russian Foundation for Basic Research (grant #18-04-00692) and Russian Science Foundation (project #14-14-00971).

Keywords O-propargylpuromycin, nascent proteome, erythropoiesis, mass spectrometry

Introduction

Regulation of gene expression is controlled by mRNA translation and thus defines the functional proteome. Experimental methodologies are needed that can rapidly capture and reveal the actual nascent proteomes. In addition, such methods must be able to measure changes in nascent protein abundances quantitatively in response to pharmacologic or environmental cues.

Methods

We have developed a protocol using an analog of puromycin, a tyrosine-tRNA mimetic, called O-propargylpuromycin (OPP), to identify nascent proteomes rapidly. OPP is cell permeable and catalytically incorporated into nascent polypeptide chains as a specific covalent label during elongation resulting in premature termination. These polypeptides are biotinylated using click chemistry, then isolated and measured by tandem mass spectrometry[1].

Results

We have chosen the erythropoiesis paradigm known to be dependent upon an intricate balance involving maintenance of erythroid precursors and their rapid differentiation to accommodate hematopoietic stresses. In this study, we employed extensively self-renewing erythroblast (ESRE) cells to define the earliest proteomic program unique to the decision between expanding erythroid precursors and terminal maturation. Using OPP-ID, we discovered a network of genes involved in splicing, nucleic acid secondary structure unwinding, and cell cycle regulation which are rapidly repressed in the absence of dexamethasone. While we observed genes previously known to be associated with early hematopoietic precursor states (such as Ddx18, Stag2 and Pold1), we also identified multiple genes such as Prpf6, Sart1, Psen2, and Mycbp2 which have not been previously implicated in erythropoiesis.

Conclusions

This OPP-ID strategy provides rapid experimental view of changes in gene expression at the nascent protein level. This opens a new window for the determination of the actual proteomic changes occurring in response to a variety of cues that direct cellular fates such as proliferation or differentiation.

Novel aspect

This OPP-ID strategy has the potential to ask innumerable questions on the composition and rapid dynamics of proteomic networks at the organismal level.

677 - QUANTITATIVE LABEL-FREE PROTEOMICS IN A NOVEL CELLULAR KNOCK OUT MODEL OF METHYLMALONIC ACIDEMIA

Michele Costanzo (1) - Marianna Caterino (1) - Armando Cevenini (1) - Ida Chiara Guerrera (2) - Margherita Ruoppolo (1)

University of Naples "Federico II", Department of Molecular Medicine and Medical Biotechnology, Naples (1) - Plateforme Protéomique 3P5-Necker, INSERM U24, Structure Fédérative de Recherche Necker and Université Paris Descartes, Paris (2)

Keywords: methylmalonicacidemia, quantitative proteomics, mass spectrometry, bioinformatics, CRISPR-CAS9

Introduction:

MethylmalonicAcidemias (MMAs) are severe autosomal recessive inborn errors of metabolism caused by deficiency of the mitochondrial methylmalonyl-CoA mutase (MUT) enzyme, which converts methylmalonyl-CoA into succinyl-CoA, a Krebs cycle intermediate. As consequence, methylmalonic acid accumulates in body fluids as biomarker of the disease. Long-term complications can include cognitive deficit, chronic kidney disease, liver and kidney failure.

Methods:

A stable MUT-knock out (KO) cell model was generated by using CRISPR-CAS9 genome editing technology on the embryonic kidney (HEK) 293 cell line. Methylmalonic acid was measured in KO cells by liquid chromatography - tandem mass spectrometry (LC-MS/MS) in the multiple reaction monitoring (MRM) mode. The proteomes of 4 biological MUT-KO and 4 wild type (WT) cell samples were compared using a quantitative label-free approach by LC-MS/MS, according to MaxQuant software.

Results:

The goodness of this new cellular model, in which MUT protein was completely knocked out, was tested measuring the levels of methylmalonic acid inside the cells. By contrast, it has not been detected in WT cells, as expected. Bioinformatics analysis was carried out downstream the proteomic experiment in order to select the significant differentially expressed proteins between the two conditions, among those identified in the 8 samples. The analysis showed a number of 178 differentially expressed proteins, which passed all the statistic tests (results from Perseus platform). Applying a more stringent parameter (the identification of each protein with at least 5 peptides in at least 3 of 4 samples per condition), the number of significant proteins was further reduced to 69, of which 39 down-regulated and 30 up-regulated in the MUT-KO condition.

Conclusions:

The selected proteins are globally involved in energy metabolism and oxidation-reduction processes and most of them have mitochondrial localization, supporting the idea of mitochondrial impairment in MMAs. The rescue of MUT protein will be performed in KO cells in order to specify if the deregulated proteins are strictly linked to MUT absence and highlight unknown molecular mechanisms underlying the cellular damage and tissue alterations in MMAs.

Novel Aspect:

This is the first cellular model of methylmalonicacidemia generated by using CRISPR-CAS9 genome editing technology.

628 - INACTIVATED POLIOVIRUS VACCINE ANTIGEN DETERMINATION: A PROTEOMICS APPROACH

Marybeth Creskey (1) - Diane Viel (2) - Tong Wu (3) - Terry Cyr (3)

Health Canada, Biologics and Genetic Therapies Directorate, Ottawa (1) - Health Canada, Biologics and Genetic Therapies Directorate, Ottawa (2) - Health Canada, Biologics and Genetic Therapies Directorate, Ottawa (3)

Inactivated Poliovirus Vaccine Antigen Determination: A Proteomics Approach

Marybeth Creskey, Diane Viel, Tong Wu and Terry D. Cyr*

Centre for Biologics Evaluation

Biologics and Genetic Therapies Directorate

Health Products and Food Branch

Health Canada

Keywords: vaccine, quantitation, proteomics, bottom-up, antigen

Introduction:

Polio (poliomyelitis) once a widespread, occasionally paralytic disease is almost eradicated. Key to this success has been broad vaccination programs with oral poliovirus vaccine (OPV) but the endgame requires a switch to inactivated vaccines (IPV)(1). IPV potency is assayed *in vivo* (immunogenicity)(2) or *in vitro* (antibody based)(3) by relative comparison to international references; improved IPV testing methods are desired(4).

Methods:

Reference Antigens (RA), Inactivated Polio Vaccine (IPV), monovalent bulks, and combination vaccines (DTaP-IPV) were disulfide cleaved and capped then digested with trypsin. The peptides were separated on a C18 column connected to Orbitrap Fusion MS collecting MS/MS in data dependent mode with HCD fragmentation. The data was analyzed with Proteome Discoverer 2.1 by searching a custom database and quantification of proteins based on top 3 precursor intensity(5).

Results:

We compared numerous polio standards and vaccines using proteomics and label free quantitation. The database search required generation of a custom database consisting of individual polio capsid proteins and proteins derived from the other components of the combination vaccine. A recent RA with established DU/ml values was used to prepare a calibration curve and the equation relating precursor intensities to DU was determined. The calculated DU in the samples were then compared to the results obtained by the manufacturers by antibody based Methods: The DU values obtained by this method are higher than labelled amounts for the combination vaccines, IPV, and reference antigens while the bulks were lower than the labelled content. An independent preparation of the calibration curve RA has calculated DU values close to expected. Identification and quantification of polio, diphtheria, pertussis, tetanus proteins in combination vaccines is possible.

Conclusions:

The label free quantitation of Reference Antigens using optimized MS methods and bioinformatics software provides results that are closely aligned with those from antibody based Methods: The advantage of the proteomics approach is that unexpected or adventitious proteins in the sample are also identified and quantified without prior knowledge of their presence. The disadvantage of the proteomics approach is the lack of proof regarding the protein folding.

Novel Aspect:

A rapid proteomics and bioinformatics approach has been developed for polio vaccine antigen quantitation.

Introduction: MS-based Proteomics on Natural Compounds

MS-based proteomics represents a cleaver tool to disclose unclear bioactivities of small molecules such as natural compounds in nutraceuticals [1]. The latter are rising as significant building block in prevention or/and treatment of numerous diseases [2].

Monacolin K (MNK), abundant in red yeast rice extract, is used to lower hematic concentration of cholesterol. Recent scientific evidences link statins to antiproliferative and apoptotic effects in a wide panel of cancers [3].

Methods: TMT-based quantitative proteomics

A kinetic proliferation assay was performed using IncuCyte ZOOM® system to find out the IC50 of MNK to set up proteomics experiments.

Proteomes obtained upon different treatments of MDA-MB231 cells with MNK were digested and pooled together, after former TMT 10-plex™ labeling of the related peptide mixtures [4][5].

The obtained multiplexed pool was prepared for the UPLC-MS/MS analysis of proteomes and phosphoproteomes. Bioinformatic analysis were carried out by MaxQuant and Perseus [6][7].

Results: Monacolin K affects proteome and phosphoproteome of MDA-MB231

MDA-MB231 cells were treated with different concentrations of MNK and growth kinetic curves unraveled an IC50= 4.02±1.23µM.

This time-course experiment was the groundwork to drug treatments for the proteomics approach: MDA-MB231 cells were treated with MNK at 5 µM or 0.5 µM and harvested after 30', 6h or 24h. Control experiments without MNK were harvested in parallel. Then, cells were lysate and proteomes were digested. The obtained tryptic mixtures were chemically labeled with amino-reactive tandem mass isobaric tags (TMT 10-plex™). Labeled peptides were pooled together and the multiplexed sample was simplified upon HpH-fractionation. An aliquot of each fraction was used to obtain the phosphoproteome upon Fe3+-NTA affinity chromatography. NanoUPLC-MS2 experiments were carried out both for proteomes and phosphoproteomes. Raw MS data were analyzed with MaxQuant software to identify and quantify proteins. Statistical analysis of MQ results was performed by Perseus. When MDA-MB231 are treated with MNK 5µM, some alterations in their proteome and phosphoproteome have been found.

Conclusions: Monacolin K regulates proliferative pathways in TNBC cells

MNK has an antiproliferative effect on MDA-MB231, as shown by growth kinetic curves. MS-based proteomics unveiled the potentiality of this bioactive metabolite, abundant in red yeast rice, in modulating expression and phosphorylation of proteins involved in cellular pathways responsible for cellular proliferation. These findings configure Monacolin K as an interesting metabolite in adjuvant therapies for the treatments of triple negative breast cancer.

Novel Aspect:

Exploiting TMT-10plex™, a quantitative MS-based proteomics approach was used to investigate antiproliferative effect of the natural compound Monacolin K on MDA-MD231 cells.

Title: High throughput signaling pathway monitoring based on fast LC-PRM analyses

Authors: Sebastien Gallien^{1,2}, Aaron Gajadhar³, Bhavin Patel³, Tabiwang Arrey⁵, Dave Sarracino², Yue Xuan^{2,5}, Emily Chen²

Affiliations: ¹Thermo Fisher Scientific, Paris, France; ²Thermo Fisher Scientific, Precision Medicine Science Center, Cambridge, MA, USA; ³Thermo Fisher Scientific, San Jose, CA, USA; ⁴Thermo Fisher Scientific, Rockford, IL, USA; ⁵Thermo Fisher Scientific, Bremen, Germany.

Keywords

Parallel reaction monitoring; signaling pathway; high throughput

Introduction

Targeted analyses based on HRAM parallel reaction monitoring (PRM) measurements have opened new opportunities in quantitative proteomics. Here PRM was combined with fast capillary-flow LC separation to accelerate the execution of analyses. The setups developed turned out to be ideally suited to high throughput monitoring of signaling pathways in the context of clinical research applications, typically encompassing thousands of samples.

Methods

The analyses were performed on a Thermo Scientific™ Q Exactive™ HF mass spectrometer operated with several PRM-based acquisition schemes (using instrument programming interface in some cases). Chromatographic separation were carried out using a Thermo Scientific™ UltiMate™ 3000 RSLC system equipped for capillary flow and a Evosep-One system (Evosep). Various gradient lengths and MS parameter settings were employed to analyze samples of various complexities.

Results

Fast LC methods have been designed with the objective to increase the analytical throughput, therefore requiring both higher flow rate (typically 2-3 $\mu\text{L}/\text{min}$) and gradient length reduction, while maintaining acceptable duty cycle. Different experiments have been developed for conventional PRM, dynamic retention time-PRM (dRT-PRM), and internal standard triggered-PRM (IS-PRM) analyses of ten to a few hundred endogenous peptides. Another IS-PRM method variant, relying on the concomitant measurement of each pair of internal standard and endogenous peptides in a single scan, was explored to further shorten analysis time. The final methods differentiated themselves by their unique combination of acquisition scheme, experiment scale, gradient length, and MS parameter settings. They were applied to the analyses of samples of high complexity, e.g., digests of cell lines, optionally mixed with

Yeast digest, and samples of moderate complexity obtained through multiplex immunoprecipitation targeting proteins of AKT/mTOR pathway.

Conclusion

A detailed comparative evaluation of the quantification performance (e.g., quantification precision, accuracy, and sensitivity) obtained for various experimental configuration was carried out. This in-depth investigation enabled the establishment of a reference baseline demonstrating sensitive quantification of a few dozens of peptides in 100 samples within one day under high acquisition efficiency (typically through dRT-PRM and especially IS-PRM mode).

Novel aspect

Sensitive PRM-based signaling pathway monitoring with the unique combination of analytical throughput and experiment scale required for clinical research applications.

367 - QUANTITATION OF AMYLASE/TRYPsin-INHIBITORS IN VARIOUS WHEAT SPECIES

Sabrina Geisslitz (1) - Katharina Scherf (1) - Peter Koehler (2)

Leibniz-Institute for Food Systems Biology, Technical University of Munich, Freising (1) - Biotask AG, Technical University of Munich, Esslingen am Neckar (2)

Keywords: α -amylase/trypsin-inhibitors, non-celiac gluten sensitivity, ancient and modern wheat species, stable isotope dilution assay, intensity based absolute quantitation

Introduction:

The “ancient” wheat species einkorn, emmer and speltare claimed to have sensory and health benefits compared to “modern” bread and durum wheats [1]. To date, it is not known if ancient wheat species contain lower contents of α -amylase/trypsin-inhibitors (ATI), which have been associated with intestinal inflammation and symptoms typical of non-celiac gluten sensitivity (NCGS) [2]. Therefore, the aim of this study was to develop a method to quantitate ATI in wheat.

Methods:

ATI were extracted from eight wholegrain flours of the five wheat species with salt solution. Proteins were reduced, alkylated and digested with trypsin. Peptides were analyzed by LC-MS/MS and five ATI-types were quantitated by stable isotope dilution assays (SIDA). For the validation of trueness, the results of SIDA were compared with an independent LC-MS/MS system and data evaluation by intensity based absolute quantitation algorithm (iBAQ).

Results:

Precision (< 8 %), recovery (80 – 120 %) and limits of detection (< 5 mg/kg) showed the good performance of the method. The accuracy of SIDA was confirmed by iBAQ, which yielded comparable results. In contrast to the other wheat species, only three of eight einkorn cultivars contained ATI in very low concentrations (0.2 ± 0.1 mg/g). On average, all spelt (4.7 ± 0.5 mg/g) and emmer cultivars (5.0 ± 0.5 mg/g) had higher ATI contents than bread wheat (3.7 ± 0.3 mg/g) and durum wheat (4.2 ± 0.9 mg/g). The ATI content was not correlated with the total crude protein content ($r = 0.01$). Finally, differences in the distribution of ATI-types were found. The percentages of 0.19 and 0.28 ATI to CM-type ATI was balanced (52 %/48 %) in bread wheat and spelt, whereas CM-types were predominant (25 %/75 %) in durum wheat and emmer.

Conclusions:

We developed a novel sensitive LC-MS/MS method based on SIDA for the quantitation of ATI in ancient and modern wheat species. Applying the new method, the assumption that ancient wheats contain less ATI than modern ones was disproven for spelt and emmer. The results indicated that different wheat species can be distinguished by the distribution of ATI. Comparison with iBAQ showed that one internal standard was sufficient for SIDA.

Novel Aspect:

The ancient wheat species spelt and emmer contain more ATI than modern ones. Therefore it is not confirmed that ancient wheat species might be more suitable for NCGS patients.

1327 - QUANTIFICATION OF HUMAN INSULIN AND ITS ANALOGUES BY IMMUNOPURIFICATION AND LC-MS/MS

Jeroen Kooistra (1) - Josipa Grzetic Martens (1) - Younes Lamkadam (1) - Theo Noij (1)

Charles River Laboratories, Bioanalysis, Den Bosch, Schaijk, Netherlands (1)

Keywords: human insulin, aspart, quantification, LC/MS, immunopurification

Introduction:

Diabetes, a disease altering the normal insulin production, affects 422 million of people globally and research into its mechanisms and treatment is a growing research area¹. Current quantifications for insulin and its analogues, such as ELISA, have flaws in terms of performance and throughput². Liquid chromatography–mass spectrometry (LC-MS/MS) approaches have recently been developed as alternative strategies for analysis of biomolecules, including insulin.

Methods: Insulin immunocapture followed by LC-MS/MS

Sample preparation includes capturing of insulin (aspart and human) using immobilized (on magnetic beads) biotinylated antibody from insulin spiked (rat or human) plasma. Insulin is then eluted and subjected to the Glu-C digestion prior LC-MS/MS analysis using Waters UPLC Peptide CSH C18 combined with Sciex Qtrap 6500+.

Results: Method validation for quantification of insulin aspart and human insulin

All investigated calibration curves were characterized by a high correlation coefficient ($R^2 \geq 0.99$).

For Insulin aspart a method was developed from 1.75 to 700 ng/mL. Good selectivity of the method was confirmed with only 2.6% relative analyte response in the blank sample. Quality control samples of 1.75, 5.25, 36.8 and 525 ng/mL were analyzed (in fivefold for each level), with high accuracy (97%, 97%, 101% and 95 % respectively), demonstrating good precision of the method (CV=4%, 6%, 11% and 22 % respectively).

The assay for human Insulin quantification is under development and currently viable for quantification of human insulin in BSA/PBS for 0.35 ng/mL to 15 ng/mL. For this assay we have the ultimate goal to go lower to 70 pg/mL in human plasma, which is necessary for insulin quantification assays according to the clinical guidelines. By improving the selectivity of method by antibody and internal standard selection, and by LC-MS parameter optimization, this goal is considered to be feasible, on which the method is currently under development.

Conclusions

With significant reduction of matrix interference by immunoaffinity sample preparation and with sensitivity of Sciex Qtrap 6500+, a low level of quantification of 1.75 ng/mL and 0.35 ng/mL for insulin aspart and human insulin, respectively, is achieved. To set the LLOQ to 0.07 ng/mL the blank response has to be reduced. To achieve that, additional tests are on the way: to use another more selective antibody and to investigate other selective MS transitions.

Novel Aspect: Outlook of the method

This research investigates the possibilities to overcome inabilities of current insulin quantification of human and animal origin and insulin drug analogues by developing a LC-MS assay instead. At Charles River we go towards the implementation of LC-MS protein quantitation to set a sensitive, selective and reproducible method for the quantification of insulin according to the clinical guidelines that is soon to become a fast, reliable and routine analysis.

1106 - PEPTIDE MIGRATION PROFILES: A TOOL TO TRACE PROTEOLYTIC PROCESSES - FACTOR XII CONTACT SYSTEM ACTIVATION

Laura Heikau de Figueiredo (1) - Hartmut Schlüter (1)

University Medical Center Hamburg-Eppendorf, Mass Spectrometric Proteomics, Hamburg (1)

Keywords: Proteolysis, Factor XII, coagulation, LC-MS/MS, SDS-page

Introduction:

Many signaling pathways are activated when proenzymes are proteolytically cleaved releasing the active enzyme (e.g. auto-activation of Factor XII by contact with negatively charged surfaces, starting pathways of coagulation and inflammation). In this work, we use migration profiles [1] for differential analysis of Factor XII contact activation by dextran sulfate (DXS) and poly-phosphate (polyP) and downstream effects.

Methods:

Human Plasma was activated using DXS or polyP. An immunoprecipitation with anti-FXII antibody was performed on the activated plasma samples and a control sample. Eluates were loaded onto a 10% SDS-page. Each of the obtained lanes was cut into 19 bands for in gel tryptic digestion and LC-MS/MS analysis. Migration profiles were obtained by plotting the relative intensity of the identified peptides against the corresponding empirical molecular weight.

Results:

The obtained migration profiles show a distinguished pattern for the FXII peptides in plasma activated with PolyP or DXS and in the control. When plasma is activated by DXS, it shows a clear separation of the heavy chain from the light chain, this separation is not observed in the case plasma was activated by polyP and in the control. In both cases of activated plasma, the downstream proteolytic processes are activated. Compared to the control, the activation of plasma kallikrein (PK) and release of bradykinin from high molecular weight kininogen (HK) is clearly demonstrated. These results corroborate previous findings by Engels et al. that suggest activation of FXII by polyP to be due to conformational changes, and not by cleavage at the activation site (R353-V354) [2].

Conclusions:

Migration profiles of all identified proteins from differentially activated plasma allowed a comprehensive study of the activated proteolytic pathways. It's shown that the use of different activators has an impact on the mechanism of FXII activation. These findings might provide an explanation for FXII activation by polyP resulting in coagulation and activation of the kallikrein-kinin system, whereas by DXS only activates the kallikrein-kinin system [3].

Novel Aspect:

The method presented is a useful tool to understand the differential activation of FXII and can be applied on a wide array of fields where proteolysis is an issue.

Keywords: myelin, FASP, automation, quantification, neuropathies

Introduction:

Myelin, a plasma membrane specialization of glial cells, facilitates rapid signaling in the nervous system. A key tool to approach failing glia-axonal support in neurological disorders is the proteome analysis of myelin, but membrane protein content and dynamic range pose technical challenges (reviewed in [1,2]). We show advances in label-free quantification of myelin proteins and applications to a mouse model for a heritable peripheral neuropathy.

Methods:

Myelin was solubilized with ASB-14 and subjected to FASP-based digestion automated on a liquid handling workstation (Tecan Freedom EVO 150). Data were acquired on a QTOF LC-MS system (Waters Synapt G2-S) using three different data-independent acquisition (DIA) strategies: MSe, without ion mobility separation (IMS); UDMSe, with IMS; DRE-UDMSe, with IMS and dynamic range enhancement. Label-free protein quantification was performed with the IsoQuant software.

Results:

As a proof-of-principle for robustness and accuracy of quantification, we first compared CNS myelin from wildtype mice (Cnp^{WT/WT}) with myelin from mutant mice heterozygous for the CNP gene (Cnp^{WT/null}). In three independent experiments, each comprising 24 MSeruns (three biological replicates per condition, duplicate digestion and injection), we determined the ratio of the abundance of CNP^{Cnp^{WT/WT}:Cnp^{WT/null}} as 1.98:1 (CV < 10%), exactly matching the ratio of 2:1 as expected from Cnp gene heterozygosity. In UDMSeruns, however, levels of high-abundant myelin proteins including CNP were misquantified due to the compression of the dynamic range caused by IMS of peptides. This issue was addressed by DRE-UDMSe, a novel data acquisition method in which a deflection lens is used to cycle between full and reduced ion transmission during one scan. All three data acquisition methods were applied to PNS myelin from mice deficient for periaxin (Prx^{null/null}), a model for a demyelinating neuropathy of the Charcot-Marie-Tooth type (CMT-4F).

Conclusions:

While MSe and UDMSe are well suited for accurate quantification of highly abundant proteins and deep proteome coverage, respectively, DRE-UDMSe provides a compromise between dynamic range and identification rate needed for routine quantification of myelin proteins. Analysis of Prx^{null/null} mice systematically revealed altered abundance of potentially disease-relevant PNS myelin proteins and thus allows insights into myelin-related pathology in this model.

Novel Aspect:

development and automation of a customized FASP procedure; improved label-free quantification of myelin proteomes; routine proteomics phenotyping of mutant mice

Keywords: DIA, SWATH, proteomics, libraries, cloud computing

Introduction

As the use of data independent acquisition (DIA) grows in proteomics research, the need for improved data processing workflows increases. The most common data processing workflow is to use spectral ion libraries to drive targeted extraction of peptide / fragment areas from the data, using the m/z and retention time information contained in the library. Increasing the size and quality of the ion library has been shown to increase the proteins reliably quantified from a dataset. Retention time (RT) correlation between ion library and the dataset is another key factor that determines quality of data extraction. Simplifying how ion libraries are built and used during data extraction was explored in this work.

Methods

Two algorithms were explored to simplify the data extraction workflow for SWATH® Acquisition data within the OneOmics™ Project cloud processing pipeline, the automatic merging of related ion libraries followed by auto RT calibration. During library merging, ProteinPilot™ Software group files are combined by selecting the largest file as seed library, then peptides from smaller libraries are merged in using a non-linear calibration strategy. New peptides are added to existing proteins and new proteins are added if not present in seed library. During SWATH processing, endogenous peptides are automatically selected across time bins and the best peptide are chosen based on precursor intensity and ID confidence. Best scoring peak groups are used for RT calibration.

Results

Previous data has shown that increasing the size of the ion libraries used provides improved protein quantitation. Moving from ion libraries generated from 1D data dependent acquisitions to libraries generated from 2D fractionation experiments to pan proteome libraries provides a >100% gain in peptides quantified (~60% gain in proteins) to >300% peptide quantified over 1D libraries (>100% gain in protein). Therefore the ability to easily combine and align ion libraries for greater depth of sample interrogation would provide a significant workflow benefit.

To evaluate the quality of the retention time alignment during SWATH processing using the new AutoRT calibration function, it was compared to using the typical RT calibration process using a set of spiked standards peptides. In 33/48 tests, AutoRT approach found similar or more proteins quantified than the standard approach and similar linear fit equations, indicating the new, easier to implement process was as good or better than the currently used standard peptide workflow.

The quality of library merging on SWATH results was explored with a series of small datasets using non-linear retention time alignment. By merging libraries from replicates of a 1D dataset, a 20% gain in peptides was observed. The gain in peptides identified and quantified by SWATH is primarily attributed to an increase in peptide coverage rather than improved ion selection.

Full pipeline was then used on some biological datasets (PBMC and Mouse cell lines) to measure performance, where a series of libraries were available to merge. Results will be discussed.

Conclusions

Non-linear retention time alignment was shown to be effective for merging of libraries with identical or differing gradient lengths resulting in better results.

Novel Aspect:

Simplifying DIA data processing in the cloud by pipelining ease of use algorithms

Introduction:

Alzheimer's Disease (AD) is a neurodegenerative disorder characterized by memory loss and cognitive decline. (1)The current AD treatment methods are aim to prevent cognitive loss. There is no treatment to slow down progression of the disease or stop it.(2)In this study, the effects of new natural compounds on cognitive impairment will be examined and localization of the compounds will be demonstrated by mass-spectrometry based approach.

Methods:

The natural compounds were administered at 2 different doses to 12 months old transgenic mice(5XFAD) for 7 days i.p. (n = 8). Non-transgenic littermates (LM) were used as the control group. Morris Water Maze test was performed to measure cognitive impairment. The MALDI-IMS technique was applied to demonstrate whether the natural compounds pass the blood brain barrier and determine the localization of the compound in the brain regions.

Results and Conclusion:

Cognitive changes related to learning and memory were measured by Morris Water Maze test after injection of low and high doses of 6 different compounds. When compared to control groups, it was observed that 2 of the 6 compounds positively affected both the learning process and memory. It was demonstrated that the compounds were localized in certain brain regions after they have passed the blood brain barrier by utilizing MALDI-IMS.

Novel Aspect:

This is the first study to show the regional localization of the novel native compounds administered on the 5XFAD mouse model.

Keywords: Aspergillusfumigatus, neutrophilextracellulartraps, dualproteome, phosphoproteome, host-pathogeninteraction

Introduction:

Invasiveaspergillosis caused by the fungus *Aspergillus fumigatus* is a life-threatening infection in immunocompromised hosts. Neutrophils are indispensable in eliminating the fungal pathogen by various strategies, i.a. phagocytosisand neutrophil extracellular traps (NETs) [1, 2]. To discover how fungalhyphae activatepathogen-specific responses of neutrophils and to explore fungal counter-defense mechanisms we conducted a quantitative dual proteome study.

Methods:

Neutrophils forming NETs against*A. fumigatus*were compared with chemically induced NETs.Hyphae trapped by NETs were compared against those controls grown under equal conditions devoid of neutrophils. LC-MS/MS-based bottom-up proteomics was used to quantify proteins based on the MS2 reporter ion intensities of multiplexed unique peptides labeled with tandem mass tags (TMT). Protein-protein interactions (PPIs) were studied using a network modeling approach.

Results:

We were able to quantify 454 differentially abundant proteins of 843 proteins in total on the fungal side and 335 differentially abundant proteins of 1906 proteins in total on the host side. Neutrophils induce fungal proteins involved in the cell wall stress response, toxic secondary metabolite production, and the unfolded protein response. *A. fumigatus* modulates the trace metal ion utilization. Neutrophils and NETs also strongly repress the fungal protein biosynthetic machinery. Analysis of the neutrophil response upon fungal confrontation revealed an altered stoichiometry of alternative and core histones and a modulation of the nuclear envelope. Neutrophils also induce antimicrobial proteins and a repression of proteins involved in calcium-dependent membrane scaffolding. Furthermore, the neutrophil-fungal interaction caused an impairment of the energy metabolism on both sides. PPI network modeling revealed the induction of an autophagy pathway in *A. fumigatus* and a regulatory role of CDK1 during NETosis.

Conclusions:

We investigated the responses of human neutrophils to *A. fumigatus* hyphae using a simultaneous dual proteome analysis. The challenging approach provided us with an ample dataset of differentially abundant proteins on both sides. We generated a model of interaction that allowed us to reveal protein interaction partners and regulatory circuits governing the counter response of *A. fumigatus* and the mechanism of hyphal induced NETosis.

Novel Aspect:

Our study revealed the fungistatic effects of NETs and the host-pathogen interplay on the molecular level.

Department of Biomedical Laboratory Science, College of Health Sciences, Eulji University, Seongnam-si, Gyeonggi-do (1) - Department of Senior Healthcare, BK21 Plus Program, Graduate School, Eulji University, Daejeon (2)

Keywords: Biomarker, Proteomics, Stroke, Subtype

Introduction:

Ischemic stroke is classified into large artery atherosclerosis (LAA), cardioembolism and small vessel occlusion. In this study, LAA that is the most common cause of stroke is analyzed compared to healthy subjects. Patients with LAA stroke is approximately 85%. To increase efficacy of diagnosis and recovery, our aim is to discover biomarker of LAA using individual serum of patients.

Methods:

We conducted proteomics analysis of serum protein in patients with LAA stroke. 52 patients and 43 healthy subjects are used to identify global proteins and to compare level of serum proteins. Individual samples were analyzed using Sciex 5600 TripleTOF. Identification and quantification of proteins were conducted by information dependent acquisition (IDA) mode and SWATH-MS acquisition.

Results:

As a result, differentially expressed proteins by more than 2 fold were 149. Differentially expressed proteins by more than 2-fold were related with GO processes such as regulated exocytosis, exocytosis, secretion by cell, immune response and regulation of response to stress. And, alternative complement pathway were top scored. Among differentially expressed proteins that is related with alternative complement pathway vitronectin, complement factor B, complement component C7, and complement component C5 had the most statistical significance. Vitronectin, complement factor B and complement component C7 were upregulated and complement component C5 was downregulated in patients with LAA stroke.

Conclusions:

A proteomics approach discovered associations of LAA stroke with several immune responses compared to healthy subjects. This study highlights four alternative complement pathway-related proteins including vitronectin, complement factor B, complement component C7, and complement component C5. These four proteins contribute to immune responses and B cell and T cell activation and can be potential biomarker to understand LAA stroke.

Novel Aspect:

The proteomics analysis of serum of patients with LAA stroke showed alternative 4 immune-related proteins can help to distinguish subtype of stroke from healthy subjects.

831 - DEVELOPMENT OF A SIMPLE AND EFFICIENT QUANTIFICATION METHOD OF HUMAN FOLLICULAR FLUID (HFF) PROTEOME

Aleksandra Lewandowska (1) - Anna Fel (1) - Katarzyna Macur (1) - Paulina Czaplewska (1) - Joanna Liss (2) - Krzysztof Łukaszuk (2) - Stanisław Ołdziej (1)

Intercollegiate Faculty of Biotechnology UG-MUG, University of Gdansk, Gdansk (1) - INVICTA Fertility Clinic, -, Gdansk (2)

Keywords: human follicular fluid, proteomics, SWATH-MS, MED-FASP, Total Protein Approach (TPA)

Introduction:

Human follicular fluid (hFF) is a potential source of biomarkers of the oocyte quality, which could be assayed in a non-invasive manner prior to oocyte fertilization. In our previous study [1], we investigated the proteome and peptidome of hFF by SWATH-MS methodology [2]. Here, we combine and compare that methodology with MED-FASP procedure and quantitative MS measurements by TPA [3] to develop an efficient quantification method of hFF proteins.

Methods:

Sample of pooled hFFs from patients undergoing the IVF procedure was acquired from the INVICTA Fertility Clinic in Gdansk. Samples after prior ultrafiltration (>10 kDa fraction) or without preliminary treatment were digested by two distinct protocols: i) in-solution trypsin digestion [1]; ii) FASP or MED-FASP [3]. Afterwards, samples were analyzed by two distinct MS methods: i) SWATH-MS [2]; TPA [3].

Results:

We have developed a methodology for hFF proteome and peptidome identification and SWATH-MS quantification strategy. To increase the size of the spectral library used for quantification, we applied extensive multistep fractionation consisting of ultrafiltration, optional immunodepletion, and high pH RP-HPLC. We managed to identify 400 proteins with high confidence: 302 in High Molecular Weight Fraction (HMWF, >10 kDa), and 161 proteins in peptidomic Low Molecular Weight Fraction (LMWF, <10 kDa). In order to improve our method, we intend to conduct comparative experiments of two sample preparation procedures: previously used in-solution digestion and FASP or MED-FASP. Our preliminary results suggest that both protocols allow for high confidence discovery of slightly different sets of proteins. Moreover, ultrafiltration prior digestion improved the outcomes. We plan to carry out more experiments to further test both protocols along with two quantification methods: SWATH-MS and TPA.

Conclusions:

Our methodology enables a relatively simple quantitative measurement of a high number of proteins in one run. A time and cost efficient fractionation method, such as ultrafiltration significantly improves the qualitative and quantitative analyses of hFF, at the same time allowing for investigations of scarcely studied peptidomic fraction (LMWF). MED-FASP is a promising sample preparation strategy with a high potential of application in hFF proteomics.

Novel Aspect:

This is a first work employing MED-FASP and TPA strategy for hFF proteome identification and quantification, as well as their combination with SWATH-MS.

Keywords: toxin, MALDI, PRM, proteomics, bottom-up

Introduction:

Biological toxins are relevant in the security, health and food sectors. Development of new analytical methods for rapid and unambiguous identification of low toxin concentrations in various complex matrices is essential. We reported previously a method based on LC-ESI-MS/MS for abrin quantification in food and environmental matrices [1]. Here, immuno-MALDI-TOFMS was evaluated for rapid and chromatography-free quantification of abrin.

Methods:

Magnetic beads coated with abrin-specific antibodies were mixed with 500 μ L of food samples spiked with the toxin. After harsh washing conditions with PBS-tween, analytes were eluted from beads by incubation with 0.1% TFA. Abrin was heated for 15 min at 95 °C in RapiGest SF 0.05% for denaturation and digested with trypsin in a bath-type sonicator. Peptides were co-crystallized with CHCA matrix on a disposable plate for MALDI-TOF analysis using a Bruker UltrafleXtreme.

Results:

Up to 29 peptides of abrin isoforms were detected by MALDI-TOF MS in a pure standard and the 4 most intense, different to the best ESI peptides, were selected. Isotope-labeled peptides were added for quantification. Immuno-capture conditions were improved for MALDI-TOF MS, including additional washes of antibody-coated beads. On-beads digestion resulted in high interfering signals from antibody peptides, and abrin was therefore eluted before digestion. Trypsin amount was reduced 10 times and digestion time increased to 1 hour in the bath-type sonicator. Using the new protocol, interfering peaks and ionization suppression in apple juice and milk samples were decreased significantly, resulting in spectra with predominant abrin peptide signals at 250 ng/ml. At this concentration, about twenty peptides of abrin isoforms were detected in the two food matrices. On-going parallel evaluation with LC-ESI-MS/MS shows sensitivity in the same range with limit of quantification in milk at 10 and 40 ng/ml for LC-ESI-MS/MS and MALDI-TOF, respectively.

Conclusions

Bottom-up proteomics and immuno-MALDI-TOF MS allowed quantification of abrin and its isoforms in complex matrices, without time-consuming peptide chromatography or extraction resulting in simple and fast (< 5 min) MS analysis. The method was found specific, reliable, and sensitive in milk. Further optimizations are on-going to reach equal or better limit of quantification than LC-ESI-MS/MS and to reduce the total analysis time by automatization of the workflow.

Novel Aspect:

Evaluation of MALDI-TOF and LC-ESI-MS/MS for rapid and sensitive quantification of abrin in complex matrices.

804 - A TARGET FISHING AND SHOTGUN PROTEOMICS APPROACHES TO STUDY THE EFFECT OF A NEW DRUG AGAINST M. TUBERCULOSIS

Marcello Manfredi (1) - Laurent Chiarelli (2) - Arianna Buzzi (1) - Marilina Pasca (2) - Fabio Gosetti (1) - Elettra Barberis (1) - Elisa Robotti (1) - Emilio Marengo (1)

University of Piemonte Orientale, Department of Sciences and Technological Innovation, Alessandria (1) - University of Pavia, Department of Biology and Biotechnology, Pavia (2)

Keywords: Quantitative proteomics, Target fishing approach, Click chemistry, Drug effect, M. tuberculosis.

Introduction:

Mycobacterium tuberculosis (MT) is the causative agent of tuberculosis. The development of more effective and shorter MT treatments requires the killing of both MT growing and non-growing bacilli.

Today, mass spectrometry based proteomics can address challenges that cannot be approached by genomic analysis. The study of the effect of a drug and the molecular mechanisms contributing to disease pathogenesis can be performed using quantitative proteomics.

Methods:

A target fishing proteomic approach for the in vitro study of the effect of a new drug, TP053, on MT was performed. The target fishing experiment, which is based on click chemistry, was used to understand if an active metabolite was able to bind a possible target in MT. Moreover, in order to explore the possible pathways affected by the new drug, MT cell lines were treated with TP053 and a shotgun proteomic approach was used to identify modulated proteins.

Results:

The TP53 treatment negatively affected the redox reactions, intermediary metabolism and DNA. There is a down regulation of proteins linked to growth processes and generation of metabolites but also a down regulation of carbon and lipid metabolism and ATP generation proteins. All this data are in agreement with the inhibition of aerobic respiration which is a well known NO target.

There is also a modulation of enzymes involved in lipid metabolism and an over expression of many ribosomal proteins, most of them belonging to the 30s ribosome unit.

Using the target fishing approach we were able to identify a direct interaction of TP053 with 30S ribosomal protein S13.

Conclusions:

By a shotgun proteomic approach and a target fishing experiment, it has been demonstrated that the activated TP053 is responsible for a global perturbation in the mycobacterial cells through the release of nitric oxide, as well as by a direct interaction with 30S ribosomal protein S13.

Novel Aspect:

A target fishing experiment coupled to shotgun proteomic approach allowed to study the effect of a new drug and the interaction drug-proteins.

648 - A COST-EFFECTIVE APPROACH TO PRODUCE ¹⁵N-LABELLED AMINO ACIDS EMPLOYING CHLAMYDOMONAS REINHARDTII CC503

Juan Manuel Marchante-Gayón (1) - Jesús Nicolás Carcelén (1) - Pablo Rodríguez González (1) - Luis Valledor González (2) - María Jesús Cañal Villanueva (2) - José Ignacio García Alonso (1)

University of Oviedo, Department of Physical and Analytical Chemistry, Oviedo (1) - University of Oviedo, Department of Biology of Organisms and Systems, Oviedo (2)

Keywords: *Chlamydomonas reinhardtii*, ¹⁵N-labelled amino acids, GC-MS.

Introduction:

The synthesis of isotopically labelled compounds from enriched stable isotopes is an expensive and difficult task. Both chemical and biochemical methods have been proposed to produce labelled molecules, but few cost-effective methods have been described [1]. Previously reported biochemical methods to prepare labelled amino acids have only considered their use as hydrolyzed proteins to grow cell cultures or in proteomics[2].

Methods:

The aim of this study was to use the microalgae *Chlamydomonas reinhardtii* to produce, at laboratory scale, ¹⁵N-labelled amino acids with a high isotopic enrichment. To do that, a culture medium containing ¹⁵NH₄Cl was used. The labelled proteins biosynthesized by the microorganism were extracted from the biomass. Then, the ¹⁵N-labelled amino acids were obtained after a protein hydrolysis with HCl and their isotopic enrichment was measured by GC-MS [3].

Results:

No differences in cell growth were observed when they were feeding with natural abundance N or ¹⁵N, demonstrating an absence of isotopic effects. On the other hand, the use of the strain CC503 cw92 mt+ and ¹⁵NH₄Cl in the culture medium reduces the incorporation of natural abundance nitrogen, as this strain is not able to incorporate nitrates or other nitrogen containing compounds. Moreover, this wall deficient mutant facilitated the extraction of proteins, leading to higher extraction yields (32.5±4.0%) than those obtained for a wildtype strain 137c (12.7±3.8%). The average isotopic enrichment obtained for the 16 detected proteinogenic amino acids was 99.56±0.05% demonstrating the lack of natural abundance nitrogen incorporation through the whole procedure. The amino acid content ranged from 18–90 µg/mL, depending on the occurrence of the amino acids present in the proteins. A derivatization procedure based on the use of MTBSTFA was optimized to convert the amino acids into volatile compounds.

Conclusions:

Sixteen ¹⁵N-labelled amino acids were obtained with an extremely high enrichment from the strain *Chlamydomonas reinhardtii* CC503. As the effective incorporation of ¹⁵N has been proved, other labelled biomolecules should be present in the cells, and this biomass could be employed to isolate ¹⁵N-labelled nucleic acids and other metabolites in future experiments. Additionally, multiple labelling could be performed if ¹³C were supplied to the culture media.

Novel Aspect:

An innovative, simple, and fast method to produce isotopically labelled amino acids, which could be used for future quantitative proteomics studies, is presented.

Keywords: Spirulina, phycobiliprotein, microbial fermentation, Lactobacillus plantarum, Orbitrap

Introduction:

Arthrospira is a cyanobacteria with a high nutritional and therapeutic potential. It is a source of essential and non-essential nutrients and bioactive compounds with antiinflammatory and antioxidant activity[1]. Large proportion of Arthrospira dry weight comprises phycobiliproteins of high bioactive value[2, 3]. Microbial fermentation can contribute to products nutritional and bioactive efficiency due to new metabolite production and transformation[4].

Methods:

Arthrospira samples were fermented with *L. plantarum* culture, protein extraction of fermented and non-fermented samples followed. Yeast culture was treated with protein concentrates and later extracted. Protein content and pathway alterations were analyzed by Bradford assay and HF Orbitrap. Liquid chromatography tandem mass spectrometry was used to determine protein changes and Proteome Discoverer for protein identification against the UniProt database.

Results:

Exposure of yeast cells to fermented or non-fermented protein extracts affected yeast cell protein content. A higher protein concentration was determined in yeast cells treated with fermented and non-fermented Arthrospira extracts compared to control. Furthermore, label free high mass resolution proteomics enabled us to determine protein changes during microbial fermentation in Arthrospira water-phase protein extracts.

Conclusions

Arthrospira microbial fermentation using *Lactobacillus plantarum* culture offers great possibilities for protein efficiency and uptake improvement. During lactic acid fermentation proteins are modulated with enhanced digestibility and bioavailability and adding bioactive properties to the food component. This method enables us to develop a food product with an upgraded functional value.

Novel Aspect:

Further analysis of lactic acid fermentation of Arthrospira is needed to specify its effects on products nutritional and bioactive properties.

Keywords: autophagy-related protein 7, unconventional protein secretion, epithelial ovarian cancer, secretome

Introduction:

The cancer secretome comprises numerous proteins that promote tumorigenic processes [1]. A substantial number of proteins lack signal peptides and are released via unconventional mechanisms[2]. Herein we analyzed the contribution of autophagy-related (ATG) based unconventional protein secretion to the microenvironment of epithelial ovarian cancer cells.

Methods:

Epithelial ovarian cancer cells (OV-90, ATCC) were transfected with siRNA targeting human ATG7 or control siRNA. A label free quantitative approach was applied to analyse secreted proteins of ATG7 deficient cells and ATG7 intact (control) cells. Conditioned media was collected over 24 hours. Samples were digested using FASP[3] and analysed by nanoLC-MS/MS (Orbitrap MS). Raw data processing was performed with MaxQuant.

Results:

ATG7 siRNA transfection efficiently reduced ATG7 protein levels. The secretome was highly enriched with extracellular localized proteins. Approximately one-third of these proteins contained a signal peptide as predicted by SecretomeP. Multivariate analysis of the data further demonstrated changes of the secretory protein profile upon siRNA mediated ATG7 knockdown. A subset of proteins emerged that were not quantified in the conditioned media of ATG7 deficient cells, including proteins involved in cell-cell adhesion.

Conclusions:

Besides the well-known function of ATG7 in the elongation reaction and the formation of the autophagosome[4], the present proteomic approach shows the contribution of ATG7 protein to the extracellular release of a subset of proteins in epithelial ovarian cancer cells.

Novel Aspect:

Novel insights into the complexity of the epithelial ovarian cancer cell microenvironment.

729 - QCONCAT-BASED ABSOLUTE QUANTIFICATION OF THE LYSOSOMAL PROTEOME BY MULTIPLE REACTION MONITORING

Peter Mosen (1) - Roman Sakson (2) - Thomas Ruppert (2) - Volkmar Gieselmann (1) - Dominic Winter (1)

-, IBMB Bonn, - (1) - -, ZMBH Heidelberg, - (2)

Keywords: QConCat, MRM, Absolute Protein Quantification, Lysosome

Introduction:

Absolute quantification of proteins relies on externally quantified peptide standards which are spiked in the sample [1]. For the quantification of large numbers of proteins, the QConCat strategy [2] efficiently provides multiple internal standard peptides concatenated in one proteolytically cleavable artificial fusion protein. We applied this strategy for absolute quantification of the currently known lysosomal proteome using targeted mass spectrometry.

Methods:

12 QConCats were expressed in E. Coli using stable isotope labeled amino acids and purified via a His tag at their C-Terminus. Tryptic digestion was performed by in gel digestion, in solution digestion in the presence of 1 M GCL or RapiGest as well as by the FASP [3] and SP3 [4] strategies. The generated peptides were desalted and analyzed using LC-MS/MS. Data analysis was performed by Mascot and scheduled MRM transitions were established using Skyline [5].

Results:

Based on in house and published large scale proteomics studies, we selected 422 unique tryptic peptides of lysosomal proteins acting as representatives. We were able to cover 143 lysosomal proteins representing 94 % of the known lysosomal proteome [6]. The selected peptides were used to design 12 QConCats which were reverse translated and generated by gene synthesis. After expression in E. Coli and His tag purification of the QConCats, we optimized tryptic digestion. We tested in gel digestion, in solution digestion using RapiGest or 1M GCL as well as the FASP and SP3 approaches. RapiGest gave us the lowest number of missed cleavage sites and was therefore used for sample processing. A mixture of all QConCat peptides was analyzed by LC-MS/MS using an Orbitrap Velos and QTrap 5500/6500 mass spectrometers. For 417 of the 422 peptides we defined MRM transitions and are currently in the process of assigning specific retention times. In an initial study, we absolutely quantified 48 lysosomal proteins from mouse embryonic fibroblast using the first 4 QConCats.

Conclusion:

We successfully designed, expressed and purified 12 QConCats providing internal standard peptides for absolute quantification of the majority of currently known lysosomal proteins. We optimized purification and proteolytic digestion of the QConCats. Assay development for targeted quantification by MRM is almost finalized. Our assay will allow for the first time to perform absolute quantification of the known proteins of a whole organelle.

Novel Aspect:

The approach allows for the first time the absolute quantification for almost all proteins of an organelle, the lysosome.

233 - THE KEY TO BIG BIOBANKS: ANALYZING 24 PROTEOMES PER DAY BY MICRO-FLOW SWATH® ACQUISITION AND SPECTRONAUT PULSAR ANALYSIS

Jan Muntel (1) - Nick Morrice (2) - Roland Bruderer (1) - Lukas Reiter (1)

Biognosys AG, R&D, Schlieren (1) - AB SCIEX UK Limited, AB SCIEX, Warrington (2)

Keywords: DIA, SWATH, high throughput proteomics, micro-flow, FFPE

Introduction:

Micro-flow chromatography provides a similar workflow sensitivity compared to nano-flow separations but greatly increased robustness enabling high throughput proteomics for 100's of samples. In combination with data-independent acquisition methods (DIA) such as SWATH® acquisition, 1,000s of proteins can be quantified with high data completeness and high quantitative precision. Here, we show the potential of the workflow for 105 cancer samples.

Methods:

FFPE colon tissue samples (10 healthy, 95 cancer) were obtained from a public repository. Proteins were extracted as described previously [1]. Tryptic digests were spiked with iRT peptides (Biognosys) and separated on a NanoLC 425 system (SCIEX) by a 43min gradient at a flow rate of 5µl/min coupled to a TripleTOF® 6600 system (SCIEX) operated in SWATH mode. Run time per sample was 1h. Data were analyzed in Spectronaut Pulsar (Biognosys) with a project specific library.

Results:

The sample preparation resulted in average in >100µg peptides per 10µm slice, which is plenty for the micro-flow SWATH® acquisition workflow. The whole dataset (105 samples) was acquired in only 4.5 days. Data analysis in Spectronaut Pulsar took one additional day demonstrating the large potential of the workflow for even more samples. In total, about 4,500 protein groups were quantified at 1% peptide and protein FDR (3,600 in average per run) providing a sufficient depth for biological interpretation of the data. Data analysis revealed that a larger number of proteins were expressed in the cancer cohort. Unsupervised clustering of the data separated the healthy and the cancer cohort. Interestingly two samples of the healthy cohort clustered together with the cancer cohort. Within the cancer cohort, three major groups were identified, potentially different cancer subtypes. The data will be further biologically interpreted using ingenuity pathway analysis (IPA).

Conclusions:

This study demonstrates, how high throughput proteomics can be used to analyze large sample sets from tissue biobanks. Application of the micro-flow SWATH® acquisition workflow combined with Spectronaut Pulsar data analysis generates data from these large resources in a timely fashion and therefore pave the way to a better understanding of health and disease.

Novel Aspect:

Micro-flow/SWATH® acquisition and Spectronaut Pulsar analysis enables efficient and comprehensive analysis of large sample cohorts (>100 samples).

Keywords: Proteomics; Mass spectrometry; Bacterial infections;

Introduction:

Avian pathogenic *E. coli* (APEC) gives rise to colibacillosis which result in economic losses in the production system and reduced animal welfare. At the same time, an extensive use of antibiotics to combat infections promotes selection of resistant bacteria. We investigated the proteome of an *E. coli* ST117 strain during infection of the mucus layer of oviduct to suggest potential genes (essential and redundant) as targets in development of antibiotics or helper drugs.

Methods:

A combination of reducing agent and a number of enzymes was used to purify and enrich bacteria from mucus in quantities enough for LC-MS based quantitative proteome analysis. Peptides from infecting bacteria and the host (in the same sample) were labelled with TMT isobaric tags and mixed with peptides derived from proteins of ST117, grown in culture media (log and stationary phase), labelled with complementary TMT tags.

Results:

By combining reducing agent and selected enzymes we successfully purified and enriched bacteria from mucus of infected hens. We identified over 2000 bacterial proteins and were able to quantify approx. 1500 of them across all the samples. This relatively high number of positive hits was greatly facilitated by spiking TMT labelled peptides derived from proteins extracted from ST117 grown in culture media into these obtained from infection experiments. The abundant spiked in TMT labelled peptides served as factor to isolate *E. coli* derived peptides for fragmentation in the LC-MS/MS analysis, as otherwise peptides from co-isolated proteins of the host highly suppressed the signal of peptides originating from isolated bacterial proteins.

Conclusions

The approach presented here is suitable for detection and quantification of relatively high number of proteins of bacteria isolated from infected oviduct of hens, where proteins of the latter highly dominate the sample. Apparently, this approach could be adopted to investigate pathogen/host interactions, or proteomes of mixed population of different organisms.

Novel Aspect:

Improved method for isolation of mucus infecting bacteria. Combination of TMT labelled peptide populations derived from pure cell culture and isolates from infected hosts.

1024 - VALIDATION STRATEGIES FOR THE PURITY ASSESSMENT OF PEPTIDE STANDARDS BY ISOTOPE DILUTION MASS SPECTROMETRY

Jesus Nicolas-Carcelen (1) - Adriana Gonzalez-Gago (1) - Amanda Suarez-Fernandez (1) - Juan Manuel Marchante-Gayon (1) - Pablo Rodriguez-Gonzalez (1) - Jose Ignacio Garcia-Alonso (1)

University of Oviedo, Analytical and Physical Chemistry, Oviedo (1)

Keywords: Peptide hydrolysis, Method validation, Isotope Dilution, Amino Acid Analysis, Peptide purity assessment.

Introduction:

Traceability of protein and peptide quantifications to the International System of units is still a challenge in analytical chemistry. Due to the lack of certified reference materials peptide purity assessment must be carried out through amino acid analysis. This procedure is based on the addition of isotopically labelled aminoacids before the application of a time-consuming acid hydrolysis.

Methods:

The only commercially available peptide certified reference materials SRM 998 (Angiotensin I from NIST) and CRM 6901-a (C-peptide from NMIJ) were used for validation purposes. The hydrolysis time was optimized for both materials applying either classical thermal heating or focused microwaves during hydrolysis. Labelled amino acids were spiked to the samples prior hydrolysis with HCl 6N and the peptides were quantified by Isotope Dilution Mass Spectrometry.

Results:

The quantification of the peptides was performed by GC-MSMS employing 5 different isotopically labelled amino acids (Valine, Isoleucine, Leucine, Proline and Phenylalanine), which were previously characterized in terms of concentration by reverse isotope dilution using natural abundance certified analogues. The isotopic enrichment of the labelled amino acids was determined as reported elsewhere [1]. The hydrolysis time required to achieve a complete hydrolysis was optimized for SRM 998 and CRM 6901-a when applying thermal heating at 130°C or focused microwaves. Finally, the purity of four isotopically labelled proteotypic peptides of two protein glaucoma biomarkers was assessed applying the optimized conditions. A final validation of the methodology was carried out by quantifying both proteins in human serum samples by isotope dilution and LC-MSMS. An accurate assessment of the peptide purity can be demonstrated if no statistical differences are obtained in the protein concentrations obtained by each labelled peptide.

Conclusions:

The application of focused microwaves significantly reduces the time required to achieve a complete hydrolysis of peptide standards. Besides the hydrolysis of peptide certified reference materials, the determination of proteins in real samples by LC-MSMS through proteotypic peptides allow an additional validation of peptide purity assessment within the optimized hydrolysis method.

Novel Aspect:

Focused microwaves to decrease peptide hydrolysis time. Validation with reference materials and tryptic peptides applied for absolute quantification of proteins.

Introduction

Krabbe disease (KD) is an autosomal-recessive sphingolipidosis caused by a deficiency of galactosylceramide beta-galactosidase, and is characterized by an accumulation of psychosine in the nervous system. In this study, we applied a quantitative microproteomic workflow for the characterization of the central and peripheral nervous system of the Twitcher mouse (a mouse model for KD). The analyses focused on the corpus callosum, motor cortex and sciatic nerves.

Methods

The brains and sciatic nerves of 5 Twitcher and 5 littermate wild type mice were extracted and snap frozen. Cryosectioning and laser capture microdissection was then used to isolate small 1mm² regions of interest from each mouse brain. The workflow combined SP3 digestion, TMT labeling and high-pH fractionation followed by LC-MS/MS analysis using a nanoLC-Orbitrap Fusion system. Data analysis was performed using Proteome Discoverer 2.1, Perseus and WebGestalt.

Results

We performed three TMT-10plex experiments to separately compare the proteomes of the sciatic nerve, corpus callosum and motor cortex of 5 TWI and 5 WT mice. Overall, more than 3000 protein groups were quantified in each of the three datasets. Principal component analysis was performed on the protein expression levels and the TWI and WT mice fell into two distinct clusters, well separated by PC1 in all datasets. A two-sided t-test (FDR=0.01) was performed to compare the expression values of specific proteins. We found 75, 14 and 386 protein groups differently regulated between TWI and WT mice in the corpus callosum, motor cortex and sciatic nerves datasets, respectively. Gene ontology analysis revealed several pathways upregulated in the TWI mice related to inflammatory response (i.e. antigen processing and presentation, and complement pathway) and to phagocytosis and lysosomes.

Conclusions

The comparison between TWI and WT mice proteomes highlighted many proteins with distinct expression profiles. Most of the enriched biological processes in the TWI mice were related to immune response, accumulation of lysosomal proteins and reduced nervous system development. These initial results will be further investigated and validated in order to gain new insights into the molecular mechanisms of KD.

Novel Aspect

This work is the first reported mass spectrometry-based in-depth proteomic characterization of the Twitcher mouse proteome to study Krabbe disease.

Keywords:

Proteomics, FAIMS, PTM, TMT quantification

Introduction:

Proteomic analyses are often limited by the overwhelming proportion of confounding background ions that compromise the identification and quantification of low abundance peptides. Gas phase ion fractionation using high field asymmetric waveform ion mobility (FAIMS) can reduce sample complexity[1], and improve quantitative proteomic measurements[2]. Here we report a new FAIMS interface that further expand the sensitivity and depth of proteomic analyses.

Methods:

LC-MS/MS experiments were performed with and without FAIMS on an Orbitrap Fusion mass spectrometer. We used cylindrical FAIMS electrodes (1.5 mm gap) with both electrodes set to 100°C, pure nitrogen as carrier gas and a dispersion voltage (DV) of -5000V. LC-FAIMS-MS/MS experiments were conducted by stepping through 2-4 different CVs in a single run. Cell extracts were reduced, alkylated and digested with trypsin. TMT at 1:2 label excess was done in HEPES buffer, pH 8.3.

Results:

To evaluate the advantages of FAIMS, we first compared the number of identification obtained for triplicate injections of a 500 ng HEK293 digest analyzed by LC-MS/MS with and without FAIMS. These analyses revealed that FAIMS provided a 30% enhancement in identification with 39791 peptides (2876 protein groups) compared to 31397 peptides (2414 protein groups) without FAIMS. We next used isobaric peptide labeling with TMT to profile the dynamic changes in protein abundance for HEK293 cells exposed to heat shock. A different TMT label was used for each 1h interval for a treatment period up to 9h. Samples were analyzed using both synchronous precursor selection (SPS-MS3)[3] and LC-FAIMS-MS/MS. SPS-MS3 enabled the quantification of 12400 peptides corresponding to 1229 proteins, of which 375 proteins showed dynamic changes in abundance. FAIMS further enhanced the comprehensiveness of quantitative proteomics by more than 2-fold with 30848 peptides assigned to 2646 proteins, of which 902 proteins showed dynamic changes in abundance.

Conclusions

A new FAIMS interface was coupled to the latest generation of Orbitrap instruments and enabled unparalleled sensitivity in proteomics analyses where multiple CVs can be combined in a single LC-MS/MS run. The enhancement in ion transmission and duty cycle of the extended the depth of proteomic analyses by at least 30% and expand the comprehensiveness of multiplex quantitative proteomics using isobaric peptide labeling by at least 2-fold compared to SPS-MS3 analyses.

Novel Aspect:

Novel FAIMS interface combined with an Orbitrap tribrid MS improves the sensitivity of proteome analyses and the comprehensiveness of quantitative proteomic measurements.

417 - QUANTITATIVE STUDY OF METABOLIC PATHWAYS IN C. ELEGANS USING MS WESTERN

Bharath Kumar Raghuraman (1) - Andrej Shevchenko (1)

Max Planck Institute of Molecular Cell biology and Genetics, Biological Mass spectrometry, Dresden (1)

Keywords: MS Western, C. elegans, metabolic enzymes, systems biology, stoichiometry, isoform interplay

Introduction

Traditionally, metabolic pathways are quantitatively characterized by correlating gene expression profiles to protein abundances. However, owing to poor congruence between them, an alternative approach was needed to resolve this issue.

In C. elegans, metabolic transitions are crucial for development and survival. They are tightly regulated by tweaking dynamically the components of the pathways, but very less is known on how absolute protein amounts can contribute to this regulation.

Methods:

53 Metabolic enzymes from central carbon metabolism of C. elegans were quantified by MS Western method [1]. Unique quantitative peptides were selected from sequences of metabolic enzymes and from reference protein BSA and expressed as a single chimera in Δ Lys Δ Arg double auxotroph E.coli strain supplemented with isotopically labelled arginine and lysine. The isotopically labelled chimera, full length BSA & whole worm extracts were co-digested and analyzed by LC-MS. The abundances of tryptic peptides from the labelled chimeric protein and the unlabelled target protein were compared and absolute molar quantities of target proteins were calculated.

Results:

53 metabolic enzymes spanning glycolysis, gluconeogenesis, TCA and glyoxylate shunt were accurately quantified in fmole/worm using a single isotopically labeled 300 kDa chimera protein standard comprising, in total 200 quantitative peptides. Molar concentrations of endogenous enzymes determined with CV <10% allowed to determine stoichiometric ratios between subunits of multiprotein complexes and between individual members of metabolic pathways. To the best of our knowledge, for the first time this work provided a quantitative overview of the molecular organization of 4 metabolic pathways at the protein level. Although the abundance of enzymes is independently regulated, their molar abundances were ranging from 0.03 fmole/worm to 4 fmole/worm and within each pathway, differed less than 4-fold. High accuracy of the protein quantification allowed to confidently determine concentration difference of 2-fold, typically disregarded by label free quantification. By comparing molar abundances of metabolic enzymes in several mutants, this work provided molecular insight into the metabolic regulation at different stages of C. elegans development, including the dormant dauer stage.

Conclusions:

Absolute quantities of 53 metabolic enzymes provided crucial evidences of tight regulation of metabolic pathways. The changes in the specific gluconeogenic enzymes primed towards the conclusion that dormant worm uses gluconeogenesis as their survival strategy by exploiting all possible metabolic bypasses [2].

Novel Aspect:

Comprehensive absolute quantitation of 53 metabolic enzymes spanning 4 major pathways in one experiment with a CV < 10 %
Detailed study of isoform specificity in pathway regulation.
Easy estimation of subunit stoichiometry of enzyme complexes.
Unique repository for system biologists for pathway studies.

Keywords: microgradient device, peptide sample fractionation, basic reversed phase chromatography, nanoLC-MS/MS

Introduction:

Proteomic analyses using mass spectrometry often rely on suitable chromatography separation of complex peptide mixtures. In some cases, multidimensional chromatography application is even needed for a deeper insight of proteome. A combination of basic reversed phase chromatography fractionation with subsequent acidic reversed phase chromatography coupled to ESI-MS/MS analysis may be applied.

Methods:

Manual gradient chromatography device was used for fractionation of complex peptide mixture. Mobile phases were composed of acetonitrile in 20 mM ammonium formate at pH 10. Microcolumn (250 μm i.d., 50 mm length) contained core-shell particles (Kinetex EVO C18, 2.6 μm) and sample was fractionated either into 17 or 33 fractions that were further dried and analyzed using nanoLC-MS/MS (Q-Exactive).

Results:

The nanoLC-MS/MS analysis of a complex peptide mixture without fractionation enabled identification of 1975 protein groups. The fractionation of this sample using manual chromatography device in basic reversed phase chromatography revealed identification of up to 6197 protein groups. Not only the number of identified proteins was increased, but also the number of identified peptide sequences was increased about 4 times.

Conclusions

The manual chromatography device fractionates low amounts of peptides (tens of micrograms) into several fractions that provide a much deeper insight into the analyzed proteome after the nanoLC-MS/MS analysis. The device is advantageous for its simplicity of application, speed of fractionation (about 45 min per samples) and its low cost.

Novel Aspect:

Manual chromatography device for peptide sample fractionation prior to nanoLC-MS/MS analysis.

868 - A CHEMICAL PROBE FOR UNDERSTANDING HOW PROTEOME FOLDEDNESS CHANGES UNDER PROTEOSTASIS STRESS

Gavin Reid (1) - Dezeræe Cox (2) - Yuning Hong (3) - Danny Hatters (2)

University of Melbourne, School of Chemistry, Department of Biochemistry and Molecular Biology, Parkville (1) - University of Melbourne, Department of Biochemistry and Molecular Biology, Parkville (2) - La Trobe University, Department of Chemistry and Physics, Bundoora (3)

Keywords: proteostasis, protein folding, chemical proteomics

Introduction:

The components of the cellular quality control network responsible for maintaining proteostasis, some of which function to protect the folded state of proteins, are now well understood. However, it is still unknown which proteins in the proteome are most vulnerable to unfolding, misfolding, or aggregation, in response to diverse proteostasis stresses.

Methods:

Here, we demonstrate the application of a thiol-specific probe, tetraphenylethene maleimide (TPE-MI), coupled with stable isotope labelling and MS-based quantitative proteomic analysis, for measuring changes in the reactivity of free cysteine residues that are normally buried in the core of globular proteins but become exposed upon unfolding due to proteostasis stress¹.

Results: (Limit 900 characters without spaces)

We have demonstrated the potential of this method to (i) probe the kinetics of single-protein folding/unfolding for endogenous proteins on a proteome-wide scale, and (ii) monitor the specific changes in cellular proteome foldedness that occur in response to a variety of stressors (e.g., ER stress (tunicamycin), Heat Shock, HSP-70 inhibition, proteasome inhibition, or overexpression of a non-native misfolded protein, barnase²). Notably, we show that different stress conditions result in little overall similarity in changes in foldedness, and share only a small subset of common vulnerable core machinery.

Conclusions

TPE-MI is demonstrated as a promising tool to probe proteostasis at both the proteome wide and individual protein scales. This knowledge will contribute to our understanding of disorders characterised by proteostasis imbalance, and will assist in targeting those proteins most prone to misfolding under stress conditions.

Novel Aspect:

This approach enables analysis of folding/unfolding kinetics for endogenous proteins on a proteome-wide scale, without expression of specific protein reporters.

Keywords: proteomics, Isobaric labelling, data independent acquisition, quantification, comparison

Introduction

Label free quantification (LFQ) and isobaric labelling quantification (ILQ) are the two most popular quantification workflows in discovery proteomics. Here, we wanted to objectively compare the two workflows given a fixed amount of LC-MS time. For ILQ, we chose TMT 10-plex, for LFQ we chose single shot data-independent acquisition (DIA). We joined forces with a laboratory at FLI where ILQ is well established to compare the two workflows.

Methods

We generated a gold standard set of ten samples composed of a complex mouse cerebellum background spiked with the UPS2 protein standard (Sigma) in five different concentrations. LC-MS data was acquired on an Orbitrap Fusion Lumos (Thermo) in both laboratories and with both workflows. For TMT an MS3 method was used, for DIA a method as described in (Bruderer et al. 2017) was chosen. Data were analyzed with Proteome Discoverer (Thermo) and Spectronaut (Biognosys).

Results

In the four experiments (two workflows in two laboratories) we identified 48,500 (FLI TMT), 47,700 (BGS TMT), 51,800 (FLI DIA) and 53,500 (BGS DIA) peptides. On the protein level this corresponded to 6,500 (FLI TMT), 6,200 (BGS TMT), 5,700 (FLI DIA) and 5,900 (BGS DIA) identifications. 16 (FLI TMT), 15 (BGS TMT), 14 (FLI DIA) and 17 (BGS DIA) UPS2 spike in proteins were detected.

Generally, protein identifications were higher with TMT and protein sequence coverage higher with DIA. The quantitative performance in detection of differential abundance was very similar with a slight edge towards LFQ-DIA at both sites (FLI and BGS) and for two criteria used (partial area under the curve or true positives in the top 200 candidates).

We also performed an ILQ-TMT experiment with very deep pre-fractionation (24 fractions). This illustrated that ILQ-TMT is particularly suited for very deep proteome coverage. In this experiment we were able to quantify 8,800 protein groups, 160,000 precursors and 26 of the UPS2 proteins.

Conclusions

The quantitative performance of both methods was very similar in both laboratories. It turned out that for the analysis of the DIA data it was beneficial to use both quantitative information levels available in DIA, at MS1 and MS2 level. We see the strength in LFQ DIA particularly in a single shot workflow for dozens to thousands of samples and for ILQ TMT particularly for very deep coverage of a few samples.

Novel Aspect

Comparison of isobaric labelling workflow with single shot label free DIA quantification on a gold standard sample set

536 - HIGH SPEED, HIGH SENSITIVITY AND HIGHLY REPRODUCIBLE AND ACCURATE LABEL FREE QUANTIFICATION USING THE PASEF METHOD ON A TIMS QTOF

Bruker Daltonics Inc, Proteomics, Billerica (1) - Bruker daltonik GmbH, Proteomics, Bremen (2) - Bruker Dalotnik GmbH, Proteomics, Bremen (3) - Bruker Daltonik GmbH, Application, Bremen (4) - Bioinformatics Solutions inc, Development, Waterloo (5) - Max Plank Institute für Biochemistry, Computational Systems Biochemistry, Martinsried (6) - Bruker Daltonik GmbH, Proteomics, Bremen (7)

Keywords: TIMS, Targeted Proteomics, PASEF, DIA

Introduction:

Mass spectrometry-based proteomics has become a powerful technology for the identification and quantification of proteins. We recently introduced the Parallel Accumulation Serial Fragmentation (PASEF) method on TIMS QTOF instrument, delivering high robustness, speed and sensitivity, for shotgun proteomics. Here we show reproducible and accurate quantification using the PASEF acquisition method and the optimized PEAKS and MaxQuant software packages.

Methods:

The peptide mixtures (< 200 ng) were separated with a nanoElute (Bruker Daltonics) nano-flow LC on-line coupled to a high-resolution TIMS QTOF (Bruker Daltonics). Chromatographic separation was carried out at a flow rate of 400 nl/min using a 30-90 min linear gradient. LC-MS/MS data were acquired using the PASEF method. Data analysis was performed using PEAKS studio (Bioinformatics Solutions Inc.) and MaxQuant (Jürgen Cox, Max Planck Institute of Biochemistry).

Results:

200 ng of a complex peptide mixture derived from a mammalian cell line in the single-run format were analyzed using a 90 min gradient and optimized PASEF parameters. More than 5300 proteins families were identified in each run with a good reproducibility when comparing the protein identities between replicates. Comparing label free intensities between technical replicates shows excellent reproducibility with a $R^2 = 0.98$ using either a 90 min or with a 30 min gradient. To evaluate the reproducibility of PASEF, we determined the coefficient of variation of the label free intensities. Also here good reproducibility could be shown. For the evaluation of the accuracy of quantification over a wide concentration range we performed a spike-in experiment. We spiked E.coli digest in different ratios (1:2, 1:5 and 1:10) into HeLa digest and injected 100 ng sample material and measured each concentration in triplicate analyses. With all different concentrations, expected ratios could be determined.

Conclusions

tims-PASEF allows to perform reproducible, accurate and high sensitive label-free quantitation from shotgun proteomics samples.

Novel Aspect:

Label free quantification using PASEF

991 - FAIMS REDUCES INTERFERENCE AND IMPROVES QUANTITATIVE ACCURACY IN MULTIPLEXED PROTEOMICS.

Harvard Medical School, 240 Longwood Ave, Building C, Boston (1) - Thermo Fisher Scientific, Life Sciences Mass Spectrometry, San Jose (2) - Harvard Medical School, Cell Biology, Boston (3)

Keywords: Multiplexed, TMT, quantitative proteomics, FAIMS

Introduction:

Ratio compression reduces dynamic range in multiplexed quantitative proteomics studies, particularly for high-resolution MS2 Methods: SPS-MS3 has been highly successful for improving quantitative accuracy by reducing interference-based compression. Building on this, we tested whether the use of high-Frequency Asymmetric Ion Mobility Spectrometry (FAIMS) could further reduce interference in multiplexed quantitative analyses on an Orbitrap Fusion Lumos.

Methods:

Three complex samples were used to test the utility of FAIMS to reduce interference: (1) Triple-knockout yeast (TKO, 100% yeast), (2) canonical interference standard (CIS, 46% yeast), and (3) a novel small change interference model (SCI, 10% yeast). Known peptide ratios across channels ranged from 1.5-fold to infinite. Peptides were analyzed on an Orbitrap Fusion Lumos (Thermo Scientific) for analysis with or without a FAIMS source (three CVs tested: -40, -60, -80V).

Results:

Thermo recently developed a FAIMS source with improved measurement sensitivity/speed and FAIMS was previously shown to reduce interfering precursors by ion-mobility-based separation [1]. Here, we tested if Thermo's new FAIMS source could reduce co-eluting interfering ions to improve quantitative accuracy for multiplexed samples. We compared HRMS2 with and without FAIMS using a CIS (labeled yeast dilutions with/without mouse background), and strikingly observed a 55% reduction in quantitative interference. We identified 2288 total yeast peptides with FAIMS-HRMS2 compared to 2423 total yeast peptides for HRMS2 without FAIMS (94%) indicating similar PSM sensitivity with or without FAIMS.

For the TKO sample [2], a 9-plex with triplicates of three KO strains ($\Delta met6$, $\Delta ura2$, $\Delta pkf2$), FAIMS improved the average interference free index by 22% (reduced avg. interference by 62%) compared to the same method without FAIMS. Additionally, we observed a 2.2-fold increase in total peptide identifications for FAIMS-HRMS2 compared to FAIMS-SPS-MS3.

Conclusions

We observed that FAIMS-SPS-MS3 (with the SCI model) had the least quantitative interference (most accurate ratios), followed by non-FAIMS-SPS-MS3 and closely thereafter by FAIMS-HRMS2. Non-FAIMS-HRMS2 had the highest levels of interference and ratio compression. Total peptide identifications for FAIMS-HRMS2 were 54% higher than for SPS-MS3. Our findings suggest that Thermo's new FAIMS source would be a valuable tool for any multiplexed quantitative workflow.

Novel Aspect:

FAIMS (HRMS2 or SPS-MS3) consistently improved quantitative accuracy without sacrificing peptide identifications for multiplexed samples compared to standard Methods:

Title: A targeted multiple reaction monitoring method for quantifying Nav1.6 protein in HEK239 cells and mouse hippocampus

Authors: Tung M (1,2), Kwan R(1), Xi C(1), Li J(1), Dang C, (1,3) and Sojo, L E (1,2)

(1) Compound Properties Group, Bioanalytical Laboratory, Xenon Pharmaceuticals Inc., Burnaby, B.C., Canada. (2) Department of Chemistry, Simon Fraser University, Burnaby, B.C., Canada. (3) Department of Chemistry University of Victoria, Victoria, B.C., Canada

Keywords: Nav1.6, targeted proteomics, MRM, Human Embryonic Kidney (HEK) 293, Scn8a hippocampus

Introduction:

Nav1.6 expression and activity in hippocampus are shown to mediate seizure resistance (1). HEK293 cells expressing human sodium channel Nav1.6 are used to screen compounds targeting Nav1.6 for the discovery of drug candidates to treat epilepsy. Expression of Nav1.6 proteins is traditionally analyzed by Western blot analysis. Here we show that targeted multiple reaction monitoring mass spectroscopy can provide protein quantitation using stable isotope dilution of unique Nav1.6 peptides.

Methods:

Membrane proteins were extracted from Nav1.6 expressing HEK293 cells, and from Scn8aN1768D/+ and WT mouse hippocampus (2) using Mem-PER Plus kit (Thermo 89842). Detergents were removed using spin columns (Pierce 87777). Protein (80 µg) from Nav1.6 HEK293 cells and 240 µg of Scn8a and WT hippocampal protein were subjected to in-solution tryptic digestion (Thermo 89895). Samples were dried and reconstituted in 50 µL 1:1 ACN:water + 0.1% TFA for UHPLC-MS/MS analysis.

Results:

A total of 39 tryptic peptides, based on an in-silico digestion of a complete human Nav1.6 protein were targeted for MRM analysis of Nav1.6 expressed in a stably transfected HEK293 cells as well as in mouse hippocampus. Out of the 39 peptides, 11 were detected with at least three specific fragment ions. The remaining peptides were present, but not all fragments were detected. From these 11 peptides, seven were unique to Nav1.6. The other four peptides shared homology with other sodium channels. Peptide DSLFIPIR (480.781 m/z, 598-605) was selected for Nav1.6 quantification due to its intense and robust signal. Light and heavy (internal standard) versions of DSLFIPIR were synthesized and used to quantify Nav1.6 using an isotopic dilution method. Nav1.6 HEK293 cells showed Nav1.6 expression of 3.3 fmol/µg of total membrane protein. Scn8aN1768D/+ and WT mouse hippocampus showed 0.41 and 0.39 fmol/µg of total membrane protein, respectively.

Conclusions:

A simple and fast turnaround proteomic work-up was tested for detecting and quantifying Nav1.6 expression in a stably transfected Nav1.6 HEK293 cell line as well as in Scn8a mouse hippocampus. The success of these Nav1.6 proteomic studies enables the use of proteomics to screen and select optimal cell lines for epilepsy drug development. Changes in Nav1.6 expression in mouse hippocampus could also be monitored using proteomics. The same approach can be applied to other ion channels of interest.

Novel Aspect:

This is the first time that quantification of Nav1.6 protein expression in HEK293 cell lines and mouse hippocampus is reported.

1410 - COMPARATIVE STUDY OF THREE MS-BASED APPROACHES FOR QUANTITATIVE PROTEOMICS ANALYSIS

Domenico Taverna (1) - Marco Gaspari (1) - Marco Catracchia (1)

Proteomics-UMG lab, Department of Experimental and Clinical Medicine, Magna Graecia University of Catanzaro – ITALY (1)

Keywords: quantitative proteomics, TMT, LFQ, dimethyl labeling

Introduction:

Several approaches are available for performing MS-based quantitative proteomics. These include label-free and label-based methods [1]. However, which quantification strategy is best suited for identification of biologically relevant changes at the protein level is still not clear [2]. In this study, the analytical performance of three different strategies for relative protein quantification using shotgun proteomics have been compared: LFQ, DML and TMT.

Methods:

Two protein mixtures were analyzed, both containing the same amount of human proteins, but different protein amounts from *E. Coli* (1.5-fold difference) and soybean (3-fold). After protein denaturation and tryptic digestion (5 technical replicates), peptides were divided in three aliquots: one was used for label-free analysis; the second was labeled by TMT, while the third was derivatized by dimethyl labeling. All samples were analyzed by LC-MS/MS on a Q-Exactive.

Results:

Data were processed for statistical analysis (MaxQuant/Perseus) aiming to find out the best conditions for acceptable diagnostic accuracy. For 5 replicated samples per protein mix, a total of 2495 (LFQ), 1385 (DML), and 1803 (TMT) proteins with minimum 2 peptides (FDR 0.01) were quantified. Parameters such as specificity, precision and sensitivity were evaluated for each of the three quantification strategies. Differentially expressed proteins between protein mix A and B for LFQ and TMT datasets were identified by using a corrected Student t-test (permutation-based FDR < 0.05, S0=0.2). Instead, DML data were processed using the following criteria: one sample t-test, S0=0.2, p-value <0.05. The diagnostic accuracy has been evaluated for all the three datasets: LFQ data returned 95% specificity, 71% precision, and 87% sensitivity; samples labeled with TMT obtained 100% specificity, 96% precision and 51% sensitivity; DML labeling instead gave back the following values: 96% specificity, 64% precision, 79% sensitivity.

Conclusions

Since LFQ and DML provided comparable diagnostic accuracy, in our analytical pipeline LFQ was preferred because it provided deeper proteome coverage and faster sample preparation. TMT provided excellent precision (low number of false positives), though sensitivity was poor, especially at low fold changes (1.5-fold).

Novel Aspect:

Comparison of the diagnostic accuracy of the three main categories in quantitative proteomics: label-free, isobaric tagging and label-based with full MS quantification.

1371 - PROTEOMIC AND METABOLOMIC ALTERATIONS IN THE RAT BRAIN AFTER ISCHEMIC STROKE

Jaakko Teppo (1) - Anu Vaikkinen (1) - Kert Mätlik (2) - Tapio Kotiaho (1) - Mikko Airavaara (2) - Risto Kostainen (1)

University of Helsinki, Faculty of Pharmacy, Helsinki, Finland (1) - University of Helsinki, Institute of Biotechnology, Helsinki, Finland (2)

Keywords: ischemic stroke, proteomics, metabolomics

Introduction

Stroke is one of the major causes of death worldwide, and in non-lethal cases often leads to permanent symptoms[1]. Understanding the biological phenomena occurring in the brain after stroke on a molecular level is crucial for the development of new treatments to alleviate these symptoms. The aim of our study was to characterize the effects of stroke on the proteome and metabolome of rat brain at a timepoint in which the brain's response to stroke has been active for days.

Methods

Rats were subjected to 60 min cerebral ischemia or a sham operation as a control. The peri-infarct areas were dissected 4 days later, and the samples were homogenized and divided into two aliquots. Sample preparation was done separately for proteomics and metabolomics, and the untargeted analyses were performed with Thermo EASY-nLC 1000/Q Exactive MS and DionexUltiMate 3000 UHPLC/Orbitrap Fusion MS, respectively. Data was analyzed with MaxQuant, MZMine2, and R.

Results

Hierarchical clustering and PCA of the data indicated major differences between the sample groups, and in the case of PCA, higher between-sample variability in the stroke group than in the control group in both proteomics and metabolomics. Across the samples, in total 2403 proteins were quantified, of which 277 were upregulated and 167 downregulated in the stroke samples relative to the control samples ($q < 0.01$). In line with the literature, inflammatory response-related proteins were upregulated in the brain after stroke[2]. Further processes identified by the bioinformatic analysis include e.g. increased translation and decreased energy metabolism in the stroke samples. In metabolomics, 470 features were significantly different ($q < 0.01$, fold change > 2) between the sample groups. Based on MS/MS identifications, the abundance of e.g., sugars and sugar phosphates, unsaturated fatty acids and a wide variety of other lipid species increases in the brain after stroke, whereas the abundance of nucleosides (adenosine, guanosine) decreases.

Conclusions

Ischemia causes extensive damage to the brain, and with the consequent reperfusion, induces various biological processes. Our work identified major alterations in the brain after stroke on both proteomic and metabolomic level, including proteins and metabolites related to inflammation, protein synthesis, and energy metabolism.

Novel Aspect

This study integrates proteomics and metabolomics data from the peri-infarct brain area of rats subjected to cerebral ischemia and sampled several days post-stroke.

1321 - DETERMINATION OF PEPTIDE PURITY BY UV-MS AND QUANTITATIVE NMR

Frank A. Torma (1) - Milena Quaglia (2) - John Warren (2)

LGC LTD, Chemical Measurement and Calibration, Teddinton, United Kingdom (1) - LGC LTD, Chemical Measurement and Calibration, Teddington, United Kingdom (2)

Keywords: peptide, quantification, SI-traceable, UV-MS, standardization

Introduction:

Accurate quantification of peptides and proteins rely on the availability of certified reference materials. Here we investigated the use of ultraviolet (UV) and mass spectrometric (MS) detection for the simultaneous determination of the quantity and identity of peptidic impurities present in peptide standard solutions. The data combined with amino acid analysis can provide accurate determination of the SI-traceable concentration of peptide calibrants.

Methods:

Peptide solutions were SI-traceably quantified by amino acid analysis using exact matching isotope dilution mass spectrometry (EM-IDMS). The relative amount and the identity of the impurities was determined by UV-MS. Relative response factors (RRF) were verified by varying the injection volumes of the stock solution. The amino acid results were corrected for peptidic impurities. The results were confirmed by quantitative NMR (qNMR).

Results:

The SI-traceable concentration of the peptide solutions can be determined by peptidic impurity corrected amino acid analysis (PICCA). The peptide and its impurities must absorb UV light and the impurities must be baseline-separated. The peptidic impurities were sequenced by MS/MS. The main impurities are deletion products and related sequences with post translational modifications on unstable amino acid residues. The determined purity of the synthetic peptides used in this study is indirectly proportional with the length of the peptide sequence. The validation of the method for the determination of the purity of potential peptide calibrators will take place by applying it to the determination of the purity of oxytocin as part of an international comparison study. Quantitative NMR results complement the findings of the UV-MS results.

Conclusions:

The relative (detector) response ratios for the impurities vs the main compound can be determined without the use of solid impurity standards, and the determination of the purity of a peptide solution by the evaluation of the UV chromatogram is possible. The agreement between the purity results determined by UV and MS using the orbitrap mass analyzer suggests linear behavior for the orbitrap.

Novel Aspect:

Determination of purity of synthetic peptides is achieved with the use of universal (UV) and mass spectrometric detection and quantitative NMR.

465 - COMPARATIVE PROTEOGENOMIC ANALYSIS OF COLISTIN-DEPENDENCE IN ACINETOBACTER BAUMANNII

Sherley Chamoun (1) - Jenny Welander (1) - Carina Claesson (1) - Elena Vikström (1) - Maria Turkina (1)

Linköping University, Department of Clinical and Experimental Medicine, Linköping (1)

Keywords: proteogenomics, label free quantification, multidrug-resistant bacteria, hospital-acquired infections

Introduction:

The multi-drug resistant bacteria *A. baumannii* belong to the group of human opportunistic pathogens responsible for most common life threatening nosocomial infections. The resistance of *A. baumannii* to the last-resort antibiotic colistin is increasing and, recently, a high rate of colistin dependence has been demonstrated [1, 2]. However, the mechanisms of antibiotic resistance and dependence are not yet fully understood.

Methods:

Colistin-susceptible clinical isolate of *A. baumannii* and its subpopulation that exhibited a colistin-dependent growth pattern were studied. The whole-genome sequencing (WGS) and the shotgun proteome analysis by high-resolution mass spectrometry with following bioinformatics analyses were performed to characterize the molecular mechanisms of antibiotic dependence in *A. baumannii*.

Results:

We utilized a proteogenomic approach to explore the molecular mechanisms of colistin dependence. The bioinformatics analysis of the obtained WGS data identified multiple antimicrobial resistance genes which were identical in colistin-susceptible and colistin-dependent subpopulations; however colistin-resistant genes were not detected by ResFinder server. WGS data were used to construct a custom strain-specific six-reading frame database, which was used for the proteomic analysis. We found that 183 proteins were expressed differently in the two phenotypes and 119 of them were downregulated in the colistin-dependent subpopulation. The significant part of these proteins are metabolic enzymes, chaperones, outer membrane proteins, efflux pumps and porins. Notably, in addition to novel proteins, several of differentially expressed proteins are known to be involved in colistin-resistance mechanisms.

Conclusions:

Our study shows that the significant part of proteome is modified in colistin-dependent subpopulation of *A. baumannii*. This proteogenomic study also indicates that the colistin-dependence mechanisms are closely related to colistin-resistance. Our research provides a new analytical platform and a foundation for further research of multi-resistant *A. baumannii*.

Novel Aspect:

This is the first study to use proteogenomics approach for identification of the molecular mechanisms behind antibiotic dependence in *A. baumannii*.

1175 - TMT QUANTIFICATION USING SPECTRAL LIBRARIES IN SPECTROMINE

Lynn Verbeke (1) - Tejas Gandhi (1) - Oliver M. Bernhardt (1) - Lukas Reiter (2)

Biognosys AG, Bioinformatics, Schlieren (1) - Biognosys AG, R&D, Schlieren (2)

Keywords: TMT-quantification, spectral library searching, SpectroMine

Title: TMT Quantification Using Spectral Libraries in SpectroMine

Authors: Lynn Verbeke, Tejas Gandhi, Oliver Bernhardt, Lukas Reiter

Introduction:

SpectroMine can search both data-dependent (DDA) and data-independent acquisition (DIA) data using in silico generated search spaces (from FASTA files) or spectral libraries. The advantage of using libraries is the greatly reduced search space, leading to a speed-up and improved sensitivity/reproducibility [1]. Here we set out to see if a library-based targeted approach can lead to improvements, both in identification and quantification, in a TMT-experiment.

Methods:

We used a published data set of 7 TMT10-plex experiments, all from different mouse tissues. Every experiment consists of 12 fractions of 5 controls and 5 nicotine-treated samples [2]. We combined all 7 experiments to generate a library in SpectroMine with 1% false discovery rate at PSM, peptide, protein group level. SpectroMine also identifies the TMT reporter ions, in MS2 or MS3 scans. These are used to calculate differential abundances between conditions.

Results:

The generated library has a size of 673'204 fragments, 112'587 precursors, 10'120 protein groups (11 hours for processing 84 runs). We used this library to search the brain experiment. In the case of library searching, SpectroMine uses normalized retention time (iRT) [3] available from the libraries to further improve the search: only peptides within an expected retention time window will be matched to the scans. This resulted in 48'126 precursors and 7'627 protein groups (20 min). With a Q-value of maximum 0.05 and a minimal absolute log ratio, we found 18 candidates. When searching this data with the mouse FASTA file, we find 39'098 precursors, 6'617 protein groups (2 hours). Applying the same criteria, leads to only 16 candidates. Comparing the quantities of the candidates we obtained with those of the paper, resulted in correlations of 0.98 for both the FASTA as well as for the library approach.

Conclusions

When using a library instead of a FASTA file to identify TMT-labeled peptides, we managed to get an increase of 23% at precursor level and of 15% at protein group level. On top of that, quantification can still be applied by extracting the reporter ions from the MS3 scans. Very similar quantification results are obtained, showing that the library-searching approach of DDA-data can be combined with TMT-quantification.

Novel Aspect:

Library searching of TMT-labeled data, while making use of normalized retention time (iRT) to increase identifications while maintaining quantitative accuracy.

427 - MULTIPLEX QUANTITATIVE ASSAY OF INFLAMMATION PROTEIN MARKERS IN FECES SAMPLES

Veronika Vidova (1) - Vojtech Thon (2) - Jana Klanova (3) - Zdenek Spacil (3)

Research Centre (RECETOX), Masaryk University, Faculty of Science, Brno (1) - St. Anne's University Hospital, Department of immunology, Brno (2) - RECETOX, Masaryk University, Faculty of Science, Brno (3)

Keywords: inflammation markers, feces, selected reaction monitoring, targeted proteomics

Introduction:

Inflammatory bowel disease (IBD) and food allergies represent a wide group of intestinal disorders that may lead to chronic inflammation of the gastrointestinal tract (e.g. Crohn's disease, celiac disease). Food allergies are abnormal reactions to an allergen presented in food however the cause of IBD remains unclear [1,2]. Quantification of specific inflammation markers in feces allow to characterize an inflammation and estimate its progress in digestive tract.

Methods:

Proteins were extracted from both lyophilized and fresh feces samples for comparison, using 1x phosphate saline buffer and centrifugation. The supernatant was subjected to bottom up proteomics workflow. We have tested isolation of neutrophils and eosinophils from feces and characterize their CD markers. Proteotypic tryptic peptides were selected, inspected for isoforms and SNPs and quantified using UHPLC-SRM analysis.

Results:

We have developed and validated multiplex protein assay based on ultra-high performance liquid chromatography (UHPLC) and selected reaction monitoring (SRM) mass spectrometry for the absolute quantification of six inflammatory proteins (i.e. ECP, EDN, CAL S100A8, CAL S100A9, F-MPO and A1AT) in feces. Inflammation proteins were quantified in both lyophilized and fresh feces samples. Higher concentrations of inflammation proteins were quantified in lyophilized samples, most likely due to contribution from lysis of neutrophils and eosinophils, which contain these inflammation proteins and occur in feces. Lyophilization allowed us to normalize concentration of each protein to dry weight of lyophilized feces and to achieve lower limit of quantification. Certain inflammation proteins were cross-quantified using ELISA and results of both methods were correlated.

Conclusions:

We have developed UHPLC-SRM method for quantitative analysis of selected inflammation proteins in feces to identify an inflammatory status and potentially a specific type of inflammation. We have cross-validated quantitative results of newly developed UHPLC-SRM assay to the results obtained using ELISA assay as a reference method.

Novel Aspect:

A novel multiplex method applicable to study development of gastrointestinal immune system, development of IBD disease and food allergies.

198 - DEVELOPMENT OF A QUALITY CONTROL STANDARD FOR TANDEM MASS TAGS (TMT) WORKFLOWS

Jae Choi (1) - Aaron Robitaille (2) - Tabiwang N. Arrey (3) - Rosa Viner (2) - Andreas Huhmer (2) - John C. Rogers (1)

Thermo Fisher Scientific, research and development, Rockford (1) - Thermo Fisher Scientific, marketing, San Jose (2) - Thermo Fisher Scientific, marketing, Bremen (3)

Keywords: TMT, proteomic standard, QC, method development

Introduction:

Quantitative proteomics strategies using Tandem Mass Tags (TMT) enable sample multiplexing and precise measurement of protein abundance. However, co-isolated ion interference can suppress accurate ratio quantification and thereby mask true differences in protein abundance across biological systems [1]. To be able to detect and diagnosis co-isolation interference, we developed the Thermo Scientific™ TMT11plex™ labeled peptide reference sample.

Methods:

Lysates from four strains of *Saccharomyces cerevisiae* were prepared and labeled with TMT11plex reagents and mixed in equimolar ratios. Peptides from each knockout strain were labeled in triplicate, while the parental line was labeled in duplicate. The samples were then analyzed on a range of Thermo Scientific™ Orbitrap™ instruments using LC-HCD MS2 or MS3 fragmentations. Data analysis was performed with Thermo Scientific™ Proteome Discoverer™ 2.2 software.

Results:

To develop a widely applicable TMT11plex standard, we modified the selection of yeast strains from Paulo et al. 2016 [1] and included the parental strain BY4742 as reference channels. We show the yeast triple knockout (TKO) standard has less than 20% variability with lot to lot reproducibility. We then used the TMT11plex standard to establish a standardized workflow for liquid chromatography, MS acquisition on Orbitrap mass spectrometers, and data analysis software. Synchronous precursor selection (SPS) based methods provided the best accuracy and precision as compared to MS2 Methods: Depending on precursor isolation purity and notches (fragments) selected for MS3, ratios for knock out proteins can be still distorted. We then implemented an additional filter into the Proteome Discoverer software quantitation node to exclude precursors if more than the user defined number of isolated fragments were not from the identified peptide. Implementation of a new filter significantly improved quantitation accuracy and precision for all proteins.

Conclusions:

We demonstrate that the TMT11plex standard can be used an LC-MS system suitability standard to measure and optimize protein/peptides identification, acquisition, and data analysis methods to limit co-isolation interference, while also diagnosing MS instrument status by monitoring mass accuracy, ion injection time, and reporter ion signal to noise. The TMT11plex TKO standard provides users a tool to measure and assess different mass spectrometry approaches.

Novel Aspect: We present a widely-applicable, high quality TMT11plex yeast peptide standard for LC-MS quality control and application development.

Max Planck Institute for Chemical Ecology, NMR Group, Jena (1) - Max Planck Institute for Chemical Ecology, Mass Spectrometry / Proteomics Group, Jena (2) - Max Planck Institute for Chemical Ecology, Department of Entomology, Jena (3)

Keywords: biosynthesis, integrated -omics approach, nudicaulins, Papaver nudicaule

Introduction:

Indole alkaloids are a widespread group of secondary metabolites with huge structure variety. Nudicaulins, yellow flower pigments from *Papaver nudicaule* (Island poppy), are unique representatives of this compound class, combining structural elements from indole and flavonoids.[1] Previous studies identified indole and pelargonidin glucosides as final precursors.[2] The aim of our work is to understand the biosynthesis of the nudicaulins.

Methods:

Our approach on the biosynthesis of nudicaulins is based on four pillars: NMR studies on their chemistry, UPLC-MS/MS and LC-UV/Vis based metabolomics, transcriptomics, and DIGE-based quantitative proteomics.

Results:

The development of the *P. nudicaule* flowers was divided in five stages. These stages were monitored by transcriptomics, proteomics, and metabolomics approaches. Thereby, the most important genes and their products involved in the phenylpropanoid/ polyketide as well as indole biosynthetic pathway were identified. Relevant metabolites were semi-quantified over the flower development.

Additional experiments showed that the final nudicaulin formation from indole and pelargonidin glucosides is also possible in vitro under acidic pH conditions. This raises the question about the exact mechanism of this reaction in vivo, which is a work in progress.

Conclusions:

Based on transcriptomic, proteomic, metabolomic, and NMR studies we propose a biosynthetic pathway of nudicaulins in yellow petals of *P. nudicaule*. This opens new insights into this unique class of indole alkaloids.

Novel Aspect:

With the help of a multi method approach, our investigation provides access to the unique biosynthetic pathway of nudicaulins, the yellow pigments of *P. nudicaule* petals.

413 - UNIVERSAL S-TRAP SAMPLE PROCESSING: STANDARDIZED REPRODUCIBLE SAMPLE WORKUP FROM < UG TO > MG SCALES FOR ALL SAMPLE TYPES

John Wilson (1) - Darryl J. Pappin (1)

Cold Spring Harbor Laboratory, Cold Spring Harbor, NY, USA (1)

Universal S-Trap sample processing: standardized reproduciblesample workup from <ug to >mg scales for all sample types

John P. Wilson^{1*}, Darryl J. Pappin¹
¹Cold Spring Harbor Laboratory, Cold Spring Harbor, NY, USA

Keywords: sample preparation, digestion, sample cleanup, bottom-up proteomics, FFPE

Introduction:

Sample preparation has long hampered bottom-up proteomics. Proteins' vastly different solubilities and myriad extraction protocols yield very different data depending on what proteins are [not] extracted. S-Trap sample processing[1] solves this problem by integrating: 1) complete 5% SDS protein solubilization; 2) total protein denaturation (pH < 1 and > 70% organic); 3) simultaneous sample concentration/cleanup; and 4) rapid reactor-type proteolytic digestion.

Methods:

S-Traps were obtained from ProtiFi (www.protifi.com, Huntington NY). S-Trap micros were used from sub-ug to 100 ug max, S-Trap minis from 100 – 300 ug, S-Trap midis > 300ug, and 96 well plates for high throughput applications. Briefly, all samples were extracted with 5% SDS, fully denatured, captured on the S-Trap where they were cleaned of all contaminants including Laemmli sample buffer, PEG, detergents, urea, reduction and alkylation reagents, etc. and digested.

Results:

S-Trap sample processing allowed unbiased protein analysis including poorly soluble proteins (membrane proteins, chromatin and muscle, etc.) and was successfully applied without alteration to all samples including tissues, FFPE blocks, cell lines, biological fluids, etc. Using only standard lab equipment, S-Traps enabled reproducible sample processing with < 10% CVs from protein to peptides in around 1 – 2 hrs from sub-microgram to multi-milligram scales.

Conclusions

S-Trap processing is highly reproducible (CVs typically < 10%) and independent of the properties of the proteins under study. Without change, its harmonized protocol is applicable to all kinds of samples from liquid biopsies (serum and dried blood spots [DBS]) to FFPE blocks to tissues or cell lines. S-Trap processing increases protein recovery, affording analysis of very small sample quantities, and can enable simultaneous proteomics and metabolomics.

Novel Aspect:

Use one protocol for all samples from <ug to >mg scales greatly improves reproducibility and ease of research. Throughput is greatly improved by 1 hr digests. The ability to remove contaminants is especially helpful to core labs.

Keywords: label-free quantitation, data-independent acquisition (DIA), high-throughput, reproducibility, robustness

Introduction:

A reproducible and robust global proteome profiling workflow is required to confidently determine putative protein marker panels. In this work, we illuminate the impact of key components of the DIA workflow, including chromatography, MS resolution & accuracy, spectral library quality, as well as the statistical analysis to demonstrate the label-free quantitation advantages of the HRMS1 – DIA workflow on a complex multi-proteome sample set.

Methods:

Experiments were performed on a Thermo Scientific™ Q Exactive™ HF mass spectrometer using a method consisting of full scan MS with interspersed DIA acquired for qualitative analysis. Chromatographic separations were performed using a Thermo Scientific™ UltiMate™ 3000 RSLC system, equipped for capillary-flow using a 60-minute gradient. The samples consisted of three separate proteomes (HeLa, yeast, and E.coli), which are mixed in various proportions.

Results:

The quality and breadth of the spectral library has a critical impact on the detection of peptides and proteins from DIA data sets. Therefore an exhaustive spectral library is created using multiple off-line high pH reverse phase fractions of each proteome. Quantification by DIA is based on the precursor level in the high resolution full scan. Scan cycles consisting of multiple full- MS1 scans with interspersed DIA scans are employed to improve the precision of MS1 based quantification. For robust and reproducible chromatographic separation, a 60-minute capillary LC-DIAMS method is developed without compromising sensitivity along with high-throughput. The median CV of all the experiments are < 10%. A roll-up statistics strategy is applied to calculate peptide p-Value, improving quantitation precision to 95% by removing the interferences from the real quantitative signals. As a result, the ratios of the mixed three proteomes accurately reflect the expected values.

Conclusions

An HRMS1–DIA workflow solution has been developed by streamlining each key component to achieve ease-of-operation and reproducible label-free quantitative performance in a high-throughput manner. The initial data demonstrate >7000 proteins were reliably quantified. For a higher proteome coverage, a 120-minute DIAMS method based on the nano-LC separation is developed, where ~20% more protein groups (> 8000) were quantified.

Novel Aspect:

With the novel and complete HRMS1-DIA workflow ca. 10,000 protein groups are identified with 1% FDR and ca. 8000 protein groups are quantified with 95% quantitation precision.

Keywords: Cancer moonshot multi-site study, Large-cohort study, High Resolution MS1 based Data-independent acquisition (HRMS1-DIA), High-throughput, Reproducibility

Introduction:

A high-throughput and streamlined analytical workflow using high resolution MS1-based quantitative data-independent acquisition (HRMS1-DIA) is standardized with well-defined experimental steps, and systematically applied to a set of samples. The study was benchmarked across multiple Cancer Moonshot sites worldwide utilizing same instrument platform, procedures, and software, and demonstrated to be stable in a 24/7 operation mode for 7 consecutive days.

Methods:

Experiments were performed on a capillary chromatographic separation with 1h gradient online coupled to Q Exactive HF mass spectrometer. HRMS1-DIA method contains multiple MS1 scans with interspersed DIA MS2 scans. The samples consisted of three separate proteomes mixed in various proportions. HeLa digest served as a quality control (QC) sample. Spectral libraries were created by performing LC-MS/MS analysis of multiple off-line high pH reverse phase fractions.

Results:

>250 QC files and >360 mixed proteome sample files are acquired by the participated laboratories in a 24/7 operation mode for 7 consecutive days.

With the 1 hour capillary LC-HRMS1 DIA workflow, > 5,000 protein groups from > 40,000 peptides of the HELA QC sample are consistently identified with 1% FDR across all sites and all 7 days. The peptide intensity correlation of all the 250 QC files is > 0.85, demonstrating an ultrahigh inter-laboratory and inter-day reproducibility.

> 7,000 protein groups from > 50,000 peptides of the mixed proteome sample are reliably quantified across all 11 international labs and 7 days. >80% proteins are overlapped identified and quantified across the laboratories. Additional to the 1% FDR, a rollup strategy is developed and applied to remove the non-reliable peptide quantitation ratios, to successfully enhance the quantitation precision to > 90%. As a result, the label-free

quantitation ratios of the mixed three proteomes accurately reflect the expected values at each laboratory across all 7 days.

Conclusions

To elevate discovery proteomics to translational research in the pipeline of precision medicine, large-cohort studies are essential in discovery and verification of protein biomarkers. Yet, reproducible proteome profiling and quantitation in different laboratories remains a challenge. This multi-site study across the globe demonstrates the high-throughput, reproducibility, and scalability of the standardized HRMS1-DIA workflow for large-cohort studies.

Novel Aspect:

Multi-site reproducibility, robustness, and method transfer evaluation for HRAM MS-based global proteome profiling using a standardized DIA analytical workflow

Keywords: post-translation modification, systems oncology, immunoprecipitation, PTM crosstalk

Introduction:

It is widely known that post-translational modification (PTM) is important for regulation of protein activity and several cellular functions. Therefore, abnormality in those modification is closely related to oncogenesis. Thus, understanding of global PTM status significantly contribute to cancer biology and drug discovery against cancer. So far, several PTM proteomics were conducted by using immunoprecipitation with pan-PTM antibodies.

Methods:

One of examples is phosphotyrosine proteomics. When performing large-scale phosphoproteomics, phosphorylated tyrosine sites account for less than 1%. To increase identification of phosphotyrosine sites, we optimized enrichment step of phosphotyrosine peptides with immunoprecipitation, and achieved highly sensitive detection of phosphotyrosine peptides (more than 1,000 sites) from samples without pervanadate treatment [1].

Results:

In this study, we examined optimization for enrichment step of peptides containing other PTM sites. Newly developed protocol is commonly applicable for enrichment of several types of PTMs. We successfully measured several PTM status from single sample.

Conclusions

We concluded that optimization for enrichment of each type of PTM peptides is crucial for comprehensive proteomics of multiple PTM.

Novel Aspect:

This technique would lead to understand complexed crosstalk between multiple PTM signalings and find novel therapeutic targets.

1265 - NEXT-GENERATION PROTEOMICS INSIGHTS INTO BACILLUS CEREUS VIRULOME HIGHLIGHTS THE KEY ROLE OF METHIONINE OXIDATION OF EXOPROTEINS

BEATRICE ALPHA-BAZIN (1)

CEA, DRF/JOLIOT/DMTS, BAGNOLS-SUR-CEZE, France (1)

Keywords: bacillus cereus, shotgun proteomics, methionine oxidation, comparative exoproteome

Introduction:

Bacillus cereus is a food-borne pathogen responsible of toxi-infections in humans. During the course of infection the survival and growth of the bacteria depend on its capacity to maintain an intracellular redox state in response to environmental changes. Its virulence depends on the production of virulence factors secreted in the extracellular milieu. In order to determine the key factors that contribute to redox homeostasis and virulence, we have performed high-throughput shotgun proteomics.

Methods&Results:

In the studies cellular proteome and exoproteome time courses were monitored by nanoLC-MS/MS. When required comparisons were performed between wild-type and the mutant of interest cells. The roles of the redox balance sensor Rex [2] and the organic hydroperoxide stress resistance system OhrRA [1] in the machinery that maintains intracellular redox state was deciphered by next-generation proteomics. Their role in toxinogenesis was highlighted through a detailed analysis of exoproteome [1,2]. Exoproteome analysis also highlighted that toxins and other extracellular virulence factors contained oxidized methionine residues[3]. We showed that oxidation of Met residues in extracellular proteins is regulated by methionine sulfoxide reductase AB (MsrAB), a key factor of the antioxidant system, suggesting that secretion of virulence factors could contribute to maintain intracellular redox homeostasis [4]. Furthermore, interactions of bacteria genomic information and their recently acquired plasmids were reported once again through the proteomics viewpoint [4]. We also contributed to identify by proteogenomics a new key virulence factor that we named EntD which was revealed to be pivotal for pathogenesis[5], meanwhile it was missed by automatic annotator software.

Conclusions:

Bacillus cereus is well able to survive to various environment conditions. The bacteria exploits its metabolic flexibility to grow and produce extracellular toxins. We have shown that Met residues in exoproteins and their recycling by MsrAB serve as an antioxidant strategy. This project illustrates the potential of next-generation proteomics in microbiology.

Keywords: thiols, redox biology, cold physical plasmas

Introduction

The proteome is a sensor and mirror of the redox state in mammalian cells [1]. Cysteine is the amino acid most sensitive to oxidation since its thiol group forms different biologically relevant chemotypes [2]. In this study, possible derivatives of cysteine formed by impact with cold physical plasma as means to produce oxygen and nitrogen centered reactive species (RONS)[3] were surveyed by high resolution MS/MS in order to predict the potential impact of plasma in vivo.

Methods

Different concentrations of cysteine standard solutions were treated by various cold plasma jets with respective parameter variation. The unknown compounds were then separated using an HILIC column in an HPLC system, and identified by using a high resolution q-TOF mass spectrometer. A relative quantification was made by relating the intensities in each spectra to the one of the L-cysteine-¹³C₃, ¹⁵N at known concentration.

Results

A large number of oxidation products from cysteine were identified and the potential pathway of formation relative to RONS generation by the plasma was described. Modifications were mostly oxygen driven and located on the thiol moiety, with the cysteine sulfonic acid as major, but not ultimate, compound. By distinct modulation of the plasma parameters, e.g. nitrogen shielding of the effluent or addition of water to the feed gas, the formation of specific cysteine bioactive derivatives such as S-nitrosocysteine, cysteine-S-sulfonate, or cystine di- and tetra-sulfoxides were increased. By varying the plasma parameters, cysteine's biochemical impact could be modulated ultimately reflecting back on the biological impact of cold plasma treatment in redox related conditions, e.g. wound healing[3].

Conclusions

Cold plasmas are valid tools to produce RONS and simulate molecular changes occurring in oxidative environments. It was observed that cysteine product profile reflects treatment conditions, allowing cysteine variants with potential relevance in redox signaling to be characterized. These observations imply a profound impact on protein thiol groups when treated by oxidizing conditions like plasma in vivo, with consequences on cellular redox signaling pathways.

Novel Aspects

Rare but potentially biologically relevant cysteine derivatives were observed after physical plasma treatment, allowing a forecast of thiol oxidation products in vitro.

A rapid, multiplexed kinase activity assay using iTRAQ labeling and MALDI-TOF/TOF MS

Keywords: multiplexed, kinase assay, MALDI-TOF/TOF, insulin stimulation, inhibitor

Introduction:

Substrates from chemically synthesized peptides have been used for in vitro phosphorylation using purified kinase or cell lysates. Because of its high specificity and high throughput, MALDI-TOF-MS has been a powerful platform for the detection of phosphorylated peptide substrate from enzymatic reactions. However, for screen assay, a direct readout and comparison among different experimental conditions without using internal standard would be preferred.

Methods: The peptide substrates labeled with 8-plex iTRAQ reagents were separately added in 8 different experimental conditions. For kinase activity comparison among 8 samples, the lysates of each experimental conditions containing individual iTRAQ-labeled peptide substrates were pooled for protein removal using SPE, followed by enrichment of phosphorylated peptide substrates using TiO₂ plate and MALDI-TOF analysis.

Results: We found that abundant proteins in cell lysate can severely affect the purification efficiency of phosphorylated peptides on TiO₂ plate. Therefore, SPE approach was first optimized to remove abundant proteins without significant influence of the recovery of phosphorylated peptides from the TiO₂ plate. To enable our platform applicable in insulin stimulation and cancer drug inhibition, a list of the peptide substrates was designed. The protein amount and incubation time for kinase assay of insulin stimulation and drug inhibition were optimized. By labeling peptide substrates with 8-plex iTRAQ reagents, protein kinase activities in 8 samples can be directly compared by the mass tags on their fragmented ion spectra. The kinase activity results from our multiplexed-kinase activity MALDI-TOF assay are consistent with the results from western blots analysis.

Conclusions:

We have successfully developed a rapid and quantitative measurement of multikinase activity based on MALDI-TOF. In this assay we combined 8-plex iTRAQ labeled peptide substrates for quantification with a phosphorylated peptide substrate purification plate to rapidly determine multikinases activities in cell lysates. The effect of insulin stimulation and an inhibitory drug on the cellular protein kinase activity were successfully evaluated.

Novel Aspect:

This study is the first report to use iTRAQ-labeling strategy combined with TiO₂ plate and MALDI-TOF/TOF for sensitive and high throughput multikinase activity analysis.

565 - USING SUB-RANKED DATABASE MATCHING SCORES FOR IMPROVING THE PEPTIDE AND PROTEIN IDENTIFICATION PERFORMANCE

Yet-Ran Chen (1) - Ying-Lan Chen (1) - Wei-Hung Chang (1)

Academia Sinica, Agricultural Biotechnology Research Center, Taipei (1)

Keywords: Peptidomics, Database Search, Proteomics

Introduction:

In peptidomics and proteomic study, a large portion of the MS/MS spectra acquired by the data dependent acquisition (DDA) approach cannot confidently match to a specific peptide sequence. To improve the peptide and protein identification performance, a new database search approach was proposed. Performance and application of this approach were studied and discussed.

Methods:

The processed DDA analysis spectra were searched against a protein database using semi-tryptic peptide specific (sTPS) and non-enzyme specific (NES) setting in the identification tryptic peptides and endogenous peptide, respectively. The 1st to the 10th peptide matching scores for each of the MS/MS spectrum were used to develop new peptide matching score.

Results:

In this study, we showed that the score distributions of 1st and 2nd ranked hits were similar if the 1st ranked hits matched to random sequences but distributions were differentiated if the 1st ranked hits matched to forward sequences. Because the differences of the 1st and 2nd ranked score for random matched hits are smaller than the true positive hits, the use of delta score (DS) can make the true positive hits to be more discriminated from the random hits. We further developed a new scoring method named confidence scoring (CS), which considered the 1-10th matching scores of each spectrum. For the identification of tryptic peptide using NES search, the peptide identification sensitivity of CS was 12% and 2% higher than the Mascot score and DS, respectively. In the sTPS search, the number of the identified peptides of CS and DS was 12% and 25% higher than the Mascot score, respectively.

Conclusions

A new approach for performing the tryptic and endogenous peptide identification was developed. This new approach not only can improve the identification performance of endogenous peptides but also on tryptic peptides. In the analysis Tomato peptidomics, we demonstrated that the majority of the endogenous plant peptides are derived from the C-terminal of precursor proteins.

Novel Aspect:

This method does not require complex computational steps and can significantly improve the sensitivity for detecting tryptic and endogenous peptide.

374 - SEPARATION OF COMBINATORIAL PTMS ON HISTONE H3 TAIL WITH AN ADVANCED DATA ANALYSIS AND ION MOBILITY

Yoko Chikaoka (1) - Hiroki Ueda (2) - Ryo Kajita (3) - Kazuki Yamamoto (1) - Lee Sujin (1) - Toshiya Tanaka (4) - Takeshi Kawamura (1)

-, The University of Tokyo/Proteomics Laboratory, Isotope Science Center, Tokyo (1) - Fujitsu Limited, The University of Tokyo/Biological Data Science Division, RCAST, Tokyo (2) - Bruker Japan K. K., -, Yokohama (3) - -, The University of Tokyo/Laboratories for Systems Biology, RCAST, Tokyo (4)

Keywords: protein modifications, ion mobility, data analysis, histone, middle-down

Introduction:

Mass spectrometry is suitable to investigate protein post-translational modifications (PTMs). Any modifications on any proteins are detectable as mass shifts. Combinations of the PTMs are often called as 'codes' and they are thought to have different biological meanings [1]. Histones are representative proteins that have the code. Since the codes can be formed between PTMs on distant amino acids, typical LC-MS/MS analysis using trypsin often loses their combinatorial information.

Methods:

Histone H3 was purified from cells by histone extraction and HPLC fractionation. Histone H3 tail 1-49 amino acid long peptides are digested with AspN. LC-MS/MS with electron transfer dissociation (ETD) was performed using the Orbitrap Fusion with high-resolution MS/MS and Ion mobility separation-MS/MS analysis was performed using the timsTOF Pro. Data was analyzed with MASCOT and a developing software in house.

Results:

Histone H3 tails have multiple positional isomers of PTMs that is difficult to separate by liquid chromatography. Consequently, the obtained MS/MS spectra had the mixed ones of the positional isomers of modifications. An in-house software has been developed by using de Bruijn Graph to resolve the mixed spectra.

We are examining the effects of ion mobility separation [2]. We have obtained several species that have different drift time from one precursor, which might be positional isomers.

Conclusions:

Advanced data analysis and ion mobility separation might improve combinatorial PTM identification.

Novel Aspect:

We are developing novel software to improve PTM identification of histone middle-down analysis.

119 - PROTEOME-WIDE EFFECTS OF SINGLET OXYGEN PRODUCED BY NEXT GENERATION IRIIDIUM ANTI-CANCER METALLODRUGS

Cookson K. C. Chiu (1) - Pingyu Zhang (1) - Yuko P. Y. Lam (1) - Christopher A. Wootton (1) - Mark. P. Barrow (1) - Peter J. Sadler (1) - Peter B. O'Connor (1)

Department of Chemistry, University of Warwick, Coventry (1)

Keywords: anticancer, photodynamic therapy, proteomics, Fourier Transform Ion Cyclotron Resonance (FT-ICR) MS, post-translational modification

Introduction:

New metal-based anticancer drugs have been the focus of next-generation chemotherapy. Novel Ir(III) based drugs have been designed to minimise side effects on healthy cells, while increasing selectivity and efficacy towards cancer cells by inducing reactive oxygen species (ROS) when triggered with blue visible light. The catalytic production of $1O_2$ with Ir-complexes, and effects on target species within cells were investigated to uncover their mechanism of action on a proteome-wide scale. [1]

Methods:

FT-ICR MS analysis was conducted using a 12T Bruker Solarix (Bruker Daltonik GmbH, Bremen, Germany) FT-ICR mass spectrometer. nLC-MS/MS experiments were conducted via coupling an EASY nano-LC II system (Proxeon, Hemel Hempstead, UK) to the Solarix FT-ICR MS, separation was achieved using a water/acetonitrile gradient and a C18 reverse phase column. All data was analysed with Data Analysis v4.2 (Bruker Daltonik GmbH, Bremen, Germany) and the Mascot database search engine.

Results:

Activation of the Ir metallodrugs caused production of reactive singlet oxygen species and extensive oxidation of nearby biomolecules. A whole range of oxidation products, up to 6 per peptide, were observed. The high resolution and mass accuracy and extensive MS/MS capabilities of the FT-ICR MS allowed unambiguous identification of the oxidation sites and the modifications induced. $1O_2$ was found to cause many methionine oxidation events (to sulfoxide and sulfone), but also oxidation of tryptophan residues, producing diagnostic kynurenine and 3-hydroxy kynurenine moieties. Histidine residues were oxidised to 2-oxo-histidine, which is commonly observed in $1O_2$ oxidation events. Bottom-up nLC-MS/MS experiments of drug-treated cancer cells revealed two key targets; aldose reductase (AR) and heat shock protein 70 (Hsp70). Quantitative nLC-MS/MS showed the increase in oxidised products in the drug-treated samples, calculated as 3.0-fold up-regulation with AR and 5.8-fold up-regulation with Hsp70, together with 9 proteins up-regulated along the glycolysis pathway.

Conclusions:

New Ir-based anticancer drug was designed to be highly and selectively cytotoxic to cancer cells when activated with visible blue light. Generation of $1O_2$ was confirmed by observing diagnostic oxidised species in peptides. Damage to specific cellular proteins, AR and Hsp70 was discovered in cells, induced by photodynamic therapy. 9 proteins along the glycolysis pathway were found up-regulated, which happened in the mitochondria of cells, disrupting the energy source of cancer cells.

Novel Aspect:

Top-down and bottom up FT-ICR MS/MS approaches shed light on new anticancer, catalytic photoactivated Iridium complex targets and proteome effects

521 - QUANTITATIVE PHOSPHOPROTEOMICS IDENTIFIES ALTERATIONS OF DOUBLECORTIN-LIKE KINASE 1 (DCLK1) IN NEURAL PROGENITOR CELL DIFFERENTIATION

Alireza Dehghani (1) - Markus Goedderz (1) - Volkmar Gieselmann (1) - Dominic Winter (2)

Institute of Biochemistry and Molecular Biology, University of Bonn, Bonn (1) - Institute of Biochemistry and Molecular Biology, University of Bonn, Bonn (2)

Keywords: Quantitative phosphoproteomics, Neurosphere differentiation, LC-MS/MS, DCLK1, BioID

Introduction

Oligodendrocytes are the myelinating cells of the central nervous system and originate from neural stem cells through differentiation mechanism which is only incompletely understood.[1] It has been shown that kinases play important roles in this differentiation process.[2-3] Therefore, in this study, we performed a large-scale phosphoproteomics experiment to investigate phosphoproteome alterations during the differentiation process.

Methods

Samples were harvested at 3 time points of differentiation, labeled using 3-plex dimethyl, and separated into 12 fractions using SCX chromatography. Phosphopeptides were enriched and analyzed by LC-MS/MS. For follow-up experiments, proximity biotinylation by DCLK1-BioID fusion proteins was performed: 8 BioID constructs were generated resembling distinct splice variants of DCLK1. Samples were biotin- and phosphopeptide-enriched and analyzed by LC-MS/MS.

Results

Neural progenitor cells were differentiated over 2 weeks to oligodendrocyte precursor cells. Samples were harvested at three time points: 0, 7, and 14 days of differentiation. Harvested samples were lysed, digested, dimethyl labeled and fractionated using LC-SCX fractionation. Phosphopeptides were enriched using TiO₂ and analyzed by LC-MS/MS. 6963 unique phosphopeptides were quantified covering 9053 phosphorylation sites. In total, 1118 phosphosites were up- or downregulated at least 2-fold. Among the most highly upregulated candidates, several phosphorylated peptides of DoublecortinLike Kinase 1 (DCLK1) were found. Phosphomimetic studies showed that DCLK1 phosphorylation alters its stability. We therefore employed BioID[4]-DCLK1 fusion proteins to investigate DCLK1 substrates and interaction partners. In these experiments the phospho-enriched fractions revealed 2574 phosphosites representing 2086 phosphopeptides from 1229 phosphoproteins while the flow through yielded 33623 peptides from 4616 proteins.

Conclusion

9 residues of DCLK1 were found to be differentially phosphorylated during the differentiation process. Site directed mutagenesis revealed that phosphorylation in the SP-rich domain of DCLK1 altered its stability. Applying a combination of BioID-DCLK1 fusion proteins and phosphopeptide enrichment, Neurofilament medium polypeptide (NEFM), Filamin-A (FLNA), and Fatty acid synthase (FASN), mTOR, and CAMKK1 were found as possible DCLK1 interaction partners.

Novel Aspect

First phosphoproteomic analysis of neural progenitor cell differentiation identifying differential phosphorylation of DCLK1 and follow up by BioID fusion proteins.

Abstract for THE 22nd INTERNATIONAL MASS SPECTROMETRY CONFERENCE (IMSC) 2018

Comprehensive NISTmAb reference spectral libraries for reliable and robust identification of post-translational modifications in human and recombinant IgG antibodies

Qian Dong, Yuxue Liang, Xinjian Yan, Sanford P. Markey, Yuri A. Mirokhin, Dmitrii V. Tchekhovskoi, Tallat H. Bukhari, and Stephen E. Stein

Biomolecular Measurement Division, National Institute of Standards and Technology, 100 Bureau Drive, Stop 8362, Gaithersburg, Maryland 20899, United States

Key Words:

Monoclonal antibodies, post-translational modifications, spectral library, 1D/2D LC-MS, glycation

Introduction:

We report an alternative peptide and PTM identification method based on matching experimentally derived spectra in a comprehensive library of the NISTmAb IgG1k. We show that this method is advantageous over the database tools for reliably determining low levels of biologically modified species in antibody drugs. The simultaneous detection of these modifications, challenging for conventional methods, can be achieved without using special settings or procedures.

Methods:

500µg of NISTmAb was denatured using various chemicals and solvents in 50µL of 100mmol/L Tris HCl buffer at room or 85 °C. Parameters for 13 protocols were used during denaturing, reduction, and alkylation of the NISTmAb. Each sample was digested with trypsin for 0.25, 2, and 18h. 1D/2D LC-MS was used for various digestion conditions. Initial identifications were made using MS-GF+ search engine against a fasta-file containing the sequence.

Results:

We created a high-resolution mass spectral library of all identified peptides produced in the tryptic digests of a humanized IgG1k mAb reference material (NISTmAb). The reference library contains over 12,600 high-quality tandem spectra of more than 3,300 peptide ions identified and validated by accurate mass, differential elution pattern, and expected peptide classes in peptide map experiments. These include a variety of biologically modified peptide spectra and method-induced artifacts obtained from 1D/2D LC-MS/MS analyses. The 12 varieties of spectra included in the library are derived from peptides of unmodified major classes, N-linked glycosylated, oxidized, deamidated, modified N-/C terminal, glycated, metal-ion adducted, overalkylated, and other types of modifications. A complete glycation profile was obtained for the NISTmAb with spectra for 58% and 100% of all possible glycation sites in the heavy and light chains, respectively. The site-specific quantification of methionine oxidation in the protein is described.

Conclusions:

The library of annotated spectra of all NISTmAb peptide ions acquired in this work, along with the library search software, is freely available. The general utility of this library is demonstrated by the analysis of Humira, where 60% sequence coverage for constant regions of this commercial mAb. The NISTmAb library platform may be used as a tool for facile identification of the primary sequence and PTMs for human and recombinant IgG antibodies.

Novel Aspect:

Facile, reliable, and simultaneous identification of low levels of biological modifications in mAbs by advanced NISTmAb reference material spectral library.

Humira

207 - SEAGAL: THE METHOD TO FISH FOR UNCOMMON PHOSPHORYLATIONS

Vladimir Gorshkov (1) - Yaseelan Palarasah (2) - Karsten Skjødt (2) - Frank Kjeldsen (1)

Department of Biochemistry and Molecular Biology, University of Southern Denmark, Odense (1) - Department of Cancer and Inflammation Research, University of Southern Denmark, Odense (2)

Keywords: phosphorylation, enrichment, gallium, immunopurification

Introduction:

Traditional methods for phosphopeptide purification are reported to introduce strong bias and hence detected phosphorylations only partially reflect the true phosphoproteome distribution of the cell [1]. Importantly, part of phosphoproteome, especially, N-linked phosphorylations (i.e. histidine, arginine, lysine) are generally out of the scope of conventional enrichment methods, despite high interest in those type of phosphorylation.

Methods:

The mixture of phosphopeptides was modified by the recently developed by dimetallic gallium complex [2] in 20 mM triethylammonium bicarbonate (pH 8). Modified peptides were enriched by immunopurification using an immobilized antibody against the introduced metal complex and analyzed by LC-MS/MS. Raw data analysis was performed in Thermo Proteome Discoverer 2.2, including home-built data deconvolution and pre-processing step and conventional database search.

Results:

The developed dimetallic complex is highly specific for the phosphate moiety, irrespective of its nature, thus, the same method allows simultaneous enrichment of peptides having O-linked (Ser, Thr, Tyr) and N-linked (His, Lys, Arg) phosphorylation. The modification and enrichment are performed at close to neutral pH (optimal range 5 – 8), thus, avoiding destabilization of N-linked phosphorylation and providing less bias of the phosphoproteome. Modified peptide and all fragments containing the modification display distinct isotopic pattern preventing efficient data analysis by conventional proteomics tools. To solve this issue, data pre-processing software was developed as a processing node for Thermo Proteome Discoverer. The source code and complete description of algorithms are made available for the community. Alternatively, the introduced modification could be removed by pyrophosphate in a simple one-step process compatible with conventional LC-MS-based proteomics.

Conclusions:

The proposed phosphopeptide enrichment approach is based on specific phosphate-capturing dimetallic complex and immunopurification of complexed phosphopeptides. The enrichment can be performed at neutral pH, preserving labile modifications. The present proof-of-concept study clearly indicates the potential of the method, however, further optimization is necessary to apply the method in biologically-relevant cases.

Novel Aspect:

The presented method allows for obtaining comprehensive information on O- and N-linked phosphoproteome simultaneously at neutral pH.

277 - ANALYSIS OF PROTEIN-PHENOLIC COMPOUND MODIFICATIONS USING ELECTROCHEMISTRY COUPLED TO MASS SPECTROMETRY

Constanze Kallinich (1) - Simone Schefer (1) - Sascha Rohn (1)

Hamburg School of Food Science, University of Hamburg, Department Food Chemistry, Hamburg (1)

Keywords: Electrochemical oxidation, phenolic compounds, adduct formation, EC-MS, phenol-protein interaction

Introduction:

Posttranslational modifications of proteins are associated with influencing the essential structural and regulatory properties of each protein. For example, one of these post-translational modifications is the covalent addition of other food compounds to diverse side-groups of (food) proteins or peptides [1]. Influences on the biological properties such as the enzyme activity [2], the nutritional protein quality [3], and changes in the allergenicity of the proteins/protein derivatives, seem to be more or less obvious.

Methods:

Electrochemical oxidation of phenolic acids (e.g., chlorogenic acid) was performed using a preparative electrochemical thin-layer cell consisting of a boron-doped diamond working electrode. A solution of the phenolic acid was injected into the electrochemical cell and a constant potential was applied [4,5]. Detection of oxidation products was performed using an ESI-MS ion trap mass analyzer in negative ion mode. Subsequently, a second flow system was used to combine both analyte solutions, phenolic acid and mixture of tryptic peptides of a dietary protein e.g., alpha-lactalbumin, to generate and detect potential adducts.

Results:

After optimizing the reaction parameters for the four phenolic compounds selected, various oxidation products were detected and identified by means of ESI-MS. By connecting a flow system with a tryptic peptide solution of digested dietary proteins, oxidation products of the phenolic substances, and further reaction products of phenolic oxidation products and tryptic peptides were identified. It has been shown that an electrochemically induced oxidation of the model phenols is possible as well as a reaction of the oxidation products with selected, previously tryptically digested dietary proteins. A preparation of the reaction products in higher concentrations could be generated by preparative LC. Structural elucidation of the resulting products by means of NMR are carried out.

Conclusions:

Electrochemistry coupled with mass spectrometry was successfully used to investigate the redox potential of dietary phenolic acids such as chlorogenic acid. It was possible to create optimized conditions for the oxidation of chlorogenic acid to generate a wide variety of oxidation products. Electrochemically oxidation of chlorogenic acid, caffeic acid, ferulic acid, and sinapinic acid generated a variety of reactive intermediates. Feasibility of this technique for the research topic was shown.

Novel Aspect:

The young field of electrochemical coupled mass spectrometry (EC-MS) is a suitable system for generating and identifying potential metabolites. Target compounds can be identified directly by mass spectrometry. After separation of generated metabolites, structural elucidation can occur in following steps.

Introduction:

Phosphoprotein is involved in cellular processes such as proliferation, cell signaling, and apoptosis.[1-3] Mass spectrometry is commonly used to identify both phosphorylated protein(s) and its site(s). However, phosphoproteins in MS analysis have several limitations due to low abundant and low ionization efficiency caused by negative charge of phosphates in a positive mode.[4-5] Herein, we introduce a MW sorting-based new strategy for phosphoproteomics.

Methods:

The tryptic peptides from MCF7 were mixed with phospho-antibodies (pAbs, above 150 kDa), and followed by which the mixtures introduced into the mHFER (50-100 kDa in MW-cutoff) with continuous flow rate of 5 μ L/min. During breakthrough run, ordinary peptides having no affinity with pAb are first washed out through membrane wall of HF. The remaining peptides bound to pAb can be simultaneously exited via online tryptic digestion in mHFER for next nLC-ESI-MS/MS run.

Results:

For mHFER-based phosphopeptide enrichment, we optimized the experimental conditions according to the kind of pAbs, reaction time between peptides and pAbs, reaction temperature, reaction ratio, and the length of mHFER. From our experimental results, the enrichment yield of phosphopeptides was dramatically enhanced when used the mixture of phospho-serine, -threonine and -tyrosine antibodies at the ratio of 1:1 (proteins/pAbs, w/w) reacted for 1 hour at 4 $^{\circ}$ C. Finally, we found total 11282 phosphorylation site from 5673 phosphopeptides of MCF7 cells utilizing online mHFER-2D-nLC-ESI-MS/MS and confirmed that the pAbs-based enrichment coupled with online mHFER can be the best way with the small amount of proteins (\sim 10 μ g) for phosphoproteomics than conventional methods [e.g., immobilized metal affinity chromatography (IMAC), titanium dioxide (TiO₂), and filter aided sample preparation (FASP)] with a large amount (above 500 μ g).

Conclusions

We found that the developed pAbs-based online mHFER is highly selective, precise, and suitable for phosphopeptide enrichment with the small amount of proteins, compared to that of conventional methods (IMAC, TiO₂, and FASP). Additionally, our phosphopeptide enrichment strategy with online mHFER is a promising tool for phosphoproteomics, and for the development of therapeutic agents.

Novel Aspect:

The developed a mHFER-based phosphoproteome enrichment platform is one of advanced strategy for understanding the biological functions of protein PTMs study.

592 - HISTONE MIDDLE-DOWN ANALYSIS USING BY MULTIPLE DISSOCIATION METHODS

Takeshi Kawamura (1) - Hiroki Ueda (2) - Daisuke Higo (3) - Yoko Chikaoka (1) - Kazuki Yamamoto (1) - Lee Sujin (1)

Isotope Science Center, The University of Tokyo, Tokyo (1) - Research Center for Advanced Science and Technology, The University of Tokyo, Tokyo (2) - Thermo Fisher Scientific, -, Tokyo (3)

Keywords: Histone modifications, epigenome, ETD, UVPD

Introduction:

Mass spectrometry is a powerful tool for protein post-translational modifications (PTMs) analysis. A state-of-the-art mass spectrometer distinguishes very small mass differences. Histone has many PTM sites and their theoretical PTM combinations can be above trillion. Semi-bottom-up and middle-down proteomics are used for PTMs identification or decision of their combinations. Here, we used middle-down proteomics and compared various fragmentation methods.

Methods:

Purified histone or histone H3 HPLC fraction were digested with AspN to obtain 49 or 23 aa length of H3 or H4 tails. They were fragmented with CID, ETD, or UVPD method and were analyzed by Mascot database search for PTM identification. The identification number and the identified kinds of PTMs were compared. The search was performed after deconvolution into the masses of singly charged ions.

Results:

Although all fragmentation methods enabled PTM identifications, ETD showed relatively accurate identification in the middle-down proteomics. However, it was difficult to differentiate citrullination from z, z+1, z+2 ions generated by hydrogen rearrangement in ETD. In addition, the molecules of molecular weights above 5kDa with multiple charged ions showed deformed isotope pattern of distributions, which make it difficult to determine monoisotopic ions. We have developed an algorithm to determine monoisotopic ions by matching to theoretical isotope distributions and compared with the Advanced Precursor Detection (APD) in the Orbitrap Fusion Lumos. Moreover, CID and UVPD were compared and the CID was suitable for shorter peptide analysis. Longer peptide analysis was better in UVPD and the UVPD generated relatively frequent b, y series ions.

Conclusions:

Appropriate combination of ETD, CID, and UVPD and selection of the optimized fragmentation method according to molecular size and charge might improve the accuracy of histone PTMs analysis. Further, the PTM site locations are examined.

Novel Aspect:

We have compared the fragmentation methods to reveal complicated histone PTMs.

Keywords:

Monoclonal antibodies, post-translational modifications, trypsin digestion, low pH digestion, peptide mapping

Introduction:

Post-translational modifications (PTMs) on monoclonal antibodies (mAbs) are potential critical quality attributes that define therapeutic efficacy and safety[1]. Mass spectrometry based peptide mapping (PM) is the gold standard methodology for the in-depth study of PTMs on mAbs. Artificial PTMs, however, may be induced during sample preparation for PM, e.g. asparagine deamidation [2]. The current work describes the effect of digestion pH and incubation time on Trastuzumab PTMs. Trastuzumab, marketed as Herceptin, is a humanized IgG1 mAb used in the treatment of HER2 positive breast cancer.

Methods:

The regular trypsin digestion protocol for peptide mapping involved the use of RapiGest, dithiothreitol (DTT), and iodoacetamide (IAM) in Tris-HCl buffer at pH 7,5. The low pH protocol, based on a commercial kit from Promega, made use of guanidine-HCl, Tris(2-carboxyethyl)phosphine (TCEP), IAM, trypsin, and low pH resistant rLys-C. Peptide mapping was performed on an Agilent Technologies 1290 Infinity UHPLC and Agilent Technologies 6540 Accurate-Mass Quadrupole Time-of-Flight LC/MS. Peptides were separated on a Waters Acquity UPLC CSH 130 C18 (2,1 x 150 mm, 1,7 µm) analytical column operated at 60°C at a flow rate of 0,4 mL/min using 0,1% formic acid in water or acetonitrile.

Results:

Post-translational modifications of Trastuzumab peptides produced under regular alkaline, and low pH digestion conditions were identified and compared. Aspartate isomerization, methionine oxidation, N-glycosylation, N-terminal cyclization, and asparagine deamidation were PTMs of primary interest. Digests with incubation periods of 2, 4, 6, and 16 hours were obtained and analyzed by LC-MS. Results show the progression of artificial modifications, especially asparagine deamidation, using regular tryptic digestion conditions with longer incubation periods up to 16 hours at 37°C. On the contrary, the low pH digestion protocol showed less identified artificial modifications while providing longer peptides and higher sequence coverage. Moreover, modifications not associated with sample preparation were identified, such as oxidation, deamidation, glycosylation, and cyclization of certain peptides.

Conclusions:

The accurate determination of PTMs is important to ensure the quality of therapeutic mAbs. Artificial PTMs introduced by sample preparation using alkaline tryptic digestion can be reduced with shorter incubation times while providing sufficient peptide profile and protein sequence coverage. Acidic digestion effectively prevents modifications caused by sample preparation.

Novel Aspect:

Post-translational modifications of Trastuzumab under different digestion conditions were identified and compared. Shorter incubation times for regular trypsin digestion or the use of low pH digestion conditions is advised.

163 - IDENTIFICATION AND CHARACTERIZATION OF O-XYLOSYLATION AND O-GLYCOSYLATION OF RECOMBINANT PROTEIN THERAPEUTICS BY MASS SPECTROMETRY

Vincent Larraillet (1)

Roche Pharmaceutical Research and Early Development, Biochemical and Analytical Research, Roche Innovation Center Munich (1)

Keywords: antibody fusion proteins, post-translational modification

Introduction:

To connect the different functionalities of antibody fusion proteins in a single molecule G4S linker are often used. O-Xylosylation is a recently described post-translational modification (PTM) of a heterogeneous glycan structure on the serine of the G4S linker [1, 2]. Content, structure vary between different therapeutic proteins and expression hosts. O-Glycosylation is a known PTM with well described glycan structures [3, 4] and located on serine or threonine.

Methods:

Intact measurement: Protein samples were N-deglycosylated and desalted by size exclusion chromatography. ESI mass spectra were recorded on a Q-TOF instrument (maXis, Bruker) equipped with a nano ESI source (TriVersa NanoMate, Advion).

Peptide Mapping: Protein samples were denatured and reduced, carboxymethylated and digested by trypsin. LC/ESI-MS/MS was done on an Orbitrap Fusion system (Thermo). Peptides were separated using RP HPLC (Waters NanoAcquity).

Results:

Here we describe mass spectrometry based methods to detect, differentiate and locate O-Xylosylation and O-Glycosylation in recombinant protein samples. We will show that intact measurement of deglycosylated antibody derivatives using ESI-TOF-MS is an easy and reliable method to quickly get an initial impression of present protein modifications which exist with significant amount. A major disadvantage of this method is that detected O-Xylosylation signals are often overlaid by other modification or adduct signals or detected peaks are not fully resolved. Measurements after deglycosylation and reduction can provide remedy regarding peak resolution issues. But, as we will show, LC/MS-MS peptide mapping using an Orbitrap Fusion is the method of choice to get a more detailed view on the modification, to locate the particular modification site in protein sequence and to make an exact estimation of the O-Xylosylation and O-Glycosylation content.

Conclusions:

Detection and quantification of O-Xylosylation and O-Glycosylation in antibody fusion proteins using the combination of intact measurement and peptide mapping.

Novel Aspect:

Detection of O-Xylosylation and O-Glycosylation of recombinant protein therapeutics.

958 - SPECIFIC MASS TAG OF METHYLATED AMINO ACID VALIDATES THE SUMOYLATION SITES BY HCD ON ORBITRAP MASS SPECTROMETER

Fu-An Li (1) - Yu-Hsiang Cheng (1)

Institute of Biomedical Sciences, Academia Sinica, Taipei (1)

Keywords: SUMOylation, methylated, HCD, Orbitrap

Introduction:

The identification of SUMOylation sites by mass spectrometry is not easy because of the large SUMO chain remnant attached to peptides after tryptic digestion. Therefore, the widely adopted method is still the site-directed mutagenesis. Here, we will demonstrate the utility of specific mass tag from the methylated terminal to facilitate and validate the identification of SUMOylation sites by HCD on Orbitrap mass spectrometer without mutagenesis.

Methods:

The digested peptides are reductively methylated using formaldehyde-d₂ and subsequently subjected to LC/MS/MS analysis with LTQ-Orbitrap Elite. The digested peptides were analyzed in data-dependent mode by LC/MS/MS. The data-dependent acquisition method consisted of ten sets of HCD/CID scans. Here, the HCD spectrum is used for monitoring specific a₁ ions, and the CID spectrum is used for peptide sequencing.

Results:

The signal enhancement for a₁ ions of dimethyl labeling peptides in the CID of Q-TOF instrument had observed and applied for identifying the N-terminal amino acid.¹⁻³ In this study, we identified the spectra of SUMOylated peptides by monitoring two a₁ ions of HCD spectrum, one is from the SUMO chain remnant and the other is from the SUMOylated peptide. The optimal collision energy of HCD for monitoring two a₁ ions simultaneously was 40%. For peptides sequencing, the identification of the MS/MS spectra generated by the SUMOylated peptide using the Mascot database search is still difficult. To address this problem, the candidate spectra selected by specific mass tag were submitted to do the sequence match by the software "ChopNSpice".⁴ The results showed the specific mass tag of methylated amino acid could dramatically narrow down the candidates of possible spectra, thus the number of identified spectra were more than the one without spectra selection before ChopNSpice search.

Conclusions:

We use a di-SUMO-2 protein as a model to demonstrate the method and successfully applied to identify the SUMOylated sites on the p53 protein. The results show the methylated mass tag (two specific a₁ ions) is suitable for screening SUMOylated spectra in complex protein mixture. This method is more sensitive than direct database search, and it also greatly reduced the false identification.

Novel Aspect:

The method could dramatically narrow down the candidates of possible spectra and is more sensitive than direct database search for SUMOylation sites identification.

How does CE-MS compare with LC-MS in PTM analysis?

Klaus Faserl¹, Bettina Sarg¹, Herbert Lindner¹, Jim Thorn², Christopher Lößner³ and Stephen Lock²

¹Medical University of Innsbruck, Innsbruck, Austria, ²SCIEX, Warrington, United Kingdom and ³SCIEX, Darmstadt, Germany

Keywords: PTM, CE-MS, phosphorylation, deamidation, isomerisation

Introduction:

Post translational modifications (PTMs) are important indicators of change in cells. Two of the top four most abundant PTMs are deamidation and phosphorylation and the location of the phosphorylation site is an important factor in understanding the effect of this modification on the activity of proteins.

Results:

Traditional LC-MS methods can sometimes struggle with the identification of positional isomers of phosphorylated peptides as they are identical in mass and may not separate by traditional reverse phase LC. Phosphorylated peptides are often polar, and elute early in reverse phase chromatography (especially when more than one phosphorylation site is present on the peptide) which can make them difficult to detect by trap-elute LC-MS. LC-MS methods also struggle to identify and quantify Aspartate and iso-Aspartate isomers (associated with deamidation) as they have the same mass and similar fragmentation patterns which often result in false positive identifications.

Conclusions:

As CE separates analytes based on their charge and size (a different mechanism to LC) it can often overcome some of the separation challenges seen by LC. In this poster we will show how CESI-MS has been used to tackle these challenges and how it compares to LC-MS and find out how it has been applied to real biological samples in proteomics research.

Novel Aspect:

Separation of isobaric and/or co-eluting post-translational modifications by CE-MS

1359 - IDENTIFYING THE DISULFIDE BOND PATTERN AND ECM INTERACTION SITE OF TGFBIp

Marie V. Lukassen (1) - Carsten Scavenius (2) - Ida B. Thøgersen (2) - Jan J. Enghild (2)

Aarhus University, Interdisciplinary Nanoscience Center (iNANO), Aarhus, Denmark (1) - Aarhus University, Department of Molecular Biology and Genetics, Aarhus, Denmark (2)

Keywords: Disulfide, Cysteinylation, RP-HPLC, ECM, Cross-link

Introduction:

Transforming growth factor β -induced protein (TGFBIp) is an extracellular matrix (ECM) protein composed of an NH₂-terminal cysteine-rich domain (CRD) and four fasciclin-1 (FAS1-1 to FAS1-4) domains. Previous studies have shown that TGFBIp is cross-linked to type VI and type XII collagen through a reducible bond [1,2]. TGFBIp contains 11 cysteine residues and is thus able to form five disulfide bonds, leaving a single cysteine residue available for the cross-link.

Methods:

Recombinant human TGFBIp was digested with Glu-C and trypsin to get cleavages between all cysteine residues except Cys84 and Cys85. The generated peptides were separated by strong cation exchange (SCX) followed by reversed-phase high-performance liquid chromatography (RP-HPLC) and analyzed by mass spectrometry (MS) and NH₂-terminal sequencing. For verification, the disulfide bond pattern of TGFBIp from human cornea was also analyzed by MS.

Results:

The NH₂-terminal CRD contains six cysteine residues, and one of these (Cys65) was identified as the candidate for the reducible cross-link between TGFBIp and the ECM molecules type VI and type XII collagen. This residue was not engaged in any disulfide bond, but was modified by a cysteinylation. The cysteinylation can be exchanged with a cysteine residue of another protein forming an intermolecular cross-link. In addition, the CRD contained two intradomain disulfide bonds (Cys49-Cys85 and Cys84-Cys97) and one interdomain disulfide bond to the FAS1-2 domain (Cys74-Cys339). The cysteine residues in the FAS1-3 domain (Cys473 and Cys478) were shown to form an intradomain disulfide bond. Finally, an interdomain disulfide bond between the FAS1-1 and FAS1-2 domains (Cys214-Cys317) was identified. The disulfide bond pattern was verified in human corneal tissue and Cys65 was also found in a cysteinylated form.

Conclusions

The results contradict the predicted assignment of the CRD as an emilin domain [3] and we have renamed the domain to the cysteine-rich domain of periostin and TGFBIp (CROPT). The interaction to the ECM is through Cys65 of the CROPT domain. The interdomain disulfide bonds indicate that the NH₂-terminus of TGFBIp adopts a compact globular fold. This together with the disulfide bond pattern has recently been validated by a crystal structure of TGFBIp [4].

Novel Aspect:

We identified Cys65 of the renamed NH₂-terminal CROPT domain to be the residue forming a reducible bond to other ECM molecules such as type VI and type XII collagen.

Keywords: diatoms, biosilica, post-translational modification, polyamines, AQC

Introduction:

Diatoms are unicellular algae that use highly specialized proteins to produce nano silicified cell walls. These proteins, termed silaffins, share no homology across diatom species. Silaffins are heavily modified [1] and their lysine residues bear polyamine chains [2]. However, their structure and physiological roles remain elusive.

Methods:

Total biosilica extracts from *Thalassiosira pseudonana*, *T. oceanica* and *Cyclotella cryptica* species were isolated as described [3], subjected to acidic hydrolysis and derivatized with AccQ•Ultra Reagent (Waters). Lysine derivatives were quantified by LC-MS and confirmed by MS/MS on Q-Exactive HF mass spectrometer (Thermo Scientific). Modifications were mapped to protein sequences by GeLC-MS/MS [4] on OrbitrapVelos mass spectrometer (Thermo Scientific).

Results:

We developed a method to identify and quantify polyamine-modified lysines and map them back to silaffin sequences. In total, 17 novel modifications were discovered, including acid-resistant phosphoester-containing polyamines. We demonstrated that the pattern of polyamine modifications reflects the phylogenetic proximity of the diatom species. Modified lysine residues were identified by polyamine-specific fragments in MS/MS spectra followed by iterative searches and deconvolution of raw MS/MS spectra. We localized 130 polyamine-modified sites in 26 proteins from three diatom species and revealed 3 consensus motifs common to all three diatoms.

Conclusions:

We report a novel approach to identify, quantify and localize 130 polyamine modifications in three diatoms and demonstrated that they occurred at conserved consensus motifs, despite full sequences of the modified proteins were not conserved.

Novel Aspect:

Identification of consensus motifs of polyamine modifications

805 - CHARACTERIZATION OF NIST MONOCLONAL ANTIBODY ON INTACT, SUBUNIT, AND PEPTIDE LEVEL WITH MONITORING OF CQA'S ON THE 6600

Chris Nortcliffe (1) - Kerstin Pohl (2) - Jorg Dojahn (3) - Ferran Sanchez (4)

SCIEX, SCIEX PHOENIX HOUSE, LAKESIDE DRIVE, WARRINGTON (1) - SCIEX, Applications Support, Darmstadt (2) - Sciex, Market Manager, Darmstadt (3) - Sciex, Market Manager, WARRINGTON (4)

Keywords: Mass Spectrometry, Biologics, Antibodies, MAM, Biopharmaceuticals

Introduction:

Monoclonal antibodies (mAbs) can be incredibly complicated with hundreds of residues, varying degrees of glycosylation and PTMs which may be critical to quality. MS can uncover a wealth of information of these mAbs with a synergistic workflow used to maximise data quality and fidelity. Here BioPharmaView™ and the 6600 characterize the NIST mAb on an intact, subunit, and peptide level. Additionally the MAM workflow in BioPharmaView™ has been used to control CQAs.

Methods:

All measurements were carried out in replicates on a 6600 Q-ToF equipped with IonDrive™ source and the high flow ExionLC™ system. For all analyses solvent A consisted water containing 0.1 % formic acid and Solvent B consisted acetonitrile containing 0.1 % formic acid. Intact and subunit analysis were performed with a C4 column with a flow rate of 200 ul/min at temperatures of 80°C and 60°C respectively. Peptide mapping was performed with a C18 column at 250 ul/min at 50°C.

Results:

As complexity of biopharmaceuticals increases the need for accurate reliable data acquisition becomes ever more important. The NIST mAb has five major intact glycoforms G0F/G0F, G0F/G1F, G1F/G1F, G1F/G2F, and G2F/G2F representing one glycan on each heavy chain Fc region. The ratios of these various glycoforms are highly regulated and have been measured accurately after reconstruction with BioPharmaView™.

Due to the number of overlapping features at high charges states features can be difficult to discern at the intact level, these features can become clearer at the subunit level. The glycoforms on the subunit level are clearer to distinguish due to the reduced complexity of a single glycan per fragment. The subunit fragments were matched with the BioPharmaView™ software providing the same glycan ratios as on the intact level.

The NIST mAb was digested and analysed with the 6600 with a SWATH analysis. Data was analysed with BioPharmaView™ software with 100 % of the protein sequence observed at the MS level and validated via MS/MS fragmentation.

Conclusions

As biologics become increasingly heterogeneous the need for complete characterization across all points in upstream and downstream production increases. Sciex provides a complete workflow solution for LC-MS analysis of complex protein products with Multiple Attribute Monitoring of Critical Quality Attributes.

Novel Aspect:

Complete characterization of NIST antibody and glycoforms with MAM analysis in BioPharmaView™ software.

1197 - RAPID, SENSITIVE AND QUANTITATIVE PHOSPHOPROTEOMICS FOR LARGE-SCALE CELL PERTURBATION ANALYSIS

Jesper Velgaard Olsen
Jesper Velgaard
Jesp Olsen (1)

University of Copenhagen, Faculty of Health and Medical Sciences
(1)

Keywords: Phosphoproteomics, signaling, kinase, DIA, Ti-IMAC

Introduction: Protein activity is mainly modulated by dynamic reversible post-translational modifications (PTMs) such as site-specific phosphorylation, which regulates essentially all cellular processes. Despite continuous improvements, global analysis of protein phosphorylation is still challenging due to its sub-stoichiometric nature and low abundance.

Methods: We present a high-throughput IMAC based enrichment method to routinely quantify ~7000 phosphopeptides in 15 min of LC-MS/MS time on a Q Exactive HF-X MS [1]. But we have now reached the sequencing speed limit for data-dependent analysis (DDA) for phosphoproteomics. To overcome this, we have used data-independent analysis (DIA) for phosphoproteomics based on project-specific spectral libraries.

Results: To directly compare DDA and DIA in a biological setting, we performed a global kinase-substrate analysis, where we treated EGF stimulated RPE1 cells with three different MEK inhibitors. Phosphopeptides were enriched from only 200ug of peptides per sample using Ti-IMAC in 96-well format and analyzed with both DDA and DIA using label-free quantification. For the DIA analysis we generated a project specific spectral library containing ~55,000 unique phosphopeptides. From the DDA analysis we quantified ~7000 phosphopeptides per sample, whereas from the DIA analysis, we were able to quantify ~20,000 phosphopeptides per sample with few missing values. From the DIA runs we were also able to reproducibly identify ~400 phosphotyrosine-containing peptides in each sample, which is comparable to antibody-specific phosphotyrosine enrichments. Reassuringly, we found the same biological kinase signature using both DDA and DIA with strong overrepresentation of proline-directed ERK substrate motif sites among the inhibited phosphorylation sites.

Conclusions: DIA holds great promise for rapid phosphoproteomics profiling with deep coverage and accurate label-free quantification with few missing values.

Novel Aspect: Rapid DIA-based quantitative phosphoproteomics of hundreds of cell states

1274 - INCREASING VARIANTS IN HYDROPHOBIC INTERACTION CHROMATOGRAPHY DURING STABILITY STUDY OF HUMANISED MONOCLONAL ANTIBODY IDENTIFIED BY LC-MS ESI Q-TOF TOP DOWN, MIDDLE DOWN AND BOTTOM UP ANALYSES

Martin Pauers (1) - Katharina List (1) - Dorothee Wetzel (1)

Boehringer Ingelheim Pharma GmbH & Co KG, Pharmaceutical Development Biologicals, Biberach an der Riss, Germany (1)

Keywords:

Biotherapeutics, humanized monoclonal antibodies, stability studies, hydrophobic interaction chromatography

Introduction:

Development of therapeutic mAbs includes real time and accelerated stability studies to address critical Quality Attributes. Typically, these include e.g. protein structure, formation of particles as well chemical modifications of amino acid residues. This case study presents results from LC-MS analyses of samples from a stability study of a humanised IgG, which showed a storage temperature/ duration dependent increase of unknown variants within HIC analyses.

Methods:

Samples stored at -70 °C/ +5 °C/ +25 °C for 12 months and +30 °C for 6 months were analysed by LC-MS ESI Q-TOF using a Waters UPLCI-Class coupled to a Waters Synapt G2-S. Performed analyses covered top down and multiple middle down analyses of IgG and its subunits using reducing conditions and/or IDeS treatment. Further analyses included bottom up analyses like tryptic and chymotryptic peptide mapping and determination of free thiol levels and disulfide mapping.

Results:

LC-MS top down analyses resulted in detection of slightly increased protein fragment levels for samples stored at +25 °C and +30 °C, as well as detection of an additional hydrophilic light chain species without mass shift in middle down analyses. Bottom up analyses of these samples (+25 °C/ +30 °C) by peptide mapping resulted in slight increase of methionine oxidation, asparagine deamidation and aspartate isomerisation of DG motifs. Free thiol levels as well as scrambled disulfides in disulfide mapping showed slight increases at +25 °C and +30 °C. In-depth data evaluation of peptide mapping data indicated high levels of three additional retention time-shifted peptide species. These peaks were further investigated by LC-MS including electron transfer dissociation resulting in the identification of two discrete non-DG aspartate isomerisation sites in the variable domain of the light chain and one isomerisation site in the hinge region of the heavy chain.

Conclusions:

LC-MS ETD analyses of samples stored at +25 °C/ +30 °C detected elevated isomerisation levels of three non-DG motif aspartates. Two of them are located in the CDR1 and CDR2, therefore impact on the target binding was suggested. Analyses like DLS, fluorescence spectroscopy, RALS, ITF, IR and UV absorbance detected no major differences. Thus only in-depth LC-MS analyses revealed the root cause of additional HIC peak. Identified isomerisation sites were assessed as cQAs.

Novel Aspect:

Unexpected high isomerisation levels for three Aspartates during the accelerated stress study have been identified.

1375 - HIGH RESOLUTION MASS SPECTROMETRY CHARACTERIZATION OF THE OXIDATION PATTERN OF METHIONINE AND CYSTEINE RESIDUES IN HUMAN MITOCHONDRIA VOLTAGE-DEPENDENT ANION SELECTIVE CHANNEL ISOFORMS

Rosaria Saletti (1)

University of Catania, Department of Chemical Sciences, Catania, Italy (1)

Keywords:

Voltage dependent anion selective channel isoforms; Cysteine over-oxidation; Mitochondrial intermembrane space; High Resolution mass spectrometry

Introduction:

Voltage-dependent anion selective channels are a quantitatively relevant component of the mitochondrial proteome. They are located in the outer membrane, which separates the cytosol from the inside of the organelle [1] and are responsible for the exchange of ions and small molecules in and out of mitochondria. Since the mitochondrial intermembrane space has an oxidative potential, we have investigated the oxidation state of cysteine and methionine residues of hVDACs.

Methods:

Intact mitochondria, extracted from HAP1 cell culture, were reduced with DTT, alkylated by addition of iodoacetamide and then lysed. After centrifugation, the supernatant containing the mitochondrial proteins was loaded onto a hydroxyapatite column. The hVDACs enriched eluate obtained was desalted, in-solution digested using porcine trypsin or chymotrypsin, and the resulting peptide mixtures analyzed by UHPLC/High Resolution nanoESI-MS/MS.

Results:

Our results demonstrate that all the three mitochondrial hVDACs, in physiological state, contain all the methionines partially oxidized to methionine sulfoxide. Furthermore, in the isoform 1 Cys127 is detected exclusively in the oxidized form of sulfonic acid, while the Cys232 is observed totally carboxyamidomethylated. In the hVDAC2, the cysteine residues 8, 13, 47, 133, 210, and 227 are only carboxyamidomethylated, Cys138 was identified trioxidized, and the cysteines 76 and 103 are partially in the form of sulfonic acid. Finally, also for the isoform 3 the results confirmed the presence of some cysteines (2, 8, and 229) reduced and the partial oxidation of Cys36 and Cys65. The peculiar behavior of Met and Cys residues of hVDACs may be related with the accessibility of the protein to a strongly oxidizing environment and may be connected with the regulation of the activity of this trans-membrane pore proteins.

Conclusions:

In this work, adopting the same procedure developed for the structural investigations of rVDACs [2,3], a detailed profile of the oxidation state of methionine and cysteine residues have been obtained in all the three human isoforms. Our results demonstrate that the mitochondrial hVDACs, in physiological state, contains methionines oxidized to methionine sulfoxide and cysteines in the form of sulfonic acid.

Novel Aspect:

The structural features elucidated by the present work may be helpful for a better understanding of the functional role of these proteins in the cell.

Keywords: TIMS, PASEF, Phosphopeptides, isobaric

Introduction:

Analysis of protein phosphorylation by mass spectrometry serve as a powerful tool for biologists and clinical researchers. However, the abundance differences as well as the variety of phosphorylation sites are pushing the need for instruments with higher sensitivity and selectivity. Here we evaluate the performance of a dual trapped ion mobility separation (TIMS) - QTOF that provides an additional dimension of separation and higher peak capacity.

Methods:

Phosphopeptides were enriched from 50-200 µg of proteolytic digests, separated using 15 to 90 min nano-HPLC gradients (nanoElute, Bruker Daltonics) and analyzed on a timsTOF Pro instrument using the Parallel Accumulation Serial Fragmentation (PASEF) method (Bruker Daltonics). Post-processing analyses were performed in PEAKS (Bioinformatics Solutions Inc.) and MaxQuant (Jürgen Cox, Max Planck Institute of Biochemistry).

Results:

Applying the PASEF method on the timsTOF Pro instrument enables on average the selection of 12 precursors within 100 ms. In addition to the high speed, sensitivity in the timsTOF Pro is achieved by a close to 100 % duty cycle of the dual TIMS cell design, cleanup of MS/MS spectra by ion mobility and time and space focusing in the TIMS analyzer. Using the combination of speed and sensitivity in PASEF method we identified more than 66,000 peptide spectrum matches (PSMs) resulting in around 25,000 unique peptides and 16,000 unique phosphopeptides within a 90 min gradient run. In addition to m/z separation, phosphopeptides are separated by space to charge, which increases the peak capacity with the most pronounced effect on very short gradients. Together, the high speed of PASEF phosphopeptide separation in the m/z to Ω/z space, combined lead to 7,000 and more than 10,000 unique phosphopeptides identified at 15min and 30 min gradient times respectively, at a speed of up to 500 unique phosphopeptides/min. Some of those separated phosphopeptides were isobaric.

Conclusions

TIMS-PASEF allows to increase phosphopeptide analysis depth and selectivity.

Novel Aspect:

High speed and sensitivity provided by PASEF for fast and comprehensive phosphoproteome analysis.

Keywords: citrulline, citrullination, citrulline effect, tandem mass spectrometry, peptide sequencing

Introduction:

Protein deimination is a post-translational modification of proteins converting certain arginines to citrullines. Overcitrullination could be associated with severe pathological conditions. Mass spectrometric analysis of the modified proteins is hindered by several problems. Based on our tandem mass spectrometric experiments, we report here a new and pronounced amino acid effect.

Methods:

Model peptides containing either one or two citrulline residues as well as their native, arginine-containing variants were synthesized. Their solutions were injected directly to the electrospray source of a high accuracy and resolution quadrupole-time of flight instrument and were analysed by tandem mass spectrometry using low-energy collision induced dissociation.

Results:

A preferential cleavage site was observed at the amide bond of citrulline and any other following alpha amino acid (Cit-Aaa) yielding intensive complementary b and/or y type ions. If citrulline was located at the C-termini of the peptides, an enhanced cleavage of Aaa-Cit amide bond was perceived instead. These phenomena were described by us for the first time [1] and was coined citrulline effect, analogously to ornithine effect reported previously [2]. Loss of isocyanic acid from the citrulline side chains observed earlier [3] was also significant and effective for confirming the site of modification.

Conclusions:

Fragmentation behaviour of citrulline containing peptides is similar to ones not containing them, however, significant intensity differences can be observed due to the newly identified citrulline effect. The loss of isocyanic acid is also a pronounced fragmentation pathway. Our results are in concordance with the mobile proton hypothesis.

Novel Aspect:

The citrulline effect facilitates the MS/MS confirmation of citrulline residues in a peptide sequence, besides the neutral loss of isocyanic acid.

Keywords: histones, chemical acetylation, isotopically-labeled acetic anhydride, sodium borate

Introduction:

Age-related diseases are associated with alterations in energy metabolism and with chronic inflammation. Research indicates that changes in energy metabolism are closely linked to gene expression via changes in histone acetylation profiles, possibly leading to a pro-inflammatory phenotype [1]. To investigate the histone acetylation dynamics by mass spectrometry, an efficient chemical acetylation reaction of unmodified histone lysine residues is necessary.

Methods:

Histones derived from RAW264.7 and 16HBE cells were chemically acetylated using stable isotope labeled acetic anhydride in combination with different buffer systems; ammonium bicarbonate (ABC), triethylammonium bicarbonate (TEAB) or sodium borate (SB). After in-solution tryptic digestion, peptides were analyzed by liquid chromatography tandem-mass spectrometry (LC-MS/MS). Chemical acetylation efficiency was assessed by using Xcalibur software.

Results:

LC-MS/MS analysis resulted in identification of histone proteins (H1, H2A, H2B, H3 and H4) with a high sequence coverage, between 86% and 98%. The average acetylation efficiency of 14 selected lysine residues of the core histone proteins H2A, H3 and H4 was significantly increased by using isotopically-labeled acetic anhydride in combination with either the TEAB and SB buffer (on average 99.6%) compared to the ABC buffer (94%). For some acetylation sites (for example H3K14, H3K56 and H4K20), no considerable differences in the acetylation efficiency were observed between the three different buffer systems. For other acetylation sites (for example H3K18, H3K79 and H4K20), the acetylation efficiency achieved by the TEAB and SB buffer was significantly increased compared to the ABC buffer. Complete acetylation of the histone 4 4-17 peptide, which contains four lysine residues, was significantly increased as well by using the TEAB and SB buffer (95%) compared to the ABC buffer (84%).

Conclusions

Chemical acetylation of unmodified histone lysine residues by using isotopically-labeled acetic anhydride in combination with TEAB or SB provided, in contrast to ABC, a sufficient acetylation efficiency (>95%). This acetylation method can be used to study the histone acetylation turnover in age related diseases. Furthermore, the method can be used to study the effects of histone deacetylase (HDAC) inhibitors on the acetylation status of specific lysine residues.

Novel Aspect:

Acetic anhydride in combination with SB results in an almost complete chemical acetylation of histone lysine residues. SB outcompetes the more commonly used ABC buffer.

Introduction

Free radical oxidation in the human body causes the accumulation of oxidized forms of proteins, which have an impaired function and can also be used as the markers of many pathological conditions, induced diseases such as cancer, nephropathy, and cardiovascular diseases. High resolution mass spectrometry approach is promising for characterization of oxidative protein modifications by reactive oxygen species (ROS) [1].

Methods

Protein isolation, analyses of enzyme activity and the polymerization of fibrinogen were accomplished as described in [2,3,4]. After the oxidation of samples by ozone or HOCl, the proteins were hydrolyzed, using a suitable technique for each protein. HPLC-MS/MS experiments were performed on an Agilent 1100 nanoLC (Agilent Technologies, USA) coupled to 7T LTQ-FT Ultra (Thermo, Germany). PTM searching was carried out by PEAKS Studio software (v. 8.5, BSI, Canada).

Results

The site-specific oxidative modifications in the proteins (fibrinogen, plasminogen, fibrin-stabilizing factor) under induced oxidation in model systems with various oxidants were analyzed by HPLC-MS/MS method.

Oxidative modifications have been found in some functionally significant amino acid residues, as well as in sites whose function remains unclear and should be further investigated.

The variation of the coverage in native and oxidized samples is compared. These results obtained were also used to analyze the effect of oxidation on the structure of the protein molecules [5].

Interestingly, along with the sulfur-containing residues of Met and Cys, aromatic residues of Tyr and Trp, polar residues of Glu, Lys, and Asp and non-polar Pro residues, are also targets for the oxidants.

The information obtained by biochemical methods in complex with HPLC-MS/MS data, make it possible to suggest a mechanism for the functional property loss of proteins underoxidation.

Conclusions

The data obtained make it possible to evaluate the availability of amino acid residues of proteins for oxidants under conformational changes in enzyme molecules, to reveal oxidation sites and the degree of oxidation of amino acid residues by using different concentrations of oxidants. Moreover it is one may suggest the mechanism for the functional property loss of proteins underoxidation [6].

Novel Aspect

High resolution mass spectrometry based approach was developed for the characterization of plasma proteins oxidative modifications by ROS.

Keywords: Post-translational modification (PTM), Cold atmospheric plasma (CAP), Mass spectrometry, Peptides

Introduction:

Oxidative PTM's of proteins and peptides play a role in many signaling pathways with potentially drastic changes in structure and activity of this molecule by distinct chemical groups [1]. Creating a library of such PTM's facilitates global mapping of PTM's in mammalian tissue and ultimately foster understanding of complex redox controlled processes, e.g. wound healing. Here, cold atmospheric plasma (CAP) was used as means to simulate oxidative conditions on various peptides.

Methods:

Different CAP sources were used for a determined modification of the model peptides Bradykinin, Angiotensin, and the artificial peptide LYTFAD. The resulting products were analyzed by LC-HRMS/MS-measurements (Q Exactive™) by direct infusion ESI or by LC-ESI coupling using a PepMap column. A workflow for the identification of the modified peptides with various MS software solutions was developed by using different algorithm for an optimal result validation.

Results:

Using manual annotation, a time dependent increase in number and quantity of PTM's was observed for the plasma treatment. Single and double oxidation and hydroxylation were identified in high intensities. For Bradykinin, the observed adducts were compared with literature [2] showing that only up to five oxygen adducts were found after kINPen treatment instead of 10 as described for the COST-jet. In contrast, the synthetic peptide carried up to 10 oxidation adducts after 5 minutes of plasma treatment. The two amino acids phenylalanine and tyrosine were oxidized particularly efficient. Investigation of additional modification patterns are currently under way. After testing different evaluation softwares for a manual identification of the PTM's, the next step will be the optimization of a semi-automatic workflow for PTM annotation and quantification by using isotopic labeled peptides.

Conclusions:

Cold physical plasma can act as a rich source for oxidative PTM's of a peptide, with numerous modifications detected by LC-ESI-MS in the model used. Plasma sources differ in modification efficacy, e.g. the He-COST-Jet is more effective than Ar-kINPen, due to the presence of atomic oxygen. Using cold plasma, an oxidative and nitrosative focused PTM-library for peptides and amino acids is under construction and should ultimately forecast PTMs in complex samples.

Novel Aspect:

Usage of cold physical plasma as a tool to create an oxidation focused PTM library using relevant model peptides with the ultimate goal of predicting PTMs in complex samplers.

Keywords: top-down mass spectrometry, plant, epigenetics, post-translational modifications, molecular biology

Introduction:

Sorghum is a cereal crop noted for its ability to survive water-limiting conditions. We are studying epigenetic control of drought responses in sorghum to understand how to equip similar crops to better survive climate change, and also potentially design ways to increase yield under low-water conditions. This study focuses on understanding changes in sorghum histone modifications through developmental stages and in response to drought stress in two genotypes.

Methods:

Sorghum leaf tissue was collected in the field at Kearney Agricultural Research & Extension Center (Parlier, CA, USA) and frozen in liquid nitrogen on-site. Nuclei were extracted from ground leaf powder and lysed. Histones were purified from the lysate with weak cation exchange chromatography and directly analyzed with reversed phase liquid-chromatography (Waters NanoAcquity) mass spectrometry (Thermo LUMOS Orbitrap). Data were processed with TopPIC.[1]

Results:

Sorghum plants from pre-flowering(PreF) and post-flowering(PostF) drought-tolerant genotypes, RTx430, and BTx642, respectively,[2] were replicated in 3 plots. All plots were watered prior to planting. The control and PostF plots were watered from the 3rd week. The PreF plot experienced 8 weeks of drought from planting to flowering. The PostF plot experienced drought after flowering in week 9 through harvest. We analyzed leaf histones from the 3rd, 9th and 10th week. LCMS experiments identified >300 histone proteoforms out of ~30 histone proteins (unique FASTA entry) per sample, including two distinct subtypes of H2A around 16 and 14kDa, respectively. Most notably, comparative analysis revealed significant differences in the relative abundances of truncated H4 proteoforms, which showed highly elevated levels only at week 9 for leaves from control and PreF plots from BTx642, and week 10 for PreF in RTx430. The distinct responses imply that H4 clipping is related to post-flowering development and epigenetic control of drought resistance.

Conclusions

Earlier studies have suggested regulatory functions of H3/H4 clipping on nucleosome conformation and dynamics.[3] However, it is challenging to characterize histone clipping and other combinatorial modifications using standard bottom-up proteomics methods [4–6]. Herein, we demonstrate the potential of top-down MS in profiling combinatorial histone modifications to improve our understanding of these elusive epigenetic control mechanisms.

Novel Aspect: (Limit of 150 characters without spaces)

First comprehensive top-down study of histones extracted from sorghum plants grown in the field reveals significant changes of modifications related to drought resistance.

1278 - SOLUTION AND GAS-PHASE STRUCTURES OF DNA G-QUADRUPLEXES: ION MOBILITY MASS SPECTROMETRY, SOLUTION SPECTROSCOPY, AND COLLISION CROSS SECTION CALCULATIONS

Anirban Ghosh Ghosh (1) - Frédéric Rosu Rosu (1) - Valérie Gabelica Gabelica (1)

INSERM, University of Bordeaux/IECB, Pessac, France (1)

Keywords: G-quadruplex, conformational polymorphism, Ion mobility mass spectrometry, Collision Cross section, 1H NMR

Introduction:

G-quadruplexes are guanine-rich sequences mostly found in promoters and telomeres associated with key cellular processes [1-2]. They are polymorphic in terms of number of tetrads, strands orientation, cation involved and loop arrangement [3]. Here we are using Ion mobility mass spectrometry (IM-MS) to characterize conformations of diverse sequence topology in native MS buffer [4]. This is further supplemented by 1H NMR, CD and UV melting.

Methods:

All IM-MS experiments were performed on Agilent 6560 IMS-Q-TOF in negative ion mode with Helium in the drift tube [5]. All circular dichroism (CD) and UV melting experiments were carried out on Jasco J-815 and SAFAS UV mc² spectrophotometer at 25°C. All 1H NMR experiments were performed on Bruker Avance 700 MHz with TXI probe. The theoretical CCS values for each charge state were calculated from Gaussian optimized conformations by modified EHSS method by Siu et al. [6-7].

Results:

CD in native MS buffer (100 mM TMAA + 1 mM KCl) shows preservation of the high-[KCl] G-quadruplex conformation. This is further supported by the 1H NMR spectra of the imino proton (10-14 ppm) regions, which agree well with the literature. ESI-MS shows a major population of 2-K⁺ complex for all 3-quartet conformations, and also a 1-K⁺ complex (2-quartet) for a few human telomere sequences. The collision cross-section (CCS) distributions are broad for all hybrid and anti-parallel conformations, and narrower for parallel conformations. For a given sequence length and charge state, the loop configuration, quartet polarity, bulges and flanking bases give rise to significant differences in CCS. The starting PDB structures give a higher theoretical CCS values compared to experimental ones. The structure neutralized to match the experimental charge states are optimized in the gas phase at the semi-empirical PM7 level and closely match the experimental CCS values. EHSSrot (Siu parameters) or the TM are used to calculate the theoretical CCS values.

Conclusions:

Most examined G-quadruplexes fold with the same topology in native MS (1 mM KCl) and traditional high KCl content buffers. IM coupled with ESI-MS is able to distinguish different shapes formed in solution. With these well-characterized G-quadruplexes, we validate the gas-phase structure optimization with PM7 to generate 3D models from which to calculate the CCS values.

Novel Aspect:

G-quadruplexes fully characterized by CD, UV and NMR in MS-compatible solutions were used to validate the interpretation of IM-MS data in terms of structure.

312 - CHARACTERIZATION OF LILBID-MS USING DNA STRUCTURES

Genia Hense (1)

AK Morgner, Physical and Theoretical Chemistry at the Goethe University Frankfurt, Frankfurt am Main (1)

Keywords: DNA dissociation, LILBID-MS, soft ionization, native MS, non-covalent interaction

Introduction:

LILBID-MS is a soft ionization method for mass spectrometry in which non-covalent complexes are transferred into the gas phase via microdroplets of a native-like aqueous buffer, which are irradiated by a mid-IR laser pulse.¹ This leads to an explosive expansion of the sample droplets and release of ions into vacuum. As a result of the desorption process, the ions receive an energy input from the laser pulse, which can be controlled via laser energy transfer parameters.

Methods:

This technique is able to detect intact ssDNA and dsDNA. Here we use DNA strands, which consist of 15-20 bp. Under soft laser conditions, we observe nearly no dissociation of the duplex DNA, while harsh conditions lead to the complete dissociation of the dsDNA. We can create melting curves of dsDNA with LILBID by use of a heatable droplet generator. Comparison of LILBID melting curves with UV/Vis shows how LILBID can monitor the solution behavior of DNA.

Results:

The tolerance of LILBID-MS towards different buffers and high salt concentrations enables the use of the temperature-independent MgHPO₄ buffer. These buffer conditions ensure the stability of double helices without compromising the spectral resolution. By increasing the temperature of a sample we can achieve different dissociation states of dsDNA. To calculate the duplex ratio, the total peak areas of duplex signals were divided by the sum of all peaks. Plotting the calculated duplex ratio against the temperature of the solution allows the determination of an apparent melting temperature (T_m) of dsDNA because the shape of curves recorded by LILBID-MS mimics the sigmoidal fit of melting curves recorded by UV/Vis spectroscopy. The detected T_m reflects the length of the dsDNAs. Comparison of the apparent LILBID T_m with the measured UV/Vis T_m allows assessing the amount of dissociation caused by energy transfer during the desorption process.

Conclusions:

Double-stranded DNAs as non-covalent complexes are suitable for investigating dissociation caused by energy transfer to the molecules during LILBID desorption. Apparent melting curves from LILBID-MS correlate with melting curves recorded by UV/Vis spectroscopy, indicating that LILBID-MS can give reliable information on binding affinities of bimolecular compounds.

Novel Aspect:

The method of creating melting curves of dsDNA via LILBID-MS allows the assessment of the amount of transferred energy during the desorption process.

Biomolecular Characterization Unit, RIKEN Center for Sustainable Resource Science, Wako (1) - Department of Chemistry, Tokyo Metropolitan University, Hachioji (2) - Department of Chemistry, Tokyo Metropolitan University, Hachioji (3)

Keywords: RNA, post-transcriptional modification, epitranscriptome, tandem mass spectrometry, methylation

Introduction

The discovery of dynamic post-transcriptional modifications (PTMs) of ribonucleic acid (RNA) including N⁶-methyladenosines affect transcriptome, emerging field of 'epitranscriptomics.' Although its analysis requires a general sequencing method of modified nucleosides on RNA, conventional methods fail to provide such information. We present here an MS³-based method to sequence positional isomers of methyl nucleosides in RNAs.

Methods

Base-methyl adenosines (mAs), cytidines (mCs), guanosines (mGs), and uridines (mUs) were analyzed by pseudo MS³ [1] with a Q-Exactive; a base anion generated by in-source collision-induced dissociation (sCID) of each nucleoside was fragmented by MS/MS to obtain its characteristic pattern. An RNase T1 digest of tRNA-Phe was sequenced by nano-flow liquid chromatography-MS/MS in data-dependent [2] and pseudo MS³ [1] modes. The data were processed by Ariadne [3].

Results

To sequence monomethyl nucleoside isomers in RNA, we extended the pseudo MS³ method [1]. We inspected sCID spectra of RNase-digested oligonucleotides containing mono-methyl nucleoside in detail and confirmed an ion at m/z 225.02 exclusively from 2'-O-methylated oligonucleotides and another ion at m/z 148.07 specific for the methyladenine (mAde)-containing oligonucleotides. To further distinguish those mAde isomers, we examined their fragmentations using commercially available mAs; we found each sCID generated mAde anion exhibited a characteristic product-ion pattern for each mA isomer. Likewise, we defined the MS³-derived signature patterns for mCs, mGs and mUs. We then validated the method by determining the chemical structure of yeast tRNA-Phe, which is mono-methylated at 8 positions out of 76 nucleotides. The MS³-based analysis of its RNase T1 digest (500 fmol) unambiguously confirmed the site and positional isomerism of all monomethyl nucleosides in the tRNA. The method will be applied to sequence methyl nucleosides on any RNAs.

Conclusions

We have established signature fragmentation patterns for mAs, mCs, mGs and mUs and, using them in the pseudo MS³ method, sequenced monomethyl nucleosides on RNA. In addition, the method should extend to the other nucleosides, e. g. dimethyl ones. Because the method is applicable to a sub-picomole quantity of RNA sample, it will serve as a useful tool for analyzing the structure/function of cellular RNAs and toward the comprehensive understanding of epitranscriptome.

Novel Aspect

A pseudo MS³ analysis allows discrimination of a monomethyl nucleoside from its positional isomers with a sub-picomole quantity of RNA.

971 - TEAD1: YIN AND YANG OF THE CELL REGULATION.

Petr Novak (1) - Ruzena Liskova (1) - Lukas Slavata (1) - Jiri Cerny (2) - Karel Valis (3)

Institute of Microbiology, Laboratory of Structural Biology, Prague (1) - Institute of Biotechnology, Laboratory of Biomolecular Recognition, Vestec (2) - Institute of Microbiology, Laboratory of Structural Biology, Vestec (3)

Keywords: structural proteomics, protein/DNA interaction, chemical cross-linking, H/D exchange, chromatin immunoprecipitation.

Introduction:

TEAD transcription factors mediate gene expression regulation through interactions with their DNA response M-CAT motif. They are active during growth and development and activate gene expression of proteins responsible for cell proliferation, differentiation or apoptosis. To understand the principles of interaction between TEAD1 and M-CAT motifs originating from regulatory regions of human genes, several structural mass spectrometry techniques were used.

Methods:

TEAD1 DNA binding domain (TEAD1-DBD) was expressed in E.coli. Fluorescence anisotropy was used to determine KD for TEAD1-DBD/M-CAT complexes. H/D exchange was carried out for DNA-free TEAD1-DBD or in complex with each M-CAT motif. DSA in non/¹³C-labelled forms was used for quantitative cross-linking. LCMS analysis was performed on 15T solariX. Structural models were built using MODELLER and in vivo quantification of M-CAT occupancy was determined byChIP-Q-PCR.

Results:

According to KD values, tested M-CAT motifs can be divided into two groups one with ten times higher affinity to TEAD1-DBD than the other. H/D exchange results revealed differences in deuterium uptake in helix H3, part of helix H2 and in the loop connecting them, identifying this as DNA-binding region. In correlation with dissociation constants, protection from deuteration in higher-affinity complexes was more intense than in low-affinity complexes. Quantitative chemical cross-linking resulted in 14 distance restrains. Three of them were not affected by presence of DNA, two were favored in presence of M-CAT and eight constrains were discriminated by DNA binding. Cross-link formation ability of lysines K57 and K88 significantly decreased in complexed state. Again, the effect of high-affinity duplexes was more significant than the effect of low-affinity ligands. H/D exchange and cross-linking results allowed creation of TEAD-DBD/M-CAT structural models. The chromatin immunoprecipitation confirmed such observation in living cells.

Conclusions

Experimental data uncovers higher affinity of TEAD1 to 5'-3' than 3'-5' oriented M-CAT motifs and enables molecular docking of TEAD1/M-CAT complex. Based on structural models TEAD1 recognizes its response motif by the shape of DNA major groove and the complex is stabilized by specific aminoacid-nucleotide interactions. TEAD1 binds to inverted M-CATs 180° degrees rotated, less and weaker bonds are formed. Such observation correlates with the in vivo situation.

Novel Aspect:

Structural mass spectrometry sheds a light on the tumorigenesis orchestrated by TEAD1 transcriptional factor.

252 - THE SIMULTANEOUS DETERMINATION OF INTRACELLULAR NUCLEOSIDE TRIPHOSPHATES AND CYCLIC DINUCLEOTIDES WITH LC/MS/MS

Reinhard Oertel (1) - Rayk Behrendt (2) - Ali El-Armouche (3)

Institute of Clinical Pharmacology, GWT TU Dresden, Dresden (1) - Institute for Immunology, TU Dresden, Dresden (2) - Centrum for Pharmacology and Toxicology, TU Dresden, Dresden (3)

Keywords: dNTP/NTP, dinucleotide, LC/MS/MS, isomeric separation

Introduction:

The determination of nucleoside triphosphates and cyclic dinucleotides in cells is of interest for various issues: The cyclic dinucleotides adenosine monophosphate-guanosine monophosphate (cGAMP) and diGMP could be a tumor marker in human fibroblasts. The quantification of deoxynucleoside triphosphates (dNTPs) and the corresponding ribonucleotide triphosphates (NTPs) can be used to measure enzyme activity in knockout cells

Methods:

ATP and dGTP are isomers, CTP, UTP and dTTP have very similar masses. Therefore a complete chromatographic separation was an aim of the study. An HPLC-Method with a reversed phase column and a mobile phase gradient were applied to separate all analytes in less than 10 min. Two transitions per substance were used in multiple reaction monitor (MRM) mode of the tandem mass spectrometer.

Results:

An 8-point external calibration curve in buffer at the range from 7.8 – 1000 ng/mL for 10 nucleoside triphosphates and cyclic dinucleotides was prepared and measured with samples of the assay. Quantification was performed by peak area method. A weighted (1/x) regression first order was performed to determine the concentration of the analytes. The calibration curves were accurate and precise over the range from 7.8 – 1000 ng/mL and the correlation coefficient (r) exceeded 0.996 in all cases. The concentrations 7.8 and 1000 ng/mL are the lower and the upper limit of quantification (LLOQ and ULOQ). Coefficients of variation and accuracy were calculated for each standard and are supposed to vary by less than 15%. All tested real samples contained nucleotide. To estimate the matrix effect, the samples were additionally analyzed by the standard addition method.

Conclusions

A simple and sensitive LC / MS / MS method was developed to separate different, partially isomeric nucleotides. The method provides a convenient tool for measuring intracellular dNTP / NTP levels that can be used to measure the molecular phenotype of mouse cells. In addition, cyclic dinucleotide concentrations in human cells were determined to be potential tumor markers.

Novel Aspect:

The novel aspect of the study is that with only one measuring method different nucleotides in different matrices can be determined simultaneously for different questions.

Intro (400 Characters w/out spaces)

Aptamers are Nucleic Acids (NAs) capable to bind selectively to a ligand, or to a family of molecules. In aptamer-based technology (e.g., drug delivery or sensors), it is crucial to understand how binding is occurring, to quantify affinities, and how they can be tuned. We interrogated several RNA and DNA aptamers by native MS and ion mobility, to understand how they fold upon binding and which quantifications limits are attainable.

Methods (400 Characters w/out spaces)

All NAs are analysed in MS-compatible solutions such as TMAA or NH₄OAc with Mg²⁺ and K⁺ (when needed) to mimic bio-relevant conditions. An Agilent 6560 ESI-IMS-Q-TOF in negative mode is used for most experiments and CCS were determined in helium. A Waters SynaptG2 HDMS is used for IMS comparisons on cocaine aptamers. A MicroCal ITC 200 is used as an independent measurement of KDs. UV-melting and CD in solution is used to get information about NAs folding state in solution.

Results (900 Characters w/out spaces)

Among the different systems tested, only DNA Cocaine aptamers MN4, MN19 and OR8 [1] and RNA Tetracycline aptamer [2] are giving significant conformational change upon binding by IM-MS. Although for tetracycline complex and free-aptamer two distinct conformations are present, cocaine aptamers are showing a transition between two conformational ensembles only for the free-aptamer ion. For cocaine aptamers CIU on charge state 7⁻ is best revealing their relative stabilities in gas phase in function of length.

Unfortunately, UV-T_m and CD do not allow to predict the conformational space in gas phase for the NAs tested. But we had recently evidence that collapsing can occur on duplex structures in gas phase [3].

Besides their shape, aptamer-ligand affinities are determined by MS-titration using a dT6 internal standard [4], and we defined the lower and higher KD attainable. ITC and MS KD values are comparable, both in TMAA and NH₄OAc. For Malachite green and Cocaine aptamer MS data were precious to clarify the number of sites on ITC.

Conclusions (400 Characters w/out spaces)

Hairpin patterns in Aptamers are prone to compact and lose the in solution structure "memory" during ESI, if the charge states are too low. Here we show for the first time two cases, Cocaine (bound-form) and Tetracycline aptamers, where bound and unbound-form are giving distinct IMS signature at some charge states. We also suggest native MS as an independent quantification technique and to reconcile puzzling data from ITC and NMR.

Novel Aspect (150 Characters w/out spaces)

We discuss the advantages and limitations of native MS and ion mobility of DNA and RNA aptamers and their ligand complexes

1206 - STRUCTURES, ENERGETICS AND REACTIVITY OF NUCLEIC ACIDS AND THEIR MOLECULAR BUILDING BLOCKS VIA TANDEM MS AND COMPUTATIONS APPROACHES

Mary T. Rodgers (1)

Wayne State University, (1)

Keywords: Collision-induced dissociation; Glycosidic bond stability; Infrared multiple photon dissociation action spectroscopy; Nucleic acids; Nucleosides

Introduction:

Synergistic tandem mass spectrometry and computational chemistry approaches enable questions related to the structure, energetics and reactivity of nucleic acids and their building blocks to be investigated. Here the effects of modification and the local environment on nucleoside conformation and glycosidic bond stability and the reactivity of nucleic acids with potential drug candidates (amino glycoside, peptide and metal-ligand complexes) are presented.

Methods:

Several types of tandem mass spectrometers (GIBMS, QITMS, and FT-ICR MS) and approaches including: threshold, energy-resolved, and sustained off-resonance collision-induced dissociation (TCID, ER-CID, and SORI-CID) and wavelength-resolved infrared multiple photon dissociation (IRMPD) action spectroscopy, complemented by electronic structure calculations of the stable structures, energetics, IR spectra, and reactions mechanisms are employed.

Results:

Combined IRMPD action spectroscopy, TCID, ER-CID, and computational chemistry studies of the protonated and sodium cationized forms of the canonical DNA and RNA nucleosides as well as a variety of naturally occurring and synthetically modified nucleosides have been performed. The preferred sites of protonation or sodium cationization, nucleobase orientations, sugar puckerings, conformers populated by electrospray ionization, and glycosidic bond stabilities are determined. The reactivity and preferred sites of binding of potential drug candidates with pre-micro and ribosomal RNA hairpins are elucidated using top-down sequencing and SORI-CID approaches. The RNAs investigated include: Helix 69, a hairpin RNA structure containing 19 nucleotides in the large subunit of the ribosome, and TAR, the HIV trans-activation response element, a hairpin RNA that acts as the binding site for the Tat protein. Drug candidates examined include: cisplatin and a series of amino acid-linked cisplatin derivatives, amino glycosides, and peptides.

Conclusions

The structures and glycosidic bond stabilities of protonated and sodium cationized canonical and modified nucleosides provide insight into structure-function of these genetics building blocks, evolutionary aspects of roles of modification, and impact of unnatural modifications. The binding and reactivity of drugs to RNAs provide insight into structure-function of functional RNAs, and sample preparation lessons for achieving quality mass spectral analyses.

Novel Aspect:

Effects of local environment/modifications on structures/stabilities of nucleosides are elucidated. Reactivity/binding sites of drug candidates to RNAs are determined.

501 - SEMI-QUANTITATIVE DETERMINATION OF OLIGONUCLEOTIDE DRUG IMPURITIES: MAIN AND CO-ELUTING SPECIES

Stilianos Roussis (1)

Ionis Pharmaceuticals, ADQC, Carlsbad (1)

Title

Semi-Quantitative Determination of Oligonucleotide Drug Impurities: Main and Co-Eluting Species

Authors

Stilianos G. Roussis, Claus Rentel
Ionis Pharmaceuticals, Carlsbad, CA

Introduction

An advanced Ion Pair Reverse Phase (IP RP) LC MS characterization method for impurities co-eluting with the main component is currently available and extensively used in our labs for release and stability testing of oligonucleotide therapeutics. However, the method requires individual extraction of each impurity with integration of the resulting ion chromatogram. For certain applications, e.g. optimization of synthesis conditions, purification development or evaluation of reagents, the number of samples requiring analysis is often large, but a semi-quantitative determination comparing impurity levels between the samples is sufficient. In this work, a process is described for using the average mass spectrum of the main product LCMS peak to automatically determine the amounts (%area) of the co-eluting impurities.

Methods

Ion Pair-Reversed Phase (IP-RP) HPLC chromatography coupled to low- and high-resolving power mass spectrometers has been used for the experiments using Agilent instrumentation. For an oligonucleotide drug component a list of chemical formulas of known impurities is generated using an established template. An algorithm was developed to automatically determine the isotopic distribution of each formula and its most abundant mass (MAbM). For each chemical formula, a list of MAbMs is determined corresponding to the charge states of the impurity in the ESI spectrum. An average mass spectrum is obtained by summation of the signal across the main LC peak incorporating the trace impurities. The relative amounts of the co-eluting impurities are determined by integration of the peak abundances of each species determined in the spectra.

Preliminary

The method has been extensively applied for the automated comparison of co-eluting oligonucleotide impurity levels in samples. For five different oligonucleotides, results have also been compared to those obtained by the quantitative conventional method, and were in very good agreement. The average absolute difference between the two approaches was 0.3%, with the best agreements achieved when the square root of the measured ESI abundance was used for the calculations. The repeatability of the method was evaluated, indicating an average standard deviation of 0.04% (calculated from all detected species). Application of the method for monitoring impurity changes in different lots of drug product readily identified the specific impurities statistically deviating from established values. Principal component analysis (PCA) was used to determine outliers. The loadings of PCA analysis were used to classify a set of 10 oligonucleotides in classification groups according to similarities in the formation of the same type of impurities. A plot of the PCA scores outlined the impurity types primarily contributing to the classification. For some impurities, multiple linear regression revealed a linear dependence of the total amounts detected to the number and type of a combination of base residues in the oligo. The current approach due to its rapidity and simplicity can be readily applied to determine relationships between the impurities detected and the experimental process development and manufacturing conditions potentially affecting them.

Novel

Development and application of an automated approach for the determination of impurity species co-eluting with the main oligonucleotide drug component.

330 - INTERACTIONS OF OXALIPLATIN AND CARBOPLATIN WITH DNA BUILDING BLOCKS AS STUDIED IN THE GAS PHASE: A COMBINED EXPERIMENTAL AND THEORETICAL STUDY

Jean-Yves Salpin (1) - Maria Elisa Crestoni (2) - Davide Corinti (2) - Simonetta Fornarini (2) - Debora Scuderi (3) - Barbara Chiavarino (2)

CNRS, LAMBE - UMR 8587 - Université d'Evry Val d'Essonne, Evry (1) - Università di Roma la Sapienza, Dipartimento di Chimica e Tecnologia del Farmaco, Roma (2) - Laboratoire de Chimie-Physique (LCP), Université Paris-Sud, Orsay (3)

Keywords: Pt-based anti-tumor agents, IRMPD spectroscopy, DFT calculations, nucleic acid building blocks

Introduction

In spite of clinical successes for treating different types of tumors, cisplatin [cis-Pt(NH₃)₂(Cl)₂] displays severe toxic side effects and therapy resistance. This has motivated searches for structurally and/or functionally analogous alternatives, leading to carboplatin and oxaliplatin as second and third-generation platinum drugs. The aim of this work is to study the interactions occurring in the gas phase between these two drugs and a set of DNA building blocks.

Methods

10⁻⁴M water solutions of either carboplatin or oxaliplatin and analyte (5'-dGMP) or (5'-dAMP) were mixed together and stored at room temperature for 24 h, to allow the formation of the different complexes. Complexes were generated in the gas phase by electrospray ionization. Their structure was probed by combining mass spectrometry and IRMPD spectroscopy to DFT calculations at the B3LYP/6-311G(d,p) level.

Results

This combination of approaches allows operating in the gas phase, which makes it possible to overcome any solvent or counter-ion effect, and thus allows describing the intrinsic reactivity of the metal cations. Presently, the complexes generated in the gas phase with adenine (A) and guanine (G) nucleobases are of the type [(platinum drug)H(nucleobase)]⁺. Our DFT survey indicates that protonation preferentially occurs on one of the carbonyl groups of both oxaliplatin and carboplatin. This is consistent with mechanisms proposed in previous studies.[1,2] Comparison between IRMPD spectra and DFT calculations suggests that both oxaliplatin and carboplatin specifically interact with the N7 position of guanine. This interaction mode is therefore similar to what was observed with cisplatin.[3] Data obtained with adenine are more delicate to interpret. IRMPD spectroscopy points to a mixture of structures of comparable relative energies with both platinated agents, corresponding to different coordination schemes.

Conclusions

The present study shows that the interactions occurring between these two platinum drugs are similar to those observed with cisplatin. Concerning guanine, the interaction specifically occurs at the N7 position, in agreement with the remarkable stability of the corresponding structures. As for adenine, interaction with either N1, N3 or N7 sites results in structures which are close in energy, in agreement with the mixture of forms observed experimentally.

Novel Aspect

To our knowledge, this work is the first gas-phase experimental study of the interactions taking place between carboplatin and oxaliplatin, with A and G.

Keywords: RNA, thiophosphate, modified nucleotide, isotope labeling, quantitative analysis

Introduction

Messenger RNA (mRNA) is a promising therapeutic agent with potential uses in cancer therapy, gene therapy, and cell reprogramming. The stability of mRNA largely depends on the 3'-end and 5'-end structures, which are targets for enzymatic degradation. Chemical modifications in those regions can be introduced into in vitro transcribed mRNAs in order to confer on them resistance to degradation and increase their translation efficiency, thereby increasing their therapeutic potential.

Methods

We developed an LC-MS method for quantitative assessment of incorporation of ATP analogs modified at the α -phosphate (ATP α S, ATP α BH3) into transcripts by RNA polymerases. Modified RNA was enzymatically degraded to single nucleotides, which were then resolved and quantified by ion pair chromatography coupled with ESI-QQQ. In order to improve the quantification, we synthesized RNA degradation products labelled with heavy oxygen (^{18}O) within the phosphate and used them as internal standards.

Results

We obtained chemically modified RNA by in vitro transcription, wherein standard ATP was replaced or mixed at different ratios with an appropriate chemically modified ATP analog (ATP α X) containing an O-to-X substitution (X=S, BH3) at the alpha phosphate and differing in stereochemistry (SP versus RP). The assessment of efficiency and frequency of incorporation of the modified NTP versus natural NTP by SP6 and T7 RNA polymerase was analyzed by LC-MS. First, RNA was subjected to complete degradation into single 5'-nucleotides by SVPDE enzyme. The concentrations of AMP and phosphate-modified AMP analog (AMPX) in the resulting mixture were quantified by LC-MS method employing ^{18}O -labelled standards. The analysis of AMP:AMPX ratio in the analyzed transcript as a function of ATP:ATP α S ratio in the transcription reaction provided insights into the structure of RNA as well as substrate stereoselectivity of RNA polymerases.

Conclusions

Proposed LC-MS quantitative method enabled determination of frequency of incorporation of different modified nucleotides into in vitro transcribed RNA, thereby providing a tool for establishing mRNA structure-biological properties relationship.

Novel Aspect

The proposed procedure could contribute to popularization of the application of low resolution equipment in the analysis of large molecules such as nucleic acids.

269 - HSA-MIR-1587 G-QUADRUPLEX FORMATION AND DIMERIZATION INDUCED BY NH₄⁺, MOLECULAR CROWDING ENVIRONMENT AND JATRRORRHIZINE DERIVATIVES

Wei Tan (1) - Long Yi (2) - Zhentao Zhu (2) - Lulu Zhang (1) - Jiang Zhou (1) - Gu Yuan (1)

Peking University, Chemistry, Beijing (1) - Beijing University of Chemical Engineering, Beijing Key Laboratory of Bioprocess, Beijing (2)

Keywords: miR-1587; G-quadruplex; dimerization; jatrorrhizine derivatives;ESI-MS

Introduction:

G-quadruplexes widely exist in genome and transcriptome [1], which have been considered as promising therapeutic targets [2]. However, reports about RNA G-quadruplexes are relatively fewer [3,4] and factors that influence high-order RNA G-quadruplex formation are still under to be investigated. In this study, ESI-MS was utilized to study the formation and properties of a RNA G-quadruplex formed by miR-1587.

Methods:

Most of the ESI-MS experiments were performed on a Finnigan LCQ Deca XP Plus ion-trap mass spectrometer in the negative ion mode. The high resolution ESI-MS spectra were collected on a Bruker Solarix XR FT-ICR mass spectrometer with a 9.4T magnet. All the CD experiments were carried out on a JASCOJ-815 CD spectrometer equipped with a Peltier junction temperature controlled cell holder and a 1.0 cm cell.

Results:

A guanine-rich human mature microRNA, miR-1587, was discovered to form stable intramolecular G-quadruplexes in the presence of K⁺, Na⁺ and low concentration of NH₄⁺ (25 mM) by electrospray ionization mass spectrometry (ESI-MS) combined with circular dichroism (CD) spectroscopy. Furthermore, under high concentration of NH₄⁺ (100 mM) or molecular crowding environment, miR-1587 formed a dimeric G-quadruplex through 3'-to-3' stacking of two monomeric G-quadruplex subunits with one ammonium ion sandwiched between the interfaces. In contrast, DNA-1587 and dU-DNA-1587 sequences also formed three-layer G-quadruplexes, but was less stable and could not form dimeric G-quadruplex structures. Specifically, two synthesized jatrorrhizine derivatives with terminal amine groups could also induce the dimerization of miR-1587 G-quadruplex and formed 1:1 and 2:1 complexes with the dimeric G-quadruplex. In contrast, jatrorrhizine could bind with the dimeric miR-1587 G-quadruplex, but could not induce dimerization of miR-1587 G-quadruplex.

Conclusions:

In this study, the formation and property of intramolecular miR-1587 G-quadruplex were investigated. High concentration of NH₄⁺, molecular crowding environment and two jatrorrhizine derivatives were discovered to be capable of inducing the formation of dimeric miR-1587 G-quadruplex. The results expanded our knowledge of RNA G-quadruplexes and provided new insights into the targeting of higher-order structures of miRNAs to regulate their functions.

Novel Aspect:

A dimeric miRNA G-quadruplex was first found by ESI-MS under high concentration of NH₄⁺ or molecular crowding environments.

A.05 LIFE SCIENCES - NATIVE MS AND STRUCTURAL PROTEOMICS

54 - XPlex ACTIVATED DIACIDS: A MULTIPLEX ALTERNATIVE TO NHS ESTERS FOR FASTER CROSS-LINKING REACTIONS AT LOWER TEMPERATURES

Bruno Cesar Amaral (1) - Fabio Cesar Gozzo (1) - Diogo Borges Lima (2) - Paulo Costa Carvalho (3)

Dalton Mass Spectrometry Laboratory, University of Campinas / Institute of Chemistry, Campinas (1) - Mass Spectrometry for Biology Unit, Institut Pasteur, Paris (2) - Group for Computational Mass Spectrometry & Proteomics, Carlos Chagas Institute, Fiocruz Paraná, Curitiba (3)

Keywords: Keywords: Cross-linking, XPlex, Adipic Acid, Multiplex

Introduction:

Traditionally, chemical cross-linking is performed using NHS esters that react with nucleophilic groups. However, they are easily hydrolysable and have low solubility (sulfonated versions are very expensive). Reaction time, temperature and coverage are also suboptimal. Here, we describe a new cross-linking chemistry (Acid XPlex) overcoming these limitations using cheap, easily available reagents.

Methods:

Myoglobin and cytochrome C were subjected to cross-linking reaction using XPlex activated adipic acid at 5, 15 and 27 Celsius degrees, followed by tryptic digestion. Samples were subjected to MS and MSMS analysis a Q-TOF and an Orbitrap Fusion Lumos. Data were interpreted using Waters MassLynx and SIM-XL software. Cross-linking reactions using DSS were also performed for comparative reasons.

Results:

After condition optimization steps, reaction of myoglobin using adipic acid at 27 Celsius degrees showed 9 cross-linker molecules incorporation per protein compared to 6 of DSS. This difference is even more pronounced at lower temperatures where at 5 degrees only 2 DSS incorporations were observed, compared to 8 of adipic acid. The same results were obtained when using cytochrome C as the target protein. The method also allowed for a reduced reaction time (from 2 hours using DSS to 30 minutes using adipic acid), Another advantage of XPlex chemistry is the broader reactivity as cross-links are observed between Lys/Lys, Lys/Ser, Ser/Ser, Lys/Glu, Lys/Asp, Ser/Glu and Ser/Asp residues, improving the protein surface coverage and number of distance constraints. Special algorithms have been implemented in SIM-XL software to efficiently identify these multiplex cross-links.

Conclusions:

The Acid XPlex method presents several advantages over the use of NHS based cross-linkers, such as higher solubility, reduced reaction time, lower reaction temperatures, higher incorporation rates and, more importantly, broader reactivity and protein surface coverage, showing a potential to expand the use of XL-MS to proteins unstable in solution at higher temperatures or for prolonged periods.

Novel Aspect:

Novel chemical cross-linking chemistry with improved incorporation rates and reactivity at low temperatures.

1357 - TOP-DOWN AND MIDDLE DOWN SEQUENCING OF IMMUNOGLOBULIN USING ELECTRON CAPTURE DISSOCIATION – TIME OF FLIGHT MASS SPECTROMETER COMBINED WITH ONLINE DISULFIDE BOND REDUCTION

Takashi Baba (1) - L. C. Yves LeBlanc (1) - Pavel Ryumin (1) - Bill Loyd (1)

Sciex, Research, Concord, Canada (1)

Keywords: electron capture dissociation (ECD), antibodies, top down analysis, middle down analysis, online disulfide bond reduction

Introduction:

Intact antibody sequencing is one of the goals in current mass spectrometry. Electron capture dissociation (ECD) provides unique features on top-down sequencing of proteins, which can be an ideal tool to analyze intact antibodies. We have developed a small and high throughput ECD device based on an RF ion trap [1]. This technology was applied to an antibody. We also implement an online disulfide bond reduction technique [2].

Methods:

The ECD cell [1] was installed between Q1 and Q2 in a research grade quadrupole-TOF system. Typical electron beam irradiation time was 10 ms, and the electron beam intensity was tuned to obtain appropriate dissociation efficiency. The mass resolution of the TOF-MS is 35,000-47,000, which resolved isotope patterns of fragments up to $Z \sim 30+$. A desalting LC column (Waters) was used for desalting, online reduction [2], and LC separation.

Results:

Humanized monoclonal IgG (NIST-mAb) was obtained from NIST. This mAb was analyzed by the LC-ECD-TOF mass spectrometer. De novo sequencing on the intact ECD spectrum obtained by a single LC run indicated three sequences, and two of them were matched to N terminal partial sequences of the variable parts in a light chain and a heavy chain appeared in the human genome. The intact ECD spectrum was further analyzed in top-down manner using the suggested full sequences (the full sequence is provided by NIST), where the data covered the variable parts of the light chain and the heavy chain in the mAb. ECD at 3 eV did not cleave the disulfide-bonded rings in the protein. To obtain nearly complete sequence coverages, IdeS digestion (Genovis) was applied. For the online reduction of disulfide bonds (ref. 2), DTT was injected to the intact mAb and the IdeS digest trapped on the desalting column for 1 min.

Conclusions:

By the reduction, we obtained sequence coverages of 84.7 % for the light chain, 78.3 % for the variable part of the heavy chain (Fd'), and 84.7% for the fixed part of the heavy chain (scFc). Further, ECD indicated the glycosylation site and its mass in scFc and CID informed the glycan composition.

Novel Aspect:

High throughput antibody analysis using LC-ECD TOF mass spectrometer combined with online disulfide bond reduction technique

636 - INTACT MASS ANALYSIS OF MACROMOLECULAR PEG-FAB CONJUGATE USING MULTI-MODE NATIVE LC COUPLED TO ULTRA-HIGH MASS RANGE NATIVE MS

Aaron Bailey (1) - Guanghui Han (2) - Jonathan Josephs (1) - Wendy Sandoval (2) - Eugen Damoc (3)

Thermo Fisher Scientific, Chromatography and Mass Spectrometry, San Jose (1) - Genentech, Inc., Protein Chemistry, South San Francisco (2) - Thermo Fisher Scientific, Chromatography and Mass Spectrometry, Bremen (3)

Keywords: Pegylation, PEG dendrimer, ion exchange, size exclusion, antibody

Introduction:

Monoclonal antibody Fab domain fragments can be utilized therapeutically to bind to and sequester specific antigens to decrease activity of disease targets in the cells of patients. Large multi-pronged polyethylene glycol (PEG)-based structures can be utilized to 'bundle' together multiple Fab domains to yield a drug with highly concentrated therapeutic activity and increased bioavailability (1). PEG-Fab conjugates pose enormous potential for sample heterogeneity, and thus present a significant analytical challenge in upstream characterization. Native MS and other charge reduction strategies yield increased spectral separation to allow the accurate intact mass analysis of such highly complex spectra. We present a semi-automated workflow for analyzing high mass PEG-protein conjugates utilizing native ion exchange coupled directly to an ultra-high mass range Orbitrap MS system.

Methods:

PEG-Fab conjugate was analyzed intact in native MS conditions using nanospray infusion, size exclusion chromatography (SEC), or ion exchange (IEC) chromatography. PEG-Fab conjugate was analyzed by SEC (Thermo Scientific MabPac SEC-1) or IEC (Thermo Scientific ProPac WCX) using isocratic conditions and pH gradient conditions, respectively. For SEC we used a mobile phase of 50 mM ammonium acetate pH 6.6. For IEC we used a gradient of pH 6.6 to 10.2 in a background of 50 mM ammonium acetate at a flow rate of 200 μ L/min. LC-MS was performed using a Vanquish H-Class UHPLC with single wavelength UV detection coupled directly to an Orbitrap MS instrument capable of ultra-high mass range detection up to 80,000 m/z.

Results:

A major aspect of characterizing PEG-Fab conjugates is determining the weighted average of Fab domains which are attached to an individual PEG core structure. In order to assess the degree of Fab-conjugation, PEG-Fab conjugate was analyzed by static nano-spray infusion using an ultra-high mass range Orbitrap MS system operated with nitrogen or xenon as the HCD trapping gas for cooling ions during transmission. PEG-Fab conjugate in native conditions resulted in a complex spectrum which did not yield sufficient definition in order to confidently determine accurate masses to measure the average ratio of Fab-to-PEG. Addition of the charge reducing reagent TMGN produced a more simplified spectrum spanning a range of 20,000 to 50,000 m/z which enabled deconvolution for accurate mass determination. These results showed an average load of approximately 7 Fab domains, which is consistent with a low resolution result attained by MALDI-TOF MS data. We coupled IEC directly to our Orbitrap MS system to allow charge-based separation and on-line native intact mass analysis. We found PEG-Fab conjugate isoforms elute as individual peaks in increasing order of Fab load. IEC-MS spectra became further simplified compared to direct nano-spray infusion. Isoform identity and abundance could be further confirmed and relatively compared by leveraging both chromatographic and mass spectral data for intact mass analysis.

Conclusions

Native SEC and native IEC coupled directly to UV and Orbitrap MS with ultra-high mass range detection provides a flexible platform for analyzing large (500 kDa) compounds which exists in very complex mixtures such as PEGylated

species. SEC and IEC have unique strengths in chromatographically resolving complexity which allow the Orbitrap MS system to obtain increasingly detailed information of molecular structure.

Novel Aspect:

Intact mass analysis of a complex PEG-protein conjugate using native ion exchange chromatography ultra-high mass range Orbitrap MS

578 - NATIVE MASS SPECTROMETRY ANALYSIS OF RECOMBINANT ANTIBODIES DIRECTLY FROM THE GROWTH MEDIUM

Gili Ben-Nissan (1) - Shay Vimer (2) - Aliza Katz (3) - Shira Warszawsky (2) - Ron Diskin (4) - Sarel Fleishman (1) - Michal Sharon (1)

Weizmann Institute of Science, Department of Biomolecular Sciences, Rehovot (1) - Weizmann Institute of Science, Department of Biomolecular Sciences, Rehovot (2) - Weizmann Institute of Science, Department of Structural Biology, Rehovot (3) - Weizmann Institute of Science, Department of Structural Biology, Rehovot (4)

Keywords: Native Mass Spectrometry, Crude Proteins Samples, Recombinant Antibodies

Introduction: Typically, native mass spectrometry (MS) requires costly and labor-intensive protein purification. Formerly we presented a novel approach for native MS analysis of overexpressed proteins directly from crude bacterial lysates [1]. Here we expand the method to the analysis of secreted recombinant antibodies directly from the growth medium of secreting HEK293 cells.

Methods: Growth media from adherent HEK293 cells grown in DMEM, or suspension-grown HEK293 cells grown in Freestyle medium were transfected with plasmids encoding light and heavy chains of various antibodies. Growth media containing the secreted antibodies were collected and buffer exchanged into MS compatible buffers. Low-expressing samples were concentrated. The antibodies were analyzed using either an Orbitrap [2] or a Synapt G2 HDMS QTOF-based platform [3].

Results: Initially, we tested an antibody secreted from adherent HEK239 cells. The growth medium was 2x buffer exchanged into 1M ammonium acetate and concentrated 10x before analysis. The antibody produced a well-resolved charge state series which corresponded in mass to the glycosylated form. PNGaseF treatment directly in the medium efficiently removed the N-linked glycosylations. We next examined growth media from transfected suspension-cultured cells and showed that the secreted antibodies could be easily measured directly from the growth medium without any concentration. Antibodies could also be reduced and deglycosylated in the growth medium, for detailed structural analysis. For deeper characterization we compared wild-type and engineered antibodies, designed for increased affinity and stability, and demonstrated that the engineered antibodies were expressed to much higher levels and showed higher stability. CCS analysis demonstrated that the wild-type and designed antibodies exhibited identical collision cross-sections.

Conclusions: We showed that direct native MS can be efficiently used for the structural analysis of secreted antibodies from crude growth media. Analysis of the antibodies directly from the growth medium allowed us to rapidly determine the identity, expression level, modification level and overall structure of the antibodies. Moreover, we showed that our method is not dependent on a specific MS platform but rather it is a general approach that can be applied on various instruments.

Novel Aspect: Direct native MS can be applied to the structural analysis of secreted antibodies from crude growth media, and can overcome the need for purification, saving time and effort.

929 - CAN WE USE HDX-MS TO MODEL PROTEIN CONFORMATIONS?

Antoni Borysik (1)

King's College London, King's College London, London (1)

Keywords: Hydrogen deuterium exchange, protein structure determination

Introduction: Protein structures are commonly utilized to interpret hydrogen deuterium exchange mass spectrometry (HDX-MS) data not vice versa. But the ability to model structures by HDX-MS would exploit the many advantages of the technique particularly with regard to speed and sensitivity. The modelling of protein folds and homo/hetero protein assemblies by HDX-MS is described and the utility and limitations of the approach for different protein systems is discussed.

Methods: HDX-MS data of proteins and their assemblies were obtained by continuous labelling HDX-MS. Computational approaches were used to simulate HDX-MS data directly from protein structures or docking outputs. A range of structural analysis/evaluation techniques were employed to quantify the efficacy of the approach to model protein folds and assemblies including hierarchical clustering and binary structural classification.

Results: The HDX-MS patterns of proteins simulated directly from their atomic structures are compared to experimental data obtained in-house. Utilizing a simple expression to estimate HDX protection factors we show that it is possible to simulate protein HDX-MS patterns to sufficient accuracy to permit the modelling of protein conformations. Protein folds and hetero-assemblies can be modelled to high accuracy but the modelling of homo-assemblies is significantly more challenging due to the inability to prepare difference plots for these systems. Surprisingly, even poorly simulated HDX-MS data is shown to be efficient at identifying native conformations from a high background of decoy states. And in the case of homo-proteins the diagnostic ability of the HDX-MS simulations is shown to scale with the number of subunit interactions in the protein complex. Taken together these data add to our understanding of the use of HDX-MS for structural evaluation and provide an important foundation on which future developments in the area can be built.

Conclusions: HDX-MS has potential in protein modelling with applications in areas such as ab initio protein folding and protein-protein docking. [1] HDX-MS data can be simulated directly from protein structures significantly enhancing the throughput and applicability for quantitative ranking of modelling outputs. The present work sets a new precedent for the analysis of HDX-MS outputs and establishes greater synergy of the method with molecular modelling techniques.

Novel Aspect: The ability to utilize HDX-MS data to model protein structures represents a new way of working with the technique.

Title: Coupling online separations to native MS for the characterization of designed protein complexes.

Authors: Florian Busch, Mengxuan Jia, Zachary VanAernum, Aniruddha Sahasrabuddhe, Zibo Chen, Scott Boyken, David Baker, Vicki H. Wysocki

Introduction:

De novo designed protein complexes have significant potential to serve as future drugs and nanomaterials. Whereas it is possible to design, express, and purify a great number of proteins and protein complexes in a short time, methods for their subsequent structural characterization on a large scale are missing. Here, we demonstrate how online separation coupled to native mass spectrometry can be used to rapidly assess key properties of designed protein complexes.

Methods:

Protein samples were designed, expressed, and purified in the Baker lab. Gel filtration and ion exchange chromatography were performed with an Ultimate3000 HPLC system (Dionex) coupled to a modified QExactive EMR Orbitrap instrument (Thermo). UniDec [1] and Intact Mass (Protein Metrics) [2] were used for data deconvolution and analysis.

Results:

We determined the oligomeric states and ligand-binding properties of several hundred designed protein complexes in TBS buffer by online gel filtration coupled to high-resolution mass spectrometry. Hetero-dimeric coiled-coil structures, with characteristics matching those intended by design were further evaluated for interaction partner specificity based on their tendency to exchange/ form off-target binding during a denaturation-refolding procedure. To deal with the complexity of such mixtures, we used ion exchange chromatography coupled to mass spectrometry for analysis and processed the data with Intact Mass. All-ion fragmentation was applied to confirm the protein complex identification. With several small mixing experiments including 6-16 heterodimers in each set, we filtered out 20 orthogonal heterodimers. For this set of 20 hetero-dimers, we found negligible subunit exchange during a denaturation-refolding procedure, consistent with the high specificity of the underlying designed protein-protein interactions.

Conclusions:

Gel filtration coupled to mass spectrometry can be used to rapidly perform the initial identification of protein designs suitable for further structural analysis. Complicated mixtures can be readily separated by ion exchange chromatography coupled to MS and identified by fragmentation. In all cases, deconvolution software is highly beneficial to determine the identity and oligomeric state of the designed protein complexes with high-throughput.

Novel Aspect:

On-line separation methods for native MS were developed to help with the determination of structural properties of designed proteins at high speed with minimal sample preparation requirements.

486 - STRUCTURAL CHARACTERISATION OF WILD-TYPE AND Δ N6 β 2-MICROGLOBULIN COMPARING HDX AND FPOP CHEMICAL LABELLING

Owen Cornwell (1) - James Ault (1) - Sheena Radford (1) - Alison Ashcroft (1)

University of Leeds, Faculty of Biological Sciences, Leeds (1)

Keywords: FPOP, HDX, β 2 – microglobulin, protein, aggregation

Introduction:

Fast Photochemical Oxidation of Proteins (FPOP) is a covalent labelling technique that utilises UV radiation to produce hydroxyl radicals which covalently label solvent-accessible side-chains. Following proteolysis, LC-MS/MS is used to localise and quantify the oxidation particular residues. Here, we assess the utility of FPOP and HDX as parallel techniques to probe protein structure and dynamics on Δ N6, an aggregation-prone variant of β 2-microglobulin.

Methods:

HDX-MS experiments were carried out using the LEAP Technologies automated system in-line with an M class ACQUITY LC and HDX manager followed by a Synapt G2Si MS/MS operating in HDMSE mode. FPOP was performed employing a 248 nm CompexPro Excimer UV laser to generate hydroxyl radicals used to oxidise solvent accessible side-chains. This was followed by protein proteolysis and LC-MS/MS using a Q ExactivePlus Orbitrap.

Results:

>95% sequence coverage was obtained for both proteins using either HDX or FPOP. In the regions directly surrounding the N-terminal truncation, HDX indicates significantly higher deuterium uptake for Δ N6 compared with wild-type protein at the earliest labelling time-point (30 seconds). Key differences in labelling by FPOP were similarly clustered around the N-terminal truncation of the protein.

Examination of FPOP LC-MS/MS data showed certain modified residues eluting at multiple retention times, corresponding to the various positional isomers expected from hydroxyl radical attack on aromatic side-chains. Quantifying these peaks separately, changes in the labelling of positional isomers between the two proteins were observed (consistent with published NMR structures), and considerable differences in labelling trends between individual positional isomers and the combined residue level data were evaluated.

Conclusions:

The comparison of HDX and FPOP shows that they serve as informative parallel techniques to probe protein structure and dynamics. Moreover, FPOP can be used to interrogate structural changes at sub-residue level resolution. As protein aggregation is often caused by subtle structural changes including the exposure of hydrophobic side-chains (both of which are very sensitive to oxidative labelling), FPOP has proved invaluable to the study of protein aggregation.

Novel Aspect:

A comparison between two different probes of protein solvent accessibility and dynamics offers greater understanding and sub-residue resolution.

298 - DOUBLE MUTANT CYCLES IN THE GAS PHASE: MEASURING INTER-PROTEIN PAIRWISE INTERACTION ENERGIES FROM CRUDE CELL LYSATES BY NATIVE MS

Jelena Cveticanin (1) - Ravit Netzer (1) - Galina Arkind (1) - Sarel Fleishman (1) - Amnon Horovitz (2) - Michal Sharon (1)

Weizmann Institute of Science, Department of Biomolecular Sciences, Rehovot (1) - Weizmann Institute of Science, Department of Structural Biology, Rehovot (2)

Keywords: native MS, crude cell lysates, coupling energies, inter-protein hydrogen bonds

Introduction:

A powerful method to determine the energetic coupling between amino acids is double-mutant cycle analysis (DMC) [1]. Here, we show that double-mutant cycle analysis by native mass spectrometry [2] can be carried out for interactions in crude *Escherichia coli* cell extracts, thereby providing estimates for coupling energies under crowding conditions and obviating the need for protein purification and generating binding isotherms.

Methods:

The applicability of this native MS-based approach was tested for three different double-mutant cycles using the 1:1 complex between E2 colicin endonuclease (coIE) and the Im2 immunity protein (Im).

All proteins comprising the cycle, the two wild-type proteins and the two mutant proteins were co-expressed in *E. coli* using the pRSFDuet expression plasmid. Native MS experiments were performed using an Orbitrap EMR platform.

Results:

The charge series of the individual complexes forming each of the cycles could be well resolved in the crude lysates due to the overproduction of these proteins in comparison to the endogenous bacterial proteins and because of reduced binding of adducts. The relative concentrations in a cell lysate of the four co-existing complexes comprising each cycle were determined simultaneously from a single mass spectrum. Determining the concentrations of the complexes (without the need to define the concentrations of the individual proteins) allowed us to calculate the coupling energies under crowding conditions. We also determined the coupling energies using purified proteins in a buffer solution as a control. The values of the coupling energies determined for all three pairwise interactions in lysates are found to be very similar to the one determined for these interactions using purified proteins in buffer, thereby indicating that crowding has little effect on the strength of inter-molecular hydrogen bonds.

Conclusions:

Double-mutant cycle analysis by native mass spectrometry can be carried out for interactions in crude *Escherichia coli* cell extracts, thereby providing estimates for coupling energies under crowding conditions and obviating the need for protein purification and generating binding isotherms. Our results indicate that inter-molecular hydrogen bond strengths are not affected by crowding conditions.

Novel Aspect:

Our approach enables to characterize pairwise interactions by native MS of crude cell lysates obviating the need for any protein purification.

1015 - ADVANCES IN ORBITRAP™ INSTRUMENTATION FOR NATIVE TOP-DOWN ANALYSIS OF NON-COVALENT PROTEIN COMPLEXES

Eugen Damoc (1) - Rosa Viner (2) - Albert Konijnenberg (3) - Kyle Fort (1) - Maria Reinhardt-Szyba (1) - Mikhail Belov (1) - Alexander Makarov (1)

Thermo Fisher Scientific, Bremen, Bremen (1) - Thermo Fisher Scientific, San Jose, San Jose (2) - Thermo Fisher Scientific, Eindhoven, Eindhoven (3)

Keywords

Native MS, native top-down, pseudo-MS3, Orbitrap, Ultra-High Mass Range

Introduction

Native top-down studies of intact protein complexes have been reported since the early 1990's, but their characterization using MS3 have only recently been reported and most work has been done on homomeric assemblies. In this work we explore new ways for extending native top-down performance to allow interrogation of heteromeric protein assemblies like proteasome by top-down pseudo-MS3.

Methods

Experiments were performed using a modified Thermo Scientific™ Q Exactive™ Plus MS in which the transmission of high m/z ions and the ability to perform pseudo-MS3 scans for native top-down analysis were improved by implementing several hardware and software modifications (see the Results section). Pyruvate Kinase, GroEL, rabbit 20S proteasome, LmrP membrane protein and AmtB membrane protein complex were used as model systems.

Results

Advances towards native MS and native top-down analysis of heteromeric protein complexes became possible only after addressing several major technical challenges. First, implementation of 'in-source trapping' capability addressed the insufficient or poorly controllable desolvation issue and allowed significantly improved fragmentation into subunits and stripped complexes in the inject flatapole region. Second, the reduction of RF frequencies on all RF guides and the mass filter was aimed at increasing the transmission of high m/z ions. Third, the adjustment of the voltage ramp rate on the central Orbitrap electrode facilitated successfully transmitting the high m/z ions from the C-trap into the Orbitrap analyzer.

The improvements in performance afforded by these modifications were demonstrated in a series of pseudo-MS3 experiments performed for several homomeric and heteromeric intact soluble protein complexes and membrane protein complexes.

Novel Aspect

Improved native top-down analysis of non-covalent protein complexes

520 - ARCHITECTURE OF EUKARYOTIC MRNA 3'-END PROCESSING MACHINERY - THE ROLE OF CROSS-LINKING AND MASS SPECTROMETRY

Gianluca Degliesposti (1) - Mark Skehel (1) - Ana Casanal (1) - Ananthanarayanan Kumar (1) - Chris Hill (1) - Ashley Easter (1) - Paul Emsley (1) - Yuliya Gordiyenko (1) - Balaji Santhanam (1) - Jana Wolf (1) - Katrin Wiederhold (1) - Gillian Dornan (1) - Carol V Robinson (2) - Lory A Passmore (1)

Laboratory of Molecular Biology (MRC LMB), Laboratory of Molecular Biology (MRC LMB), CAMBRIDGE (1) - Chemistry Research Laboratory, University of Oxford, Oxford (2)

Keywords: XL-MS, Cryo-EM, pre-mRNA processing, structural proteomics

Introduction

Eukaryotic pre-mRNAs are processed at their 3' ends by the Cleavage and Polyadenylation Factor (CPF). CPF cleaves pre-mRNAs, adds a poly(A) tail and triggers transcription termination. It is unclear how the complex is assembled and coordinated. A Cryo-EM investigation of CPF aided by nanoESI-MS and cross-linking-MS (XL-MS) shines new light on its assembly and activity providing an example of how XL-MS complements other structural approaches such as Cryo-EM. 1-4

Methods

XL-MS experiments were performed on purified CPF complex, which is composed of four or five proteins: Cft1, Yth1, Fip1, Pfs2, with and without Pap1. The isotopically-coded NHS ester BS3 was used as cross-linker. Trypsin digests were fractionated at the peptide-level by SEC and fractions analysed by nano-scale LC-MS/MS on an Orbitrap Velos. Cross-links were identified using xQuest and spectra were manually validated.

Results

NanoESI-MS of CPF complex revealed an interaction network organized into three modules: nuclease, phosphatase and polymerase. The Poly(A) polymerase module of CPF was expressed in insect cells. The ~200-kDa recombinant four-subunit complex (Cft1, Pfs2, Yth1, Fip1) was imaged using cryo-EM at a resolution of 3.5 Å. Cryo-EM maps display only three ordered subunits (Cft1, Pfs2 and Yth1). AXL-MS investigation was performed to validate the structural model and to determine where Pap1 and Fip1 bind. Cross-links map agree with the atomic models, and the crystal structure of Pap1. Fip1 cross-links to the C-terminal part of Yth1 and the polymerase domain of Pap1. Pap1 also cross-links the C-terminal helical domain of Cft1, ZnF1 of Yth1, and the C-terminal region of Pfs2. Together, these data suggest that the flexible C-terminal half of Yth1 binds the intrinsically disordered protein Fip1, which in turn flexibly tethers Pap1 to the complex, allowing conformational freedom to add long poly(A) tails onto diverse RNA substrates.

Conclusions

Nuclease, Poly(A) polymerase and phosphatase activities of yeast CPF are organized into three modules. A partial cryo-EM structure of polymerase module was solved. XL-MS provided insights on the interactions of the whole polymerase module. These data, combined with in-vitro reconstitution experiments, show that the polymerase module brings together factors required for specific and efficient polyadenylation, to help coordinate mRNA 3'-end processing.

Novel Aspect

Combination of nanoESI-MS, cryo-EM, XL-MS and in-vitro reconstruction experiments described the assembly and activity of the eukaryotic mRNA 3'-end processing machinery.

843 - THE INFLUENCE OF SUBSTRATES AND NUCLEOTIDES ON COMPLEX FORMATION IN ABC TRANSPORTERS – INSIGHTS FROM MASS SPECTROMETRY

Francesco Fiorentino (1) - Jani Reddy Bolla (2) - Shahid Mehmood (2) - Carol V. Robinson (2)

University of Oxford, Department of Chemistry, Oxford (1) - University of Oxford, Department of Chemistry, Oxford (2)

Keywords: ABC importers; native mass spectrometry; ModBC; BtuCD

Introduction

ABC importers are membrane proteins that couple the hydrolysis of ATP to the translocation of different molecules across cellular membranes. Depending on the fold of the transmembrane domains, they are classified as type I or type II importers [1]. To clarify the mechanism of these proteins, some questions need to be answered, such as the influence of substrate and ATP on the interactions between the transporters and their cognate substrate-binding protein.

Methods

We selected two very well characterised ABC importers: the molybdate transporter ModBC-A and B12 transporter BtuCD as representatives of type I and type II importer families, respectively. We employed native mass spectrometry-based methods (MS), enabling us the study of membrane proteins and their ligand-binding properties [2].

Results

Following purification of BtuCD and BtuF, we optimised native mass spectrometry conditions and obtained mass spectra of the two proteins in detergent solubilised form. When a solution of BtuF was added to BtuCD, the recorded mass spectrum showed the formation of the full BtuCD-F complex. After addition of vitamin B12, the spectrum still displayed the presence of the entire BtuCD-F complex but also revealed an increase in the intensity of the population of the uncomplexed BtuCD. Conversely, the addition of molybdate led to ModBC-A complex formation, while no complex was observed in the absence of substrate.

Mass spectra of BtuCD-F recorded after ATP addition showed the presence of the full complex bound to two ADP molecules. Interestingly, we detected an increase in the intensity of ADP-bound BtuCD. As for ModBC-A, following the addition of ATP we observed ADP-bound species, but we did not detect any additional charge states corresponding to ModBC.

Conclusions

Our MS data indicate that both vitamin B12 and ATP disrupt the interactions between BtuCD and BtuF. In contrast, molybdate is needed to let ModA dock onto ModBC and ATP does not affect ModBC-A complex formation.

These observations provide critical insights into the mechanism of transport of these importers and allow us to propose new transport models that complement the previous ones and will serve as a prototype for more complicated systems.

Novel Aspect

For the first time, native mass spectrometry has been applied to unravel the mechanism of action of transporters and provides further insights into their transport mechanism.

Keywords (maximum 5 keywords defining the topics of the abstract):

Originator, biosimilar, MALDI TOF/TOF mass spectrometry, liquid chromatography, zebrafish.

Introduction: (Limit of 400 characters)

The approval authorization of a biosimilar is based on strong comparability studies with its biological references product due to the complexity of the structure and of the nature of manufacturing process of biological drugs. The proof of similarities needs both the development of analytical workflow, to characterize the protein chemically, and development of clinical trials to evaluate the efficacy and the safety of drug.

Methods: (Limit of 400 characters)

Qualitative and quantitative analyses were performed by tandem time of flight matrix-assisted laser desorption/ionization mass spectrometry (MALDI-TOF/TOF-MS) and reverse phase liquid chromatography coupled with an UV-detector (RP-HPLC/UV). The evaluation of the biological activity of the biodrugs, in particular, their effect on immune system cell proliferation, was studied in zebrafish embryo, as animal model, using an innovative functional assay.

Results: (Limit 900 characters)

The comparison studies between the recombinant filgrastim and its biosimilars were performed RP-HPLC and MALDI-TOF-MS both on intact proteins and on digested proteins. In particular, analyses were carried out to evaluate the integrity of proteins, the absence of drug-related impurities, the similarity of amino acid sequence and the protein concentration. While qualitative analyses allowed us to establish the molecular weight of the biodrugs and to verify the identity of primary amino acid sequence, quantitative analyses confirmed the protein concentration in the pharmaceutical formulations. After chemical characterization of the biodrugs, the biosimilarity was assessed by in-vivo study, using zebrafish embryos as model, to verify the biological activity. Functional studies showed that all drug had similar capacity to activate the innate immune response in zebrafish. Overall, the obtained results allowed us to demonstrate both the structural and biological similarity of the biosimilar drugs in comparison with their originator.

Conclusions (Limit of 400 characters)

The analytical analyses performed in this study highlighted the structural similarity of biosimilar drugs Nivestim™, Tevagrastim® and Zarzio® and the originator Granulokine®. This result was reinforced by a similar in vivo biological activity.

Novel Aspect: (Limit of 150 characters)

This work is focused on the comparison of the originator of filgrastim with its three biosimilars, to evaluate the structural similarity and biological activity.

1173 - CHARACTERIZATION OF CALCIUM-MEDIATED ALPHA-SYNUCLEIN AGGREGATION PATHWAY AT THE MOLECULAR LEVEL

Jong Yoon Han (1) - Hugh I. Kim (1)

-, Korea University/Department of Chemistry, Seoul (1)

Keywords: α -synuclein, Intrinsically disordered protein structures, amyloid fibrillation, ion-mobility mass spectrometry (IM-MS), solution small-angle X-ray scattering (SAXS)

Introduction: Human α -synuclein (α Syn) is an intrinsically disordered protein, whose aggregation is associated with the pathogenesis of several neurodegenerative diseases (e.g., Parkinson's disease). Although α Syn aggregation process in the patients' brain is not fully understood, dyshomeostasis of Ca^{2+} was suggested to induce the aggregation. In this study, we examined the detailed structural change of α Syn and proposed the mechanism of Ca^{2+} -mediated α Syn aggregation [1].

Methods: Ion mobility-mass spectrometry (IM-MS) and solution small-angle X-ray scattering (SAXS) were utilized for structural characterization of monomeric α Syn in the presence of Ca^{2+} . Molecular dynamics (MD) simulations were performed to generate structures that match the experimental data. Multiple biophysical techniques were also utilized for revealing aggregation kinetics and morphological properties of aggregates.

Results: First, we observed that Ca^{2+} accelerated the α Syn fibrillation. To understand the role of Ca^{2+} , we investigated the structure of monomeric α Syn in the presence of Ca^{2+} using solution SAXS and IM-MS. Our IM-MS and SAXS results imply that population of extended conformers increases when Ca^{2+} ions are bound to α Syn. Based on the representative structures generated using MD simulation and ensemble optimization method (EOM), we suggested that the 1) Ca^{2+} induces α Syn to form extended conformer by electrostatic interaction, and 2) the extended conformers are prone to aggregation because hydrophobic NAC domain is more exposed to water than compact conformers. In addition, we observed that fibrils attached to each other in the presence of Ca^{2+} . Our detailed examination showed that Ca^{2+} binds to acidic-rich C-terminal domains originated from different fibrils, provoking interfibrillar aggregation.

Conclusions: In this study, we characterized the Ca^{2+} -mediated aggregation pathway of α Syn. Our results showed that binding of multiple Ca^{2+} ions induces the structural change of monomeric α Syn to expose NAC domain which is crucial for fibrillation, and provokes interfibrillar aggregation via electrostatic interaction.

Novel Aspect: Because of the biological importance of Ca^{2+} in α Syn aggregation, our study would be valuable for understanding pathology of α Syn-related neurodegenerative diseases.

923 - CHARACTERIZATION OF INTACT MONOCLONAL ANTIBODIES UNDER NATIVE AND REVERSE PHASE CONDITIONS USING HIGH RESOLUTION MASS SPECTROMETRY

Chris Nortcliffe (1) - Ryo Yokoyama (2) - Sibylle Heidelberger (1) - Kerstin Pohl (3) - Joerg Dojahn (3) - Ferran Sanchez (4) - Annu Uppal (5)

SCIEX, Biologics, Warrington (1) - SCIEX, Biologics, Tokyo (2) - SCIEX, Biologics, Darmstadt (3) - SCIEX, Biologics, Barcelona (4) - SCIEX, Biologics, Haryana (5)

Keywords: Native, NIST, Trastuzumab, TripleTOF 6600

Introduction:

A major requirement in the development of biopharmaceuticals is extensive characterization of the molecule at the intact level to ensure safety and efficacy. More recently characterization of monoclonal antibodies under native conditions is gaining importance over reverse phase conditions as it helps preserve the noncovalent interactions and retain the folded structure.

Methods:

Two monoclonal antibodies were studied using SCIEX TripleTOF® 6600 coupled to high-flow liquid chromatography (LC). Reverse phase chromatography was performed with water and acetonitrile containing 0.1% formic acid gradient. For native analysis, isocratic gradient of 50mM ammonium acetate buffer was used. MS detection was carried out using high resolution TOFMS mode.

Results:

Two antibodies Trastuzumab, and NIST standard were analyzed under native and reverse phase conditions. The TripleTOF® 6600 system yielded high resolution accurate mass data with excellent sensitivity and reproducibility for both the molecules analyzed. The traditional reversed phase chromatography involves separation based on organic solvent gradient resulting in denaturing conditions and a broad distribution of highly charged species at lower m/z ranges. Relatively lower charge states are observed with narrow distributions and higher m/z under native conditions thus resulting in higher spatial resolution and improved baseline resolved peaks.

Conclusions

The high quality spectra obtained with TripleTOF® 6600 system along with the deconvolution using BioPharmaView™ software enabled the accurate molecular weight determination of all the possible glycoforms with excellent reproducibility.

Novel Aspect:

Evaluation of the TripleTOF® 6600 systems for the Intact Mass analysis of mAb's under native conditions.

310 - NATIVE MASS SPECTROMETRY OF BIOMOLECULES: A COMPARISON OF nESI-MS AND LILBID-MS

Nils Hellwig (1) - Oliver Peetz (1) - Nina Morgner (1)

Institute of Physical and Theoretical Chemistry, Goethe-University, Frankfurt (1)

Keywords: Native MS, LILBID-MS, nESI-MS, Membrane Proteins, Non-covalent Complexes

Introduction:

Native mass spectrometry has emerged as an important tool in structural biology and is routinely used to analyze soluble proteins. However the investigation of membrane proteins and their complexes remains challenging; until the beginning of 2017, only about 30 membrane proteins have been investigated, mostly using nESI-MS. In this area LILBID-MS has recently shown great potential, which is further examined here in a comparison of the capabilities of these Methods:

Methods:

We compared the performance of the complimentary methods nESI and LILBID in the analysis of the soluble protein Avidin (tetramer) and the dimeric membrane protein EmrE. In addition, we performed a comparative screening of different buffers, concentrations and additives to explore the current limitations of both MS techniques. The nESI measurements were performed on a Waters Synapt G2-S, while the LILBID spectra were recorded on an in-house build reTOF spectrometer.

Results:

LILBID and nESI show different dissociation pathways. Avidin tetramer dissociates via dimers in LILBID, while in nESI, a highly charged monomer exits the complex. For EmrE, the native dimeric state can be detected almost exclusively using LILBID, whereas in nESI the dimer appears only as a minor species.

While with nESI, in case of most membrane proteins, it wasn't possible to avoid a certain amount of dissociation, we were able to demonstrate a gentle analyte release via IR-laser desorption in LILBID-MS, preserving almost the entire intact protein complex.

LILBID demonstrates a slightly higher tolerance towards non-volatile buffers TRIS-HCl and HEPES. High buffer concentrations require higher energy input for desolvation, leading to partial dissociation of the protein complexes. Both methods show a significant peak broadening with increasing salt concentration, the detected complex mass also increases.[1]

Conclusions:

Soluble proteins and protein complexes can be analyzed convincingly using both Methods:

If more desolvation of the analyte is needed, as for non-volatile buffers and additives or detergents used to stabilize membrane proteins, LILBID has benefits due to its different ion release mechanism.

When the native state of membrane protein complexes is of interest, LILBID can reveal this routinely, whereas nESI has its advantages in areas, where a high resolution is needed.

Novel Aspect: This is the first study comparing the capabilities of the two complimentary native MS methods nESI and LILBID in the analysis of soluble and membrane protein complexes.

1304 - CATION EXCHANGE CHROMATOGRAPHY IN DISPLACEMENT MODE FOR ONLINE ANALYSIS OF INTACT PROTEINS BY MASS SPECTROMETRY

Siti Nurul Hidayah (1) - Dennis Kroesser (1) - Benjamin Dreyer (1) - Hartmut Schluter (1)

University Medical Center Hamburg Eppendorf, Institute for Clinical Chemistry and Laboratory Medicine, Mass Spectrometric Proteomics, Hamburg, Germany (1)

Keywords: Displacement Chromatography, Top Down Proteomics, Intact Proteins

Introduction:

Combination of mass spectrometry with chromatography is the key to successful mass spectrometric top down protein analysis [1]. Ion exchange chromatography in its classical form is incompatible with MS due to high salt concentrations in the eluent [2]. Displacement chromatography offers opportunity to perform cation-exchange chromatography (CEX) without using salt. In this study we tested if proteins eluting on-line from a CEX column into an ESI-MS can be detected.

Methods:

An equimolar protein mixture (Lysozyme, Ribonuclease A, Cytochrome C and Myoglobin) was loaded (1.5 mg) onto a CEX column until it was saturated, recognized by the detection of the breakthrough of the proteins. Adsorbed proteins were eluted by pulsed injection of the displacer spermine. First 90 pulses contained 10 mM spermine, next 50 pulses 25 mM. The HPLC system was run with 0.1% formic acid as solvent and eluting proteins were detected by an orbitrap mass spectrometer.

Results:

Lysozyme and Ribonuclease A were eluted from the column by first 90 pulses of spermine (10 mM). Three different charge states from each protein were chosen and monitored in the corresponding spectra. Over the pulses, lysozyme and ribonuclease A eluted with constant concentration. A separation of these two proteins was not observed. After the injection of 140 pulses of spermine (25mM) Cytochrome C co-eluted with both previous proteins. Only Myoglobin stayed on the column and was not displaced by spermine. It eluted by washing the column with 1M ammonium acetate.

Conclusions:

By application of displacement chromatography mode an online coupling of ion-exchange columns with MS detection for intact proteins is possible. However, the affinity of spermine obviously was not strong enough for displacing myoglobin. Thus, finding a suitable displacer with higher affinity for displacing proteins from CEX is still needed. Once found, it should be possible to even separate individual proteoforms of proteins.

Novel Aspect:

Separation and detection of intact proteins by online coupling of ion-exchange columns with MS detection by application of displacement mode chromatography.

761 - A CROSS-LINKING/MASS SPECTROMETRY WORKFLOW BASED ON MS-CLEAVABLE CROSS-LINKERS AND THE MEROX SOFTWARE FOR MAPPING PROTEIN-PROTEIN INTERACTIONS

Claudio Iacobucci (1) - Michael Götze (1) - Andrea Sinz (1)

Martin-Luther-Universität Halle-Wittenberg, Institut für Pharmazie, Halle (1)

Keywords: Cross-linking/Mass Spectrometry, Structural proteomics, Protein Interaction, Software, Collisional Activation

Introduction:

Mass spectrometry (MS)-cleavable cross-linkers are moving into the focus of the cross-linking/MS approach for studying 3D-structure of proteins and protein assemblies. They undergo specific fragmentations under collisional activation conditions generating characteristic product ion patterns. They have an enormous potential for a fast and reliable identification of cross-linked peptides even from highly complex samples, e.g. whole cells and organisms.

Methods:

We developed a robust and widely applicable workflow that allows a facile identification of cross-links for deriving spatial constraints from proteins and protein complexes. Our protocol combines the synthesis of novel cross-linkers, protein cross-linking, bottom-up proteomics analysis, and data analysis based on the in-house MeroX software [1]. Two orbitrap mass spectrometers, Orbitrap Fusion Tribrid and Q-Exactive Plus, were employed.

Results:

We designed and synthesized four novel MS-cleavable (photo)-cross-linkers. 2,2'-Azobis(2-methylpropanimidate) is an innovative cross-linking principle that after collisional activation induces free radical-initiated sequencing (FRIPS) of connected peptides in positive ion mode [2,3]. 1,1-carbonyldiimidazole is the first zero-length MS-cleavable linker for nucleophilic groups (amines and hydroxyls) in proteins [4]. 3,4-Diallylurea is a novel photo-activatable, MS-cleavable reagent to selectively target cysteines [5]. We unveiled the true reactivity of diazirine-base cross-linkers, which are in fact photo-activatable and MS-cleavable reagents to target carboxylic acids in proteins [6]. All cross-linkers were investigated to study several protein systems, such as the tumor suppressor p53, which is an intrinsically disordered protein, and the whole E. coli ribosome. We are currently extending our cross-linking/MS workflow to the in-vivo analysis of protein-protein interactions, exemplified for Drosophila embryos.

Conclusions

Our integrated cross-linking workflow allows to map protein 3D-structures and protein-protein interactions in-vitro and in-vivo. We have synthesized innovative, MS-cleavable cross-linking principles that target different functional groups in proteins, such as amines, hydroxyls, thiols or react non-specifically with all 20 proteinogenic amino acids. The MeroX software is able to analyze cross-linked products in an automated fashion.

Novel Aspect:

We present an integrated workflow based on novel MS-cleavable cross-linking principles and a fully automated analysis of cross-linked products by the MeroX software.

Evaluation of an Isotope-Labeled MS/MS-Cleavable Cross-Linker for Protein Structure Analysis

Patrizia Springorum^{1,2}, Michael Götze², Christoph Hage¹, Christian H. Ihling¹, Mathias Schäfer³, and Andrea Sinz^{1*}

¹Department of Pharmaceutical Chemistry and Bioanalytics, Charles Tanford Protein Center, Martin Luther University Halle-Wittenberg, D-06120 Halle (Saale), Germany; ²Institute of Biochemistry, Charles Tanford Protein Center, Martin Luther University Halle-Wittenberg, D-06120 Halle (Saale), Germany; ³Institute for Organic Chemistry, Department of Chemistry, University of Cologne, D-50939 Cologne, Germany

Introduction:

Previous studies have shown the benefits of the amine-reactive, CID-MS/MS-cleavable cross-linker DSBU (disuccinimidyl dibutyl urea) for structural proteomics studies based on cross-linking/MS [1, 2]. To further facilitate the automation of cross-linking/MS experiments we now introduce a D12-stable isotope labeled version of the DSBU-linker combining the advantages of MS/MS-cleavable linkers and isotope labeling.

Methods:

Non-labeled DSBU and 1:1-mixtures of DSBU-D0 and -D12 were used to cross-link bovine serum albumine as well as the E. coli ribosome. Cross-linked proteins were proteolyzed and analyzed by nano-HPLC/nano-ESI-Orbitrap MS/MS (higher energy collision-induced dissociation, HCD) on Orbitrap Fusion and Q-Exactive Plus mass spectrometers using mass difference-triggered MS/MS experiments. MS and MS/MS data were automatically analyzed and annotated with MeroX [3].

Results:

The basis for a reliable, targeted selection of cross-linked peptides for MS/MS experiments is a mass difference between two isotopic species, which is large enough (D12) to create non-overlapping isotope patterns of a single species as well as overlapping elution profiles of the D0 and D12 species during LC/MS analysis. We could show that the D12-labeled DSBU-linker meets both requirements. The observed average retention time differences between D0 and D12 species were only ca. 10 seconds when employing 90-minute LC gradients. This enabled the efficient selection of cross-linked products for fragmentation by HCD, compensating the dilution effect caused by the application of two different cross-linker species. Employing mixtures of deuterated and non-deuterated cross-linkers combined with mass difference-based, targeted fragmentation seems to be advantageous compared to standard data dependent experiments using only one cross-linker species (156 versus 116 cross-linking sites for BSA).

Conclusion:

The application of mixtures of deuterated and non-deuterated DSBU-linker is advantageous for structural proteomics studies based on cross-linking/MS. In combination with the dedicated software tool MeroX [3], a basis for automated, robust, and reliable automated cross-linking/MS studies is provided.

Novel aspect:

A D12-stable isotope labeled version of the CID-MS/MS cleavable DSBU-linker allows for an efficient mass-difference based, targeted analysis of cross-linked products.

Keywords:

Cross-linking mass spectrometry, MS/MS cleavable cross-linker, isotope-labeled cross-linker

Keywords: antibody, ion exchange, charge variant, native MS, size

Introduction:

Manufacturing of innovator biologics can be successfully mimicked to produce generic “biosimilar” drug products. In order to satisfy safety and efficacy requirements, a biosimilar drug must be reasonably comparable to an innovator. Comparability is directly assessed by measuring a panel of critical quality attributes (CQAs). Recently, a multi-attribute method has been demonstrated to measure several CQAs simultaneously using LC-MS peptide mapping data. Additional CQAs, such as charge variants or size variants are conventionally monitored at the intact level using ion exchange (IEC) or size exclusion chromatography (SEC), respectively, coupled to UV detection. Native LC-MS approaches, such as SEC-MS and IEC-MS, can be inclusive with UV detection to combine the traditional gold standard chromatographic assays with accurate mass measurement to allow isoform-specific monitoring of multiple CQAs of intact therapeutic proteins.

Methods:

Intact trastuzumab was separated by SEC or IEC directly coupled to MS. Mobile phases consisted of aqueous 50 mM ammonium acetate. SEC was performed using isocratic pH 6.6 mobile phase. IEC was performed using a pH gradient from 6.8 to 10.1. LC-MS was accomplished using a Vanquish H-Class UHPLC system with a variable wavelength detector directly connected to a Thermo Scientific™ Q Exactive™ HF-X Orbitrap™ mass spectrometer. Native LC-MS raw data were analyzed using a time-resolved deconvolution approach utilizing Sliding Window and ReSpec algorithms in Thermo Scientific™ BioPharma Finder™ software. Thermo Scientific Chromeleon software was used to integrate XIC peak areas and relatively compare CQAs of innovator and biosimilar drug samples.

Results:

Native IEC-MS analysis of intact trastuzumab resulted in a chromatographic profile consistent with previously published data. Time-resolved deconvolution analysis of the innovator drug resulted in identification of several

specific isoforms comprised of differential N-glycosylation in combination with a variety of low level charge-imparting PTMs, such as deamidation, C-terminal lysine removal, or sialylation of N-glycans. We confirmed that the main peak consisted of several isoforms corresponding to variable N-glycosylations of the trastuzumab amino acid sequence. When comparing the innovator and biosimilar products, we found marked differences in glycoform profile measured at the main peak. Furthermore we found measurable differences in several charge variant isoforms when comparing innovator and biosimilar. These differences observed were consistent with a comparison of these same two samples via MAM HRAM peptide mapping analysis. Native SEC-MS of intact trastuzumab innovator and biosimilar samples showed marked differences in the levels of fragmentation as well as aggregation in response to a forced degradation treatment.

Conclusions

Biosimilarity of antibody therapeutic drug products can be accessed at the intact level to assess size variants and charge variants using either SEC or IEC coupled to UV and MS detection. This method was effective and reproducible for determining detailed molecular differences between an innovator drug, Herceptin, and a biosimilar.

Novel Aspect:

Method for monitoring multiple CQAs of an intact biotherapeutic compound to allow direct comparison of innovator and biosimilar products in a convenient and deeply insightful. Both SEC and IEC coupled to UV and native MS can be used

526 - STRUCTURAL COMPARISON AND EPILOPE MAPPING OF INNOVATOR AND BIOSIMILAR THERAPEUTIC ANTIBODIES

Cristina Lento (1) - Kerene Brown (1) - Derek Wilson (1)

York University, Chemistry, Toronto (1)

Keywords: native MS, hydrogen/deuterium exchange, protein therapeutics, microfluidics

Introduction: (Limit of 400 characters)

Vascular endothelial growth factor (VEGF) is recognized as an essential regulator of normal and abnormal blood vessel growth.[1]The humanized mAb bevacizumab (Avastin) targets VEGF and blocks angiogenesis, resulting in suppressed tumour growth.[2,3] In this study, native MS, IM-MS, and global, as well as bottom-up HDX experiments were conducted to determine similarities in the higher-order structures of various lots of biosimilars to its innovator drug.

Methods: (Limit of 400 characters)

The main isoform of human VEGF (165) was purchased from R&D Systems. Avastin and biosimilars were exchanged into 250 mM C₂H₇NO₂ (pH 7.4) for all native MS, IM-MS and global HDX experiments. VEGF and antibodies were exchanged into 150 mM C₂H₇NO₂(pH 6.7) and HDX was performed on the VEGF/Antibody complex and VEGF only to determine the epitope sites.Time-resolved global and bottom-up HDX was conducted using an in-house rapid mixing device and microfluidic platform.

Results: (Limit 900 characters)

Native MS revealed that all six biosimilar lots had a more heterogenous pattern and an overall greater level of glycosylation compared to Avastin. IMS-MS revealed identical drift times for Avastin and the biosimilars, consistent with gas-phase structures having the same collision cross-section. In the global HDX analysis, no differences in deuterium uptake were observed between Avastin and the biosimilars between 0.046 – 3.77 seconds. To localize subtle conformational changes and elucidate epitope sites, local HDX was conducted on VEGF only and the VEGF/antibody complex. At 8 and 4 seconds, the significant decreases in uptake identified for VEGF+Avastin were located at a.a. 27-43, 91-103 and 105-119 containing most of its known epitopes. Similar decreases were observed for VEGF+Biosimilar at a.a. 91-103 and 106-122. Interestingly, at lower time points, VEGF+Biosimilar displayed significant increases in deuterium uptake at a.a. 19-22, 91-103 and 154-162, while VEGF+Avastin continued to see decreases at the epitope, albeit to a lower extent.

Conclusions (Limit of 400 characters)

Although there were differences observed in the glycosylation patterns, this did not seem to have an effect on the overall solution-phase dynamics of the antibodies.Although the binding site is the same for Avastin and the biosimilar, differences in allosteric perturbations could be observed at earlier time points which may be the result of how the antibodies engage VEGF.These increases could be attributed to differences in the thermodynamics of binding.

Novel Aspect: (Limit of 150 characters)

Using native structural mass spectrometry techniques in tandem with time-resolved HDX for biosimilar characterization and epitope mapping.

Keywords: Aptamer, Epitope, SPR, Maldi-MS, C-Met

Introduction:

C-Met is a glycosylated receptor tyrosine kinase of the hepatocyte growth factor. Upon ligand binding C-Met transmits intercellular signals by its unique multi-substrate docking site. However, pathophysiological activation of the C-Met pathway leads to tumorigenesis, schizophrenia and cardiomyocytes death [1].

Here we report a study of the C-Met interaction with two DNA aptamers that bind the target protein (C-Met) with high affinity and specificity

Methods:

The two C-Met aptamers used are CLN0003 and CLN0004 where produced using SELEX procedure [2].

For epitope identification, the aptamers where immobilized on sepharose beads. The binding epitopes were identified by proteolytic extraction and excizon-MS [3]. C-Met was digested with two enzymes. The unbound peptides where washed and the elution was done by slight acidification.

Affinity determinations were carried out with a SPR biosensor.

Results:

According to the SPR affinity data the aptamers are interacting with the protein with two different binding evets. The KDs where calculated with tree different methods to validate the results.

In the case of CLN0003 interacting with the protein we obtained the following KDs: KD1= 10^{-6} M and KD2 10^{-8} M.

For CLN0004 the KDs are as follows: KD1= 10^{-7} M and KD2 10^{-8} M

Epitope analysis showed that the protein has indeed two different binding sites for the CLN003 aptamer. The two regions for the binding sites of the C-Met protein to the CLN0003 aptamer are (524-543) and (557-568). (SEELSGTWTQQICLP AIYK and LTICGWDFGFRR).

In the analysis of the epitope for the CLN0004 aptamer the results show that two different binding sites occur as well, one in the region of (251-257) with the corresponding sequence: HTRIIRF and one in the region of (381-388) with the sequence: NSSGCEAR

Conclusions:

Because the C-Met protein has been linked to so many types of cancers it is important to determine the inhibiting mechanisms [4]. The work presented here can be used both for biomarker discovery, by using the CLN0003 aptamer or for delaying the cancer development. Furthermore, we present the discovery of the exact extracellular region necessary for inhibiting the interaction between the natural receptor and C-Met.

Novel Aspect:

By proteolytic-MS we found for the first time the interaction sites of the C-Met protein with two different C-Met aptamers.

320 - LILBID-MS REVEALS INFLUENCES OF ThT AND COOMASSIE ON AGGREGATION KINETICS OF AMYLOID-BETA (1-42) AND α -SYNUCLEIN

Janosch Martin (1) - Rene Zangl (1) - Tobias Lieblein (1) - Nina Morgner (1)

Goethe University, Institute of Physical and Theoretical Chemistry, Frankfurt (1)

Keywords: LILBID-MS, Thioflavin T, Coomassie, amyloid-beta, α -Synuclein

Introduction:

Many proteins can spontaneously self-assemble into β -sheet-rich fibrillar aggregates, so called amyloids. Two examples are amyloid-beta (1-42) ($A\beta_{42}$) and α -Synuclein (α -Syn), the proteins of interest regarding Parkinson's disease (PD) and Alzheimer's disease (AD), respectively.[1] To analyze aggregation of amyloids, a commonly used method is the Thioflavin T (ThT)-assay. Coomassie - used for staining proteins - is another important dye for protein analysis.

Methods:

In contrast to a ThT-assay laser-induced-liquid-bead-ion-desorption mass spectrometry (LILBID-MS) enables to take a detailed look at small oligomers. Furthermore there is no need to add analysis required substances. Due to this LILBID can be used to study and compare not only the oligomerization kinetic by time-resolved measurements, but also to reveal the effect commonly used dyes like ThT and Coomassie have on this aggregation kinetic.

Results:

LILBID was employed to analyze and compare the aggregation kinetics of α -Syn and $A\beta_{42}$. Using LILBID it is possible to detect a range of α -Syn and $A\beta_{42}$ oligomers. Time-resolved measurements demonstrate a faster aggregation of $A\beta_{42}$ compared to α -Syn.

The fluorescence dye ThT which tags β -sheet structures of a protein is still under discussion due to the potential to affect the aggregation of some proteins, e.g. Amyloid-beta (1-40).[2] Therefore the influence of ThT on the aggregation behavior of α -Syn and $A\beta_{42}$ was investigated. It can be shown that ThT neither promotes nor inhibits the oligomerization of these proteins, as long as it is purified.

Recent studies also indicate an influence of the protein staining dye Coomassie on α -Syn aggregation.[3] Due to this, LILBID was also used to study how Coomassie affects the amyloidogenic oligomerization of α -Syn and $A\beta_{42}$. We could show that Coomassie promotes the oligomerization in case of α -Syn, whereas $A\beta_{42}$ -aggregation is not influenced.

Conclusions:

Time-resolved experiments were performed to analyze the influence of ThT and Coomassie on α -Syn and $A\beta_{42}$. It could be shown that ThT does not influence the aggregation behavior of these proteins. In contrast, Coomassie promotes formation of off-pathway oligomers in case of α -Syn, whereas $A\beta_{42}$ -aggregation is not affected. These are important factors, relevant for interpretation of results obtained with the respective analysis compounds.

Novel Aspect:

Requiring no additional substances, LILBID enables to analyze the potential influence of fluorescence dyes commonly used for aggregation analysis (see ThT-Assay).

278 - CHARGE-INDEPENDENT MASS SPECTROMETRY OF SINGLE VIRUS CAPSIDS ABOVE 100MDA WITH NANOMECHANICAL RESONATORS

Christophe Masselon (1) - Sebastien Hentz (2) - Sergio Dominguez-Medina (1) - Shawn Fostner (2) - Mohammad Halim (1) - Martial Defoort (2) - Emeline Vernhes (3) - Pascale Boulanger (3)

CEA, DRF/BIG/Large Scale Biology Laboratory, Grenoble (1) - CEA, DRT/LETI/DCOS, Grenoble (2) - I2BC, Université Paris-Saclay, Gif sur Yvette (3)

Keywords: Nanomechanical resonators, Native MS, instrumentation, polymer, virus.

Introduction:

Nanomechanical resonators can measure the mass of individual particles accreting on their surface [1]. As their frequency-to-mass relationship scales inversely with the resonator's dimension, research groups have engaged in a race to measure the smallest detectable mass with increasingly small resonators [2]. However, nanomechanical resonators have best performances in the MDa to GDa mass range, where most technologies, including MS, struggle to measure masses.

Methods:

We developed a novel architecture for nanoresonator-based MS of high-mass biological nano-particles combining solution nebulization by surface acoustic wave nebulization, efficient transfer and focusing by an aerodynamic lens without relying on electromagnetic fields, and mass measurement using an array of frequency-addressed nanomechanical resonators.

Results:

The system's particle transfer and focusing performances were characterized using NIST standard 45 nm polystyrene nanoparticles. Particle transfer from solution to the detector chamber reached ~7.5%, and the particle beam could be collimated to a 1.5 mm diameter with divergence better than 1°. Mass measurements of NIST nano-particles were in agreement with expectations based on polystyrene density and specified size distribution. The system was then employed for the measurement of empty and filled bacteriophage viral capsids with theoretical masses up to 105.4 MDa demonstrating its bio-analytical capabilities. Measured masses were within ~1% of their theoretical values for both empty and filled capsids. The measurement of the mass of bacteriophage T5 capsids containing the viral genome is, to the best of our knowledge, the largest defined molecular mass ever measured, and with a resolution of 75, it is also the highest reported resolution for single particle measurements above 10 MDa.

Conclusions

We have successfully developed a new nanoresonator-based MS system for high mass measurement. This system determined the mass distribution of ~30 MDa polystyrene nanoparticles with a detection efficiency 6 orders of magnitude higher than previous nanomechanical-MS systems with ion guides, and successfully performed the highest molecular mass measurement to date with less than 1 picomole of bacteriophage T5 105 MDa viral capsids.

Novel Aspect:

An efficient nanoresonator-based MS system architecture allowed individual particle mass measurement without ionization in the MDa to GDa mass range.

548 - NATIVE MASS SPECTROMETRY REVEAL FUNCTIONING MECHANISM OF MEMBRANE PROTEIN TRANSLOCATION PATHWAY

Shahid Mehmood (1) - Melanie McDowell (2) - Irmgard Sinning (2) - Carol Robinson (1)

Department of Chemistry, University of Oxford, Oxford (1) - Biochemie Zentrum, Heidelberg University, Heidelberg (2)

Keywords: Membrane proteins; Tail-anchored protein translocation, native mass spectrometry;

Introduction

Native mass spectrometry (MS) has a strong potential for its application towards the systems where other biophysical techniques are futile (1). In yeast, the dedicated guided entry of tail-anchored proteins (GET) pathway targets and inserts tail-anchored (TA) proteins into the endoplasmic reticulum (ER) membrane. A complex of two membrane proteins, Get1 and Get2, captures the TA protein from the Get3 cytoplasmic chaperone and mediates its membrane insertion.

Methods

We applied high resolution native MS based methods to recombinantly purified Get complex proteins: Get1 and Get2 membrane proteins and Get3 soluble protein. The experiments were performed on a Thermo QExactive-Plus instrument that has been modified for transmission of intact protein ions under native conditions and for trapping the ion in the source region under optional elevated activation energy (2).

Results

Overexpression and purification of Get1-Get2 membrane proteins was optimised and a full detergent screen was performed to achieve correct stoichiometry of the complex. We show that Get1-Get2 forms a dimer of dimers in surfactant, providing the first direct evidence for their stoichiometry. With the help of conventional lipidomics approach we showed that the complex specifically interacts with a molecule of phosphatidylinositol and is destabilised by detergents that disrupt this interaction, indicating lipid-protein interactions are important within the Get1-Get2 complex. A separately purified Get3 protein was then mixed with Get1-Get2 complex and we demonstrate that Get1-Get2-Get3 interacts with a 2:2:4 stoichiometry and that each pair of identical membrane proteins bind one Get3 dimer, providing new insights into the structure and function of the TA protein targeting complex at the ER membrane.

Conclusions

Our native MS and denaturing lipidomics data explain the role of detergents and lipids in the stability and correct stoichiometry of membrane protein translocation pathway complex. These observations for the first time explain insights into the mechanism of TA proteins translocation to ER membranes and provide a platform for further biophysical characterisation of the complex by X-ray crystallography or electron microscopy.

Novel Aspect

MS potential for understanding the fundamental biological processes, in this case, Get complex is revealed and the study opens a door for membrane protein stoichiometry related questions.

507 - QUANTIFICATION OF INHIBITOR BINDING TO WILD TYPE AND MUTANT ISOCITRATE DEHYDROGENASE (IDH1) BY NON-DENATURING MASS SPECTROMETRY

Victor Mikhailov (1) - Shuang Liu (1) - Christopher Schofield (1) - James McCullagh (1)

Department of Chemistry, University of Oxford, Oxford (1)

Keywords: native MS, drug binding affinities

Introduction

A single point R132H mutation of human isocitrate dehydrogenase 1 (IDH1) is responsible for inhibition of epigenetic regulators and is associated with a variety of cancers including over 70% of gliomas and 30% of myeloid leukemias. Inhibitors of the R132H IDH1 isoform are currently in preclinical and clinical trials. We present 'native' (non-denaturing) MS data on the binding of several of these inhibitors to IDH1 and we compare the results with data from other Methods:

Methods

An IDH1 / inhibitor solution in ammonium acetate buffer, at different enzyme/inhibitor ratios, was analysed using a Nanomate nESI source (Advion) coupled to a Synapt qTOF MS (Waters). Inhibitors tested included Novartis 224 and GSK 864, and AGI-5198, AG 120 and enasidenib (Agiros). The binding stoichiometries for the wild type (wt) and R132H IDH1 and the dissociation constant K_D were defined and native MS data were compared with the data from UV-absorbance, ITC and NMR.

Results

Mass spectra were consistent with the dimeric state of IDH1, single-site binding for AGI-5198 and AG-120, and two binding sites for GSK864 and Novartis 224. Enasidenib showed almost no binding to R132H IDH1 and single-site binding to wild type IDH1. K_D measurements for the enzyme/inhibitor complex ranged from the low μM for AG-120 and GSK 864 to high μM values for AGI-5198/wt IDH1. For AG-120, GSK864 and Novartis 224, the difference between affinities to the wild type and R132H mutant enzyme was small. A large difference in K_D was found for AGI-5198 binding to wt and R132H IDH1: 580 μM and 80 μM , respectively. K_D values for AG-120 and GSK864 were in the same low μM range as the K_D values from our NMR measurements. K_D values for AGI-5198 and Novartis 224 were much higher than those from NMR. This may be indicative of a difference between the inhibitors in the binding sites. Native mass spectra of the complexes between the two forms of IDH1 and their respective substrates were also recorded. Studies on the effect of inhibitors on these complexes are currently underway.

Conclusions

We have demonstrated the utility of 'native' mass spectrometry in quantification of drug binding to a human enzyme involved in the development of brain and other cancers. We have compared binding stoichiometries and affinities of various inhibitors, and now are evaluating the inhibitor effect on the enzyme/substrate binding. Most of the data corresponds well with the results from other methods, the rest can be rationalised in terms of different binding mechanisms.

Novel Aspect

Stoichiometry of binding of various inhibitors to the IDH1 mutant and wild type enzyme that is involved in brain cancer, and quantification of binding affinities.

260 - AN OPTIMIZED ENRICHMENT STRATEGY FOR IMPROVED MASS SPECTROMETRY ANALYSIS OF CHEMICALLY CROSS-LINKED PEPTIDES

Rosa Viner (1) - Leigh Foster (2) - Erum Raja (2) - Chris Etienne (2) - Ryan Bomgardner (2) - Madalina Oppermann (3)

Thermo Fisher Scientific, CMD, San Jose (1) - Thermo Fisher Scientific, CMD, Rockford (2) - Thermo Fisher Scientific, CMD, Stockholm (3)

Keywords: Cross-linking, MS-cleavable crosslinkers, enrichment, protein-protein interactions

Introduction:

Chemical cross-linking in combination with mass spectrometry is a powerful method to determine protein-protein interactions. However, this method suffers from low identification rates without enrichment/fractionation. In this study, we assessed azido MS-cleavable crosslinkers. Specifically, we evaluated different probes, capture resins, elution protocols and fractionation for increased cross-linked peptide identification by mass spectrometry.

Methods:

Amine-reactive, MS-cleavable crosslinkers including DSSO and Azido-A-DSBSO[1] were used to crosslink standard proteins and cell lysates. For azido-containing crosslinkers, samples were labeled with different biotin probes before digestion and enrichment. Samples were analyzed by LC/MS on the Thermo Scientific™ Orbitrap™ Lumos™ mass spectrometer. Thermo Scientific™ Proteome Discoverer™2.2 software and XlinkX node were used for data analysis.

Results:

A major challenge of crosslinking mass spectrometry is the relatively low abundance of crosslinked peptides after protein digestion. This results in very few or no crosslinked peptide identifications by MS if the sample complexity is greater than a few hundred proteins. Therefore, enrichment of crosslinked peptides is necessary to identify them in complex samples. To specifically enrich modified peptides, affinity groups such as biotin have been incorporated into the crosslinker structure. However, biotin-enrichment of crosslinked peptides is also challenging due to highly abundant mono-linked peptides, contamination by endogenous biotinylated proteins and/or biotin in elution buffers, and poor recovery from avidin/streptavidin resins. In this work we optimized protocol for an enrichable crosslinker, Azido-A-DSBSO. The total time of sample prep was reduced 3 times. To further separate monolinks from fully crosslinked peptides, we also developed a workflow using biotin enrichment followed by SCX fractionation.

Conclusions

This new XL-MS workflow allows effective protein cross-linking in vivo to capture authentic protein interactions, selective enrichment of cross-linked proteins and peptides to improve their detection. Our optimized enrichment crosslinked peptide workflow with fractionation increased our identification of crosslinked peptides by 20% compared to enrichment alone for BSA samples and 30% for complex cell lysate samples.

Novel Aspect:

Optimized sample preparation and enrichment of MS-cleavable crosslinked peptides for mass spec analysis.

823 - TOWARDS DEFINING OF THE MOLECULAR MATURATION PATHWAY OF THE MITOCHONDRIAL SULFHYDRYL OXIDASE ERV1

Kamila Pacholarz (1) - Xiaofan Tang (2) - Hui Lu (2) - Perdita Barran (1)

Manchester Institute of Biotechnology, The University of Manchester, Manchester (1) - School of Biological Sciences, The University of Manchester, Manchester (2)

Keywords: Enzyme maturation, protein oligomerisation, cofactor binding, Erv1, activated IM-MS

Introduction:

Erv1 (Essential for Respiration and Vegetative growth) is an FAD-dependent sulfhydryl oxidase which catalyses disulfide bond formation and is required for the import and folding of small cysteine-containing proteins in the mitochondrial intermembrane space (IMS) [1,2]. Our aim is to use hybrid MS to define the maturation mechanism: oxidative folding, cofactor-binding and oligomerisation; of this essential enzyme to benefit the design of better biocatalysts.

Methods:

Experiments were performed on full length Erv1 and its isolated compact C-terminal domain. Native MS and collisional activation prior to ion mobility, (aIM-MS) were applied to provide insights into Erv1 oligomerisation and FAD-binding (Waters SynaptG2S). FAD was titrated into apoErv1 to study the assembly pathway. Charge reducing agents were used to mimic the solution like oligomeric order of Erv1.

Results:

Native MS experiments have shown full length Erv1 (purified in presence of FAD) to exist in tetrameric, dimeric and monomeric state. Both, tetrameric and dimeric Erv1 display over bimodal charge state distribution, characteristic for ordered-disordered systems. Still, Erv1 displays unusually broad charge state distribution even for a disordered system [3]. Addition of charge reducing agent to the buffer resulted in shift of the oligomerisation equilibrium to narrow dimeric and tetrameric states and mimicked solution measurements. Highly conserved C-terminal domain of Erv1 displayed a narrow charge state envelope characteristic of folded proteins. aIM-MS shows how intrinsically unfolded Erv1 species are more prone to release of FAD prior to the subunit dissociation. The energy barrier for subunit dissociation in compact multimers is lower than the cofactor release barrier. Titration experiments of FAD into apoErv1, present mainly as apo monomer and somewhat as apo dimer, show the assembly into a fully occupied tetrameric Erv1 upon binding of the cofactor.

Conclusions:

Findings from MS provide new insights to define the maturation mechanism of Erv1. Erv1 exists in several multimeric states in the presence and absence of FAD, with a preference towards monomeric species in absence of the cofactor. FAD binding is essential for coordination of monomeric and dimeric Erv1 into tetramers.

Novel Aspect:

Application of native MS and top-down IM-MS to study enzyme maturation process, along with use of charge reducing agent to mimic solution conditions.

680 - ENRICHMENT OF ELECTROCHEMICALLY CLEAVED PEPTIDES FOR MIDDLE-DOWN PROTEOMICS APPLICATIONS

Hjalmar Permentier (1) - Tao Zhang (1) - Xiaobo Tian (1) - Rainer Bischoff (1)

University of Groningen, Analytical Biochemistry, Groningen (1)

Keywords: electrochemistry, protein digestion, spirolactone, biotinylation

Introduction

Enzymatic digestion of proteins is standard procedure in bottom-up proteomics. Alternatively, digestion can be achieved by electrochemical (EC) oxidation of proteins, leading to specific cleavage at the C-terminal side of Tyr and Trp residues. EC oxidation generates a mixture of cleavage and non-cleavage products. Cleaved peptides have a unique spirolactone at the C-terminus, which can be employed for their enrichment [1,2].

Methods

Model peptides and small proteins were oxidized at 1-2 V in an electrochemical flow-through cell with a carbon or boron-doped diamond electrode. The cleavage products were specifically derivatized with amine-containing reagents, including amine-biotin, at different pH values in the presence of metal ions. Derivatized peptides were affinity-enriched and analyzed by LC-MS/MS.

Results

Model tripeptides including LWL were oxidized to optimize the cleavage conditions and the reaction conditions with amine-biotin. At basic pH the peptide-spirolactone reactivity is highest, and a hydrolysis side reaction can be prevented by stabilization with Cu(II) ions. Other metal ions do not confer stability. The optimized conditions were then applied to small proteins, including lysozyme, leading to extensive cleavage at most Tyr and Trp residues. Enrichment of the cleaved, labelled peptides with streptavidin beads allowed the identification of the proteins in the digest. The amine-biotin tag readily fragments giving rise to a peak at m/z 375 which was used to verify the presence of enriched peptides. Further improvement of the enrichment using direct coupling of peptide-spirolactones to activated resins is expected to enable analysis of more complex EC-cleaved protein mixtures.

Conclusions

Cleavage of proteins with multiple Tyr and Trp residues and efficient derivatization with amine-biotin in the presence of Cu(II) was achieved. Biotinylated peptides were enriched with affinity capture, and LC-MS/MS analysis was used to identify the protein. Specific biotin fragments enable verification of biotinylation.

Novel Aspect

An electrochemical protein digestion method was optimized for protein identification using peptide derivatization and enrichment.

HALOmem, Charles Tanford Protein Center, Institute for Biochemistry and Biotechnology, Martin Luther University, Halle (1)

Keywords: Cross-linking, native MS, protein networks, synaptic vesicles, SNARE complex

Introduction:

Synaptic vesicles (SVs) are small storage organelles for neurotransmitters. They are densely packed with proteins and pass through a trafficking cycle including fusion with the presynaptic membrane [1]. Membrane fusion depends on formation of the SNARE complex which connects the two membranes [2]. We combine chemical cross-linking and native mass spectrometry (MS) to unravel protein assemblies in SVs as well as the interactions formed during membrane fusion.

Methods:

SVs were purified from rat brain. Individual proteins were expressed in *E. coli* and purified via a His-tag. Proteins were cross-linked using BS3 cross-linker. After tryptic digestion, cross-linked peptides were enriched by gel filtration, analysed by LC-MS/MS on a Q Exactive Plus mass spectrometer and identified using pLink software [3]. Assembled protein complexes were further studied by native MS using a modified Q-ToF Ultima mass spectrometer [4].

Results:

SVs were purified from rat brain and major proteins were identified. Cross-linking then delivered first interaction networks in intact SVs showing that Syb plays a central role in complex formation presumably due to its high flexibility. Using botulinum toxin to cleave the soluble segment of Syb and thus removed it from the protein networks allowing us to identify additional protein interactions. To study Syb in detail, we purified different variants, including full-length Syb, the soluble domain and a shorter segment. Using cross-linking and native MS we found that all variants formed oligomers in solution; the shortest variant formed higher order oligomers suggesting unspecific aggregation. By incubating the soluble segments of SNARE proteins or the full-length proteins incorporated into liposomes (i.e. membrane mimics) we studied the intermediates of SNARE complex formation. Cross-linking and native MS revealed protein interactions and stoichiometries in these assemblies.

Conclusions:

Our results provide novel insights into the heterogeneous protein interaction networks in SVs which are key to our understanding of signal transduction in the neuronal synapse. In addition, by employing individually purified proteins and variants thereof, we provide insights into the interactions formed in solution or when the proteins are incorporated into membrane mimics. We are thus able to monitor SNARE complex formation and uncover intermediate states.

Novel Aspect:

We provide first insights into protein interactions in SVs and pave the way to study membrane fusion by combining complementary MS techniques.

1166 - NATIVE MASS SPECTROMETRY: A TECHNIQUE OF MANY FACES

Michal Sharon (1) - Gili Ben-Nissan¹ (1) - Shay Vimer (1) - Jelena Cveticanin¹ (1)

Department of Biomolecular Sciences, Weizmann Institute of Science, Rehovot 7610001, Israel. (1)

Keywords: Native MS, Protein Complexes, Antibodies, Crude Proteins Samples, Protein-Ligand interactions

Introduction:

Key processes in a cell are carried out by protein complexes whose functions require tight regulation. The classical, high-resolution methods used for understanding protein regulation are often insufficient when attempting to study large protein assemblies, due to their size, heterogeneity and dynamic composition – thus, new methodologies are essential. Native MS is one such method.

Methods:

I will present our studies involving different developments and applications of native MS approaches with examples focusing on protein-protein interactions, protein-ligand systems and antibodies^{3,4}. I will also show a direct MS method that enables characterization of recombinant proteins directly from crude samples. Involving proteins produced in bacteria, yeast, insect and human cells.

Results:

The direct-MS approach can be carried out for proteins produced in prokaryotic and eukaryotic expression systems. The method provides immediate information on the expression, identity, solubility, oligomeric state, post-translational modification, ligand binding, overall structure and stability of overproduced proteins. I will show that the expression profile, post-translational modifications, overall structure and stability of engineered therapeutic antibodies, as well as glycosylated proteoforms of a modified protein can be immediately assayed by analysis of the crude samples. Moreover, I will demonstrate that the method is applicable for throughput characterization of protein variants, as mutants and engineered constructs. Our method is general and can be applied on various mass spectrometry platforms.

Conclusions

The major advantage of the method is that it considerably shortens the time gap between protein production and characterization while saving the burden associated with purifying inactive variants. The approach is particularly suitable for selecting the ideal protein expression host system, optimizing codon usage, expression levels and quality and employing high throughput investigations of lead candidates.

Novel Aspect:

Given the broad use of recombinant proteins in biochemical investigations and in industrial and therapeutic applications the method is expected to be widely utilized.

1150 - HYDROXYL RADICAL FOOTPRINTING STUDY FOR STRUCTURAL CHARACTERIZATION OF ALUMINUM HYDROXIDE-ADSORBED CALMODULIN BY MASS SPECTROMETRY

Alessandro Vadi (1)

GSK Vaccines S.r.l., Analytical Research and Development, Siena (1)

Keywords: Structural MS, Calmodulin, Aluminum hydroxide, Adjuvant adsorption, Hydroxyl radical footprinting.

Introduction:

Possible conformational modifications of antigens during aluminum hydroxide adjuvant adsorption are discussed in literature for formulated vaccine for its potential impact on antigen immunogenicity [1-4].

The development of a mass spectrometry (MS) based technique called hydroxyl radicals footprinting (HRF) for the direct characterization of adjuvant-adsorbed protein is discussed in this poster showing a case study on calmodulin (CaM).

CaM is a small and well characterized protein that is part of calcium signaling pathways [5].

CaM is an acidic protein with two globular domains connected by a central linker. Each domain contains two EF-hand sites that bind intracellular Ca^{2+} ions. Upon Ca^{2+} binding the EF-hand domains undergo to a conformational rearrangement, exposing hydrophobic protein domains that can bind a wide range of target proteins.

Hydroxyl radical footprinting technique (HRF) [6] coupled to MS was chosen to detect conformational changes of CaM, if any, when adsorbed on aluminum hydroxide and then exposed to Ca^{2+} ions. Hydroxyl radicals are highly reactive species that chemically modify the surface accessible amino acid side chains with a chemical susceptibility to oxidation (+ 16 Da mass shift, or +32 or +14 depending on the residue). enabling monitoring of a wide number of target sites and consequently providing structural information.

Methods:

Sample treatment protocol was developed ex novo to be compatible with aluminum hydroxide adjuvant. Fenton chemistry catalytic reaction [6] was used to generate hydroxyl radicals in solution and regenerate the Fe(II) species with sodium ascorbate. The three Fenton chemistry reagents (hydrogen peroxide, Fe(II)-EDTA, and sodium ascorbate) were added together with the sample. Hydroxyl radicals reaction with CaM was tested at 4 different time points (0, 2, 5, and 10 minutes) then reaction was quenched with thiourea. Subsequently protein were desorbed from adjuvant to allow the enzymatic digestion. Protein desorption was obtained by overnight incubation of the samples with phosphate buffer. Tryptic peptides are then analyzed on Q-Exactive Plus mass spectrometer (Thermo Fisher Scientific) by LC-MS/MS DDA top5 experiment.

Data were processed to enable relative quantification of the oxidized methionine-residue. The 9 methionine residues distributed along the protein sequence of CaM were selected as probes for structural modification probing. Protein conformational characterization was correlated to the different solvent exposure of the methionine residues calculated on their oxidation amount linear regression slopes at different time points.

Results and Conclusions:

Nine methionine residues (belonging to the protein sequence) were monitored on 4 different conditions, considering or not adjuvant and Ca^{2+} ions:

- 1) In-solution CaM;
- 2) In-solution CaM 10mM CaCl_2 ;
- 3) Adjuvant-adsorbed CaM;
- 4) Adjuvant-adsorbed CaM 10mM CaCl_2 .

Significant change in methionine oxidation rate slopes was observed in both cases of sample 2) and 4) respect to their no- Ca^{2+} reference samples 1), and 3).

This study demonstrated that HRF was able to detect induced conformational changes of CaM when exposed to Ca²⁺ ions in aluminum hydroxide-adsorbed samples.

Novel Aspect:

HRF is a new application for interface-adsorbed protein structural characterization by MS. Implementation of this technique could provide a valuable analytical tool for adjuvanted vaccine efficacy and quality assessment.

Introduction:

Characterization of over-expressed proteins is usually coupled to costly and time-consuming purification steps. We previously presented a native MS approach for protein analysis directly from crude bacteriallysates without purification¹. Although prokaryotes expression systems are very efficient, they lack the machinery required for PTMs, highlighting the need for eukaryotic hosts. Here we present a method for characterization of proteins directly from crude samples from such systems.

Methods:

As model systems we used different eukaryotic hosts that secrete recombinant proteins, the yeast *P. pastoris* expressing the cellulose binding module (CBM) from *C. thermocellum* and human serum albumin (HSA), and Sf9 insect cells expressing Transferrin receptor 1 (Tfr-1). Growth media from cells were collected and buffer exchanged into a MS compatible buffer. The different samples were analyzed using either an Orbitrap or a Synapt G2 HDMS QTOF-based platform².

Results:

Initially we analyzed by native MS samples directly from *P. pastoris* and Sf9 growth media overcoming the need for purification procedure. Examination of the different growth conditions allowed us to monitor expression already after 24h of induction, from cultures, grown in 100µl medium in 96 well plates. We were able to monitor co-factor binding and validate that Ca²⁺ is associated with the CBM binding pocket using incubation of media with EGTA and calcium acetate. Furthermore, IM-MS spectra were measured for CBM directly from *P. pastoris* growth media. Using arrival time distribution, the CCS (Ω) was calculated and found to be highly correlated to theoretical CCS. Next, we examined the Tfr1 protein, secreted from Sf9 cells. Analysis of the crude growth medium generated highly resolved spectra, which revealed four different glycosylation states of the protein. We validated this by releasing the N-linked oligosaccharides by PNGase-F.

Conclusions:

Here we show that direct native MS can be efficiently applied to different eukaryotic secretion systems. By examining the culture media of different expression systems we demonstrate that it is possible to rapidly determine the identity, solubility, oligomeric state, ligand binding, modification level and overall structure of secreted proteins. Moreover, we show that our method is not dependent on a specific MS platform but rather it is a general approach that can be applied on various instruments.

Novel Aspect:

Here, we show that direct-MS can dramatically shorten the time gap between protein production and characterization.

197 - INTEGRATIVE STRUCTURAL PROTEOMICS ANALYSIS OF THE 20S PROTEASOME COMPLEX.

Rosa Viner (1) - David M. Horn (1) - Eugen Damoc (2) - Albert Konijnenberg (3)

Thermo Fisher Scientific, marketing, San Jose (1) - Thermo Fisher Scientific, marketing, Bremen (2) - Thermo Fisher Scientific, research and development, Eindhoven (3)

Keywords: Native MS, crosslinking, top-down, pseudo MS3

Introduction: The structural determination of protein complexes plays an important role in the fundamental understanding their catalytic function. Multiple analytical methods, including hybrid approaches such as cryo-electron microscopy, cross-linking, and native mass spectrometry, are usually required for such type of analysis[1]. In this study we combined multiple mass spec based structural proteomics techniques to characterize the rabbit 20S proteasome complex.

Methods: Rabbit 20S proteasome complex was obtained from Boston Biochem. LC/MS bottom up, crosslinking and intact/top down analysis were performed using a Thermo Scientific™ UltiMate™ 3000 RSLCnano system and a Thermo Scientific™ Orbitrap™ Lumos™ mass spectrometer. Native MS experiments were performed using a modified Thermo Scientific™ Q Exactive™ Plus MS[2]. Data were analyzed with Thermo Scientific™ BioPharma Finder3.0, Proteome Discoverer™ 2.3, and ProSightPC.TM

Results: The 20S proteasome complex contains 28 subunits arranged into four stacked rings: seven alpha non catalytic subunits and seven beta-subunits[3]. In the first series of experiments we performed bottom up, intact and top down analysis using databases of proteasome proteins from rabbit, human, and all species in UniProt. We identified 224 proteins and 17 different types of proteasome subunits and used the results to verify or correct the originally homology-based rabbit sequences. We then used this curated rabbit 20S proteasome database for all other experiments. For structural characterization, we performed native MS intact and top down experiments using a modified Q Exactive Plus mass spectrometer. The measured mass of the 28 subunits complex was consistent with expected value of 716.4 kDa and pseudo-MS3 experiments enabled identification of alpha 2 and beta 6 subunits. Crosslinking experiments using DSSO are combined with restraints from native and top-down MS to validate the structure obtained through electron microscopy.

Conclusions: Combining results from different MS methods, including novel native top-down -pseudo MS3 approach, we were able to perform comprehensive analysis of the rabbit 20S proteasome.

Novel Aspect: Complete workflow for structural characterization of protein complex

598 - ASSEMBLY STUDIES OF ACETOBACTERIUM WOODII F1FO-ATP SYNTHASE AND ANALYZING CONFORMATIONAL CHANGES OF TMRABBY NESI

Khanh Vu Huu (1)

Goethe University, Goethe University, Frankfurt am Main (1)

Keywords: Assembly of F1, LILBID-MS, ABC transport complex, ion mobility

Introduction:

The F1FO ATP synthase of *Acetobacterium woodii* and the heterodimeric ABC transport complex TmrAB from *Thermotoga thermophila* are responsible for ATP synthesis/hydrolysis and ATP-dependent membrane transport mechanism, respectively. We are interested in the assembly of subunits and investigate requirements for the different assembly steps. For TmrAB we apply ion mobility measurements to analyze conformational changes in dependency of different ligands.

Methods:

In LILBID-MS a droplet generator generates droplets of an aqueous sample. These are transferred into vacuum and irradiated with an IR laser ($\lambda = 2.94 \mu\text{m}$) which leads to an explosive expansion of the droplets, ionization and finally a detection by a time-of-flight analyzer [1]. The Synapt G2-S HDMS offers ESI-mass spectrometry combined with ion mobility (IM) measurements.

Results:

First we focused on the soluble part F1 of the F1FO ATP synthase of *Acetobacterium woodii*. The plasmids pKV003 (7036 bp), pKV004 (6928 bp) and pKV019 (6822 bp) (which include either the *atpA*- (encodes α), the *atpD*- (encodes β) or *atpG-atpC* (encodes $\gamma\epsilon$) genes) were transformed in competent *E. coli* BL21gold(DE3) cells. The α -, β -subunit and the $\gamma\epsilon$ -complex were successfully purified by tandem affinity (Ni-chelating and Strep-Tactin) chromatography and can be characterized by LILBID-MS. Recently we are able to show the assembly efficiency of α -, β -subunits and also with the central stalk $\gamma\epsilon$ -complex of the ATP synthase in dependency of ATP and Mg^{2+} . Furthermore the steps of assembly were investigated by varying the laser energy.

A second project investigates three different ion mobility experiments we monitored conformational changes (inward/outward facing structure) of the heterodimeric ABC transport complex TmrAB related to ligand transport over the transmembrane by adding ATP/ADP at permissive conditions [2][3].

Conclusions:

At soft LILBID conditions we could show that the assembly efficiency in the soluble part F1 can be improved in an ATP/ Mg^{2+} environment. Unfortunately the assembly is not yet efficient as we expected. We will vary the position for the purification tags to improve the assembly with the central stalk $\gamma\epsilon$.

With ion mobility experiments we are now able to monitor conformational changes of the ABC transport complex in dependence of substrate binding and addition of nucleotides.

Novel Aspect:

Investigation of the assembly of a protein complex, via native MS studies. Analyzing conformational changes of membrane proteins with ion mobility.

836 - GAS-PHASE ELECTROPHORESIS (NES GEMMA) OF VIRUS-LIKE PARTICLES: RELATING PARTICLE SURFACE-DRY SIZE AND MOLECULAR WEIGHT

Victor U. Weiss (1) - Ronja Pogan (2) - Samuele Zoratto (1) - Charlotte Uetrecht (2) - Günter Allmaier (1)

-, TU Wien/Inst. Chem. Technologies and Analytics, Vienna (1) - -, Heinrich-Pette-Institute (HPI), Hamburg (2)

Keywords: Gas-phase electrophoresis, Virus-like particle, VLP, nES GEMMA, native MS

Introduction:

Gas-phase electrophoresis (on a nES GEMMA aka nES DMA) [1] separates surface dry particles according to their electrophoretic mobility diameter (EMD) which corresponds to the size of spherical nanoparticles. As shown for proteins and viruses [2,3], the EMD also relates to the molecular weight (MW) enabling to calculate an analyte MW based on its EMD. We now focus on virus-like particles (VLPs) and show the deviation of their EMD / MW correlation from other analyte cases.

Methods:

VLP samples were desalted and transferred to ammonium acetate solution prior to native ESI MS and nES GEMMA analysis. Data for the following VLPs were combined / obtained: Human Rhinovirus Serotype 2 (HRV-A2) empty subviral particles [3], Hepatitis B Virus VLPs with T3 and T4 symmetry [4] and several norovirus VLP strains.

Results:

VLPs of sufficient purity and concentration can be analyzed via native ESI MS and nES GEMMA. Comparing EMD values from nES GEMMA and MW values from native ESI MS experiments yields an EMD / MW correlation for VLPs. The particle MW is related to the EMD via a function to the power of approx. 3.5. Therefore, the EMD / MW correlation for VLPs was found to be significantly different from a similar correlation obtained for viruses (power of approx. 3.7) [3] and proteins (power of approx. 2.9) [5]. Hence, in order to be able to calculate reasonable MW values based on EMD data, the substance class (protein, intact virus, VLP) of the analyte in question needs to be known. If this requirement is met, nES GEMMA based calculation of a particle MW represents an interesting alternative at atmospheric pressure to the native MS approach.

Conclusions:

We demonstrate that an EMD / MW correlation for VLPs can be obtained. Based on this data and EMD values obtained via nES GEMMA, MW values for VLPs of unknown MW can be calculated. In addition, we demonstrate the deviation of EMD / MW correlations for proteins and virus particles from the VLP case. A larger VLP dataset will further improve our EMD / MW correlation for VLPs.

Novel Aspect:

We (i) present an EMD / MW correlation for VLPs and (ii) demonstrate the deviation of this VLP correlation from the protein and intact virus case.

966 - NATIVE MASS SPECTROMETRY TO IDENTIFY STOICHIOMETRIES AND STABILITY OF CRISPR-CASCADE COMPLEXES

Sabine Wittig (1) - Marius Rutkauskas (2) - Ralf Seidel (2) - Carla Schmidt (1)

HALOmem, Charles Tanford Protein Center, Institute for Biochemistry and Biotechnology, Martin Luther University, Halle (1) - Molecular Biophysics group, University Leipzig, Leipzig (2)

Keywords: Native mass spectrometry, proteinstoichiometry, CRISPR-Cas complexes

Introduction:

The CRISPR-Cas system of bacteria or archaea is an adaptive immune system against foreign DNA. The type I system uses a large ribonucleoprotein surveillance complex called 'Cascade' in which the crRNA targets the foreign DNA by base-pairing and thus triggers DNA degradation. We used native mass spectrometry (MS) to determine the protein stoichiometries of CRISPR-Cascade complexes containing longer or shorter crRNAs than the wild-type complex.

Methods:

Streptococcus thermophilus (St) CRISPR-Cascade was purified as described [1]. The purification buffer was exchanged against 200 mM ammonium acetate prior to native MS. Intact St-CRISPR-Cascade complexes were then analyzed on a Q-ToF Ultima mass spectrometer modified for transmission of high mass complexes [2] using gold-coated capillaries prepared in-house [3]. Mass spectra were processed and analyzed using MassLynx and MassSign software [4].

Results:

St-CRISPR-cascade complex was purified and cascade subunits were identified by LC-MS/MS and database searching. All five subunits (i.e. Cse1, Cse2, Cas5, Cas6 and Cas7) were identified.

Next, we used native MS to define the stoichiometric of the wild-type CRISPR-cascade complex containing crRNA, Cse1, Cse2, Cas5, Cas6 and Cas7 subunits. The native MS spectrum revealed a Cse11(Cse2)2(Cas7)6Cas51Cas61crRNA1 complex. The native MS spectrum also showed subcomplexes which lost Cse1 and Cse2 subunits as well as some copies of Cas7.

We further analyzed the impact of shorter or longer crRNA on the stoichiometry of the cascade complex. For this, we employed crRNAs which are 12 nucleotides longer or shorter. The native MS spectrum of the complex containing longer crRNA showed one abundant CRISPR-cascade complex with a stoichiometry of Cse11(Cse2)3(Cas7)8Cas51Cas61crRNA1. In contrast, the mass spectrum of complex containing shorter crRNA revealed several complexes; the most abundant complex was Cse11(Cse2)1(Cas7)4Cas51Cas61crRNA1.

Conclusions:

We conclude that an increase/decrease of 12 nucleotides in the crRNA results in addition or loss of two Cas7 and one Cse2 subunits. The CRISPR-cascade complexes containing longer crRNA appear to be more stable when compared with the shorter crRNA containing complexes and form mostly one abundant complex. Currently, we analyse Cascade complexes with variable crRNA length to gain insights into their stoichiometries and its impact on complex stability.

Novel Aspect:

We studied the impact of crRNA length on protein stoichiometry and complex stability of CRISPR-Cascade complexes.

889 - CHARACTERIZATION OF DEUTERATED ALPHA-CRYSTALLINE USING BENCH-TOP MALDI-TOFMS.

Yuzo Yamazaki (1) - Ken Morishima (2) - Nobuhiro Sato (2) - Rintaro Inoue (2) - Masaaki Sugiyama (2)

Shimadzu Corp., Global application development center, Kyoto (1) - Research Reactor Institute, Kyoto University, Osaka (2)

Keywords: MALDI-TOFMS, deuterated protein, crystalline, cross-linker

Introduction:

Deuteration of protein is a one of the important technique in structural biology by using NMR or neutron scattering method. Incorporation of deuterated subunit protein into the hydrogenated one brings a new aspect of molecular dynamics in formation of multimer. As recent techniques for the deuteration have been more precise and more cost-effective, a quick and facile method to characterize deuterated proteins has been anticipated. In this report, we applied newly developed bench-top MALDI-TOFMS to analysis of deuterated β -crystalline to study substitution of hydrogen to deuterium in three different ways, molecular weight analysis, in-source decay, and tryptic peptide analysis. Furthermore, we will report multimer formation of the protein by using high mass detector and cross-linking chemistry.

Methods:

Human recombinant hydrogenated/deuterated β -crystalline was prepared with overexpression in E.Coli. with/without deuterated culture medium, as described[1]. Three samples, deuteration ratios of which were roughly estimated as 0%, 73%, and 98% (denoted as D0, D73, and D98, respectively), were subject to MALDI-TOFMS. Concentrations of them were 3 to 15 mg/mL. Bench-top MALDI-TOFMS (MALDI-8020, Shimadzu Corp., Japan) was applied to perform molecular weight measurement of whole proteins, in-source decay, and tryptic digest analysis in linear mode. Sinapinic acid, 1,5-DAN, and CHCA were used in those experiments. A cross-linker reagent was obtained from Covalx (Switzerland). All samples were reacted with the linker following an instruction provided from the company. After the reaction, desalted samples were mixed with sinapinic acid, then applied onto a stainless MALDI plate. MALDI-TOFMS (AXIMA-Performance, Shimadzu Corp., Japan) equipped with HM3 high mass detection system (Covalx, Switzerland) was applied to detection of cross-linked multimer in positive linear mode. The TOF analyser was calibrated using BSA and its multimer

Results:

Even though the newly developed bench-top MALD-TOFMS has only linear mode, its performance was sufficient to estimate the deuteration ratio of the protein. Whole protein analysis of three samples was conducted with sinapinic acid, and mass shifts against D0% (hydrogenated) protein were estimated. While theoretical shift for 100% deuterium substituted protein was 1107.5, an observed shift of D98% was 1100, which indicates 99% deuteration ratio as almost expected. As well, an observed mass shift of D73% was 762.8, indicating 69% deuteration ratio, which was a little lower than expected. In-source decay using 1,5-DAN was conducted to examine an internal sequence of the proteins. Despite lower mass resolution caused by higher laser irradiation, a series of c-ions, observed up to 67 residues, were well-assigned to deuterated amino acids within the modest error, suggesting almost no significant bias of the deuterium substitution at any amino acid. Then, three proteins were digested with trypsin and isotopical distributions of each digested peptides were investigated. By simulation of isotopical distribution, deuteration ration of the peptides were estimated as 99%, which was consistent with the value obtained with whole protein analysis. Additionally, hydrogenated β -crystalline was subject to cross-linking MS with high mass detector to observe multimer formation. As preliminary result, widely disperse multimers were detected at the mass range from m/z 200k to 500k. Interestingly, whereas an intense monomer signal and a weak dimer signal were also observed, there

was no intermediate formation of multimer, which is consistent with the proposed concept of “traveling subunits” that could be a transiently liberated in subunit exchange[1].

Conclusions:

Deuteration of protein was investigated with a newly developed bench-top MALDI-TOFMS. Molecular weight analysis, digested peptide analysis, and ISD enabled to estimate a deuterated ratio, which is critical factor in study of a dynamics of protein multimer with small angle neutron scattering. The accessible bench-top instrument could contribute to structural biology in prior use for the neutron scattering or NMR. Furthermore, the multimer of the crystalline was stabilized with cross-linking chemistry, and observed with high mass detector, through-put of which could be higher than native MS using ESI in analysis of multiple subjects.

Novel Aspect:

A deuterated ratio of α B crystalline was estimated with a newly developed bench-top MALDI-TOFMS, and multimer of the protein was observed with cross-linking chemistry and high mass detector successfully.

503 - DEVELOPMENT OF A CRYO-STAGE FOR LESA MASS SPECTROMETRY-TOWARDS TRULY NATIVE SURFACE SAMPLING OF PROTEINS

Bin Yan (1) - Adam Taylor (1) - Josephine Bunch (1)

National Physical Laboratory, National Centre of Excellence in Mass Spectrometry Imaging, Teddington (1)

Keywords: Liquid Extraction Surface Analysis, Cryo sampling, Native mass spectrometry, Ion mobility spectrometry, Protein unfolding/refolding,

Development of a cryo-stage for LESA mass spectrometry
– towards truly native surface sampling of proteins

Bin Yan, Adam Taylor, Josephine Bunch

National Centre of Excellence in Mass Spectrometry Imaging, National Physical Laboratory, Teddington, UK

Introduction:

Liquid extraction surface analysis (LESA) is a powerful method for measuring proteins from surfaces. In this work we present development and initial testing of a cryo platform for LESA MS. We explore the use of native sampling solutions for probing proteins directly from frozen surfaces.

Methods:

An Advion Triversa Nanomate nano-electrospray source coupled with a Waters Synapt G2Si mass spectrometer was used for LESA MS. Modifications to the sample recess were made to incorporate water cooled copper bars and a thermoelectric peltier cooling system. Protein and LESA sampling solutions were prepared using either 100 mM ammonium acetate or 1:1 water/methanol with 0.1% formic acid. Experiments were conducted at room temperature and using the frozen stage.

Results:

Preliminary results were obtained for ubiquitin. In ammonium acetate (20°C), native LESA sampling yielded ions with a narrow charge state distribution (5+ and 6+). However, H₂O/MeOH with 0.1% FA as the solvent resulted in a broad charge state distribution of ubiquitin ions (5+ to 13+) and slower average ion-mobility, indicating protein unfolding. For ubiquitin dissolved in H₂O/MeOH with 0.1% FA, denatured sampling also produced ions with a broad charge distribution. However, surprisingly, the mass spectrum acquired by native sampling of this denatured protein is dominated again by only 5+ and 6+ ions, which could be the evidence of protein re-folding. This was further supported by faster average mobility. The results using cryo sampling show very similar trend at room temperature, though the relative abundances of +5 and +6 ions differed for native LESA of denatured vs native proteins (1:2 for the former; 2:1 for the latter). The ion mobility was slightly slower than that of the original folded protein ion.

Conclusions

Protein unfolding or re-folding was observed to occur in LESA mass spectrometry study. The charge state distributions in the acquired mass spectra can not necessarily be used to judge whether the original structure of the studied protein is folded or unfolded. By employing cryo sampling method, the extent of protein unfolding or re-folding during LESA process can be largely minimized, therefore making truly native surface sampling of protein promising.

Novel Aspect:

A cryo-stage was developed for LESA-MS. With this protein re-folding and unfolding can be minimized during sampling so truly native surface analysis could be fulfilled.

Native mass spectrometry analysis of norovirus glycan interaction

Hao. Yan¹, Julia Lockhauserbäumer¹, Katharina Bücher³, Robert Creutzmacher², Alvaro Mallagaray²Thomas Peters², Laura Hartmann³, Charlotte Uetrecht^{1,4}

¹Heinrich Pette Institute, Leibniz Institute for Experimental Virology, Hamburg, Germany; ²Institute of Chemistry, University of Lübeck, Lübeck, Germany; ³Institute of Organic and Macromolecular Chemistry Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany; ⁴European XFEL, Schenefeld, Germany

Introduction:

Human noroviruses (HuNoV) are non-enveloped RNA viruses belonging to the Caliciviridae family and the main cause of viral gastroenteritis. From the crystallographic structure, it is apparent that the norovirus capsid protein protruding (P) domain binds to glycans on the cell to mediate cell attachment. A detailed investigation of P domain-glycan interaction by native mass spectrometry (MS) is used to shed light on the mechanism behind viral cell entry.

Experiments:

Native MS is applied to investigate glycan binding to different HuNoV strains. Blood group antigen B tetrasaccharide was used to characterize glycan binding affinity and build titration curves. Other groups of carbohydrates such as gangliosides, human milk oligomers and globosides have been measured. We also tested multivalent glycan mimetics with different spacing and number(s) of glycan of interest for binding to P dimers to resemble glycan-binding in the natural situation. The number of binding events per type of natural saccharides and multivalent ligands will be compared and investigated between norovirus genotype to elucidate binding profiles of glycans.

Results:

The results elucidate the dissociation constants (KD) of natural glycans and glycan mimetics in norovirus cell attachment. Blood group antigen B revealed highest binding affinity among tested glycan candidates with a range of 100 μ M KD for the first binding event. A similar value was obtained by Saturation transfer difference nuclear magnetic resonance (STD-NMR). Another galactose containing natural glycan however showed similar binding affinity in native MS, while NMR data shows that single galactose cannot bind. The glycan mimetics binding affinity increases with increasing number of galactoses. The fucose containing mimetics showed good affinity but no avidity yet indicating that the spacing or rigidity requires further optimization. Another set of glycan mimetics based on these results are currently under investigation.

Keywords:

Native Mass Spectrometry, Noroviruses, Glycan, P domain, Binding.

593 - HUMAN SALIVARY GLYCOMICS FOR SALIVA-SPECIFIC SIGNATURES BY NANOPGC-LC/MS

Bum Jin Kim (1) - Jin Young Park (2) - Hyun Joo An (2)

Asia-Pacific Glycomics Reference Site, Chungnam National University, Daejeon (1) - Graduate School of Analytical Science and Technology & Asia-Pacific Glycomics Reference Site, Chungnam National University, Daejeon (2)

Keywords: Saliva, Glycosylation, Mass spectrometry, N-glycan, Forensic

Introduction:

Human saliva, which is often found at the scene of the crime, must be distinguished from other fluids in order to be recognized as legal evidence. However, conventional methods to identify saliva have lack of specificity due to cross-reactivity with other fluids. Here, we have explored saliva glycosylation using nanoLC/MS to examine saliva-specific signatures which can differentiate human saliva from other biological fluids.

Methods:

Whole saliva was collected from 30 healthy donors. N-glycans were directly released from saliva (50 μ L) by PNGase F and then enriched by PGC-SPE. Saliva N-glycans were comprehensively analyzed by nanoLC-PGC chip/Q-TOF MS and tandem MS. To determine human saliva-specific glycans, human saliva N-glycans were compared with human fluids and animal saliva. Individual and environmental variations of saliva glycosylation were also assessed.

Results:

Approximately 100 N-glycans were determined through human saliva samples. Interestingly, most glycans found in saliva were decorated with more than one fucose. In particular, highly fucosylated N-glycans containing at least 4 fucose residues were observed in abundance (up to 14%). Interestingly, sialylated N-glycans were highly abundant (>70%) in human serum. Acidic glycans with O-acetylation on a sialic acid were found in rat saliva as major components at a high rate while sulfation on outer HexNAc was solely observed in bovine saliva. Conclusively, highly fucosylated N-glycans (n=19) and significant fucosylation levels (> 50%) were determined as saliva-specific signatures for identifying human saliva from other vital fluids. These significant glycans were further investigated to validate individual variation and sample stability. Human saliva-specific glycans were consistently observed regardless of the collection date while they were gradually decreased during storage time of saliva (1, 2, 3, and 7 days) at room temperature.

Conclusions:

This study demonstrated the feasibility of MS-based glycomic approach for distinguishing human saliva from other body fluids. Nineteen highly fucosylated N-glycans were exclusively present in human saliva and fucosylated N-glycans account for more than 50% quantity of total glycans found in saliva. Saliva-specific glycans and their amounts can be used as a bio-signature to differentiate human saliva from other biological fluids in forensic science.

Novel Aspect:

For the first time human saliva-specific glycans were identified by mass spectrometry-based glycomic approach.

29 - SINGLE-INJECTION SCREENING OF 664 FORENSIC TOXICOLOGY COMPOUNDS USING AN INNOVATIVE BENCHTOP HIGH RESOLUTION MASS SPECTROMETER

Janna Anichina (1) - Oscar Cabrices (2) - Xiang He (2) - Holly McCall (2) - Laura Baker (2) - Alexandre Wang (2) - Adrian Taylor (3)

SCIEX, Product Applications Laboratory, Concord (1) - SCIEX, Applications, Redwood City (2) - SCIEX, Product Management, Concord (3)

Keywords: Quadrupole Time-of-flight mass spectrometry, drug screening, single injection

Introduction:

Quadrupole Time-of-flight mass spectrometry (QTOF-MS) provides high-resolution, accurate-mass data for full-scan information of both precursor and product ions making it ideal for forensic screening where unknown compounds in biological samples must be identified. In this presentation, a single-injection method for screening for the enhanced identification of 664 most up-to-date forensic compounds using an innovative benchtop QTOF-MS system is described

Methods:

Urine and whole blood samples were spiked with stock standard mixtures and used to determine the retention times of the 664 compounds. Samples were extracted and further diluted with mobile phase for chromatographic separation. Mobile Phase was ammonium formate in water and formic acid in methanol, 600 μ L/min flow rate. The QTOF-MS was operated in positive electrospray mode with information dependent acquisition MS/MS methods for accurate compound identification.

Results:

Separation performance was evaluated with different mobile phases (acidic and neutral), gradient conditions, and column types. Results indicate that most of isomeric compounds were fully resolved with a neutral buffer and a 10-min linear gradient. Analyte retention time (RT) was a critical element for accurate identification all 664 compounds using this screening method. Reproducibility tests indicated that the RTs obtained from the optimized LC conditions were consistent and reproducible. RTs measured have %CVs of less than 5% for all compounds. RT inter-day reproducibility resulted in %CVs less than 5% over 3 days. RT variability in human whole blood and urine samples indicated that the %CV for 3 individual lots is less than 5%. The optimized LC conditions combined with MS/MS spectra, enabled accurate compound identification with this workflow. Retrospective analysis was also performed on the acquired data sets to screen for new compounds without having to re-inject samples, allowing to re-process data sets as new targets were discovered.

Conclusions

We have developed a QTOF-MS screening method for 664 forensic compounds, the optimized LC conditions combined with MS/MS spectra, enabled accurate compound identification. In addition, because the data was acquired in a non-targeted approach the processing method designed here for screening targeted compounds can be quickly adjusted and used for unknown compound identification using a non-targeted data processing, without having to re-inject samples.

Novel Aspect:

High resolution Mass Spectrometry Analysis of 664 forensic compounds in a single injection using an innovative benchtop QTOF-MS system.

30 - ULTRA-SENSITIVE FORENSIC ANALYSIS WORKFLOW OF COCAINE AND METABOLITES IN HAIR SAMPLES USING LC-MS/MS

Janna Anichina (1) - Oscar G. Cabrices (2)

SCIEX, Product Applications Laboratory, Concord (1) - SCIEX, Applications, Redwood City (2)

Keywords: triple quadrupole linear ion trap mass spectrometry, Cocaine metabolites, hair analysis

Introduction:

Forensic analysis of cocaine in hair requires a sensitive and reliable analytical workflow. There are two major challenges for the detection of this compound and its metabolites in hair samples: Low concentration and matrix interferences. In this presentation, an analysis workflow combining the use of triple quadrupole linear ion trap mass spectrometry with solid phase extraction (SPE) for the of picogram detection of Cocaine and Metabolites in hair is described.

Methods:

Hair samples were washed, dried and cut into ~ 2 mm segments. The analytes were extracted via sonication for four hours. Supernatants were subsequently passed through SPE cartridges, dried and reconstituted in mobile phase for HILIC separation. Mobile Phase was ammonium formate in water and acetonitrile, 400 μ L/min flow rate. A SCIEX QTRAP[®] 6500+ LC-MS/MS system operating in positive electrospray mode was used for detection, with two MRM transitions for all analytes.

Results:

One of the main challenges encountered throughout the study was to obtain of clean hair extracts for the reliable detection and quantitation of cocaine and metabolites from hair due to the presence of complex matrix contents. To remove these interferences, Phenomenex Strata-X SPE cartridges were successfully used to selectively isolate the drug and its metabolites. Analyte extraction recoveries were demonstrated to be greater than 80 % enabling the analytical workflow to obtain sub pg/mg Lower Limits of Quantitation (LLOQ) in hair matrix. The workflow showed excellent accuracy (>95%) and precision (< 15%), with excellent linearity resulting in R² values of 0.9990 for all analytes. In addition to quantitation, the SCIEX QTRAP[®] 6500+ LC-MS/MS system enabled simultaneous identification and confirmation of illicit drugs and their metabolites through utilization of Enhanced Product Ion Scan (EPI) by acquiring full scan MS/MS data. Forensic drug identification and confirmation was achieved using automated MS/MS library searching.

Conclusions

A quantitative SPE-LC/MS/MS analysis workflow for simultaneous determination of Cocaine and metabolites at picogram levels was developed and evaluated in hair matrix. The method was demonstrated to be sensitive, precise and accurate. Utilization of the SCIEX QTRAP[®] 6500+ LC-MS/MS system was demonstrated to provide unique advantages in the ability to maximize selectivity when confirming and quantifying low level metabolites in hair.

Novel Aspect:

An efficient analysis workflow designed with triple quadrupole linear ion trap mass spectrometry allows the picogram detection of the cocaine and metabolite in hair samples

963 - FT-ICR FINGERPRINTING OF HUMAN FINGERPRINTS

Ana Cristina Assis (1) - Maria Helena Florêncio (2) - Carlos Cordeiro (2)

Laboratório de Polícia Científica da Polícia Judiciária, University of Lisbon/Laboratório de FTICR e Espectrometria de Massa Estrutural, FCUL, Lisbon (1) - University of Lisbon, University of Lisbon/Laboratório de FTICR e Espectrometria de Massa Estrutural, FCUL, Lisbon (2)

Keywords: FT-ICR-MS, ESI, Lipids, Forensic Analysis, Fingerprints

Introduction:

Identification of latent fingerprint composition has been carried out by several techniques. The technological development of recent years has boosted the increasingly visible use of mass spectrometry. However, so far, the chemical / biochemical fingerprint analysis has been performed by conventional mass spectrometry Methods:

Methods:

In the present work we characterized the lipidic profile of fingerprints on a non-porous surface by direct analysis using ESI-FT-ICR mass spectrometry and demonstrate the applicability of ESI-FT-ICR-MS with Electrospray Ionization (ESI) in the detection and characterization of lipids from human fingerprints.

Results:

In a single analysis, thousands of chemical species of different origins can be identified, thus generating extremely valuable information that will lead to a chemical signature of a person at a given time. Concerning lipids, 140 lipids were identified, corresponding to 13 FA sub-classes, 6 PR sub-classes, 17 ST sub-classes, 12 PK sub-classes, 2 SP sub-classes and 1 GL sub-class, making a total of 51 sub-classes.

Conclusions:

This technique uncovered a high number of lipid subclasses, both of endogenous and exogenous origin, like what will be obtained in real cases. This characterization will allow the identification of individualizing and differentiating elements to generate forensic evidence in criminal investigations.

Novel Aspect:

FT-ICR-MS analysis of human fingerprint.

423 - A QUALITATIVE/QUANTITATIVE LC-QTOF-MS ASSAY FOR FORENSIC DRUG SCREENING IN URINE – FEASIBILITY STUDY AND BASIC METHOD VALIDATION

Laura Huppertz (1) - Ronja Peter (1) - Michaela Schmidt (1) - Zoltan Czentnar (2) - Volker Auwärter (1)

University of Freiburg, Institute of Forensic Medicine, Freiburg (1) - Bruker Daltonik GmbH, Application/Applied, Bremen (2)

Keywords: HRMS, LC-QTOF-MS, qual/quant, screening, retrospective

Introduction:

For forensic analysis, screening methods using LC-QTOF-MS are valuable tools due to the possibility of qualitative/quantitative and retrospective data evaluation in a single run. Here, a workflow was validated for qualitative and quantitative analysis of drugs and drugs of abuse in human urine and to assess its limitations and to prove that cut-off values are met, a validation including LOD, LOQ, linearity, accuracy, selectivity, and precision was carried out.

Methods:

93 substances of forensic relevance were spiked into ten different urine samples at concentrations 1 - 50 ng/mL. Samples with internal standards were precipitated with acetonitrile. The dried residues were reconstituted and analyzed on three LC-MS systems (Bruker Elute UHPLC with impact II QTOF) in ESI pos. mode with full scan and broadband CID spectra. Data evaluation was performed with TASQ using a database with MS and chromatographic information on 2184 compounds.

Results:

Identification and semi-quantification at the lowest concentration (1.0 ng/mL) was achieved for 60 % of the compounds; four compounds (paracetamol, norclomipramine, piritramid, and levetiracetam) were not detected, probably due to matrix effects and/or low ionization yields. LOD was set to the concentration at which a substance was detected in 95% of all measurements according to the following identification criteria: retention time \pm 0.3 min, signal to noise ratio > 3:1 for all ions, $[M+nH]^{n+}$ and $[M+nH+1]^{n+}$ detected (MS), and at least two qualifier ions with minimum one being a true fragment of the molecular ion (bbCID). The precision ranged from 8 % to 30 %. Overall accuracy was good. Noteworthy, designer benzodiazepines and fentanyl derivatives were detected with extraordinarily high sensitivity. Typical 'date rape drugs' like flunitrazepam, doxylamine, and diphenhydramine showed LODs sufficient for detection of a recent uptake of these drugs.

Conclusions:

All substances with legal cut-offs according to German regulations were detected below the respective concentrations (factor 5).

Extrapolating the presented urine analysis results, application to blood and hair samples seems promising and is to be evaluated/validated. Given the high frequency of new psychoactive substances emerging on web-based drug markets, this is of great interest to the forensic field due to the possibility of retrospective data evaluation.

Novel Aspect:

Fully retrospective, highly sensitive qualitative/quantitative HRMS screening assay featuring semi-automated data acquisition and evaluation.

408 - ANALYSIS OF SUBSTANCES RELEVANT TO § 24A (2) OF THE GERMAN ROAD TRAFFIC ACT USING LC-MSN – A METHOD DEVELOPMENT AS A FIRST STEP TO AVOID IMMUNOASSAY PRE-SCREENING.

Jürgen Kempf (1) - Volker Auwärter (1) - Franziska Ehrhardt (2) - Zoltan Czentnar (3)

University of Freiburg, Institute of Forensic Medicine, Freiburg (1) - Offenburg University, Applied Sciences, Offenburg (2) - Bruker Daltonik GmbH, Application/Applied, Bremen (3)

Keywords: § 24a (2) road traffic act, method development, LC-ion trap-MS

Introduction:

Cases of suspected driving under the influence of drugs (DUID) according to § 24a (2) of the German road traffic act (RTA) usually pre-screened by immunoassay (IA) and positive results are confirmed by LC-MS/MS since neither the qualitative nor the quantitative information from IAs is admissible in court. We developed a fast and automated LC-MSN method, combining the ease-of-use of IAs with unambiguous compound identification of an MS analysis.

Methods:

Step one of this project covers a general feasibility study including two different data acquisition modes (AutoMSn and sMRM) for qualitative and/or quantitative analysis. It contains a sample preparation of 0.5 ml serum using LLE with chloroform/isopropanol, applicable for all relevant analytes except THC. Analysis is carried out on an Acclaim C18 column using a UltiMate3000 LC-system coupled to an amaZon speed ion trap within 5 minutes runtime.

Results:

During this study two data acquisition methods were evaluated and implemented: The Auto-MSn-mode facilitates fast and easy qualitative analysis with automated result reporting whereas the sMRM-mode offers a first quantitative estimate of the analyte concentration, simplifying subsequent confirmation analysis. Both methods include the § 24a (2) RTA relevant compounds amphetamine, methamphetamine, ecstasy, heroin, morphine, cocaine and benzoylecgonine as well as codeine and 6-acetylmorphine and have been validated according to the GTFCh guidelines. Selectivity and LODs were verified for both Methods: For the sMRM-method linearity, matrix effects, stability and accuracy were also determined. Measurement of 60 real case samples showed that neither the AutoMSn- nor the sMRM-method generated false-positive or false-negative results.

Conclusions:

Although sample preparation is still carried out manually at this point, the developed LC-MSN approach would be a suitable replacement for IA testing in DUID cases according to § 24a (2) RTA. As a next step of this project, an online SPE is currently evaluated and will be implemented to enhance the degree of automation of this approach.

Novel Aspect:

Detection of § 24a (2) RTA relevant compounds using a fast and robust LC-MSN method to avoid immunoassay pre-screening in routine DUID analysis.

875 - ISOLATION AND IDENTIFICATION OF THICK SKIN MICROBIOTA USING MALDI-TOF BIOTYPER

Giselle de Oliveira Dias (1) - Aline Maria Araújo Martins (2) - Rafael Persighini Del Sarto (3)

Polícia Civil do Distrito Federal, Universidade de Brasília, Brasília (1) - Universidade de Brasília/CEUB, Universidade de Brasília/CEUB/Medicine, Brasília (2) - Polícia Civil do Distrito Federal, Centro Universitário UDF/Health Sciences, Brasília (3)

Keywords: fingerprints, microorganisms, MALDI-MS, Biotyper, Forensic identification.

Introduction:

In current forensic sciences, the method of Analysis, Comparison, Evaluation and Verification (ACE-V) is used as an attempt to identify people who have been at a crime scene through latent fingerprints [1]. Due to the limitations of this technique, other analysis may be necessary for criminal prosecution, such as the skin microbiome that degrades the fingerprints, which is stable over time and can delimit the list of suspects [2], [3].

Methods:

Skin microbiome samples were collected from the distal phalanges of the right hand of 6 volunteers, grown in a blood agar plate at 37°C for 24 hours, followed by the isolation in a liquid medium cultivated in the same conditions. Then, an extraction protocol to MALDI-TOF-MS was performed, applying 1 µl of each supernatant in MSP96 plate. The microorganism identification was conducted using the MALDI Biotyper software. Ethical protocol for research under number CAAE 42845114.0.0000.5650.

Results:

Preliminary results identified the phyla Firmicutes and Actinobacteria as the most prevalent ones. The genera *Staphylococcus*, *Micrococcus* and *Bacillus* were identified with scores between 2,000 and 3,000 by Maldi Biotyper, presenting a safe result of genus and species. The species *S. epidermis*, *S. capitis*, *S. warneri* and *M. luteus* were the most abundant in comparison to *S. carnosus*, *S. conchii*, *S. hominis* and *B. licheniformis* species. Fresher microbial cultures present higher scoring results in MALDI MS with Biotyper. It was also identified diversity among genders, with higher diversity in female samples versus male samples. Also, it was found different diversity degrees between omnivorous and vegetarian diets within female gender, especially in the genera *Micrococcus* and *Bacillus*.

Conclusions:

In the human skin the microbial richness and diversity on the surface are affected by several factors, such as cosmetics, diet, diseases, age, sweat, hormone production, among others [4] - [9]. Due to these interferences, the microbial "impression" would be individual [2]. Mass spectrometry by MALDI-TOF offers fast and accurate results [10] - [12] and its use in the forensic microbial analysis will provide an analytical reproducible scientific evidence for forensic experts.

Novel Aspect:

The use of mass spectrometry by MALDI-TOF and Biotyper to characterize individual and common microbiome for application in Forensic Identification.

864 - GREEN FORENSICS - ISOTOPIC TRACEABILITY IN HORTICULTURE GEOGRAPHICAL ORIGIN OF ROSES

Eva de Rijke (1) - Meyci Trisna (2) - Suzan Verdegaal (3) - Runa Magnússon (1) - Jorien Schoorl (1) - Chiara Cerli (1) - Chris de Koster (2)

University of Amsterdam, Institute for Biodiversity and Ecosystem Dynamics, Amsterdam (1) - University of Amsterdam, Swammerdam Institute of Life Sciences, Amsterdam (2) - VU University Amsterdam, Faculty of Earth and Life Sciences, Amsterdam (3)

Keywords: forensics, isotope ratio mass spectrometry, GC-MS, roses, geographical origin

Introduction

Roses are the most important Dutch cut flowers and are grown by companies under a global GAP (Good Agricultural Practice) certificate that is used by e.g. European supermarket organizations. Certified companies have strict requirements for safe, sustainably grown, high-quality and traceable products. Next to the Netherlands, Kenya and Ecuador are the main exporting countries for roses. The question rises whether roses of unknown origin, which do not meet these strict requirements, or roses from areas with a phytosanitary export ban due to occurrence of certain plant diseases, are exported illegally under this certificate to the EU. Therefore, UvA, Naktuinbouw and De Ruiters BV develop isotope analysis technology for provenance determination of roses. The stable isotopic composition of H, C, N and O from plant materials depends on regional geological and climatic patterns, and therefore provides a regional fingerprint of the plant.

Methods

In this study, we focus on development of methods for isotope ratio and gas chromatography (GC) mass spectrometry analysis of stems and water from roses that were harvested monthly throughout the 9-month season. Elemental analysis (EA) coupled to isotope ratio mass spectrometry (IRMS) was applied to investigate the use of $\delta^{13}\text{C}$, $\delta^{15}\text{N}$ and total C and N profiles in the stems as a fingerprint for the country of origin. Furthermore, the $\delta^{18}\text{O}$ isotopic composition of the xylem water in the rose stems, extracted via freeze-drying, was linked to $\delta^{18}\text{O}$ of irrigation water and the GNIP (Global Network of Isotopes in Precipitation) IAEA database, to determine differences between roses from different geographical origins. A third method used was quantitative GC-MS analysis and compound specific GC-IRMS analysis of leaf wax alkanes, extracted via solid phase extraction.

Results

The best separation of the groups was obtained from the water analysis using a combination of the $\delta^2\text{H}$ and $\delta^{18}\text{O}$ values of the rose and irrigation source water. The optimal time of freeze drying was at least 22 hours. $\delta^2\text{H}$ and $\delta^{18}\text{O}$ values of source water do not vary much over the season and the variation within one batch is low, furthermore they correspond well to the global mean water line (GMWL). The results show a correlation between the source water and the local long-term GNIP averages (Pearson's $R = 0.9168$ for $\delta^2\text{H}$ and 0.9029 for $\delta^{18}\text{O}$) and between the stem- and source water (Pearson's $R = 0.9959$ for $\delta^2\text{H}$ and 0.9921 for $\delta^{18}\text{O}$), with constant isotope fractionation between the source and the rose water data of about -4 . $\delta^{13}\text{C}$ and $\delta^{15}\text{N}$ values of bulk rose stem analysis with EA-IRMS can also be used to distinguish roses from different origins, especially Dutch roses which were clearly separated from Ecuadorian and Kenyan samples. The measured $\delta^{15}\text{N}$ isotope values also correspond well to the reported literature values [1], even though other plants were used in this study. GC-MS analysis of the relative concentrations of C_{27} , C_{29} , C_{31} and C_{33} in leaf wax extracts showed clustering according to the country of origin. In a previous study, similar results were obtained for the same alkanes in bell pepper [2, 3].

Conclusions

Three analytical strategies were investigated, based on IRMS analysis of $\delta^2\text{H}$ and $\delta^{18}\text{O}$ of rose and irrigation source water, $\delta^{13}\text{C}$ and $\delta^{15}\text{N}$ of rose stems, and on quantitative GC-MS analysis of leaf wax n-alkanes. All strategies were

able to discriminate between Dutch, Ecuadorian and Kenyan roses that were monitored monthly throughout the season. The source water and long-term regional GNIP data showed good correlation with the rose water data, with constant isotope fractionation of about -4. These multi-isotopic methods are therefore suited as a tool to verify the geographical origin of roses in order to prevent fraud and phytosanitary problems.

Novel Aspect

This is the first time a combined strategy of multi-isotopic EA-IRMS and quantitative GC-MS methods has been developed as a tool to verify the geographical origin of roses.

794 - THE DEATH OF THOMAS CHATTERTON - AN LC-MSN INVESTIGATION.

Paul Gates (1)

University of Bristol, School of Chemistry, Bristol (1)

Keywords: morphine, degradation, forensics, LC-MS/MS

Introduction: (Limit of 400 characters without spaces)

Thomas Chatterton (1752 – 1770) was a literary genius who tragically died in unexplained circumstances [1]. At the time, the Coroner claimed that he “swallowed arsenic in water and died, in consequence thereof” despite no arsenic being found at the scene. In his belongings was a memorandum book, which had a dark stain running through its pages. A police forensics report in 1947 stated that the stain “gives a positive reaction for opium alkaloids” but gives no further details.

Methods: (Limit of 400 characters without spaces)

Herein, is a study to try to shed some light on Chatterton’s death using high resolution LC-MS on an Orbitrap Elite instrument. Preliminary tests were performed with codeine (an opium alkaloid) to test if it was possible to recover it from paper after being deposited. This test proved successful, so then a sample of a stained page from the memorandum book was extracted using methanol and dichloromethane and analysed by the same Methods:

Results: (Limit 900 characters without spaces)

The preliminary study showed the recovery of codeine from office paper. The extracts also contained unidentifiable components probably from the paper itself, as well as the common phthalate and siloxane contaminants. Codeine was recovered intact as well as some possible degradation products, but these were not investigated further. In the main study, a 2mm² sample of a stained page from the memorandum book was extracted and analysed by both direct infusion ESI-MS and HPLC-MSn. As expected, from a sample of this age, the extract was very complex, and no signal was observed for any intact opium alkaloids. The LC-MS analysis, however, showed a cluster of at least 15 peaks with molecular weights in the 200-300 m/z range. 8 of these have been confirmed by accurate mass MS/MS analysis to be known degradation products of morphine [2]. A further 7 components have also been identified as being possible unpublished degradation products of morphine, codeine or thebaine.

Conclusions (Limit of 400 characters without spaces)

This study demonstrates the extraction and identification of at least 8 known morphine degradation products from a 250-year-old book by high-resolution HPLC-MSn. The presence of a further 7 opium alkaloid degradation products is also proposed. These results indicate that the stain originally contained opium alkaloids, most probably in the form of laudanum – a popularly prescribed medical treatment of the day.

Novel Aspect: (Limit of 150 characters without spaces)

The demonstration of modern analytical methods to the study of a ‘mystery’ stain in a 250-year-old book found at the scene of an unexplained death in 1770.

325 - VALIDATION OF BLOOD PROTEOMIC SIGNATURES FOR THE FORENSIC DETERMINATION OF BLOOD AND ITS PROVENANCE

Cameron Heaton (1) - Lisa Deininger (1) - Ekta Patel (1) - Malcolm. R Clench (1) - Vaughn Sears (2) - Chris Sammon (3) - Laura Cole (1) - Simona Francese (1)

Sheffield Hallam University, Biomolecular Research Centre, Sheffield (1) - Home Office, Centre for Applied Science and Technology, St Albans (2) - Sheffield Hallam University, Materials and Engineering Research Institute, Sheffield (3)

Keywords: Blood, Forensics, Proteomics, MALDI

Introduction

Analysis of blood at a crime scene can inform an investigation but current enhancement techniques can provide false positives. Bottom up proteomic MScandetect blood and indicate its origin [1]. Blood specific proteins can be visualised directly on the ridges of a fingerprint [2]. In this study, human and animal blood, biofluids, and substances that elicit a positive response to presumptive tests have been examined pre- and post-enhancement. Blood identification was based on proteotypic peptides. Manual and automated PMF methods were trialled to identify the samples.

Methods

Bloodstains and fingerprints on glass slides were received from Elite Forensics®. Stains were digested with 250 µg/ml trypsin after swabbing and extraction, followed by spot analysis via MALDI MS Profiling. Fingerprints were digested in situ using a SunCollect auto-spraying system, incubated for 1 hour and then sprayed with matrix (αCHCA) using the same system. MALDI analyses were carried out on a Synapt G2 HDMS. Images were processed using Waters HDI software.

Results

Preliminary results show a 100% correct identification rate when human blood samples were analysed blindly in enhanced and non-enhanced form. This classification rate is based on 1/3 of the samples analysed so far. The prior use of blood enhancement techniques has not interfered with the retrieval of proteotypic peptides. Other biofluids and substances such as egg yolk were correctly classified as non-blood. Manual PMF is based on specific criteria including ion signal exclusion from the mass lists. Whilst manual PMF is highly successful in sample classification, the use of the automatic PMF software correctly attributes human blood with a low probability score. Animal blood presents additional difficulties. Prior investigations have correctly classified animal blood. In this study, some animal blood samples were classified as non-blood, likely to be as a result of blood sampled from meat packets rather than venous blood, which has led to the acquisition of spectra with low signal to noise impacting on the PMF, both in manual and automatic mode.

Conclusions

This first stage validation study has developed methods to correctly classify human blood and non-blood samples. Whilst correct classification of animal blood is possible, determination of provenance has been compromised. Further research into improvement of MS acquisition methods as well as of the treatment of the data is in progress. Venous animal blood (instead of from meat packets) will also be trialled and results compared to assess robustness of the Methods:

Novel Aspect

Proteomics MALDI MS methods were validated for use in police casework. Robustness of PMF software using a peptide library was assessed against manual PMF of proteotypic peptides.

draft

1217 - EXTENDED MASS SPECTROMETRY WORKFLOW FOR THE ANALYSIS OF DRUGS OF ABUSE IN BIOLOGICAL FLUIDS AND TISSUES

Gérard Hopfgartner (1)

Life Sciences Mass Spectrometry, University of Geneva, Switzerland (1)

Keywords: Drugs of Abuse, LC-MS, Data Independent Analysis, SWATH, Differential Ion Mobility Spectrometry, ExD

Introduction:

Screening of Drugs of Abuse (DoA) in biological matrices is mainly based on triple quadrupole or high resolution mass spectrometers using data dependent acquisition workflows (DDA). The development of data independent acquisition such as SWATH, differential ion mobility (DMS) and electron induced dissociation (ExD) opens new possibilities for comprehensive and multidimensional for simultaneous qualitative and quantitative analysis.

Methods:

Data were acquired on either a triple quadrupole linear ion trap (QTRAP5500, Sciex) equipped with DMS (Selexion, Sciex) or a quadrupole time of flight equipped with DMS and a prototype chimeric collision cell allowing to perform collision induced dissociation (CID) or electron induced dissociation (EID). Human urine samples were analyzed using reversed phase liquid chromatography.

Results:

Various workflows have been development for the direct analysis of DoA on tissues or in biological fluids such as urine using multidimensional MS approaches. For direct MS analysis using ambient ionization or for LC-MS modifier assisted DMS offers an additional separation dimension. Contrarily to pharmaceutical investigation toxicological screening cannot rely and the origin/nature of the drug neither on the intake time nor the frequency. Comprehensive LC-SWATH/MS allows to collect in the same analysis precursor ions as well as fragment ions. Information can be obtained either hypothesis driven or with the use of multivariate analysis post-acquisition. This provides a powerful tool for the screening of DoA as well as the monitoring of the exposome or to monitor the change in endogenous metabolites in human urine samples. In addition to CID electron induced dissociation of singly charged precursor ions (protonated or adducts) generates additional information for structural identification of metabolites.

Conclusions

The complexity of biological samples and the problematic of DoA call for improved methods for screening and quantification. Novel development in mass spectrometry such as DIA, ion mobility and EID with or without chromatography separation can be used to extend the toxicological knowledge as the intake of a DoA can also be monitored based on theircontaminants.

Novel Aspect:

Integration of data independent acquisition, ion mobility and electron induced dissociation in drug abuse screening.

587 - DEVELOPMENT AND VALIDATION OF A GAS-CHROMATOGRAPHY MASS SPECTROMETRY METHOD FOR THE ANALYSIS OF TESTOSTERONE ESTERS IN BIOLOGICAL MATRICES

Michele Iannone (1) - Claudia Lattanzi (1) - Francesco Botrè (2) - Xavier de la Torre (1)

Laboratorio Antidoping FMSI Rome, Dipartimento di Chimica e Tecnologia del Farmaco, Sapienza University of Rome, Rome (1) - Laboratorio Antidoping FMSI Rome, Dipartimento di Medicina Sperimentale, Sapienza University of Rome, Rome (2)

Keywords: Testosterone esters, doping analysis, gas-chromatography, mass spectrometry.

Introduction:

The detection of pseudoendogenous steroid doping is currently based on the evaluation of the urinary steroid profile as described in WADA Technical Document TD2016EAAS [1]. Despite this some physiological and/or pathological conditions it could compromise the application of these criteria [2-3]. For this reason the direct detection of intact synthetic esters of testosterone in plasma/serum gives unequivocal proof of exogenous testosterone administration.

Methods:

After liquid-liquid extraction at pH 9 (carbonate buffer 20% w/v) with n-hexane/ethylacetate (70/30 v/v) [4] all plasma/serum samples were analyzed by gas-chromatography coupled to tandem mass spectrometry (GC-MS/MS) with electronic impact (EI) ionization and multiple reaction monitoring (MRM) acquisition mode. Testosterone esters were revealed as trimethylsilyl derivatives.

Results:

In the first step of our work a qualitative validation was carried out for all testosterone esters studied (acetate, propionate, valerate, isocaproate, caproate, benzoate, hexahydrobenzoate, enanthate, cypionate, octanoate, decanoate, phenylpropionate, undecanoate, laurate). Considered parameters are specificity/selectivity and limit of detection. According to the WADA rules [5] were also investigated the mass spectrometric and the chromatographic criteria for the identification of analytes for doping control purposes. The criteria were satisfied for twelve compounds and the method is specific and selective for all of these.

In a second step a quantitative validation was carried out for five compounds present in the most marketed pharmaceutical preparations probably abused by athletes. Considered parameters are specificity/selectivity, limit of detection and quantification, recovery, linearity, repeatability and accuracy. The selected esters are identified and quantified in plasma/serum with an error less than 15 %.

Conclusions

The determination of testosterone esters in plasma/serum by GC-MS/MS should allow a confirmation of the administration of exogenous testosterone for doping purpose. The presented method was qualitatively validated for twelve esters and quantitatively validated for five esters and can be used to detect the presence in blood of those testosterone esters currently present in pharmaceutical preparations that can be abused by athletes.

Novel Aspect:

Number of esters detected in each sample and possibility to confirm the composition of seized pharmaceutical preparation by responsible authorities.

324 - IDENTIFYING WOOD FROM PROTECTED SPECIES WITH DART FINGERPRINT SPECTRA AND THE SOFTWARE PLATFORM OMFF

Sandra Martínez-Jarquín (1) - Cady Lancaster (2) - Ed Espinoza (3) - Robert Winkler (1)

CINVESTAV, Biochemistry and Biotechnology, Irapuato (1) - U.S. Forest Service, National Fish and Wildlife Forensic Laboratory, Utah (2) - U.S. Forest Service, National Fish and Wildlife Forensic Laboratory, Oregon (3)

Keywords: DART-MS, wood identification, software, fingerprinting, ambient ionization

Introduction

According to the Food and Agricultural Organization (FAO), global production of major wood products increases at a 3-6% per year. Some commercially valuable wood treated products are illegally used from endangered tree species, that are not easily identified. DART-MS has been used to differentiate morphologically similar species with great results [1–3]. We want to build a software with a scalable reference database for forensic applications.

Methods

Reference spectra are generated from wood libraries at the Forensic Laboratory for Wildlife and Fish (US Forest Service) from different tree species and samples. An SQL reference database was constructed with 4,950 spectra from 301 different species. The Open Mass Fingerprinting Framework (OMFF) was designed as a webpage for easy distribution, with html and bootstrap at the front end and Django to improve security of the back end. Multivariate statistical analysis was implemented for data processing and identifying specific chemical markers.

Results

A software for tree identification based on the DART-MS chemical profile data was constructed (OMFF). DART-MS provides a fast analysis which requires minimal time and amount of sample making it ideal for processed wood products (guitars, furniture, etc.). The program is user-friendly, open source webpage that includes a reference database for identifying of wood samples. Specific chemical markers are obtained from DART-MS fingerprint reference spectra and compared with unknown samples. The results provide a list of species with a comparison probability score. The software produces statistically meaningful information. While the number of samples for some species in the reference database is small, the system can be expanded. The program was designed for non-expert users; therefore, it can be implemented at critical points such as customs and ports.

Conclusions

The implementation of the OMFF software will help diminish traffic of protected wood species. CITES provides tools for wood identification such as morphological, DNA and microscopy characterization. Using all the available tools will improve identification confidence levels for wood species.

Novel Aspect

OMFF provides a reference database and reliable classification mechanisms for non-expert users to identify morphologically similar wood samples.

1089 - ELEMENTAL ANALYSIS OF INK BY LASER ABLATION INDUCTIVELY COUPLED PLASMA MASS SPECTROMETRY (LA-ICP-MS)

Aleksandra Pawlaczyk (1) - Karolina Załęcka (1) - Małgorzata Iwona Szykowska (1)

Lodz University of Technology, Faculty of Chemistry, Institute of General and Ecological Chemistry, Lodz (1)

Keywords: forensic analysis, chemometric methods, inks, questioned documents, LA-ICP-MS

Introduction:

In real cases the analysis of questioned documents is undertaken with mostly non-invasive methods of examination of paper base & covering materials. The methods applied should provide reliable and sufficient information to address the following questions like whether the document is genuine, if it has been altered (e.g. erased, bleached, faded) or reproduced, if the covering materials (toners, inks) appearing on each page of document have the common source [1].

Methods:

ICP Mass Spectrometer with Time-of-Flight Analyzer coupled with Laser Ablation system was applied for inorganic chemical elements characterization of different inks. In this study 13 random, promotional pens were collected and used to leave a straight few cm lines on a white piece of paper. The LA-ICP-MS parameters were optimized in order to achieve satisfactory intensity of the ink signal for selected m/z , leaving the paper base almost untouched.

Results:

Inks are complex mixtures of different colorants, vehicles, and additives, which depending on the company, color and type are adjusted in composition to produce the desired writing characteristics. In order to avoid loss or destruction of a potential forensic evidence hardly destructive methods like LA-ICP-MS are desirable. This technique with high discrimination and classification power can be successfully applied to differentiate inks on the same document as well as to compare inks on other documents. In this work the mass spectra profiles for each randomly selected & commercially available on the market inks (blue and black) were recorded and compared. They all presented specific elemental features which made them distinctly different from each other. The gathered information about elemental composition differences was supported by the feedback from chemometric Methods: In the next step of analysis the "unknown" sets of 3 chosen samples using studied pens were prepared, tested, discriminated and classified according to created model.

Conclusions:

The gathered data originating from collected mass spectra coupled with multivariate statistical methods present a useful tool for discrimination of studied unknown inks with insubstantial sample destruction and without any methodological calibrations, which all being crucial from a forensic practice point of view. The same methodology can be applied to analyze real handwritten questioned documents since there is a justified need to use non-destructive Methods:

Novel Aspect:

There is a constant need to create method with high discrimination power which can deliver objective results offering the differentiation among brands & within the same brand.

462 - DETECTION OF RICIN AND ABRIN TOXINS IN COMPLEX MATRICES BY TWO NOVEL GALACTOSE ENRICHMENT METHODS AND HIGH RESOLUTION LC-MS/MS

Anne Puustinen (1) - Marja-Leena Rapinoja (1) - Maaret Karjalainen (1) - Paula Vanninen (1)

Verifin, Dept of Chemistry, University of Helsinki, Helsinki (1)

Detection of ricin and abrin toxins in complex matrices by two novel galactose enrichment methods and high resolution LC-MS/MS

Anne Puustinen, Marja-Leena Rapinoja, Maaret Karjalainen and Paula Vanninen
VERIFIN, Department of Chemistry, University of Helsinki, Finland

Keywords: ricin, abrin, galactose affinity, LC-MS/MS

Introduction:

Ricin and abrin are highly poisonous plant toxins belonging to the type 2 ribosome-inactivating protein (RIP-II) family. These proteins are composed of A- and B-chains linked by a single disulphide bond. The A-chain confers cellular toxicity, while cellular entry is through the galactose binding properties of the B-chain, which can be utilized for isolation of these toxins. There is a demand for improving toxin detection capabilities due to the terrorism threat posed by them.

Methods:

Immobilized D-galactose gel (Thermo Scientific) in self-packed microspin columns and home-made galactose-coated 96-well microplates were utilized for enrichment of ricin and abrin from different kind of samples. Peptides from the trypsin digested protein samples were identified by high resolution mass spectrometry analysis (EASY nanoLC linked to Fusion Orbitrap, Thermo Scientific). Released adenine in the depurination activity assay was measured with LC-MS/MS (UPLC linked to Xevo TQD, Waters).

Results:

Two rapid galactose affinity enrichment methods were developed for ricin and abrin analysis from complex matrices. Miniaturized immobilized D-galactose gel affinity columns were shown to be suitable for trace enrichment and high sample throughput. This method can also be adapted for preparative purification of RIP-II toxins. Also the solid-phase enrichment by galactose array worked for trace enrichment and can be automated with microplate automation instruments.

Ricin and abrin are fairly resistant to proteolysis. Protein unfolding was done with an acid-labile surfactant - urea mixture before digestion with trypsin. Identities of the resulting peptides were unambiguously confirmed by accurate mass LC-MS/MS product ion scans of peptides unique to each of the toxins. Quantification was accomplished with isotope labeled AQUA peptides for both proteins and the achieved sensitivity and detection limits were comparable to those of immunocapture enrichment Methods:

Conclusions:

Both galactosyl ligand methods were shown to have the capacity to enrich trace amounts of ricin and abrin from various matrix extracts. Together with functional assay results, the high resolution LC-MS/MS data provides

unambiguous identification of ricin and abrin in the samples. The solid-phase enrichment by galactose array can be adapted for high-throughput screening.

Novel Aspect:

High throughput galactose affinity methods for ricin and abrin with detection limits similar to the ones reported for other enrichment methods were developed.

432 - LC-HRMS VS NMR FOR THE IDENTIFICATION OF KETOCAINE IN SEIZED MATERIAL

Anna Maria Caputo (1) - Serena Detti (1) - Sabino Napoletano (1) - Giovanni De Sangro (1) - Rosanna Sacrpone (2) - Fabio Sciubba (3) - Flaminia Vincenti (3) - Manuel Sergi (4) - Dario Compagnone (4)

Ministry of Interior, Dep. of P. S., Forensic Police Service of Italian National Police, Drugs of Abuse Section, Via Tuscolana 1548, Rome (1) - Istituto Zooprofilattico Sperimentale dell'Abruzzo e del Molise 'G. Caporale', Bromatology, Teramo (2) - Sapienza University, Chemistry, Rome (3) - University of Teramo, Faculty of Bioscience, Teramo (4)

Keywords: Forensic analysis; HRMS; NMR; Ketocaine

Introduction: The timeliness of analytical assessments is fundamental for Police forces, initially relying on rapid drug-screening tests. Scientific Police Service of Italian National Police adopts Young's reagent for the detection of cocaine; however, there are numerous examples of false positives that require attention to the interpretation of test result and, in some cases, confirmatory analysis must be performed. In this study an interesting case is presented.

Methods:

The analytical protocol adopted for the identification of the suspect compound involved both NMR and HRMS. The sample was divided into two aliquots: one was analysed by means of LC-HRMS with Orbitrap technology and the other one was subjected to analysis by NMR. The two techniques have not been used in a complementary but compositive way: namely the analysis have been performed independently.

This approach involved both the comparison of the molecular ion and the fragmentation pattern with the database spectra by differential analysis, providing stronger identification.

Standard ^1H and ^{13}C NMR spectra were coupled with two-dimensional experiments: ^1H - ^1H TOCSY, ^1H - ^1H COSY, ^1H - ^{13}C HSQC and ^1H - ^{13}C HMBC.

Results:

LC-HRMS identified Ketocaine by involved both the comparison of the molecular ion and the fragmentation pattern by differential analysis, from spectra database Compound Discoverer 2.0, using ChemSpider as source. Forensic identification require something more (more identification points), so the study of the molecule and its fragmentation was also performed. The match of theoretical fragmentation pattern with the experimental one confirmed the identification.

NMR experiments carried out in different acquisition modes (^1H - ^1H TOCSY, ^1H - ^1H COSY, ^1H - ^{13}C HSQC and ^1H - ^{13}C HMBC) led to a suitable amount of data for a correct identification of the unknown compound: the interpretation of spectra and the signals assignment led to identification of ketocaine.

Conclusions

In this case, both NMR and HRMS proved themselves as self-sufficient techniques in the resolution of the analytical-forensic problem: in particular, HRMS, with the advantage of the speed of analysis and interpretation of data thanks to dedicated software, proves of undoubted utility for forensic investigations.

Novel Aspect:

The suitability of HRMS as a self-sufficient technique in the resolution of the analytic-forensic problem was demonstrated for the identification of unknown compound.

850 - TARGETED AND UNTARGETED ANALYSES BY MEANS OF LC-MS TO CHARACTERIZE THE ILLICIT SUBSTANCES ON SEIZED MATERIAL OF VEGETAL ORIGIN.

Caporale', Bromatology, Teramo (3) - University of Teramo, Faculty of Bioscience, Teramo (4) - Sapienza University of Rome, Dept. of Chemistry, Rome (5) - University of California, Collaborative Mass Spectrometry Innovation Center, San Diego (6)

Keywords: illicit drugs, seized material, LC-MS, Molecular Network, in-silico annotation

Introduction:(Limit of 400 characters)

In the field of investigations in drugs of abuse, one of the objectives of the police forces is the characterization of the spread and the consumption of psychotropic substances: this helps to trigger adequate monitoring and prevention measures [1]. Through different techniques, it is possible to identify the components present in seized samples in order to characterize the illicit substances.

Methods:(Limit of 400 characters)

A combination of targeted and untargeted analyses were performed on seized material of vegetal origin. Screening test and GC analyses showed an unusual combination of compounds. UHPLC-MS/MS analyses were performed in IDA and in MRM. LC-HRMS analyses followed by elaboration of raw data files by means of GNPS webplatform and in-silico annotations in order to predict the structure of all illicit compounds.

Results: (Limit 900 characters)

On the basis of the preliminary analyses there was the suspect of different tryptamine compounds in the seized samples so a semi-untargeted analysis by UHPLC-MS/MS were performed in IDA, showing different tryptamines that were confirmed in MRM (i.e. DMT, NMT, 2-MTHBC), together with some cannabinoids, including THC, in one sample. This issue stimulated further investigations.

With the aim to obtain a complete overview of all features, untargeted HPLC-HRMS analysis was performed. Molecular Network was generated to perform cluster of similar MS/MS spectra and to propagate spectral annotation of seized drug samples. Data shows that different compounds, belonging to tryptamines, were confirmed by spectral library search annotation on GNPS. Other 8 tryptamines were assigned comparing the results obtained with MRM analysis and similar pattern of fragmentation using in-silico prediction annotation.

Conclusions:(Limit of 400 characters)

Through different analytical techniques, it was possible to identify the main vegetable components present in samples. Combination of targeted/untargeted analysis and molecular network proves to be a useful tool for forensic investigations. Untargeted analysis and in-silico annotation allowed detecting 8 compounds undetected by MRM analysis and confirming the analytes detected in target analysis.

Novel Aspect:(Limit of 150 characters)

Combination of targeted/untargeted analysis, with suitable data managing, resulted necessary to characterize seized sample for subsequent evaluations.

1363 - APPLICATION OF TOF-SIMS TECHNIQUE TO DETECTION AND IMAGING OF FINGERPRINTS CONTAMINATED BY CANNABIS

Elzbieta Mackiewicz (1) - Jacek Rogowski (1) - Andrzej Parczewski (2) - Malgorzata Iwona Szykowska (1)

Lodz University of Technology, Faculty of Chemistry, Lodz, Poland (1) - Jagiellonian University, Faculty of Chemistry, Krakow, Poland (2)

Keywords: fingerprints; imaging; TOF-SIMS; drug analysis; development of latent fingerprints

Introduction:

Fingerprints are the most important form of evidence in the human identification [1]. Moreover, they may be composed of a number of different contaminants, for example psychoactive substances [2,3]. During the last few years, time-of-flight secondary ion mass spectrometry (TOF-SIMS) has become a very sensitive analytical technique in surface science [2,3]. This technique can be used in chemistry and forensic science for detection of various molecules (drugs).

Methods:

The mass spectra and images of the studied samples were recorded using secondary ion mass spectrometer TOF-SIMS IV (ION-TOF GmbH, Münster, Germany), which is equipped with a high mass resolution time-of-flight analyser of a reflectron type. During analysis, Bi³⁺ primary ion gun was used, working at 25 keV and an average ion current was 0,5 pA. The analysis areas were 100 × 100 μm² and 500 × 500 μm² for obtaining secondary ion mass spectra and images, respectively.

Results:

Time-of-flight secondary ion mass spectrometry (TOF-SIMS) was applied in the forensic research for detecting and imaging of cannabis in the fingerprints. The studied fingerprints were: 1. imprinted directly on the lift tape by a contaminated finger with cannabis; 2. left on a glass surface and developed with two types of latent fingerprints powders; 3. transferred using the lift tape.

In the positive and negative ion spectra of the studied samples many peaks derived from cannabis can be detected: cannabidiol, cannabidiol, tetrahydrocannabinol, cannabivarin, cannabidiolic acid. The ions characteristic of the powder, sweat and marijuana are also visible in the spectra of fingerprints revealed with latent fingerprints powder and transferred with lift tapes.

Conclusions:

The TOF-SIMS technique appears to be a very effective and useful tool in forensic investigations, which enables the identification of drug residues left on fingerprints imprinted on selected bases. Moreover, it has been shown that revealing fingerprints with the black fingerprint powder is not disadvantageous for the TOF-SIMS application in the fingerprints analysis.

Novel Aspect:

There is a possibility of detecting foreign substances on fingerprints, such as drugs, after revealing fingermarks with the latent fingerprint powder.

1364 - TOF-SIMS DETERMINATION OF DETECTION LIMIT OF AMPHETAMINE IN 'STREET DRUGS' AND POLLUTED FINGERPRINTS

Magdalena Gajek (1) - Elzbieta Mackiewicz (1) - Jacek Rogowski (1) - Andrzej Parczewski (2) - Małgorzata Iwona Szyrkowska (1)

Lodz University of Technology, Faculty of Chemistry, Lodz, Poland (1) - Jagiellonian University, Faculty of Chemistry, Krakow, Poland (2)

Keywords: Secondary ion mass spectrometry, fingerprints, drugs, forensic research, image technique

Introduction:

ToF-SIMS technique is a very effective and powerful method to examine the surface composition of different materials, including those of key importance in the forensic chemistry i.a. drugs [1-2]. Currently, drugs sold in the streets contain a variety of different 'fillers'. It is important to develop a method which has discrimination power and will allow simultaneous identification of all substances present in the mixture, even in very small quantities.

Methods:

The aim of this study is focused on the evaluation of the TOF-SIMS technique as a potential tool applied in the forensic analysis of fingerprints. Studied fingerprints were contaminated with trace amounts of amphetamine and other substances which are typically used as 'fillers'. These compounds do not occur naturally on fingertips and can present a significant value as evidence linking the suspect with the crime scene.

Results:

In this work, clean fingerprints as well as contaminated by drug were investigated. Moreover, in order to determine the limit of detection of amphetamine, the analysis of drug tablets containing various amounts of mixtures of amphetamine and caffeine (filler) in different proportions was performed. This assessed LOD was 0,625%. Also fragmentative ions derived from amphetamine and caffeine were examined, which undoubtedly indicted their potential origin. Additionally, the ToF-SIMS technique allowed the visualization of the fingerprint contaminated by a trace amount of powdered drug.

Conclusions

The results of this study has demonstrated that the ToF-SIMS technique is a powerful tool which enables the identification of drug traces left on a contaminated fingerprint. This method allows the determination of very small amounts of the drug. Moreover, ToF-SIMS technique enables not only the identification of the substance forming the fingerprint but also the visualization of very small areas of the fingerprint, including the course of the fingerprints.

Novel Aspect:

Novel aspects are: designing a method enabling the assessment of LOD of amphetamine in home made tablets and its identification and visualization in the fingerprints course.

Keywords: NPS, Nootropics substances, Metabolites, LC-HRMS

Introduction:

New psychoactive substances (NPS) represent a tough challenge, since analytical standards are not available or included in libraries[1]. When metabolic pathway is unknown, determine target analytes is critical, so metabolites identification become fundamental for clinical and forensic investigations[2]. The aim of this work was to identify the metabolites of Modafinil, a synthetic nootropic[3].

Methods:

In-silico experiments were carried out by means of MetaPrint2DReact program, used to predict possible metabolites and cultures of rat hepatocytes were used for in vitro experiments. In order to obtain information about chemical structure of metabolic pathway, LC-HRMS experiments were carried out by means of Orbitrap analyzer, while analytes separation was carried out using a PFP-C18 Column.

Results:

Once the smile code was introduced in the in silico program, a total of 15 metabolites were predicted: 7 of phase I and 8 of phase II. The incubation with hepatocytes allowed to mimic the physiological environment of the liver[4], in which the substances would be found, obtaining a realistic picture of the metabolic pathway for Modafinil. The results obtained in silico allowed to hypothesize the metabolites structures and masses to be searched in HRMS. As a positive control of the real metabolic activity of the cells, Modafinil and its metabolites were used: Modafinil Acid and Modafinil Sulfone have been identified. In the samples obtained from in vitro experiments 6 metabolites were identified, 2 belonging to phase I and 4 belonging to phase II. In order to characterize the observed metabolites, analyzes were performed in PRM at different collision energies (NCE).

Conclusions:

In this work the chemical structures of the Modafinil metabolites were identified using rat hepatocyte followed by UHPLC-HRMS analysis. The most produced metabolites are dehalogenated derivatives obtained from an initial oxidation reaction, as regards the phase I metabolites and the metabolites conjugated with glucuronic acid or methylate, deriving from the phase II reactions.

Novel Aspect:

For the first time metabolic pathway of Modafinil was identified. This information is essential to develop methods to confirm the use of this NPS[5].

262 - CLASS IDENTIFICATION OF NOVEL PSYCHOACTIVE SUBSTANCES USING MASS SPECTRAL LIBRARY SEARCHING WITH HIERARCHICAL CLUSTERING

Arun Moorthy (1) - William Wallace (1) - Anthony Kearsley (2) - Dmitrii Tchekhovskoi (3) - Stephen Stein (1)

National Institute of Standards and Technology, Mass Spectrometry Data Center, Gaithersburg (1) - National Institute of Standards and Technology, Applied and Computational Mathematics Division, Gaithersburg (2) - National Institute of Standards and Technology, Mass Spectrometry Data center, Gaithersburg (3)

Keywords: Designer Drug, Forensics, Hierarchical Clustering, Library Searching, Reference Data

Introduction:

Novel psychoactive substances have introduced significant identification challenges to the forensic science community. Developing methods that can correctly categorize emerging drug analogs is a pressing need. This presentation describes a procedure for obtaining a class-identification map of an unknown compound. The resulting classification map can be used to compute the uncertainty of the class-identification.

Methods:

The hybrid search is a new library search method that considers fragment-ions along with neutral-losses when computing spectral similarity [1]. A query spectrum is first searched against a library to generate a preliminary hit-list. The hybrid dot-product calculation is used to generate a dissimilarity matrix from the spectra in the preliminary hit-list, which is then clustered using our novel multi-objective agglomerative-hierarchical clustering algorithm.

Results:

The result of this mass spectral library search and clustering procedure is a dendrogram from which the likely classification of the query compound can be proposed. This dendrogram can be used to compute the uncertainty of the proposed class identification. As a numerical test, twenty-two SWGDRUG Library [2] compounds were assembled into a sub-library. It contained spectra for five analogs each of JWH-167, fentanyl, MDMA, and cathinone, and two additional spectra of "unknown" compounds. A preliminary implementation of the multi-objective classification method was able to classify the first unknown as a fentanyl analog with a certainty of 56%, and as a fentanyl, JWH-167, or cathinone analog with 93% certainty. The second unknown was only classifiable as a fentanyl, MDMA, or cathinone analog, but with 99% certainty.

Conclusions:

This presentation describes a procedure for obtaining a class-identification for an unknown seized compound, using the new hybrid search to compute inter-spectral similarity, and a novel multi-objective scheme for agglomerative hierarchical clustering. The resulting classification tree can be used to compute the uncertainty of the class-identification.

Novel Aspect:

The hybrid dot-product for spectral similarity, a new multi-objective hierarchical clustering algorithm, and computation of uncertainty for class identification.

48 - IDENTIFICATION OF FINE PLASTIC MATERIALS BY THERMAL DESORPTION AND PYROLYSIS COMBINED WITH DART-MS (TDP/DART-MS)

CHIKAKO TAKEI (1) - KENICHI YOSHIZAWA (1)

BioChromato, Application support, Fujisawa (1)

Keywords: Criminalistics, foreign substances analysis, TDP/DART-MS

Introduction:(400 /400 characters)

Evidentiary materials in criminal come in many forms such as fine segments of fiber or bits of resin. Adhesive collection sheets are often used, but even if a fine particle can be collected, the instrumental analysis is affected by the adhesive compound adhered to a fine particle slightly, so the difficulty of distinguishing task can also further increase. The purpose of this work is to identify fine plastic materials without confounding influence from the adhesive tape.

Methods: (397 /400 characters)

The samples of this study were “resins sticking to adhesive tape”. Thermal desorption and pyrolysis(TDP) combined with DART-MS was composed of Q-TOF mass spec equipped with DART ion source and ionRocket TDP device. The samples were cut to ~1 mm² and put into the sample pot. TDP temperature condition was room temperature to 600 °C, a rate of 100 °C/min. To structurally and compositionally characterize samples, Kendrick Mass Defect(KMD) analysis was used.

Results: (874 /900 characters)

Nylon-6, polylactic acid(PLA) and polyethylene glycol(PEG) were used as fine plastic materials and scotch tape was used as the adhesive tape. In the mass spectra at 300–400 °C (the pyrolysis reaction starting temperature), the complicated spectra of the samples show that the fine plastics were mixed with scotch tape, making it difficult to distinguish between them. From the KMD plots, the difference between the scotch tape and fine plastics were clearly identified. For the nylon-6 fine plastic, a plot of 113 Da intervals derived from its repeating structure was plotted at a different position from that of the peaks originating from the scotch tape. In a similar manner, plots with a 72 Da interval for PLA and a 44 Da interval for PEG were observed at different positions from that of the scotch tape. By setting the Kendrick mass unit based on the mass of the repeating structure, compounds with common repeat units could be aligned in the horizontal direction on the KMD plot, whereas compounds with different structures were shifted.

Conclusions: (304 /400 characters)

TDP/DART-MS enables the direct and rapid analysis of plastic samples. A combination of TDP/DART-MS and KMD analysis enables the identification of fine plastics without the need to detach foreign matter collected from adhesive tape. Thus, the combination of TDP/DART-MS and KMD analysis can be used for material identification of evidence in criminal cases.

Novel Aspect: (98 /150 characters)

A combination of TDP/DART-MS and KMD analysis is useful for material identification of evidence in criminal cases.

A.07 LIFE SCIENCES - THERAPEUTIC DRUG MONITORING AND DRUG DISCOVERY

352 - PHOSPHOPROTEOMICS OF NON-SMALL-CELL LUNG CANCER CELLS TREATED WITH ERLOTINIB REVEALS DRUG-RESISTANT SIGNATURES AND POTENTIAL TARGETS.

Jun Adachi (1) - Yuichi Abe (1) - Maiko Nagano (1) - Junko Ioyama (1) - Marina Kishida (1) - Takeshi Tomonaga (1)

National Institutes of Biomedical Innovation, Health and Nutrition, Laboratory of Proteomics for Drug Discovery, Osaka (1)

Keywords: peptide fractionation, StageTip, phosphoproteome, non-small cell lung cancer, kinase-substrate enrichment analysis

Introduction:

Mass spectrometry-based proteomics is an indispensable tool for molecular, cellular biology and for the emerging field of clinical medicine. Especially, phosphoproteome is one of key signatures to understand the mode of action and mechanism of drug resistance of kinase inhibitors at the molecular level, pathway level and system level.

Methods:

Recently, we have developed a key technology on peptide separation for rapid and sensitive phosphoproteome analysis [1]. We also developed a sensitive method to identify phosphotyrosine proteome using an immune affinity enrichment method [2]. Combining these technologies, we performed temporal characterization of non-small-cell lung cancer cell lines treated with erlotinib.

Results:

We quantified over 12000 phosphorylation sites including 600 phosphorylation sites on tyrosine residue across six cell lines. Especially, phosphotyrosine-proteome can detect bypass kinases which were known to be related to the drug resistance, such as FGFR, AXL, MET. Furthermore, network analysis and kinase-substrate enrichment analysis predicted erlotinib-dependent activation of kinases and signal signatures. We extracted kinases and other enzymes which are up-regulated in resistant cells and selected 46 inhibitors for drug screening. 24 of 46 inhibitors inhibited cell growth of at least one resistant cell line.

Conclusions

Combination of phosphoproteome and phosphotyrosine-proteome profiling is useful to detect markers for drug-efficacy and target candidates for overcoming drug resistance.

Novel Aspect:

Novel markers for drug-efficacy and target candidates for overcoming drug resistance were identified by Phosphoproteome analysis.

1293 - QUANTIFICATION OF MAJOR PEANUT PROTEIN ALLERGEN ISOFORM GROUPS FROM PEANUT PROTEIN EXTRACTS

Kim Alving (1) - Pierre DeMontigny (1) - Bing Wang (2)

Sanofi, Analytical Research and Development, Waltham, United States (1) - sanofi, Analytical Research and Development, Waltham, United States (2)

Keywords: Absolute peanut protein quantification LC/MS/MS

Introduction:

Peanut allergy is a potentially fatal condition that has seen a rise of 50% in the recent 15 years currently affecting 0.6-1.3% of the US population. Desensitization by exposure to peanut allergen doses is being evaluated in several clinical trials. Accurate quantification of the peanut allergens is key to successful desensitization. We here report on the development and qualification of a LC/MS based method for absolute quantification of peanut protein content.

Methods:

Discovery analysis of peanut protein extract PPE digests was carried out as nanoLC Orbitrap MS/MS analyses, and suitable peptides were selected for quantification. PPE digest allergen quantification was carried out on a triple quadrupole MS in MRM mode. Unlabeled and heavy isotope labeled peptides (internal standards) were used to generate calibration curves. Intact peanut protein standards were applied for accurate determination of total process recovery.

Results:

Highlights of the peanut proteome discovery efforts and quantification method development rationale, selection of representative peptides, development and qualification results for the analytical methods to quantify four major allergen proteins (Ara h1, h2, h3 and h6) including linearity, accuracy and reproducibility (triple replicate, triple inter day replicate, as well as reproducibility), will be presented together with the results from the analysis of several PPE research batches. The average recovery was determined to be 61% applying intact allergen standard protein. The intra- and inter-day CV% was below 6.6%, and accuracy is within +/- 10%. The stability data for freeze-thaw and 2-hour room temperature stability and 12 hour protein extract digest stability were all below 15%.

Conclusions

An LC/MS/MS based method for quantification of four major peanut allergens from peanut extracts has been developed and qualified. The method was found to have good sensitivity, reproducibility, and dynamic range and thus to be suitable for monitoring the concentrations of the major peanut allergen proteins in research batches obtained from peanut extracts. The method was designed to detect and quantify the isoforms of each of the 4 major peanut protein allergens.

Novel Aspect: Absolute quantification of PPE with multiple isoforms by LC/MS/MS. Application of intact proteins for accurate recovery determination

401 - COMPARISON OF METHIONINE OXIDATION PROFILES OF BIOSIMILAR TUR01 MONOCLONAL ANTIBODY TO ITS REFERENCE UNDER OXIDATIVE STRESS

Ahmet Emin Atik (1) - Z. Zeynep Yıldırım Keleş (1) - Gülipek Güven (2) - İlgü Ece Gülser (1) - Yiğit Erdemgil (1) - Deniz Bayçın (1) - Özge Can (3) - R. Serdar Alpan (1)

Keywords: mass spectrometry; surface plasmon resonance; biosimilar monoclonal antibody; oxidative stress; oxidation

Introduction

Mass spectrometry (MS) is now routinely used to monitor post-translation modifications (PTMs) levels in biosimilar monoclonal antibody (mAb) characterization. Among them, methionine (Met) oxidation is accepted as one of the most commonly observed PTM during development, manufacturing, formulation and storage processes. To ensure the safety and efficacy of the drugs, Met oxidation should be tightly controlled during mAb development. It may affect biological function, structure and stability of the protein. In the current study, one of the best-selling therapeutic monoclonal antibody and its biosimilar candidate were subjected to the chemical oxidation via different concentrations of hydrogen peroxide. Under forced oxidative stress, Met oxidation profiles as well as the binding kinetics of FcγRI for reference and biosimilar were compared.

Methods

To determine Met oxidation, UPLC-MS experiments were carried out on a Xevo® G2-XS QToF mass spectrometer (Waters, Milford, MA) equipped with electrospray ionization (ESI). Both biosimilar and reference samples were incubated in the dark with different concentrations of H₂O₂ (0.1%, 0.5%, 1.0%, 3.0%) for 24h at room temperature. After applying oxidative stress, both biosimilar and reference antibodies were denatured, reduced, and alkylated before trypsin digestion at 37°C. The resulting peptide mixture were separated by reversed phase C18 column (Waters Acquity UPLC BEH C18, 100 x 2.1 mm, 1.7 μm, 300 Å) with a 90 minute UPLC run. The separated peptides were identified by online tandem mass spectrometry (MS/MS) Q-ToFMS system. Binding kinetics of 0.1% and 3.0% H₂O₂ treated biosimilar and reference antibodies were measured and compared by surface plasmon resonance (SPR) technique on a Biacore T200 (GE Healthcare).

Results

Both biosimilar and reference comprised of one Met on the light chain (LC-Met4) and four Met residues (HC-Met34, HC-Met83, HC-Met256, and HC-Met432) on the heavy chain. LC-MS/MS experiments were used to identify and quantify Met oxidation in the amino acid sequence. Oxidation of Met residue resulted in +16 Da mass shift compared to the unoxidized counterpart. The oxidized peptides were confirmed through careful interpretation of their MS/MS spectra, i.e. 16 Da mass increase in b and/or y ions. Incubation of both products with 0.5% H₂O₂ for 24h at room temperature leads to oxidation of Met256 and Met432 residues completely. Those residues are in the Fc region (CH₂-CH₃ interface) and exposed to the protein surface. It has been shown that they are more prone to oxidation compared to the other Met residues. On the other hand, Met34 is located on the complementarity-determining region (CDR) and it may impact antigen binding kinetics. Our data showed that increasing H₂O₂ concentration has nearly the same impact on Met34 oxidation for both reference and its biosimilar candidate. Moreover, Met4 and Met83 residues have shown nearly 20% oxidation under 3.0% H₂O₂ treatment for two products. In addition, the binding kinetics data will also be discussed for oxidized biosimilar and reference mAb.

Conclusions

The high-level similarities in oxidation profiles of Met4, Met34, Met83, Met256 and Met432 residues have shown that the biosimilar and reference mAb have a similar three-dimensional structure. Additionally, SPR analysis has demonstrated that Met34 oxidation has a similar impact on antigen-binding kinetics for both products.

Novel Aspect

Comparison of Met oxidation profiles of biosimilar and reference monoclonal antibodies under oxidative stress through LC-MS/MS and surface plasmon resonance.

583 - QUANTITATIVE EVALUATION OF ADENOSINE 5'-TETRAPHOSPHATE AND OTHER FIVE ANALYTES RELATED TO NICOTINAMIDE PHOSPHORIBOSYLTRANSFERASE BY LC-MS IN MELANOMA CELLS AND MOUSE PLASMA

Michele Bianchi (1) - Ambra Grolla (2) - Cristina Travelli (1) - Silvia Garavaglia (1) - Armando Genazzani (1) - Giuseppe Orsomando (3) - Erika Del Grosso (1)

University of Piemonte Orientale, Department of Pharmaceutical Sciences, Novara (1) - University of Piemonte Orientale, Department of Pharmaceutical Sciences, novara (2) - Polytechnic University of Marche, Department of Agricultural, Food and Environmental Sciences, Ancona (3)

Keywords: Ap4, NAMPT, B16 cells, mouse plasma

Introduction:

Nicotinamide phosphoribosyltransferase (NAMPT) is the rate-limiting enzyme in nicotinamide adenine dinucleotide (NAD) synthesis[1]. Adenosine 5'-tetrphosphate (Ap4) is a nucleotide known to be a vasoactive purinergic mediator in mammals[2]. However, it has never been reported whether NAMPT can catalyze the synthesis of Ap4. So, the aim of the work was to develop abioanalytical LC-MS method to quantify Ap4 and NAMPT related analytes in biological samples.

Methods:

Three cells lines (B16 WT, B16 FLAG-NAMPT and ShNAMPTLow)and twenty-three plasma samples of healthy male C57BL/6 miceswere analyzed. The bioanalytical method developed is a LC-MS method that consists in an isocratic elution on a Phenomenex Luna HILIC column. Each analyte (Ap4, adenosine 5'-diphosphate, adenosine 5'-triphosphate, nicotinamide, nicotinamide mononucleotide and NAD) was monitored in MS/MS, SRM or MRM mode.

Results:

Intracellular Ap4 levels were increased more than two times in cells over-expressing NAMPT (B16 FLAG-NAMPT: 1.17 ± 0.20 nmol/mg protein v. B16 WT: 0.56 ± 0.10 nmol/mg protein; $p < 0.05$) and were significantly reduced in cells silenced for the enzyme (ShNAMPTLow: 0.31 ± 0.06 nmol/mg protein; $p < 0.05$).

Moreover, metabolic perturbation conditions modulated Ap4 and nicotinamide mononucleotide synthesis in B16 WT cells. In particular, Ap4 and nicotinamide mononucleotide levels were significantly reduced in low glucose concentration and serum free conditions, respectively.

Finally, Ap4 mices plasma levels showed a good correlation with extracellular NAMPT levels, despite their inter- and intra-subject variability. Not surprisingly, Ap4 also correlated, to a greater extent, with ATP levels measured in parallel [3].

Conclusions:

A new LC-MS bioanalytical method was developed to quantify six analytes including Ap4 in B16 cells and in two different biological matrices. Murine cells and plasma with engineered or naturally fluctuating NAMPT levels showed matching Ap4 fluctuations.

Novel Aspect:

This study reports that NAMPT regulates in vivo Ap4 levels, conferring an unpredicted signaling role to this enzyme.

1362 - VALIDATION OF BREATH BIOPSY PLATFORM FOR LONGITUDINAL MEASUREMENT OF VOCS IN BREATH USING TD-GC-MS

Jasper Boschmans (1) - Rob Smith (1) - Marc van der Schee (2) - Simon Kitchen (3) - Billy Boyle (4) - Max Allsworth (5)

Owlstone Medical Ltd., Chemistry, Cambridge, United Kingdom (1) - Owlstone Medical Ltd., Clinical, Cambridge, United Kingdom (2) - Owlstone Medical Ltd., Systems, Cambridge, United Kingdom (3) - Owlstone Medical Ltd., CEO, Cambridge, United Kingdom (4) - Owlstone Medical Ltd., CSO, Cambridge, United Kingdom (5)

Keywords: Breath Research, TD-GC-MS, Volatile Organic Compounds, Pharmacokinetics, Breath Biopsy

Introduction:

Exhaled breath contains thousands of Volatile Organic Compounds (VOCs) which are products of metabolic activity, and promising biomarkers for a range of diseases. Breath also includes VOCs produced during the metabolism of pharmaceuticals and other xenobiotics.

Evaluating longitudinal changes in the breath VOC profile is relevant for a wide range of applications such as disease monitoring, measuring response to therapeutic interventions, assessing effects of environmental exposures, and studying pharmacokinetics. This study describes how the Breath Biopsy platform can be used to capture multiple breath samples over time, uncovering detailed changes in the concentration of volatile metabolites present in breath.

We present two main experiments: first we analyze VOCs in breath following ingestion of a peppermint capsule and show that Breath Biopsy can be used to observe the “washout curve” in for target compounds in a single individual using repeated, robust breath collection and analysis over a period of 8 hours. Secondly, we examine the biological variation in a longitudinal study where the washout experiment is repeated in the same individual multiple times over the course of 5 weeks.

Methods:

Breath samples were collected using the ReCIVA Breath Sampler and analyzed using the Breath Biopsy platform in the Breath Biopsy Clinical Laboratory (Owlstone Medical Ltd, UK). Samples were pre-purged to remove excess water and desorbed using a TD100-xr thermal desorption autosampler (Markes International) and transferred onto a VF-5ms column (60m x 0.25mm x 0.25 μ m; Agilent Technologies) using 1:2 split injection. Chromatographic separation was achieved via a programmed method (40-310°C in 60 min. at 1.8 mL/min.) on a Trace 1310 GC oven (Thermo Fisher Scientific) and mass spectral data acquired using an electron ionization time-of-flight (i.e. EI-TOF) BenchTOF HD mass spectrometer (also Markes International). Raw Markes data files were converted from using TOF-DS (Markes International) and MassHunter Quant (Agilent Technologies) was used for further data processing.

Results:

Analysis of breath captured 30 minutes after consumption of the peppermint capsule shows a large increase in the VOCs α -pinene, β -pinene, limonene, eucalyptol and p-menthan-3-one compared to baseline pre-ingestion controls. Breath collections made every 30 minutes after this initial capture show a washout curve for all peppermint-related compounds, decreasing to baseline levels. A wide range of fold changes was observed across all peppermint-related compounds, with most abundant GC peaks not necessarily resulting in highest fold changes. In contrast, breath metabolites e.g. acetone that are not peppermint-related show little or no change compared to control.

From the washout experiment, three time points were selected (pre-ingestion control, peak at 45 minutes and plateau at 3 hours) for inclusion in a longitudinal study where the washout experiment was repeated multiple times over 5 weeks.

In the longitudinal study, fold changes for all compounds are presented for the peak and plateau time points, relative to the corresponding pre-ingestion control. Breath metabolites acetone and isoprene show only small

differences between peak and plateau fold change as expected, however large fold changes are observed for the peppermint-related VOCs such as α -pinene and β -pinene, although some variation is observed for peak data points between washout experiments.

Conclusions

The study demonstrates that the Breath Biopsy platform can be used to study longitudinal changes of exhaled VOCs in a reliable and reproducible way. The peppermint washout experiment is a useful way to assess platform performance and future work will investigate the biological variability that exists for uptake and breakdown of substrate. The Breath Biopsy platform unlocks potential new use cases for breath analysis in metabolomics and pharmacokinetics studies.

Novel Aspect:

Breath-based platform allowing standardized sample collection and pre-concentration using the ReCIVA Breath Sampler, followed by analyte separation and data acquisition via a TD-GC-MS methodology.

1108 - ANALYTICAL ASPECTS OF SUNITINIB AND ITS GEOMETRIC ISOMERISM TOWARDS THERAPEUTIC DRUG MONITORING IN CLINICAL ROUTINE

Mauro Buzzo (1) - Bianca Posocco (2) - Elena Marangon (2) - Giuseppe Toffoli (2)

National Cancer Institute of Aviano, University of Trieste, Aviano (1) - National Cancer Institute of Aviano, Clinical and Experimental Pharmacology, Aviano (2)

Keywords: TDM, Sunitinib, isomerism, light, HPLC-MS/MS

Introduction:

To perform therapeutic drug monitoring (TDM) of Sunitinib (SUN) and its active metabolite N-desethyl SUN, a robust and sensitive LC-MS/MS quantification method is required. However, the geometric photoisomerization of SUN and its metabolite makes working in the dark highly recommended. Unfortunately, these conditions are unsuitable for clinical application and the aim of this work was to study the isomerism phenomenon in human plasma to overcome this issue.

Methods:

The geometric isomerism of SUN and N-desethyl SUN has been studied in human plasma. A LC-MS/MS method developed and validated for this study, has been applied for the analysis of these samples: the analytes were extracted from the matrix with a protein precipitation and separated on a Synergi Fusion-RP column (Phenomenex, USA) and the system consisted of a Prominence UFLC XR (Shimadzu, Japan) coupled with an API 4000 QTRAP mass spectrometer (SCIEX, USA).

Results:

When the SUN samples were exposed to light, the formation of E-isomer did not reach completion with nearly 55% formed after 30 min. An analogue equilibrium achievement was noticed for N-desethyl SUN, but its E-isomer reached a maximum of only 22%. Then, the E- to Z-isomer reversion kinetics was investigated in dark conditions at different temperatures, different analyte concentrations and in presence of acids. The reversion rate resulted increased by higher temperatures thus indicating a thermal reversion, not influenced by the analyte concentration. Low pH values seemed to stabilize the E-isomer thus slowing down the reversion. To decrease the E- to Z-isomer reversion time, samples were incubated in a heated-water bath at different temperatures (40, 50, 60, 70, 80 and 90°C) just before the analysis, reaching the maximum percentage of the Z-isomer for both SUN and N-desethyl SUN in only 5 min with temperature equal or higher than 70°C. Moreover, no degradation has been observed for both the analytes after the heating step.

Conclusions:

The developed method does not require the protection from the light during the sample preparation but only a heating step with a heated water bath at 70°C for 5 min. The incubation of the samples allows the rapid reversion of the E-isomer, formed during the sample preparation, to the desired Z-form. Despite the additional step of 5 min little extends the processing time, it strongly facilitates the handling of the samples making this method more feasible for TDM.

Novel Aspect:

For the first time, the study of the geometric isomerism of SUN and N-desethyl SUN in human plasma has led to the development of an analytical method to support TDM.

For information please contact: scientific@imsc2018.it

754 - A LC-MS-BASED ASSAY FOR THE DETERMINATION OF ACTIVITY AND INHIBITION OF ANOPHELES GAMBIAE 3-HYDROXYKYNURENINE TRANSAMINASE ENZYME

Rossana Canavesi (1) - Ubaldina Galli (1) - Riccardo Miggiano (1) - Franca Rossi (1) - Erika Del Grosso (1)

Università del Piemonte Orientale, Department of Pharmaceutical Sciences, Novara (1)

Keywords: LC-MS/MS, Anopheles gambiae, Ag-HKT, Kynurenine pathway, enzymatic assay.

Introduction:

In *Anopheles gambiae*, the most efficient vector of malaria parasite *Plasmodium falciparum*, 3-hydroxykynurenine (3-HK) represents a toxic metabolite. In the adult mosquitoes, the excess of this toxic metabolite is removed by a specific 3-HK transaminase (Ag-HKT) which converts the 3-HK into the more stable xanthurenic acid. Interfering with 3-HK metabolism in *A. gambiae* is a potential approach for the development of transmission-blocking drugs and insecticides.

Methods:

LC-MS method was optimized for the evaluation of the kinetic parameters of Ag-HKT and the kinetic characterization of inhibitors of the enzyme. An enzymatic assay was set up by using the recombinant Ag-HKT. The chromatographic separation of analytes was performed in a gradient mode on a Synergi column, using an acidic mobile phase. Mass spectrometric detection was achieved with an ion trap equipped with an ESI source, in positive ionization scan, operating in SRM mode.

Results:

The LC-MS method was used for the determination of kinetic constants values for Ag-HKT. The K_m and V_{max} calculated for Ag-HKT resulted in agreement with those reported in the literature [1]. Moreover, this selective method was applied for the evaluation of Ag-HKT inhibition by using a compound whose synthesis was previously described in the literature [2] and a new promising inhibitor (3-INI).

The K_i value of the known inhibitor obtained with the LC-MS method was in agreement with that reported in the literature [2]. On the basis of the results obtained in our experiments a competitive mechanism of inhibition was delineated verifying the accuracy and reliability of the LC-MS assay. The method was applied to the characterization of 3-INI, a new synthetic compound. The determination of its mechanism of action through the analysis of the overlaid Lineweaver-Burk reciprocal plot revealed a competitive mechanism of action. The K_i value was determined suggesting that the new synthetic compound is more potent than the reference compound.

Conclusions

The LC-MS method was developed and its applicability was confirmed by determination of the kinetics parameters of Ag-HKT and the determination of inhibitory potency of a known reference compound. Besides, a new synthetic compound was analyzed resulting in a more potent inhibitor with an improved K_i . New compounds will be synthesized starting from the structure of previously studied inhibitors with the aim of discovering more potent and selective Ag-HKT inhibitors.

Novel Aspect:

The novelty is the application of LC-MS method for the determination of mechanism of action and K_i values of new potential Ag-HKT inhibitors.

647 - RAPID, SENSITIVE FENTANYL DETECTION BY THERMAL DESORPTION PTR-MS AND COLLISION INDUCED DISSOCIATION

Luca Cappellin (1) - Felipe Lopez (2)

TOFWERK AG, R&D, Thun (1) - Tofwerk AG, R&D, Thun (2)

Keywords: drugs, PTR-MS, thermal desorption, collision induced dissociation

Introduction:

Drug detection and identification is a current analytical challenge requiring a robust detector which is sensitive, quantitative, and has sufficient separation power to resolve potential interferences. Drugs such as fentanyl are typically used in combination with common street drugs, however because fentanyl is hundred times more potent than heroin it therefore poses unique dangers. An overdose of fentanyl can be caused even by trace amounts.

Methods:

PTR-TOF-MS equipped with the a VOCUS reaction cell was tested for high sensitivity drug detection in real-time. The low vapor pressure of many street drugs requires coupling to a thermal desorption system in a swab like fashion. After instrumental calibration, simulated real samples containing few nanograms of fentanyl were tested. Collision Ion Dissociation was induced by varying the extraction voltage to confirm drug identification at structural level.

Results:

Fentanyl detection was achieved in seconds without any pre-separation or sample preparation even in complex mixtures. The soft ionization achieved in the Vocus reactor protonated fentanyl ions. Calculated and measured exact mass and isotopic distribution matches perfectly giving support to the molecular composition assignment determined by exact mass analysis. Confirmation of fentanyl detection was achieved by performing real-time Collision Induced Dissociation using VOCUS PTR-TOF. The collisional energy of protonated fentanyl is varied by changing the extraction voltage after the VOCUS reactor. Higher extraction voltages produce higher collisional energies which in turn increase ion fragmentation. The fragmentation pattern provides information about the molecule structure as in MS/MS techniques. At higher collisional energies the parent ion corresponding to protonated fentanyl ($C_{22}H_{28}N_2O \cdot H^+$) is more fragmented into $C_{13}H_{18}N^+$ and $C_8H_9^+$ ions, matching fentanyl fragments from MS/MS databases.

Conclusions

Vocus PTR-TOF coupled to a thermal desorption system allowed real-time detection, identification, and quantification of fentanyl in a swab without any sample preparation or preconcentration step. Collision Induced Dissociation allowed fentanyl confirmation via matching with MS/MS databases. Single digit nanogram detection limits were achieved. Faster desorption rates for example from a swab desorber would result in even lower detection limits.

Novel Aspect:

Real-time drug identification and quantification in swabs was achieved by using PTR-TOF equipped with a VOCUS reaction cell and performing Collision Induced Dissociation.

801 - A VALIDATED AND ROBUST ANALYTICAL METHOD FOR PESTICIDES MEASUREMENT IN CANNABIS BY LIQUID CHROMATOGRAPHY TANDEM MASS SPECTROMETRY

christophe CLARYSSE (1)

PERKIN ELMER, CHROM AND MASS SPEC DIVISION, VILLEBON SUR YVETTE (1)

Authors: Erasmus Cudjoe, Dalmia Avinash, Jacob Jalali, Jingcun Wu, Josh Ye, Qin Feng, Christophe Clarysse

Cannabis Pesticide Analysis: A Validated and Robust Analytical Method for Pesticides Measurement in Cannabis by Liquid Chromatography Tandem Mass Spectrometry

Keywords: Mass spectrometry, chromatography, sample preparation, method validation

Introduction

Quantitative analysis of pesticide residues in cannabis is of great importance to scientific researchers, scientific instruments manufacturers, cannabis industry stakeholders and government regulatory institutions. Besides the complexity of cannabis matrix, more stringent regulatory action limits for pesticides from certain states within the USA, have furthered analytical challenge to accurately quantify these pesticides. Nonetheless, the need for simple, robust and validated methods for pesticide analysis with good data reproducibility and accuracy are critical to all stakeholders in the cannabis industry. This work shows a validated method for analysis of 70 pesticides, including compounds typically analyzed by gas chromatography, in cannabis flower using LC-MS/MS with ESI source. Limits of quantitation were below all current regulatory action limits for pesticides in cannabis in USA. Good reproducibility and precision were obtained for all analytes with %RSD \leq 23 for all pesticides in the cannabis matrix.

Method Summary

Acetonitrile cannabis extracts were spiked with 70 pesticides at different concentrations and internal standards added. Subsequently, spiked samples were diluted at different levels (1:1 and 1:5) with 0.1% formic acid in acetonitrile. All diluted and spiked extracts were directly injected into a PerkinElmer LC coupled with the Q-Sight MS/MS system. Calibration standard curves were generated in both diluted standard solvents and the cannabis matrix. Method reproducibility and precision were determined with 7 replicates of spiked sample injections. Limits of quantitation at two different spike levels were established with at least 3 replicate injections. A 20 min LC-MS/MS was used for pesticides analysis in cannabis on a reverse phase C18 column.

Preliminary Results

Due to the complexity of the cannabis matrix, the reproducibility, precision and stability of the instrument are always of utmost importance for any routine analysis of pesticides in a laboratory. In addition, stakeholders are interested in high sample throughput with reliable and validated methods in order to augment their overall efficiency in the cannabis industry. Chromatographic analysis including column re-conditioning for all 70 pesticides was achieved within 20 min. The instrument sensitivity ranged from 0.5 to 50 ppb for all pesticides, which was well below action limits set by California and Oregon. The limit of quantitation for the pesticides in the cannabis matrix was within 0.001–0.1 $\mu\text{g/g}$ for 1:1 diluted spiked samples and 0.001 – 0.3 $\mu\text{g/g}$ for 1:5 diluted spiked samples. The reproducibility (% RSD; n=7) for each pesticide in both diluted matrices was \leq 23 %. The calibration correlation coefficient for each analyte in the cannabis matrix was \geq 0.98 with linear range over 3 orders of magnitude. Inter-day (n=7) variability of area response was \leq 6 % without the use of internal standards and $<$ 2 % with internal standards.

Conclusion

A high throughput quantitative analytical method for analysis of pesticides in cannabis was fully validated in accordance with the FDA guidelines for chemical analysis in food using liquid chromatography in combination with tandem mass spectrometry. The limit of quantitation for each pesticide was below the required action limits set by California and Oregon states in the USA.

Novelty

Validated liquid chromatography tandem mass spectrometry method for analysis of 70 pesticide residues, including compounds that are conventionally analyzed on gas chromatography platform, in cannabis with limit of quantitation below the action limits set by Oregon and California states.

Keywords: glucocorticoids, anti-doping, administration routes, LC-MS/MS

Introduction:

Betamethasone (BET) is a glucocorticoid widely used in sports medicine for the treatment of asthma and acute injuries. BET is prohibited in sport competitions when administered by systemic routes (e.g., oral, intramuscular), and is allowed using local treatments. The aim of the present work was to examine the urinary profile of BET and its metabolites after different administration routes.

Methods:

A validated method was used to determine urinary levels of BET, 6 β -hydroxy-BET, and fifteen additional metabolites. Urine samples were hydrolyzed with β -glucuronidase, extracted with ethyl acetate and analyzed by LC-MS/MS. The method was applied to urines collected in clinical studies where BET was administered by topical, intranasal, intra-articular, peri-articular, oral and intramuscular routes to male and female volunteers (n=40).

Results:

After topical (10 mg/day for 5 days) and intranasal (320 μ g/day for 3 days) uses, maximal BET concentrations were 6 and 32 ng/mL, respectively. In most of the samples collected after intranasal treatment, BET concentrations were below 30 ng/mL.

Intra-articular and peri-articular single administrations led to maximal BET concentrations of 1420 and 981 ng/mL, respectively. All samples collected 72h after both administrations gave BET concentrations lower than 30 ng/mL.

After a single oral dose of 0.5 mg, the maximal BET concentration was 82 ng/mL, and all samples collected 24h after intake resulted in BET concentrations below 30 ng/mL. Single intramuscular doses of 6 and 12 mg gave maximal BET concentrations of 1446 ng/mL. In most of the samples collected 72h after intramuscular administration, BET concentrations were lower than 30 ng/mL. After both administrations, BET excretion rates reached maximal values during the first hours after intake and gradually decreased.

The excretion profiles of most of the metabolites were similar to those of BET.

Conclusions:

As expected, different excretion profiles were obtained depending on the administration route. It will be difficult to distinguish intra-articular and peri-articular uses from intramuscular treatments because excretion profiles obtained after these three administrations routes are similar. Topical and intranasal treatments can be differentiated from oral and intramuscular administrations, using a reporting level for BET.

Novel Aspect:

Since BET can be administered by different routes, this information could be useful for the anti-doping community to know how it behaves depending on the administration route.

1292 - VARIABILITY AND VALUES IN GLYCOSYLATION ANALYSES OF MONOCLONAL ANTIBODIES: AN INTERLABORATORY STUDY

M. Lorna A. De Leoz (1) - David L. Duewer (1) - Stephen E. Stein (1)

National Institute of Standards and Technology (NIST), Material Measurement Laboratory, Gaithersburg, United States (1)

Keywords: glycomics, glycoproteomics, NISTmAb, glycan, glycopeptide

Introduction:

Glycosylation is a critical post-translational modification in monoclonal antibodies. However, it is inherently heterogeneous and challenging to analyze, leading to a proliferation of analysis Methods: An interlaboratory study was coordinated by NIST to determine variability in measuring N-glycans across laboratories and to derive consensus values for NISTmAb, an IgGk1 reference material. This work describes results from 103 reports worldwide [1].

Methods:

Participants performed glycosylation analysis of NISTmAb and mod-NISTmAb using their own method. Labs recorded, in a provided template, methods used and percent fractional abundances of glycans in both samples. A pilot study was conducted to polish the study's protocol. Consensus values and ratios were derived for glycans reported by seven or more labs. Data was analyzed using robust techniques to assess measurement reproducibility and characterize distributions.

Results:

A total of 103 reports were submitted by 76 participants from industry, university, research, and government laboratories in Europe, North America, Asia, and Australia. Various methods were used for glycosylation analysis, including mass spectrometry, fluorescence detection, and capillary electrophoresis. Fifty-seven glycan compositions were reported at least six times; some labs differentiated between isomers. Consensus values were calculated for each of the 57 glycans. The number of glycan compositions identified by labs ranged from 4 to 48, with a median of 22. Most participants reported about the same number of glycans for NISTmAb and mod-NISTmAb. To ascertain the ability of labs to demonstrate comparability of two samples, the mod-NISTmAb/NISTmAb ratios were calculated. The ratios for the four most commonly reported glycans agreed within 8% to 30%. Notably, the extent of agreement between a participant's reported values and the study's consensus values is a strong function of the participant's measurement repeatability.

Conclusions:

Determining variability of glycosylation profiles and assigning best values from a larger number of laboratories and range of measurement methods provides a baseline for comparison in the rapidly developing field of glycosylation analysis. We thank all the scientists who participated in this study.

Novel Aspect:

Variability and values for the glycosylation of a monoclonal antibody reference material from 100+ reports worldwide

1349 - APPLICATION OF ACOUSTIC MIST IONIZATION MASS SPECTROMETRY (AMI-MS) FOR THE DEVELOPMENT OF KINASE ASSAYS

Deepika Srivastava (1) - Phillip DeLand (2) - Jonathan Wingfield (3) - Jonathan Tart (1) - Paul Clarkson (1) - Michael Tonge (3)

AstraZeneca, Discovery Biology, Cambridge, United Kingdom (1) - Labcyte Inc., Mass Spectrometry Product Management, San Jose, United States (2) - AstraZeneca, Mechanistic Biology & Profiling, Cambridge, United Kingdom (3)

Keywords: acoustic loading; mass spectrometry; high-throughput screening; kinase; ADP Glo

Introduction:

We have implemented a platform utilizing acoustics to load samples into a time-of-flight mass spectrometer capable of analysing more than 100,000 samples per day. In this poster we demonstrate the use of our platform to screen a kinase and compare the data with a classical high-throughput screening technology. Since acoustic mist ionization mass spectrometry (AMI-MS) is a direct infusion system, kinases are a challenge due to the enzyme's requirement for MgCl₂.

Methods:

An acoustic transducer generates a nebulised spray from the wells of a 384-well plate located on a moving XY-stage. High voltage is applied to a charging cone above the well, inducing charge separation in the sample. The nebulised spray is drawn through a heated transfer interface into the MS and an ion beam is generated. To utilize the platform with a kinase enzyme, ammonium phosphate at high pH is added to precipitate out the Mg²⁺ ions.

Results:

AMI-MS was used to build a kinase enzyme assay to identify inhibitors from a subset of the AZ compound collection. We established a protocol using ammonium phosphate as a stop solution at the end of the assay to remove magnesium chloride and reduce suppression in the mass spectrometer. Having established the kinetic parameters for this target we screened a 60,000 compound subset using both ADP Glo™ kits and AMI-MS endpoints. There was a strong correlation between both assay formats, over 2000 compounds were identified as active in both formats. Surprisingly, there were only small clusters of compounds which appeared active in only one of the two assay technologies (38 unique to AMI-MS and 101 unique to ADP Glo™).

Conclusions

Our data demonstrate that AMI-MS is able to screen kinase targets where there is a requirement for magnesium chloride despite this being a direct infusion MS technology. AMI-MS compared very favourably with traditional kinase screening technologies but proved significantly cheaper as there was no requirement to purchase detection kits.

Novel Aspect:

This is the first example of AMI-MS being used to screen a kinase target. The data presented clearly demonstrate that AMI-MS is comparable with existing kinase technologies.

Data Independent Acquisition Modes for Identification, Quantification and Monitoring of Low-Abundance Host Cell Proteins During Monoclonal Antibody Bioprocessing

Catalin E. Doneanu¹, Alex Xenopoulos², Romas Skudas², Ying Qing Yu¹, Asish Chakraborty¹, Weibin Chen¹
¹Waters Corporation; ²EMD Millipore Corporation;

Introduction

Quantification of large molecular weight biotherapeutics in biological matrices relies mostly on enzyme-linked immunosorbent assays (ELISAs) mainly due to several advantages: good sensitivity (1-10 ppm), high-throughput, ease-of-use and low cost per sample. In the case of low-abundance protein impurities (HCPs) present in protein therapeutics (e.g. mAbs), these biological assays typically provide the total HCP concentration (usually expressed in ppm or ng HCP/mg mAb), but ELISAs cannot identify and measure individual HCP contaminants. Several MS-based assays have been recently developed to cover this knowledge gap [1-2]. Here we explored the capabilities of a single dimension chromatographic assay, coupled with mass spectrometry using two different data independent acquisition modes for detection of peptide precursors and their fragments.

Methods

The LC/MS assay described here relies on two data-independent acquisition mode implemented on a quadrupole/time-of-flight (QTOF) mass spectrometer. While in MSE mode all peptide ions produced by the electrospray source are transmitted by the quadrupole analyzer, in SONAR mode the quadrupole slides over the mass range of interest during the time required for recording a single MS-spectrum by the TOF-analyzer. Co-eluting precursor ions with different m/z are separated during the rapid quadrupole scan and their corresponding fragmentation spectra are acquired using an identical quadrupole separation. Mass spectra are recorded with high-resolution (~ 25,000) for precursors/fragments.

A monoclonal antibody (mAb), purified by Protein-A affinity-chromatography and then by SCX -chromatography (strong-cation-exchange) using four different elution protocols, was denatured/reduced/alkylated and digested with trypsin.

Preliminary data

LC/MS-assays have recently been adopted as orthogonal techniques to ELISAs for HCP analysis due to their flexibility and sensitivity. Here we describe an efficient analytical scale two step LC/MS assay that allows the identification and quantification of HCPs during mAb purification in a CHO (chinese hamster ovary) cell line. In the first step, called the Discovery Assay, the mAb digest (100-500 µg) is analyzed in SONAR mode on a C18 column (2.1 x 150 mm, operated at 200 µL/min flow rate) using a 90 min gradient. Two HCPs and 4 spiked protein standards were identified across 5 mAb preparations (one Protein A and 4 SCX fractions) following a CHO database search using Progenesis QIP 4.0 software. The same software was also used to build a spectral library containing 13 CHO HCP peptides and 57 peptides from the spiked protein digestion standards. The spectral library contained the peptide RT, the precursor m/z and the MS/MS fragmentation spectrum of each peptide, thus facilitating subsequent HCP identification and quantification in other mAb preparations.

In the second step of the assay, the same 5 digests were analyzed in triplicate in a different acquisition mode (MSE) using higher throughput runs (30 min gradients, 45 min runs) and lower sample loads (10-20 µg of mAb digest). The

MSE acquisition is a data-independent acquisition mode which does not use precursor ion isolation. Instead, in MSE low-energy scans (for precursors) are alternated with high-energy scans (for fragments). The MSE data was searched against the spectral library (containing 70 peptides) to quantify and monitor all 6 previously identified proteins (2 HCPs and 4 spiked proteins). The sensitivity of both assays (discovery and monitoring) was 10 ppm.

SONAR acquisition offers additional selectivity to MSE acquisition, by producing fragmentation spectra with minimized background interferences.

1305 - A MASS SPECTROMETRY TOOLBOX FOR THE OPTIMIZATION OF K-RAS G12C COVALENT INHIBITORS

Florence Fassy (1) - Sophie Raibaud (2)

Sanofi, Research Platform, Vitry sur Seine, France (1) - Sanofi, Translational Sciences, Chilly Mazarin, France (2)

Keywords:

Covalent inhibitor, target engagement, K-RAS

Introduction: Covalent inhibitor of K-RAS G12C to fight lung cancer

The small GTPase K-RAS is the most prevalent oncogene in cancers. The Gly to Cys mutation at position 12 is frequent in lung cancer. The optimization of a drug, covalently bound to Cys12, would target the oncogene without affecting the wild type protein [1]. Mass spectrometry is well suited to the study of covalent complexes and we have implemented a series of tools to support a K-RAS G12C research program.

Methods: Mass spectrometry tools to study covalent complexes

Several LCMS/MS-based assays were developed either with recombinant protein or with cellular or tissue lysates: intact mass to rapidly screen or fully characterize the binding kinetics (k_{inact}/K_i) of covalent complexes, peptide mapping to determine the binding site, and targeted quantitative proteomics to measure target engagement in culture cells and tissues.

Results: Optimization of K-RAS G12C covalent binders

To discover novel covalent inhibitors of K-RAS G12C, several thousands of covalent compounds were screened in an assay measuring the extent of covalent binding on a recombinant protein by intact mass LCMS. Hits were validated by peptide mapping experiments to ascertain that the Cysteine 12 residue was the site of interaction between the compounds and K-RAS G12C. During a chemical optimization program, the newly synthesized compounds were evaluated in the intact mass LCMS assay, as a function of inhibitor concentration at a fixed incubation time (EC_{50}) or at several times (k_{inact}/K_i) [2]. Optimized compounds inhibited the growth of a K-RAS G12C dependent cell line. A targeted LCMS-based assay was implemented to directly and quantitatively determine the engagement of KRAS-G12C in cell lysates [3].

Conclusions:

Our LCMS toolbox has proven to be very robust and powerful to support the optimization of novel covalent inhibitors of K-RAS G12C. Although other biochemical or cellular assays were implemented for the research program, the LCMS assays provided the most direct and non-ambiguous results.

Novel Aspect:

An LCMS intact mass assay as a primary tool to support chemical optimization in a pharmaceutical discovery program.

494 - CLINICAL VALIDATION OF A UPLC/MS/MS-BASED ASSAY TO CONCURRENTLY MONITOR FOUR DIRECT ORAL ANTICOAGULANTS IN DRIED BLOOD SPOTS

Kathrin Isabelle Foerster (1) - Andrea Huppertz (1) - Andreas D. Meid (1) - Oliver J. Müller (2) - Lisa Tilemann (2) - Timolaos Rizos (3) - Walter E. Haefeli (1) - Jürgen Burhenne (1)

Heidelberg University Hospital, Department of Clinical Pharmacology and Pharmacoepidemiology, Heidelberg (1) - Heidelberg University Hospital, Department of Cardiology, Angiology and Pneumology, Heidelberg (2) - Heidelberg University Hospital, Department of Neurology, Heidelberg (3)

Keywords: Clinical validation, direct oral anticoagulant, dried blood spot, liquid chromatography, tandem mass spectrometry

Introduction: Monitoring blood concentrations of direct oral anticoagulants (DOAC) is not required regularly [1]. However, concentrations of some DOAC correlate well with (un)desired outcomes [2,3]. Thus, analyzing individual DOAC exposure could be useful for risk assessment, e.g. when clearance pathways are impaired. Dried blood spotting (DBS) is a practicable sampling technique for regular monitoring, enabling blood sampling at home at any relevant time point [4].

Methods: DOAC concentrations were quantified using a previously published ultrahigh performance liquid chromatography/tandem mass spectrometry (UPLC/MS/MS) multi-compound assay [5], which was refined for DBS analysis. In a clinical study, approved by the responsible ethics committee, DBS from capillary whole blood and plasma were simultaneously sampled in 33 DOAC patients. Deming regression and Bland Altman analyses were used for evaluation.

Results: Our DBS assay fulfilled pertinent validation standards for a hematocrit range of 33-65 % and was linear within a calibration range of 2.5 (apixaban, rivaroxaban), 4.4 (dabigatran), and 9.3 ng/mL (edoxaban) to 750 ng/mL with only minor ion suppression (matrix effect ≤ 12.5 %). Inter-assay and intra-assay accuracies ranged between 88.3-110 % and corresponding precisions were ≤ 13.3 %. DOAC in DBS were stable up to 52 d at room temperature, if stored in the dark and with humidity protection (desiccant). Deming regressions yielded conversion factors for each DOAC (apixaban 1.46, dabigatran 1.51, edoxaban 0.95, and rivaroxaban 1.37), which were used to predict plasma concentrations from (capillary whole blood) DBS. Bland Altman analyses confirmed that plasma concentrations predicted from DBS agreed well with actually analyzed plasma concentrations (71 % for apixaban, 94 % for dabigatran, 100 % for edoxaban, and 88 % for rivaroxaban). Thus, meeting the EMA guideline's demand that in > 67 % of all sample pairs' concentrations must not deviate > 20 %.

Conclusions: UPLC/MS/MS for DOAC quantification from DBS constitutes a practicable and sensitive technique to monitor DOAC exposure. The results of the clinical validation study confirmed that blood concentrations from DBS can accurately predict plasma exposure. Thus, the present DBS assay is an attractive option to monitor ambulatory DOACs.

Novel Aspect: We present a DBS assay capable of analyzing all DOAC at once, with minor setting requirements regarding sample collection.

LC-MS/MS method for analysis of therapeutic peptide Axon Peptide 108 in AADVac1 drug product

Keywords: liquid chromatography, tandem mass spectrometry, Alzheimer's disease, AADVac1, chemical digestion

Introduction:

Alzheimer's disease (AD) is a neurodegenerative disorder responsible for more than 70% of all dementia cases. This disease is characterized neurologically by progressive loss of memory, behavior, language, and visuo-spatial skills impairments. AD has become the focus of one of the most intensive investigation in the medicinal field because of worldwide universal phenomenon – population aging and considerable economic impact. Novel therapeutic strategies based on biologicals are currently under investigation recently. One of the innovative AD therapeutic in clinical trials is AADVac1 – immunotherapy designed to elicit an immune response against pathologically modified forms of tau protein, developed by Axon Neuroscience [1,2]. Herein, we present combination of simple acidic chemical cleavage (sample preparation step) with effective and very fast LC-MS/MS method for quantification of immunogen Axon Peptide 108 in AADVac1.

Methods:

Chemical cleavage:

A strategy based on chemical cleavage at aspartyl residues using dilute formic acid developed by Li et al. [3] was used in this study. Appropriate cleavage of the therapeutic peptide was obtained when the sample was incubated in 2% formic acid at 108°C for 2 h.

LC-MS/MS method:

The quantitative LC-MS/MS experiments were performed with a Waters ACQUITY UPLC system coupled to the Quattro Premier XE triple quadrupole mass spectrometer. ACQUITY UPLC BEH Shield RP18 column (2.1 mm x 100 mm, 1.7 µm particle size) was used for analysis. Column temperature was set for 30 °C. Mobile phase A consisted of 20mM ammonium formate/0.1% FA in MPW, and mobile phase B was acetonitrile. The flow rate was 0.5 mL.min⁻¹ and the injection volume was 5 µL. Mass spectra were acquired using positive electrospray ionization mode (ESI+) and selected reaction monitoring (SRM) mode. The following MS conditions were applied. The capillary voltage was 3 kV and the source temperature and desolvation temperature were 120 and 450 °C, respectively. The cone gas and desolvation gas flowed at 50 and 600 L/h, respectively. Argon was used as collision gas.

Results:

The effective non-enzymatic release step of Peptide 108 based on acid hydrolysis with the use of 2% formic acid was successfully tested and implemented. The main benefit of the chemical cleavage procedure performed with formic acid was high level of compatibility of the cleaved sample with the ESI-MS ionization. Moreover, formic acid was a part of used mobile phase. The developed and optimized LC-MS/MS method was then validated according to the ICH guideline Q2(R1) [4]. Calibration curve was linear within the range of 10 – 300 µg.mL⁻¹. Correlation coefficient was higher than 0.99. The intra- and inter-day precision were 0.92-5.03% and 3.05-10.36%, respectively. The recovery ranged in the interval of 99.73-101.10%. The developed and validated method was successfully applied to determine the amount of Axon Peptide 108 in several clinical batches of AADVac1. Three different batches of AADVac 1 drug product were analyzed and the determined amount of the therapeutic peptide ranged from 74.8 to 106.8 µg/mL.

Conclusions

We developed and tested an effective approach of chemical cleavage of peptide conjugated to the high molecular protein carrier which was connected with very effective, fast and simple LC-MS/MS analysis. Developed and validated LC-MS/MS method was successfully applied and the exact amount of Axon Peptide 108 presented in AADVac 1 was determined in final drug product. The obtained results were in good accordance with the declared amount. This relatively rapid, simple and robust method has a potential to be applied in to the field of biopharmaceuticals analysis.

Novel Aspect:

A simple and rapid approach based on combination of non-enzymatic cleavage and LC-MS/MS analysis was presented as a powerful tool for quantitation of therapeutic peptide against Alzheimer's disease in innovative biologic AADvac1. The use of chemical hydrolysis was associated with solubilization of the AADVac 1 adjuvant (alhydrogel) which was beneficial in term of simplicity. Moreover, it was clearly demonstrated that chemical hydrolysis is much more faster and cheaper in comparison to convenient approach based on enzymatic cleavage (e.g. asparaginase N).

Keywords

Capillary gap sampler, ESI Mass spectrometry, Solid phase microextraction, Small molecule drug conjugate, Cancer chemotherapy.

Introduction

The targeted delivery of cytotoxic agents into tissues, especially for malignant cells is an attractive strategy to avoid dose limiting toxicity. Targeting moieties can be antibodies, aptamers and low molecular weight non-peptidic ligands. Previous studies showed the advantages of conjugating small molecules to the drug over attaching macromolecules. One of the common used target moiety for selective delivery of cytotoxic agent is acetazolamide. In this area, there is a pressing need to develop rapid techniques to quantify the amount of drug in the tissue in order to investigate the tumor targeting performance of the different ligands. So-called the "capillary gap sampler" is capable of automated and site-specific extraction of very small sample amounts, which is interesting for this application.

Methods

The capillary gap sampler is a miniaturized sampling device enabling automated low-volume sample handling, for direct interfacing to ESI mass spectrometry. It consists of a liquid bridge of several nanoliters formed between two capillaries, where one acts as the ESI-MS spray needle. Sample extraction is performed by a coated stainless-steel pin which is controlled by a robot arm. Selective drug extraction is possible through immobilizing carbonic anhydrase (CA) on the pin. This modification is performed by overnight reaction between protein with epoxy modified beads which are glued to the tip of the pin. Using fluorescence microscopy, bright field and blue channel images of beads carrying protein linked to 8-anilino, 1-naphthalene sulfonate and controls confirmed the attachment of the protein.

Figure 1. Solid phase micro extraction, a) Capillary gap capillary, b) loading of sample on the extraction tool, c) SEM image of the CA modified beads on the extraction tool, d) desorption of the extracted sample in the liquid bridge and further sprayed to the ESI-MS orifice.

Results and discussion

The development started with optimization of the coating procedure, desorption solution, etc. In order to find the optimum desorption solution two tests were performed: in the first one, influence of pH on the binding of acetazolamide with CA was investigated. In the second test, different phases (ACN, MeOH, EtOH, Acetone 60% in water) were used for desorption. ACN was found to be the optimum desorption solution. Extraction of the drug from PBS was performed by dipping the CA modified extraction tool inside the solution. After a quick washing step with water, it enters into the liquid bridge, where the analyte desorbs and is sprayed in the ESI source. Peaks corresponding to the drug (drug⁺), (drug+Na⁺⁺H⁺), (drug+2H⁺), (therapeutic warhead=cytotoxic agent coupled to

the targeting agent+H⁺) were observed in the spectrum. Finally, repeatability of the acetazolamide extraction using CA modified beads are evaluated by performing thirteen 5-minute extractions from 500nM acetazolamide in PBS solution. The relative standard deviation was below 10%, which confirms the repeatability of the method. Drug extraction studies from human plasma will also be shown.

Novel aspects

Development of a extraction method for evaluation of targeted drug delivery.

Keywords: GC-C-IRMS; stable isotope; ^{13}C natural abundance; surfactant; Respiratory Distress Syndrome

Introduction:

Respiratory Distress Syndrome (RDS) is a breathing disorder affecting preterms due to lack of lung surfactant, a lipoprotein layer which prevents alveolar collapse [1]. Treatment with exogenous surfactant improves gas exchange and survival [2]. The aim of this study was to estimate the contribution of exogenous surfactant phospholipids to the rabbit alveolar pool in vivo by ^{13}C natural abundance.

Methods:

In a feasibility study we measured the $^{13}\text{C}/^{12}\text{C}$ ratio of disaturated-phosphatidylcholine palmitate (DSPC-PA) in poractant alfa and in bronchoalveolar lavages of 20 rabbits. The contribution of exogenous surfactant was then estimated in a rabbit model of RDS [3] including 7 controls and 15 rabbits treated with 50, 100 or 200 mg/kg of poractant alfa. DSPC-PA $^{13}\text{C}/^{12}\text{C}$ ratio was measured by GC-C-IRMS.

Results:

The DSPC-PA $^{13}\text{C}/^{12}\text{C}$ ratio of poractant alfa was constant among 7 batches produced over a year with a mean value of -18.8 ± 0.1 ‰ [Range: -18.9 ‰; -18.6 ‰]. The mean $^{13}\text{C}/^{12}\text{C}$ ratio of surfactant DSPC-PA recovered from the lung lavages of 20 rabbits was -28.8 ± 1.2 ‰ [Range: -31.7 ‰; -25.7 ‰]. DSPC-PA in rabbits had a significant lower ^{13}C abundance than poractant alfa, with a mean difference of 10.0 ‰, wide enough to distinguish the endogenous from the exogenous compound. The contribution of exogenous surfactant to the total alveolar surfactant was calculated in all treated rabbits and it ranged from a minimum of 42.9% in 50mg/kg group to a maximum of 90.2% in 200 mg/kg group, with a significant dose-effect.

Conclusions:

The DSPC-PA of exogenous and endogenous surfactant have a different natural abundance of ^{13}C and this difference could be exploited to estimate in vivo the alveolar contribution of exogenous surfactant in treated rabbits. Since the use of chemically synthesized tracers is not required, it could be useful in human research and in surfactant replacement studies in preterm newborns.

Novel Aspect:

This is a novel method to measure in vivo the contribution of exogenous surfactant to the alveolar pool by using stable isotopes at natural abundance.

1361 - ANALYSIS OF HOST CELL PROTEINS IN ANTIBODY PREPARATIONS USING PASEF

Michael Greig (1) - Stuart Pengelley (2) - Guillaume Tremintin (1) - Detlev Suckau (2) - Waltraud Evers (2)

Bruker, Daltonics, San Jose, United States (1) - Bruker, Daltonics, Bremen, Germany (2)

Keywords: TimsTof, PASEF, HCP, proteomics, host cell protein

Introduction:

In the arena of biotherapeutic analysis, the analysis of host cell proteins (HCP) at the ppm level is critical. ELISA is currently the gold standard for QC applications, but the advantages of mass spectrometry are abundant. We show how PASEF (parallel accumulation and serial fragmentation), as implemented on the timsTOF PRO QTOF, can be applied to HCP analysis for highly sensitive detection with enhanced data quality.

Methods:

The NISTmAb Reference Material 8671 and the Universal Proteomics Standard (UPS1, Sigma) were reduced, and digested. Peptides were separated on an Intensity Solo 2 1.8 μ m C18 column using an Elute UHPLC coupled to a timsTOF Pro ion mobility QTOF mass spectrometer (all Bruker Daltonics). A 150 minute gradient was used. For nanospray, a nanoElute UHPLC was fitted with an IonOpticks C18 column using a 210 minute gradient.

Results:

The UPS1 standard was used to make a 5-step 1:3 dilution series in a constant background of NIST mAb over a concentration range from 0.3 to 934 ppm. PASEF enabled the detection of UPS1 proteins down to low single digit ppm concentrations in the presence of 25 μ g NIST mAb. Linear response for the UPS1 protein beta-2-microglobulin in the concentration range from 132 ppm to 1.6 ppm was observed. The dilution series indicated that PASEF enabled detection of HCPs in the range of 1 to 100 ppm of the therapeutic protein. Nano UHPLC was also evaluated for its suitability for HCP identification. This setup has already been established as the new benchmark for bottom-up proteomics applications [1, 2]. More than 200 HCPs were identified in 1.5 μ g NIST mAb, including expected and previously unreported HCP proteins. The depth of HCP coverage and sequence coverage was further extended to >280 HCP identifications by employing an alternate digestion method in which only the HCPs are digested allowing the mAb to be removed prior to analysis [3].

Conclusions

PASEF improved the sensitivity of peptide mapping enabling the detection of HCPs at sub 100 ppm levels. PASEF coupled to nanoLC facilitates detection of previously unreported trace level HCPs. The quality of MS/MS sequence spectra provided by the timsTOF Pro with PASEF allows high confidence in protein ID even when only 1-2 peptides are sequenced.

Novel Aspect:

Sensitive HCP assay for routine use enabled by time and space focusing of precursor ions with a PASEF scan.

Keywords: deamidation, trastuzumab, attribute monitoring, pH

Introduction:

Deamidation is one of the most common modifications which can be induced in monoclonal antibodies during production and prolonged storage. It is critical to evaluate and monitor these biologically relevant product quality attributes (PQAs) as deamidation can cause structural changes, reducing biological activity and efficacy of the biotherapeutic. Here, we monitored the degree and site of deamidation induced in pH stressed antibody digest.

Methods:

The trastuzumab samples were exposed to pH stress by increasing the pH of digestion buffer from nearly acidic (6.8) to alkaline (8.8). All measurements were carried out in replicates on using high flow liquid chromatography and a high resolution mass spectrometer using a data dependent (DDA) acquisition strategy. The complete data processing was performed with BioPharmaView™ software using the MAM workflow and reference ranges were set for pass/fail criteria.

Results:

The monoclonal antibody digest was exposed to higher pH levels in order to induce deamidation. All asparagine sites were monitored and defined for quantification using MAM workflow in BioPharmaView™ software. The lowest levels of deamidation were observed with the neutral or nearly acidic pH (6.8) as compared to the alkaline pH (8.8) values. The MAM workflow in the BioPharmaView™ software enabled the accurate and automated quantitation of all deamidation sites within the defined criteria of pass/fail using neutral pH values as reference points. The accuracy of the method was assessed by spiking the forced deamidated samples into the control sample at different levels. The sample with the lowest deamidation levels (pH 6.8) was used as control due to lack of samples with no deamidation. Excellent linearity was observed with the increasing levels of spiking thus verifying the accuracy of the method.

Conclusions:

Using BioPharmaView™ software with the attribute calculator for the MAM workflow, levels of deamidation were calculated for all possible deamidation sites within trastuzumab. The data was automatically processed and showed the susceptibility of some residues to pH whereas others are far less sensitive. The results can be used to refine monitoring of attributes to those that are more susceptible to environmental changes.

Novel Aspect:

MAM workflow in BioPharmaView™ software for the quantitation of pH induced Deamidation.

Keywords: RLM, SPME, combretastatin A4, electrochemistry

Introduction:

Drug metabolism remains the main point of interest for clinicians, as comprehensive information regarding metabolic pathways and the mechanisms of action of new drugs are essential for recognition of their possible toxicity and biological activity in patients. The multi-tool analytical approach based on electrochemistry, *in silico* predictions and *in vitro* studies with the use of rat liver microsomes were employed for recognition of combretastatin A4 metabolism.

Methods:

In silico prediction was carried out using MetaPrint2D-React for recognition of transformations at primary sites of metabolism. For electrochemical reaction the ROXY™ system was used. It conducts redox reactions which are the most common during I phase metabolism. The rat liver microsomes was analyzed via two different extraction approaches protein precipitation and solid phase microextraction. Orbitrap HRMS was used for instrumental analysis.

Results:

The use of a high resolution mass spectrometer enabled a non-targeted investigation of metabolic transformations of the parent drug and identification of previously reported [1] as well as unreported metabolites. In total fourteen putative metabolites of combretastatin A4 were found. The main paths of CA4 metabolism are O-demethylation and aromatic hydroxylation and those metabolites were found by all aforementioned metabolism generating Methods: There was no differences found between PP and SPME analysis of RLM in terms of identified metabolites. The use of SPME allowed performing time course analysis without need of sample multiplication. The EC reaction resulted in generation 3 metabolites reported also by RLM and one exclusive metabolite not found by other techniques.

Conclusions

The high mass accuracy and fragmentation patterns supported by *in silico* data showcase the applicability of this approach as an ultimate tool for further identification of putative metabolites detected in microsomes extracts or via EC reactions, especially in cases where authentic standards are not available to confirm the tentative results attained via untargeted analyses.

Novel Aspect:

In total of eight metabolites of combretastatin A4 not reported elsewhere were identified via non *in vivo* based approaches.

Work has been supported by National Science Center No2016/23/N/NZ7//01929

Keywords: Antibody drug conjugate (ADC), RPLC, drug-to-antibody ratio (DAR), triple quadrupole MS, Middle-down

Introduction:

Antibody-drug conjugates (ADCs) are an increasingly popular class of therapeutic drugs with an inherently high heterogeneity from a large arsenal of drugs, linkers and antibodies. RPLC-MS using QTOF or Orbitrap analyzers have been used successfully to determine the average drug-to-antibody ratio (DAR) for several constructs. Here we have investigated the potential for the very common triple quadrupole(QqQ) analyzers as an alternative for this application.

Methods:

Deglycosylated Trastuzumab and in-house synthesized ADCs generated from Trastuzumab by disulfide reduction with TCEP, followed by conjugation of vcMMAE to the resulting thiols were used for the comparison. Waters Premiere QTOF and Waters XevoTQ-S Micro in combination with Waters Acquity UPLC system and Waters Xbridge C4 column was used for the RPLC separation for the comparison. Mobile phases consisted of 0.5% FA with H₂O or ACN.

Results:

Both ADCs and monoclonal antibody (mAb) were analyzed with RPLC-MS on a QTOF and QqQ instruments. Having reduced the disulfide bonds to separate the light- and heavy chains the charge envelopes moves to lower m/z so the loss of ions by a limited m/z range was small. Consequentially the loss of any ions above 2000 m/z in the QqQ was found to have no evident effect on the assigned molecular weights after deconvolution. Comparing the two instruments, preliminary data indicates that the differences in spectral quality related to differences due to age and type of ionization source had bigger effect than the loss of part of the charge envelope on the DAR determination and LOD.

Conclusions:

Preliminary data implicates that for average DAR determination of ADCs the QqQ instruments can be a cheaper and more readily available option for smaller labs in early stages of ADC development. The limited m/z range of the QqQ has thus far proven to have no major effect on DAR value determination.

Novel Aspect:

We have shown that triple quadrupoles can be used for accurate DAR determination of disulfide reduced ADCs and mAbs.

579 - DRAWING THE ACTIVITY OF AURANOFIN BY AN ELECTROCHEMICAL REACTION CELL COUPLED TO AN ESI MS/MS

Pawlak Katarzyna (1) - Monika Kupiec (1) - Robert Ziolkowski (2)

Warsaw University of Technology, Faculty of Chemistry, Chair of Analytical Chemistry, Warsaw (1) - Warsaw University of Technology, Faculty of Chemistry, Chair of Medical Biotechnology, Warsaw (2)

Keywords: electrochemical chamber, auranofin, redox reaction, pharmacokinetics

Introduction:

Gold complexes belong to a group of rapidly emerging novel therapeutic and diagnostic compounds with improved specificity for tumor tissue and strong antiproliferative potency. They are usually responsible for the cell growth-inhibiting effects related to the mitochondrial activation of apoptosis. Auranofin used in the treatment of rheumatoid arthritis was selected for the experiments because of documented activity against ovarian cancer, HIV, *E. Histolytica* and *M. Tuberculosis*.

Methods:

Redox activity of selected gold(I) complex was investigated by means of a ROXY ERC system (Antec, The Netherlands) consisting of a potentiostat, equipped with an electrochemical micro-reactor cell (μ -PrepCell, Antec, The Netherlands) and an infusion pump (KD Scientific, model KDS100, USA, Figure 1c). The Roxy system was online hyphenated to an Agilent 6460 LC/MS ESI triple quadrupole mass spectrometer (Santa Clara, USA) as a detector.

Results:

Reduction and intermediate electrochemical conditions corresponding to conditions of cytosol and blood were found optimal to obtain most probable reactive forms for auranofin: (tEP)₂-Au and tetra(tri and di)AtgS-Au, which can interact with bioligands in human organism. Obtained products are in agreement with forms of auranofin bound to GSH and human albumin. Products of deacetylation were minor and observed mainly in the presence of sodium cations. Moreover, sodium ions were found to enhance creation of disulfide bridges during anodic process. ERC-ESI MS results additionally allow to state that deacetylation and loss of Atg or tEP groups by auranofin are irreversible as is disulfide formation. Nitrile group attaching to gold and its influence on transformation of auranofin can mimic the behavior of ligands typical for physiological conditions. Ligand exchange can be proposed as the most probable mechanism for metabolic changes of auranofin.

Conclusions

Electrochemical reaction chamber (ERC) coupled to ESI MS was found to provide significant information considering the transformations of auranofin. Moreover, molecule-specific mass spectrometry delivers complementary data to square-wave voltammetry, which aids in understanding the nature of electrochemical conversions of complex or unstable compounds.

Novel Aspect:

For the first time ERC-ESI MS was used to study the transformations of cytotoxic metal transition complexes such as auranofin.

Keywords: Alzheimer's Disease, neurodegeneration, LC-MS/MS, natural compounds, proteomics

Introduction:

Alzheimer's disease (AD), the most common form of dementia (%70). Current drug treatments aim to prevent cognitive decline. No new drug have been approved by FDA since 2003. Studies have revealed that alkaloids with anticholinesterase activity are a promising resource in drug discovery.[1] The aim of the project is to discover natural compounds for the treatment of AD and investigate their effects on neurodegeneration in a comprehensive manner.

Methods:

Natural compounds (2 different doses) were administered for 7 days, to 12 m old (pathological phase) 5XFAD transgenic mice (n=8). Littermate mice were used as control group. FDA approved AD drug Galantamine is also used as positive control. Morris water maze (MWM) was performed to investigate changes in learning and memory impairment. Action mechanism of drugs were investigated in 3 different regions of the brain which are cerebellum, cortex and hippocampus via LC-MS/MS based protein expression analysis.

Results and Conclusion:

2 of 6 compounds showed significant improvement in learning and memory according to MWM test. The compound which improves the condition most, was used for further proteomic investigation. Protein expression changes between control and drug-administered groups were determined by LC-MS/MS analysis. In each samples, approximately 1250 proteins were identified and differentially expressed proteins between groups were subjected to pathway analysis to enlighten the molecular mechanisms affected by the drug.

Novel Aspect:

This is the first study that nLC-MS/MS based proteomics approaches were used in the research of molecular effect mechanism of novel compounds on 5xFAD mouse model.

53 - SIMULTANEOUS DETERMINATION OF ARIPIPRAZOLE, DEHYDRO-ARIPIPRAZOLE, OLANZAPINE, RISPERIDONE, PALIPERIDONE, QUETIAPINE AND CLOZAPINE IN HUMAN PLASMA BY LC-MS/MS

Dóra Koller (1) - Aneta Wojnicz (1) - Francisco Abad-Santos (1)

Hospital Universitario de la Princesa, Clinical Pharmacology Department, Universidad Autónoma de Madrid, Instituto de Investigación Sanitaria la Princesa, Madrid (1)

Simultaneous determination of aripiprazole, dehydro-aripiprazole, olanzapine, risperidone, paliperidone, quetiapine and clozapine in human plasma by LC-MS/MS

Keywords: antipsychotics, LC-MS/MS, SPE, pharmacokinetics, quantification, method validation

Introduction:

A simple and sensitive LC-MS/MS method was developed and validated for the simultaneous quantification of aripiprazole (ARI) and its active metabolite dehydro-aripiprazole (DARI), olanzapine (OLA), risperidone (RIS) and its active metabolite paliperidone (PAL), quetiapine (QUE) and clozapine (CLO) in human plasma. These drugs have been widely used in the treatment of schizophrenia and schizoaffective disorders [1]–[3].

Methods:

Stable isotopically labeled internal standards - [2H8]-ARI, [13C,2H3]-OLA, [2H4]-RIS, [2H4]-PAL, [13C4]-QUE and [13C,2H3]-CLO - were used for all analytes. Three-step phospholipids-eliminating microelution-solid-phase extraction was used for analyte extraction. The chromatographic separation was performed during 8 min under gradient conditions through a mobile phase consisting of 0.2% formic acid and acetonitrile with a flow rate of 0.6 ml/min.

Results:

The analytical method has been validated according to the recommendations of European Medicines Agency (EMA) and Food and Drug Administration (FDA) through tests of precision, accuracy, stability, sensitivity and specificity. The coefficient of variation was not more than 20% for the lower limit of quantification and was below 15% for the rest of quality controls. The method is able to detect the drug levels in the ranges of 0.18-120 ng/ml for ARI, 0.25-80 ng/ml for DARI, 0.5-1000 ng/ml for CLO, 1-100 ng/ml for OLA, 0.7-60 ng/ml for RIS, 0.2-30 ng/ml for PAL and 0.5-160 ng/ml for QUE during therapeutic drug monitoring. Comparing with protein precipitation (PPT), our SPE sample preparation method resulted to be effective in removing phospholipids from plasma.

Conclusions

We have developed a sensitive LC-MS/MS method to determine the levels of 5 antipsychotics and 2 active metabolites with the usage of stable isotopically labeled internal standards in human plasma. The method is currently being utilized in pharmacokinetic studies. Its application could help to optimize the effectiveness of treatment and manage side effects or toxicity leading to individualized therapeutic decisions for each patient.

Novel Aspect:

The present method applies effective phospholipids' removal during SPE and therefore results in exceptional recoveries and low matrix effect.

Keywords: Bleomycin, metal complex, serum, tumor, LC-MS analysis

Introduction

Bleomycin (BLM) is a cytotoxic antibiotic that appears as a mixture of more than ten structurally strongly related glycopeptides, most abundant being BLM-A2 and BLM-B2 fractions. In vivo BLM chelates with several metals, in particular with copper. Aiming to investigate its biodistribution and pharmacokinetics as a part of a wider electrochemotherapy study, we developed a specific and sensitive mass spectrometry-based analytical method for determination of BLM in serum and tumor tissues.

Methods

Frozen tumors were grinded to fine powder, the suspension was sonicated, the supernatant filtered and loaded onto a preconditioned solid phase extraction (SPE) cartridge. Reversed-phase SPE of diluted serum and tumor suspensions was performed as the enrichment step. BLM behavior was investigated with UHPLC coupled to a QTOF MS [1]. To improve quantification characteristics the instrumental method was later translated to UHPLC coupled to QTRAP MS.

Results

The optimized sample preparation method used Oasis HLB™ cartridges at acidic pH of the sample matrix, water as the wash solvent, and 40% methanol followed by acetonitrile for BLM elution. For UHPLC separation we selected BEH Amide stationary phase, which clearly and distinctively separated the Cu complexes of BLM-A2 and BLM-B2 fractions.

The investigation of BLM chelating properties implies that Cu complexes form in vitro and in vivo, and offer a viable form for the quantitative determination of BLM in biological samples. The amount of Cu available in the serum is insufficient to quantitatively chelate metal-free BLM even at its highest concentrations. Metal-free BLM-A2 shows a 2+ charged fragmentation at m/z 707.76, but it is a "transient" species that forms the Cu complex. The latter shows an abundant ion at m/z 707.21, and m/z 707.71 as the second isotope ion in the typical Cu isotopic pattern. In the complex mixture of several BLM fractions and their metal complexes, and considering also background ions from the biological tissue matrices, this second isotope ion may easily be misinterpreted and incorrectly assigned to the metal-free BLM-A2, which could be the reason, why the attempts to determine BLM with MS have been so scarce.

Conclusions

Except in the controlled metal-free environment BLM is not found in a free form, but is highly prone to form chelates. Thus, MS analysis results in the apparent disappearance of BLM characteristic fragment ions. In addition, the chelates may be hidden at first sight, since they tend to form double charged ions. Choosing a HRMS proved crucial for recognizing BLM MS behavior, since it enabled us to follow the isotopic pattern of the double charged ions in the clusters.

Novel Aspect

The LC-MS analytical method for determination of bleomycin in serum and tumor tissues is developed for the first time.

1397 - A RAPID AND HIGHLY SENSITIVE LIQUID CHROMATOGRAPHY-TANDEM MASS SPECTROMETRY METHOD FOR SIMULTANEOUS DETERMINATION OF MELOXICAM AND 5'-CARBOXYMELOXICAM IN HUMAN PLASMA AND ITS APPLICATION TO A PHARMACO

Choong-Min Lee (1) - Eui Hyun Jung (1) - Yun Jeong Lee (2) - H.Y. Lee (3) - J. Lee (1) - Seok-Yong Lee (1)

Sungkyunkwan University, School of Pharmacy, Suwon, Korea, Republic Of (1) - Dankook University, College of Pharmacy, Cheonan, Korea, Republic Of (2) - Konyang University, Dept. of Pharmacology, Daejeon, Korea, Republic Of (3)

Keywords: Meloxicam; 5'-carboxymeloxicam; LC-MS/MS; Human plasma; Pharmacokinetics.

Introduction: Meloxicam belongs to oxicam class of nonsteroidal anti-inflammatory drugs (NSAIDs) and is widely used to treat pain or swelling caused by osteoarthritis or rheumatoid arthritis. After oral administration of meloxicam, it is absorbed with bioavailability of 89% and has long half-life (22–24 hour). Meloxicam is extensively metabolized to four inactive metabolites by cytochrome P450 (CYP) 2C9 with a minor contribution of CYP3A4. The primary metabolic pathway of meloxicam is oxidation and 5'-carboxymeloxicam has been known for the major metabolite of meloxicam. The aim of the study was to develop and validate a more rapid and sensitive analytical method for simultaneous determination of meloxicam and 5'-carboxymeloxicam based on LC-MS/MS system.

Methods: After addition of 100 μ L of 1 M hydrochloride acid, 200 μ L aliquot of human plasma was extracted with an internal standard (piroxicam) by simple liquid-liquid extraction using methyl-tert butyl ether. The chromatographic separation of each analyte was achieved on a reversed phase Luna C18 column (50 mm \times 2.0 mm i.d., 5 μ m particles) in a run time of 3 min, using a mixture of methanol and 10mM ammonium formate buffer (pH3.5) (80:20, v/v) at a flow rate of 200 μ L min⁻¹. The tandem mass spectrometry was operated in multiple reaction monitoring acquisition mode using positive ion mode.

Results: This method was linear over the concentration range of 2–3000 ng/mL for meloxicam and 0.5–50 ng/mL for 5'-carboxymeloxicam, respectively. The lower limit of quantifications of meloxicam and 5'-carboxymeloxicam were 2 ng mL⁻¹ and 0.5 ng mL⁻¹, respectively.

Conclusions: The present analytical method showed better sensitivity and reduced running time than a previous study and successfully applied to a pharmacokinetic study after administration of 15 mg oral dose of meloxicam to healthy male subjects.

Novel Aspect: A rapid, simple, sensitive analytical HPLC-MS/MS method for the determination of meloxicam and 5'-carboxymeloxicam in human plasma was developed and successfully validated. Our study showed 4-fold more sensitivity for both analytes and reduced run time, compared to the only study for the simultaneous determination of meloxicam and 5'-carboxymeloxicam.

1395 - SIMULTANEOUS DETERMINATION OF TRAMADOL, O-DESMETHYLTRAMADOL, AND N-DESMETHYLTRAMADOL IN HUMAN PLASMA BY LIQUID CHROMATOGRAPHY-TANDEM MASS SPECTROMETRY AND ITS APPLICATION TO A PHARMACOKINETIC STUDY

Keywords: Tramadol; O-demethyltramadol; N-desmethyltramadol; HPLC-MS/MS; Human plasma; Pharmacokinetics

Introduction: Tramadol is a centrally acting analgesic drug and indicated for the treatment of moderate to moderately severe pain. To determine the tramadol and its two main metabolites, O-desmethyltramadol (ODT) and N-desmethyltramadol (NDT), in human plasma, a sensitivity-enhanced LC/MS/MS method was developed in this study.

Methods: A simple, rapid and sensitive high performance liquid chromatography analytical method coupled with tandem mass spectrometry (HPLC-MS/MS) for the simultaneous determination of the tramadol, ODT and NDT was developed and validated. Metoprolol was used as an internal standard (IS) and the analyte was extracted with methyl tert-butyl ether (MTBE). The chromatographic separation of tramadol, ODT, and NDT was achieved on a reversed-phase Luna C18 column (50 mm × 2.0 mm i.d., 5 μm particles), using a mixture of 10 mM ammonium formate buffer (pH 3.5)-methanol (30:70, v/v) at a flow rate of 200 μm/min. The total run-time was 2.5 min and the retention times of tramadol, ODT, NDT and IS were 0.88 min, 0.82 min, 0.90 min, and 0.85 min respectively. The analytes and IS were ionized using a positive ion mode and analyzed using multiple reaction monitoring (MRM) of the transitions at m/z 264.3 → 58.1 for tramadol, 250.3 → 58.2 for ODT, 250.3 → 44.1 for NDT, and 268.2 → 116.1 for IS.

Results: The weighted (1/x²) calibration curves were linear over plasma concentration range 0.20-400 ng/mL for tramadol (r = 0.999) and 0.25-200 ng/mL for ODT and NDT (r = 0.998 and r = 0.997, respectively). The lower limit of quantifications (LLOQ) of tramadol, ODT, and NDT using 100 μL of human plasma were 0.02 ng/mL, 0.25 ng/mL, and 0.25 ng/mL, respectively. This HPLC-MS/MS method showed improved sensitivity for quantification of tramadol, ODT, and NDT using lower volume of human plasma and reduced running time, compared with previously described analytical Methods:

Conclusions: The method was successfully used to a pharmacokinetic study following the administration of a single 100 mg oral dose of tramadol to healthy male subjects.

Novel Aspect: To best our knowledge, there was only one case report using achiral determination of tramadol, ODT and NDT in human plasma employing HPLC-MS/MS and has lower sensitivity than this method

Keywords: Chemotherapy, in vivo lung perfusion, human trial, drug monitoring, solid phase microextraction.

Introduction:

In vivo lung perfusion is a novel technique designed to localize chemotherapy to the lung tissue suffering metastasis. Effectively, increased doses of chemo agents can be used while reducing systemic exposure to the individual thus decreasing associated side effects.1As there are currently no techniques available to determine drug tissue concentration during IVLP without taking biopsies, SPMEemerged as a feasible strategy for invivo quantification of doxorubicin.2

Methods:

In vivo lung perfusion (IVLP) was used to administer doxorubicin for treatment of metastasized lung tumor in a human being. BioSPMEfibers were insertedin vivointo three sections of the lung to monitor drug concentration, distribution and effect in lung tissue during IVLP.Liquid chromatography tandem mass spectrometry was used for drug quantification, while high resolution mass spectrometry was employed for untargeted analysis to determine markers of tissue stress or damage.

Results: (Limit 900 characters without spaces)

An administered dose of 5 µg/mL of doxorubicin in perfusate solution resulted in a drug tissue concentration 40 times higher than the administered dose, reaching a concentration of 200µg/mLwithin the first hour of IVLP. This increase was marked by a ~ 50 % decrease in the perfusatedrug concentration. Subsequent analysis of the perfusate solution as well as the lung tissue at hourly intervals showed a decreasing trend in the concentration in both biological matrices.Untargeted metabolic profiling processed via multivariate analysis using Metaboanalyst 4.0 showed an interesting feature at m/z 166.0864 tentatively identified as L-phenylalanine, an endogenous metabolite that could serve as a possible marker of tissue stress or damage since it is known to be a metabotoxin at high concentrations.

Conclusions

Targeted analysis for doxorubicin quantitation and metabolic profilingto assess chemotherapeutic effect in lung tissue could be achieved using SPME. A decreasing trend of doxorubicin concentration in perfusate is linked to its continuous accumulation in tissue duringIVLP. Furthermore, it is hypothesized that the decreasing doxorubicin concentrations in lung tissue may be due to intracellular uptake of the drug, making it less available to the SPME fibers that extract via free concentration.

Novel Aspect:

For the first time, concurrentsemi-quantification of doxorubicin and chemical tissue biopsies in vivo in human lung during surgery can be achieved via SPME.

Assessment of antibody-derived therapeutics at the intact and middle-up level by CESI-MS

Elena Domínguez-Vega¹, Rob Haselberg², Govert W. Somsen²; Jim Thorn³, Christopher Löbner⁴ and Stephen Lock³

¹Leiden University Medical Center, Leiden, The Netherlands; ²Division of BioAnalytical Chemistry, Vrije Universiteit, Amsterdam, The Netherlands, ³SCIEX, Warrington, United Kingdom and ⁴SCIEX, Darmstadt, Germany

Keywords: CE-MS, CESI, antibody-based pharmaceuticals, nanobodies, proteoforms

Introduction: (Limit of 400 characters)

Antibody-based pharmaceuticals often contain complex structural heterogeneity which requires enhanced analytical methods for reliable characterization of variants and degradation products. In this poster we will describe how CE-MS (CESI-MS which integrates CE and electrospray ionization (ESI) into a single device) in combination with high-resolution MS detection has been used for profiling antibody therapeutics.

Methods: (Limit of 400 characters)

By using a neutral capillary coating (to provide near-zero electroosmotic flow) and an acidic background electrolyte intact model proteins were detected with overall migration-time RSDs below 2.2% (using 3 different capillaries). Samples, including mono- and bivalent nanobodies, and three monoclonal antibodies (mAbs) were tested.

Results: (Limit 900 characters)

Intact nanobodies were resolved from their degradation products, which could be assigned to deamidated, cleaved, and truncated forms at the C-terminal tag with excellent resolution of isomeric deamidated products obtained. The mAbs were analysed intact and after digestion by the IdeS endoproteinase (middle-up approach). CE-MS of intact mAbs resolved clipped species (e.g. light chain and light chain-heavy chain fragments) from the native protein as well as glycoforms containing sialic acids from their non-sialylated counterparts. For IdeS-digested mAbs, F(ab)₂ and Fc/2 were efficiently resolved. While migration of Fc/2 fragments were fairly similar for the three mAbs, the migration of the F(ab)₂ strongly depended on the mAb. All Fc/2 charged variants, which included glycoforms containing sialic acids and other PTMs such as loss of C-terminal lysine or deamidation of Asn, were nicely separated in less than 20 min. This allowed a detailed and reliable assessment of the Fc/2 heterogeneity (18-33 proteoforms) for the mAbs studied.

693 - DETECTION AND CHARACTERIZATION OF STABLE IMINIUM ION REACTIVE METABOLITE USING HIGH RESOLUTION MASS SPECTROMETRY.

Tommaso Miraval (1)

Idorsia LTD, DMPK, Allschwil (1)

Keywords: Drug Metabolism, Reactive Metabolites, High Resolution Mass Spectrometry

Introduction: Iminium ion reactive metabolites

Xenobiotics including drugs may be metabolized to form reactive metabolites that covalently bind to protein or DNA. Such bioactivation is suspected to play a causative role in various adverse drug reactions. Thus, early detection of reactive metabolites has become an important part of the drug discovery process. Several tertiary amine-bearing drugs undergo P450- or MAO-catalyzed oxidation to unstable iminium ion species which readily hydrolyze to aldehydes, both of which being potentially reactive. However, due to their inherent chemical instability, the use of trapping agents (e.g. cyanide, methoxyamine) is required to put them into evidence. In this poster, we report unusual iminium ion metabolites which appear sufficiently stable to be directly detected and characterized using liquid chromatography (LC) coupled with high resolution mass spectrometry (HRMS).

Methods: In vitro incubations and metabolites identification

10 μ M incubations of compound P, bearing a piperazine moiety, were performed with human liver microsomes in potassium buffer (0.1 M, pH 7.4) for 60 minutes with and without 1 mM solution of potassium cyanide. The reaction was initiated by addition of NADPH after 5 minutes of preincubation and stopped with an equal volume of acetonitrile.

10 μ M incubations of compound P were also performed using fresh rat and cryopreserved human hepatocytes in suspension at cell density of 1 million cell/mL. An aliquot of each sample was taken at various time points and reaction was stopped with an equal volume of acetonitrile. After centrifugation at 13000 RPM for 10 minutes, all the samples were transferred to an HPLC vial and submitted to the Q-Exactive HF (ThermoFisher AG, Reinach) LC-MS system. After a preliminary full scan experiment in positive ion mode, representative samples, using a blank matrix without compound as a control, were chosen and then processed using Compound Discoverer 2.0 (ThermoFisher AG, Reinach) to identify the main metabolites. After the selection of molecular ions of interest, production reaction monitoring (PRM) experiments were performed to elaborate the fragmentation pattern of each metabolite. To refine structural elucidation, a deuterium exchange experiment was also performed, in which the number of exchangeable proton present in the molecule were established.

Results: Metabolic Profiling

Metabolic profiles were similar between human microsomes and hepatocytes. No conjugated phase II metabolite was observed whereas parent drug (P) was the most prominent entity detected in either matrices.

Several prominent phase I metabolites were also seen. This included the N-dealkylated product M1, which was further oxidized to M2 and M3, the N-oxide M4 and a doubly dehydrogenated product M5. In addition, the dehydrogenated M7 and amide derivatives of M1 (M8 and M9) and of P (M10) were also detected in hepatocytes.

In the rat cells, the nitrene derivative of M1 was the main entity detected. Parent drug (P) M1, M2 and M3, M4, M5, M8, M9, M10 were also observed. Based on fragmentation patterns, all biotransformations were assigned to the piperazine ring.

Both M5 and M7 did not exhibit any shift in the deuterium exchange experiment, suggesting that these metabolites were already charged and did not require an ionization proton for MS detection. Metabolite M7 was successfully trapped with the iminium trapping agent cyanide in human liver microsomes, and the concomitant lowering of M5 abundance was observed.

Conclusions :

The involvement of an intermediary iminium ion metabolite in the metabolic pathway of P was initially suspected from characteristic downstream metabolites of such species, the dealkylated M1 and the amide derivative M10 only seen in hepatocytes, which would be consistent with a common aldehyde oxidase-mediated detoxification process. This was further substantiated by the successful trapping of the postulated iminium ion in the presence of cyanide. However, the detection and characterization of M7, which appears to be the iminium ion itself, was quite unexpected. The potential conversion to a dimer or an enamine derivative were excluded based on MS and deuterium exchange data, respectively. The exact position of the unsaturated bond on the piperazine ring could not be allocated with more precision. The presence of the pyrazinium metabolite M10 suggested that M7 was also undergoing secondary metabolism in the incubation matrices.

Novel Aspect: Based on these results M7 was assigned as an unusually stable iminium ion species. This metabolite appeared not only stable in solution and during LC-MS analysis, but it could still be detected after several days of sample storage in autosampler. The isolation and further characterization of this iminium ion metabolite by alternative analytical techniques (e.g. NMR) would be required for definitive structural elucidation.

Commission Libanaise de l'Energie Atomique - CNRSL (5)

Keywords: Lebanese cedar, extraction methods, Characterization, GC/MS

Introduction: (Limit of 400 characters)

Lebanon Cedar is a native Mediterranean species with a pleasant odor and valuable wood. Despite the efforts devoted to the study of this plant, it remains little characterized from the analytical, technological and biological point of view. The aim of this study is to determine the phytochemical profile of leaves and wood of cedrus libani by using GC/MS and extract all components by maceration, soxhlet and ultrasound-assisted extraction (UAE) techniques.

Methods: (Limit of 400 characters)

Lebanese cedar leaves and wood samples were collected from a natural reserve in Nabatieh, southern Lebanon. These samples were extracted using three different methods: ultrasound assisted extraction, maceration and Soxhlet extraction. Four different extraction solvents were used: hexane, ethyl acetate, acetonitrile and methanol. The extracts thus obtained were analyzed by gas chromatography coupled with mass spectrometry (GC/MS).

Results: (Limit 900 characters)

The results show that among the chemical classes extracted, five are interesting: terpenes, polyphenols, phytosterols, vitamins and cortisol. Hexane appears to be an ideal solvent for the extraction of terpenes. Methanol is an excellent solvent for the recovery of polyphenols. About the phytosterols and vitamins, the four solvents are able to extract them. As for cortisol, only methanol makes it possible to obtain it. On the other hand, ultrasound assisted extraction seems the best method of extracting the five chemical classes of interest. However, Soxhlet extraction due to the high level of hydrocarbons extract does not have the ability to use for the extraction of a very large number of compounds as compared to the other two Methods: For maceration, its weak point is that it cannot extract the cortisol. In addition, several compounds of medical and industrial importance were extracted from lebanese cedar, such as vitamin E, vitamin A1, 24,25-dihydroxyvitamin D3, and phytol.

Conclusions (Limit of 400 characters)

Analysis of these results shows that the ultrasound assisted extraction using methanol solvent of leaves and wood was the best method in order to obtain the five interesting families: terpenes, polyphenols, phytosterols, vitamins and cortisol. The extraction method was optimized and the identification of compound was completed by the GC/MS using the library of NIST and should be completed by LC/HRMS and LC/RMN by putting in evidence its analytical fingerprint.

Novel Aspect: (Limit of 150 characters)

The results illustrate the importance of optimizing the extraction of the principal families present in the leaves and wood of libani cedrus prior to their measurement using GC/MS.

151 - A COMBINATION OF CHEMICAL PROTEOMICS AND DARST-BASED APPROACHES TO DISCLOSE NATURAL PRODUCTS BIOLOGICAL TARGETS.

Federica del Gaudio (1) - Federica Pollastro (2) - Alberto Minassi (2) - Raffaele Riccio (1) - Maria Chiara Monti (1)

Dept. of Pharmacy, University of Salerno, Fisciano (Salerno) (1) - Dept. Pharmaceutical Sciences, Università degli Studi del Piemonte Orientale Amedeo Avogadro, Novara (2)

Keywords: target identification, affinity based chemical proteomics, DARTS (drug affinity responsive target stability), natural molecules.

Introduction: Disclosing Natural Products Interactome

The identification of the biological and potential therapeutic targets of small molecules, along with their off-targets, is a significant concern. Here, a combination of the affinity-based chemical proteomics (AP-MS) and a simple, universally applicable approach based on the drug affinity responsive target stability (DARTS) has been applied to disclose the interactome of Arzanol, a natural prenylated phloroglucinylypyrone, used in folk medicine to treat infections and inflammatory diseases [1].

Methods: Combining AP-MS and DARST approaches

AP-MS [2] is based on the preparation of an Arzanol bearing solid support, the isolation of its potential targets from a crude cell extract, SDS-PAGE of Arzanol bound targets and their identification by MS. The DARTS approach [3] takes advantage of a reduction in the protease susceptibility of Arzanol targets, easily revealed by SDS-PAGE-LC-MS analysis or by immunoblotting, without Arzanol modification or immobilization.

Results: Brain Glycogen Phosphorylase as a novel Arzanol target.

AP-MS revealed brain glycogen phosphorylase (bGP) as the major target of Arzanol together with the muscle GP isoform and ATP-dependent 6-phosphofructokinases. DARTS experiments followed by both nano-LC-MS and immunoblotting confirmed bGP as a direct interactor of Arzanol. bGP catalyzes the rate-limiting step of glycogen mobilization in brain; its allosteric modulation by AMP, ADP, ATP and phosphorylation, finely tunes its activity in response to different signals. Thanks to AP-MS competition assays, the interaction site of Arzanol on bGP has been disclosed.

Conclusions: Expanding Arzanol potential bioactivity

The natural heterodimeric polyphenol Arzanol is known for its anti-inflammatory and antioxidant properties [4]. Up to now, a full screening of its biological most relevant interactors was still missing and, thus, a combination of chemical proteomics and DARTS experiments has been carried out on this intriguing natural compound, disclosing its interaction with bGP. Brain glycogen metabolism plays a critical role in major brain functions such as learning or memory consolidation: alteration of glycogen metabolism and glycogen accumulation in the brain contributes to neurodegeneration

Novel Aspect: DARST as the ideal approach to support AP-MS data.

In the past, AP-MS has been widely employed to identify targets of chemically reactive drugs. DARTS strategy is an ideal alternative and/or complement to AP-MS working on native unmodified molecules.

draft

1319 - INVESTIGATION OF AMYLOID-BETA 1-42 REACTIVITY AND STABLE ADDUCT(S) FORMATION BY MASS SPECTROMETRY-BASED APPROACH

Marina Naldi (1) - Angela De Simone (2) - Daniele Tedesco (1) - Manuela Bartolini (1) - Vincenza Andrisano (2)

University of Bologna, Department of Pharmacy and Biotechnology, Bologna, Italy (1) - University of Bologna, DepartmentforLifeQualityStudies, Rimini, Italy (2)

Keywords: LC-MS analysis; amyloid β 1-42aggregation; CORM-3; Alzheimer's Disease

Introduction:

Amyloid β -peptide 1-42 ($A\beta$ 42) aggregation is a central event in the pathogenesis of Alzheimer's disease (AD). Carbon monoxide-releasing molecules (CORMs) are able to carry and release controlled amount of CO and are known to exert anti-inflammatory/apoptotic activities [1]. The study focus on the evaluation of the inhibitory properties of the carbon monoxide-releasing molecule 3 (CORM-3) towards $A\beta$ 42 aggregation and the investigation of its mechanism of action.

Methods:

$A\beta$ 42 samples were prepared as previously reported [2]. CORM3/ $A\beta$ 42 adduct(s) formation and inhibition of $A\beta$ 42 oligomerization were monitored by ESI-Quadrupole-Time of Flight (Q-ToF) flow injection analysis using reserpine as internal standard. Thioflavin T (ThT) assay [3] was used to monitor fibril formation, while circular dichroism (CD) spectroscopy was applied to follow $A\beta$ 42 conformational changes [4].

Results:

MS analyses showed that CORM3 can form stable adduct(s) with $A\beta$ 42 monomers in a dose- and time-dependent manner. Confirming the evidence reported in a previous study [5], adduct formation involves histidine residues on $A\beta$ 42 skeleton and the RuII(CO)₂ portion of CORM3. Inhibition of $A\beta$ 42 aggregation strongly depends on CORM3/ $A\beta$ 42 ratio and was confirmed by both ThT assay and CD analysis. The latter offered further insights into the mechanism of action of CORM3, highlighting that CORM3 could prevent the conformational shift toward an amyloidogenic β -sheet rich conformer.

Conclusions:

CORM3 emerged as a promising inhibitory agent toward $A\beta$ 42 aggregation. The application of a MS-based method allowed confirming the formation of CORM3/ $A\beta$ 42 adduct(s) and highlighted CORM3 inhibitory activity. Combination of MS and spectroscopic data, such as fluorescence and CD, shed light on the mechanism of action of this compound. Furthermore, MS and ThT studies quantitatively contributed in identifying optimal CORM3/ $A\beta$ 42 ratio for best inhibitory effect.

Novel Aspect:

The work highlighted CORM3 is endowed with a good inhibition capacity toward $A\beta$ 42 aggregation, in addition to known anti-inflammatory properties.

126 - FOCAL ADHESION KINASE BINDING PARTNER STUDY IN HUMAN COLON CANCER CELL HCT-116 USING IMMUNOPRECIPITATION METHOD COUPLED WITH NANO-LC/MSMS TECHNIQUE

Binh Thanh Nguyen (1) - Min-Jung Kang (1)

Korea Institute of Science and Technology, Korea University of Science and Technology, Seoul (1)

Keywords: Binding partners, Colon cancer cell HCT-116, Focal Adhesion Kinase, Immunoprecipitation, Proteomics
Introduction

Focal adhesion kinase (FAK) is a non-receptor tyrosine that regulates migration, proliferation and survival of cells. A large number of studies have strongly implicated FAK in the development of colon cancer. The novel potential functions of FAK in the regulation of epithelial-mesenchymal transition (EMT) has been studied extensively in invasive and metastatic cancers. The study focuses on new binding partners of FAK as therapeutic targets for colon cancer.

Methods

Human colon cancer HCT-116 was cultured, harvested and lysed. The protein concentration was measured by BCA kit. FAK expression was confirmed by Western blot. FAK and binding partners were captured by immunoprecipitation method and separated by SDS-PAGE. Gels were excised and digested with trypsin. Tryptic peptides were injected to nano-LC/MSMS system and data were searched against the Mascot search engine. The binding candidates were analyzed with Western blot.

Results

FAK was expressed highly in colon cancer cell HCT-116 compared to the other cancers and normal colon cell. Immunoprecipitation of FAK protein was optimized in the manner of bead selection, cell lysate amount, antibody amount, washing conditions, and elution volume. Gel-LC/MSMS data and mascot search revealed about 350 protein identity. FAK was found with the highest score indicating the successful pull-down and digestion. Among the matched proteins, reportedly known binding partners of FAK include growth factor receptor-bound protein 14 GRB14, integrin-linked protein kinase ILK, Ras-related protein RAB-22A, Rho-related GTP-binding protein RhoU. New candidates for FAK binding partners proposed in our result include SACS, saccin; SYNE3, nesprin; ZYX, zyxin; PLK1, serine/threonine protein. The new binding partner candidates were confirmed using Western blot.

Conclusions

The further work include the effect of growth factors, FAK inhibitors on colon cancer cells to elucidate the upstream regulators or downstream regulators involving the FAK signaling pathways. New binding partners of FAK once validated and characterized will be potential biomarkers for colon cancer diagnosis and useful for the development of therapeutic targets.

Novel Aspect

The literatures have not shown evidences for interaction between new binding candidates of FAK. Necessary confirmation would be novel for therapeutic target development.

460 - COMPREHENSIVE N-GLYCAN STRUCTURE CATALOGUE OF THERAPEUTIC ANTIBODIES

Myung Jin Oh (1) - Nari Seo (1) - Hyun Joo An (1)

AGRS, Chungnam National University, Daejeon (1)

Keywords: monoclonal antibody, N-glycan, reference, mass spectrometry

Introduction:

Glycosylation of monoclonal antibody (mAb) therapeutics plays vital roles in drug's biological activity and safety. Monitoring of glycosylation affected by various environment conditions is highly required to access QA/QC of mAbs. Here, we developed a LC/MS based N-glycan library for rapid and high-throughput identification in various mAbs.

Methods:

The N-glycan catalogue was constructed using human immunoglobulin G and five different mAb therapeutics produced by various cell-based expression systems. Reduced native N-glycans were separated and analyzed by porous graphitized carbon (PGC)-chip nano-LC/MS. Accurate masses were used to compositionally profile N-glycans and their structures were further elucidated by CID MS/MS. Major glycans (G0F, G1F, and G2F) on mAbs were quantified by UHPLC-HILIC-FLD.

Results:

Representative commercial mAbs (adalimumab, bevacizumab, infliximab, rituximab, and trastuzumab) produced by CHO cell and Sp2/O cell were selected to construct detailed N-glycan catalogue for rapid characterization. In parallel, human IgG was used as the reference to confirm human-like glycan structures. The majority of the N-glycans from five commercial mAbs were characterized by matching the RT and accurate masses with the structure of glycans found in a human IgG reference. Corresponding compositions were further confirmed using structural connectivity of the individual monosaccharide residues by tandem MS. In particular, non-human glycans found in non-human mammalian cell system were newly identified by accurate masses, RTs, and tandem MS. Antibody N-glycan catalogue containing over 70 distinct glycan compositions provides structures, relative quantity, and chromatographic retention time (RT) based on PGC column.

Conclusions;

We created the N-glycan catalogue for rapid identification of glycans in mAbs. The combination of accurate masses and LC retention times enables real-time identification for glycan structures. Product ions of each N-glycan by tandem MS were also recorded in the catalogue. N-glycan catalogue of mAbs can be used as a valuable reference in order to evaluate mAb variants and/or biosimilars for both developmental and regulatory purposes.

Novel Aspect:

Comprehensive N-glycan catalogue makes it possible to identify their structures in a high-throughput manner by matching LC retention times and accurate masses.

999 - MONITORING OF SEQUENCE VARIANTS BY MAM USING HIGH RESOLUTION MASS SPECTROMETRY

Kerstin Pohl (1) - Yihan Li (2) - Chris Nortcliffe (3) - Annu Uppal (4) - Ferran Sanchez (5) - Joerg Dojahn (1) - Sibylle Heidelberger (3)

SCIEX, Biologics, Darmstadt (1) - SCIEX, Biologics, Redwood City (2) - SCIEX, Biologics, Warrington (3) - SCIEX, Biologics, Gurugram (4) - SCIEX, Biologics, Barcelona (5)

Keywords: Biologics, Sequence Variants, Data-Independent, Antibodies, MAM

Introduction:

Sequence variants (SVs) are unintentional amino acid substitutions and contribute to the overall heterogeneity of biotherapeutics. The presence of these replacements can be at differing levels, dependent on the cause of the variant, making identification difficult. Here, we monitor the low level SVs using a highly sensitive, high resolution mass spectrometer, the SCIEX TripleTOF® 6600, coupled to built-for-purpose BioPharmaView™.

Methods:

NIST mAb reference standard (#RM8671) was digested using standard conditions. First, digested NIST was run using a 3 hour gradient on a ExionLC™ AD system coupled to a TripleTOF® 6600 and data was acquired in DDA mode. Data was searched using ProteinPilot™ including a search for SVs. Subsequently NIST was acquired using SWATH® acquisition. The data was processed in BioPharmaView™ software to identify and relatively quantify the sequence variants.

Results:

NIST mAb was digested and run using a 3 hour reversed-phase gradient in data-dependent acquisition mode. The data was searched with ProteinPilot™ with an emphasis on IgG antibody and SV identification in order to look for variants. Once the SVs were identified, these sequences were input into BioPharmaView™ as impurities to monitor with SWATH® acquisition on a shorter gradient. Using the peptide mapping workflow including MAM analysis in BioPharmaView™, SVs can be identified and also quantified based on the non-variant peptide despite the shorter gradient and their low abundance. The data-independent SWATH® acquisition ensures that MS/MS data is available on the whole mass range throughout the gradient.

SVA requires a mass spectrometer with a high linear dynamic range, high sensitivity and speed to ensure that the variants are seen at MS level and also fragmented resulting in a good quality MSMS data.

Conclusions

SVs contribute to the overall heterogeneity of biologics and are a measure of product, and production stability along with potential detrimental effects on physicochemical properties, tertiary structure, and efficacy of the product. Misfolded proteoform variants may be toxic impurities. The ability to detect these variants at low level assists manufacturers in determining the potential consequences of the variant and differences from the expected product.

Novel Aspect:

Sequence variant analysis using MAM workflow.

Biosensor-MS combination; Antibody epitope identification; Lysosomal diseases; Enzyme replacement therapy; Neutralizing epitope peptides.

Introduction

Epitope analysis is a key step in the development of therapeutic antibodies. Lysosomal Storage Diseases (LSDs) are successfully treated by Enzyme Replacement Therapy (ERT); however substantial, life threatening effects arise from antibodies that block the infused enzyme. A new online proteolytic excision SPRMS combination (PROTEX-MS) enables simultaneous structure identification and affinity quantification of antibody epitopes. Here we report a new therapeutic concept by identification of antibody epitopes upon ERT. Synthetic epitopes against pathophysiological antibodies open new clinical therapy approaches by (i), hyposensitization of patients, and (ii) molecular apheresis to deplete antibodies.

Methods

Epitopes from antisera of Fabry disease (FD; α -Galactosidase deficiency) patients were identified using the PROTEX-SPR-MS combination. Tryptic peptide mixtures were loaded onto the SPR-MS; after washing out nonbinding peptides, epitope peptides were eluted with 0.01% TFA into the affinity interface, ESIMS was performed with a Waters QuattroUltima MS. The epitope peptide, α -Gal(309-332) was identified from 2 FD patients and revealed high affinity (KD, 39 nM) comparable to the full length enzyme (KD, 16 nM). Linear, stabilized epitope peptides were prepared by SPPS.

Results

Key tools of the online PROTEX SPR-MS Epitope Analyzer are (i), a new SPR suitable for direct application of ESI-MS without any buffer change (T-SPR); (ii), a new high pressure proteolytic system with substantially enhanced

efficiency of protease digestion.

The PROTEX

SPR-MS analyzer was applied to the epitope elucidation and affinity characterization of antibodies upon ERT in FD patients, and provided the epitope, α Gal(309-332), in which the lysine residues K-315 and 326 were shielded upon antibody binding. The epitope α Gal(309-332) was synthesized by solid phase peptide synthesis (SPPS) and purified by HPLC on a semipreparative C4-column, yielding homogeneous peptide with >95 % purity. SPR determination of the epitope peptide and the full length enzyme provided high affinities (KD, 39 and 16 nM, respectively). The α Gal(309-332) epitope contained two internal lysine residues that were not cleaved upon proteolytic epitope excision, consistent with the shielding upon antibody binding.

Conclusions

The clinical application potential of the PROTEX SPRMS Epitope Analyzer was shown in epitope elucidation from therapeutic and pathophysiological antibodies of lysosomal enzymes, with affinity constants (KD) amenable from milli- to nanomolar ranges. Epitope peptides in FD patients are currently developed for antibody neutralization in clinical ERT by systemic application and apheresis at physiological conditions. Thus, the identification, chemical synthesis, and biochemical evaluation of antibody epitopes open provide new clinical treatment approaches for reversing the immunogenicity and reconstituting the therapeutic efficacy of ERT in lysosomal diseases.

Novel Aspect

Antibody epitope identification in ERT of lysosomal diseases opens new clinical therapy to neutralize antibodies and reconstitute therapeutic efficiency.

950 - CHROMATOGRAPHY COUPLED TO MASS SPECTROMETRY FOR STABILITY STUDIES IN DRUG DISCOVERY

Laurence Queguiner (1) - David Speybrouck (2) - Sebastien Thomas (2)

Janssen Research & Development, Discovery Sciences, Val de Reuil (1) - Janssen R&D, Discovery Sciences, Val de Reuil (2)

Keywords:

Mass Spectrometry, Chromatography, Stability studies, Pharmaceuticals.

Introduction:

Pharmaceutical companies always try to reduce the time spent on Drug Discovery to push forward compounds of interest into Clinical Development. To achieve the pre-clinical phase, Analysts need to provide the right and critical physicochemical data to the chemists.

Thanks to hyphenated techniques, we have developed in house-procedures and methods to test the stability of compounds, only looking for information which are relevant for the developability of a compound.

Methods:

Depending on the compounds to be tested, we develop methods in SFC/MS for the chiral stability if compounds are pure enantiomers, after a screening to define the best separation. Chemical stability is monitored in UHPLC/MS either in LR or HRMS. If a compound is found unstable, High-Resolution equipment allows the identification of degradation compounds.

Our protocols are set up after discussion between chemists and analysts depending on the information they need.

Results:

The chemical stabilities are monitored in UHPLC/UV/MS, on a UPLC/UV/MS (Quattro-micro) or a UHPLC/UV/MS (Q-Exacte) instruments, UV results are reported in tables and peak areas are compared to areas obtained at the beginning of the study, this is useful to discriminate precipitation and degradation. If degradation occurs, MS data are examined to give information about the degradation compounds to the chemists, if needed, HRMS data (full MS and after fragmentation) can provide structural information.

For the chiral stability, the same solutions are run in SFC/MS. SFC/UV having a low sensitivity, solutions are analyzed in MS in SIM (Selected Monitoring ions) mode. Most of the time, this technique allows to detect less than 1% of diastomer but to improve the sensitivity on poorly ionizable compounds or to discard salts coming from the highly charged buffers a step of Solid Phase Extraction (SPE) on cartridges can be added.

Conclusions

To push forward or discard compounds showing good or bad pharmaceutical potencies, the combination of different hyphenated techniques available in our laboratory helps the analytical chemists to fully describe the stability of a compound, depending on the product itself and the information needed by the chemists.

Novel Aspect:

The combination of MS coupled to different chromatographic techniques are useful to obtain critical physicochemical data of pharmaceutical compounds.

41 - A HIGHLY SELECTIVE AND SENSITIVE LC-MS/HRMS ASSAY FOR COPORPORPHYRIN-I AND -III, EMERGING ENDOGENOUS BIOMARKERS OF OATP, IN FIRST-IN-HUMAN CLINICAL TRIALS

Ragu Ramanathan (1)

Pfizer, Inc, Medicine Design, Groton (1)

A Highly Selective and Sensitive LC-MS/HRMS Assay for Coproporphyrin-I and -III, Emerging Endogenous Biomarkers of OATP, in First-in-Human Clinical Trials

Ragu Ramanathan, Amanda King-Ahmad, Christopher L. Holliman, A. David Rodrigues
Pfizer Inc., Medicine Design, Groton, CT 06340, USA

Keywords: High Resolution Mass Spectrometry (HRMS), Transporter Biomarkers, Organic Anion Transporting Polypeptides (OATP), Coproporphyrins, Drug-Drug-Interactions (DDI)

Introduction (Limit of 400 characters): The evaluation of transporter biomarkers in early clinical trials could help identify NCE candidates with true drug-drug interaction (DDI) liabilities and thus reduce the number of costly clinical DDI studies being conducted. Coproporphyrin-I and Coproporphyrin-III are two such endogenous isomeric compounds which have emerged as potentially viable biomarkers of organic anion transporting polypeptide (OATP) mediated DDIs.

Methods (Limit of 400 characters): A UHPLC-MS/HRMS assay was developed using, previously unreported, CP-I/CP-III doubly charged ions as precursor ions to improve the assay sensitivity over the singly charged precursor ions. The TOF-MS/MS selectivity of the assay was improved by monitoring and post-acquisition summing the responses from the major doubly charged product ions. The LC-MS/HRMS assay, developed and qualified, supported the quantitative determination of CP-I/CP-III in human plasma.

Results (900 characters): In this study, we used both singly- ([M+H]⁺) and doubly-charged ([M+2H]²⁺) precursor ions of CP-I/CP-III respectively at m/z 655.3 and 328.1 to evaluate high-resolution MS (TOF-MS) for untargeted and MS/HRMS for targeted quantification data on a high-speed Triple TOF 6600 LC-MS/MS system. For the first time, we were able to demonstrate that the doubly-charged ([M+2H]²⁺) precursor ions of CP-I/CP-III are present and detectable with 5-10 times more intensity.

Calibration and quality control samples were prepared to cover a range of 50-1000 pg/mL in 3-times charcoal stripped plasma, and parallelism to native plasma established. The LC-MS/HRMS assay, developed and qualified, supported the quantitative determination of CP-I/CP-III in human plasma with an assay range of 0.05-10 ng/mL. In control pooled human plasma, levels of CP-I and CP-III ranged from 0.45 and 1.1 ng/mL and from 50 and 500 pg/mL, respectively. In control pooled human urine, levels of CPs were at least 10-fold higher than those detected in plasma.

Conclusions (Limit of 400 characters): The NCE in this study had been shown to inhibit OATP in vitro and the probe drug DDI study was incorporated into the clinical study. At the highest dose of the NCE, CP-I showed a 1.37-fold increase in plasma AUC_{0-48hr} versus placebo, which was comparable to the plasma AUC_{0-48hr} ratio change observed with atorvastatin (1.62). These results support that UHPLC-MS/HRMS assay is sensitive and selective to measure endogenous biomarkers of DDIs.

Novel Aspect (Limit of 150 characters): Clinical application of UHPLC-MS/HRMS assay for endogenous OATP biomarkers, CP-I and CP-III, and correlation of AUC_{0-48hr} ratio changes with those from atorvastatin.

Keywords: LC-MS, intact monoclonal antibody (mAB), antibody drug conjugate (ADC), drug-to-antibody ratio (DAR)

Introduction:

Monoclonal antibodies (mABs) and antibody drug conjugates (ADCs) are a fast growing class of therapeutics. ADCs and mABs are complex heterogeneous populations of molecules. The NIST IgG mAB was used to validate our Agilent LC-nanoESI-CHIP-MS system performance. We additionally monitored the structural stability and degradation products of several intact and reduced forms of the Infliximab, Panitumumab, Rituximab, Kadcylya (ADC) and others.

Methods:

For de-salting Amicon ultra 100 kDa spin filters, reduction with 4.4 molar eq. TCEP. For LC-MS Agilent CHIP cube on Agilent 6520, sample captured (0.2 µL inj on 40 nL Zorbax 300SB-C8, 5 µm) using 4 µL/min H₂O + 0.1 % formic acid (FA), then eluted off trap column onto the analytical column (43 mm x 75 µm with Zorbax 300SB-C8, 5 µm) using ACN:H₂O 90:10 with 0.1% FA. Processing with Agilent MassHunterMaxEnt deconvolution with mass using NIST Mass and Fragment Calculator, v1.32 [1].

Results:

Evaluation of the system using the NIST IgG showed expected glycoforms for the intact protein [2]. Overall the mass accuracy for both intact and reduced mABs and ADC were within acceptable ranges (-12.1 and 20 ppm, respectively). For the Kadcylya ADC heterogeneous light chain D0, D1 and D2 proteins were shown with distinctive 957 Da emtansine payloads [3, 4]. In cases where TCEP was used to reduced mABs, partial or uncompleted reduction of disulfides was observed. This could have been due to potential steric hindrance of TCEP and inaccessibility of sequestered hydrophobic disulfides [5]. The inter-month mass stability and accurate mass reproducibility of an ADC suggested experiments should be run alongside controls for comparison. For ADCs under alkaline conditions and elevated temperatures the drug payload distribution was shown to be affected.

Conclusions

LC-nanoESI-MS is a useful analysis method, amongst other orthogonal techniques, to determine heterogeneous distributions of intact (non-reduced) and reduced forms of both mABs and ADCs.

Novel Aspect:

LC-nanoESI-CHIP-MS system was suitable for intact and reduced analysis of mABs and ADCs and able to monitor drug payload stability on ADCs under accelerated stress conditions.

Keywords: Hybrid Method, LC-MS/MS, ADC, Antibody Conjugated Payload, Bioanalysis, NBE

Introduction

Antibody Drug Conjugates (ADC) are a novel class of targeted therapeutics that consist of a potent cytotoxic drug (payload) covalently bound to a monoclonal antibody (mAb) through a cleavable or non-cleavable linker [1,2]. ADCs can selectively deliver potent drugs through an antigen-antibody recognition mechanism. This step is followed by ADC-receptor complex internalization, enzymatic or chemical cleavage of the linker or protease degradation of Ab to intracellularly release the drug. The goal of ADCs is to improve therapeutic window by avoiding limitations related to classical antibody (Ab) based therapeutics or chemotherapy that uses potent cytotoxic small molecules.

Due to their multi-component structure and inherently heterogenous nature, both antibody related analytes (total antibody, conjugated antibody) as well as small molecule related analytes (free payload, antibody-conjugated payload and total payload) are needed to understand ADC disposition in vivo. The bioanalytical assays to support ADC pharmacokinetics studies thus often require a combination of antibody (ligand binding assay, LBA) and small molecule analysis (LC-MS/MS) platforms.

Antibody-conjugated payload analyte describes the payload that is still conjugated to the antibody. Recently, there is a growing attention in Ab-conjugated payload determination to better define the ADC PK profiles [3,4,5].

Methods

A specific LC-MS/MS method was established and qualified for Ab-conjugated payload analyte for an ADC bearing a payload covalently bound through a cleavable linker. The method consists of an immunocapture of the ADC on a spin plate containing Protein A that selectively binds IgG antibodies. Subsequently a hydrolysis step was applied to the immobilized ADC on the plate to generate free payload. Eluates from the plate were subjected to a protein precipitation technique (PPT) step and supernatants are finally analyzed by LC-MS/MS to quantify the free toxin.

Results

The analytical method was qualified for linearity, accuracy, precision, selectivity, carryover, stability (freeze/thaw, benchtop, autosampler), and for dilution range.

To verify the reliability of the obtained results, a set of samples previously tested using conjugated payload method, were assayed by an orthogonal conjugated antibody assay, successfully qualified. This protocol, exploiting Meso Scale Discovery (MSD) technology, was developed and qualified to quantify ADC molecules in animal species (mouse, rat and cynomolgus plasma). A goat human IgG-heavy and light chain, monkey-adsorbed biotin labeled antibody was used as a capture antibody and a Sulfo-tag labeled monoclonal antibody against the toxin (was used as detection). The biotin labeled ADC target receptor was used as capture reagent instead of the goat anti human IgG to quantify the ADC in human plasma.

Conclusions

A good agreement between LBA conjugated Ab and LC-MS/MS conjugated payload results was found confirming the reliability of the two assays. The conjugated payload method was applied to support in-vitro (plasma stability studies) and in-vivo (PK) studies.

Novel Aspect

A novel hybrid LC-MS/MS method was developed and applied for the determination of Antibody Conjugated Payload in ADC bioanalysis. The procedure consists of an immunocapture step, digestion and detection of free toxin using an LC-MS/MS method.

Keywords: epitope identification; affinity mass spectrometry; MALDI-TOF MS; SPR; glycoconjugate vaccine characterization

Introduction:

Tuberculosis (TB) is the first cause of death from infectious diseases worldwide. Only a single anti-TB vaccine is currently available for clinical use, but its efficacy is not achieved with certainty [1]. The aim of this work is to provide a basis for the rational design of a neo-glycoconjugate vaccine against TB.

Methods:

All proteins, glycoconjugates and antibodies used in this study were characterized by MALDI-TOF MS. The antibody epitope of recombinant Ag85B antigen was determined by proteolytic extraction-MS. Antibodies from sera of TB-patients, vaccinated subjects and a healthy control were employed, together with a commercial monoclonal antibody. Affinity binding constants were defined by SPR biosensor analysis.

Results:

The MS epitope determination and SPR analysis allowed the identification and characterization of the interactions between Ag85B antigenic protein from Mycobacterium tuberculosis (MTB) and antibodies from different sources, both qualitatively and quantitatively.

It was possible to use human clinical samples to determine the Ag85B epitope. The identification of the same binding areas of the protein interacting with a monoclonal antibody and with antibodies from human sera allowed to validate the simplified monoclonal model, confirming its applicability in SPR experiments. Therefore, an alternative screening method for the immunological evaluation of antigenic proteins from MTB has been developed. With this in vitro approach, the effects of the introduction of conservative mutations in Ag85B protein, as well as Ag85B conjugation with saccharidic moieties, were studied.

Conclusions:

The combination of two analytical approaches yielded the identification of different assembled epitope regions on recombinant MTB antigens, their affinity binding constants in the interactions with specific antibodies and revealed the importance of protection from excessive glycosylation. These findings provide a molecular basis for an improved rational design of a new potential glycoconjugate vaccine against TB.

Novel Aspect:

A qualitative and quantitative investigation of antigen-antibody interactions was performed to characterize a potential vaccine against TB.

Keywords: in vivo solid-phase microextraction, doxorubicin, therapeutic drug monitoring, LC-MS/MS

Introduction

The real-time monitoring of the concentration of doxorubicin (DOX) in lung tissue aims to enhance the effectiveness of applied chemotherapy while reducing severe side effects [1]. To precisely assess the level and biodistribution of DOX, in vivo solid-phase microextraction (SPME) has been introduced as a minimally invasive technology that integrates sampling, extraction and sample clean-up, and allows for repeated sampling of different tissue compartments [2-4].

Methods

In optimized SPME conditions, sterile 15 mm (45 µm thickness) mixed-mode fibers underwent preconditioning in acetonitrile/water mixture (80:20, v/v) for 60 min. Next, the fibers were directly introduced into lung tissue for 20 min extraction of DOX under static conditions, followed by a desorption step in acetonitrile/water (80:20, v/v) with 0.1% formic acid for 60 min and finally the obtained extract was subjected to LC-MS/MS analysis.

Results

In SPME method development, several parameters that could influence the extraction efficiency of DOX (e.g., selection of optimal preconditioning and desorption solvents, fiber sterilization) were evaluated. SPME extraction in lung tissue reached equilibrium in 20 min. The entire procedure was performed without internal standard correction, enabling the methodology to be implemented in in vivo SPME sampling. Under optimized conditions, SPME exhibited excellent linearity ($R^2 \geq 0.99$) within the range of 2.5-50 µg/g, a LOQ of 2.5 µg/g, good precision ($RSD < 14.7\%$) and accuracy (≈ 103.2). Relatively short sampling time ensures that alterations in the level of DOX can be monitored during chemotherapy, and that a near-real-time profile of drug biodistribution in the lung tissue can be provided. Due to the minimal invasiveness of SPME probes to the living system, sampling can be performed several times in different tissue compartments during the treatment of cancer metastases in lungs with the use of in vivo lung perfusion (IVLP) [5].

Conclusions

An analytical system based on SPME sampling coupled to LC-MS/MS method was developed to accurately and precisely quantitate the level of the anticancer drug, DOX, by direct sampling of lungs. The optimized SPME method facilitates near to real-time monitoring of the concentration and biodistribution of DOX in the lung tissue of a living organism (in vivo SPME) during IVLP in the operating room.

Novel Aspect

In vivo SPME method for repeated sampling of DOX under equilibrium conditions without internal standard correction was developed to monitor drug level in different lung areas.

Keywords: solid-phase microextraction, atypical antipsychotic drugs, therapeutic drug monitoring, LC-MS/MS

Introduction

The analysis of biological fluids to directly control the psychoactive substances is especially important in patients vulnerable to drug overdosing, e.g. pediatric and geriatric patients [1]. To provide fast and reliable information about the drug concentration, solid-phase microextraction (SPME) is introduced as a high-throughput sample preparation technique that facilitates accurate quantitation of the level of drugs in biological matrices [2,3].

Methods

Under optimized SPME conditions, the extraction of atypical antipsychotic drugs (risperidone, olanzapine, clozapine, quetiapine and aripiprazole) and internal standard (promethazine) from saliva and serum samples was performed with the use of C18 blades for 60 min at 1000 rpm. Then SPME blades were rinsed with nanopure water for 10 sec, and next desorption was performed for 10 min at 1000 rpm. Finally obtained extracts were analyzed with the use of LC-MS/MS system.

Results

SPME conditions for the analysis of antipsychotic drugs in biofluids were optimized in order to select the most effective extraction phase, and finally C18 blades were chosen, as they provided good recoveries and the lowest carryover effect. Desorption of the analytes was performed in optimal desorption mixture (ACN/H₂O/FA, 80:20:0.1, v/v/v) and reached equilibrium within only 10 min. The obtained kinetic profile of antipsychotic drugs in saliva samples was compared to the kinetic profiles of these drugs obtained for serum samples. Although the level of antipsychotics in saliva samples was much lower (ng/mL) in comparison to the concentration of drugs measured in serum samples (µg/mL), the kinetic profile of analyzed compounds was similar. Therefore, SPME may be implemented for direct monitoring of the level of antipsychotic drugs in non-invasively collected saliva samples and can be used as alternative to traditional methods utilizing serum samples for the measurements of these drugs.

Conclusions

High-throughput method based on SPME technique coupled to LC-MS/MS was developed for quantitative analysis of five antipsychotics in human saliva and serum samples. The optimized SPME method facilitates non-invasive monitoring of analyzed drugs present at low level in saliva samples, without the need for blood collection. SPME allows for a control of drug intake and dose modification, and may be a part of personalized therapy during long-term treatment.

Novel Aspect

SPME technique for direct monitoring of therapeutic level of atypical antipsychotic drugs in saliva and serum samples was developed.

944 - MULTI-ATTRIBUTE MONITORING (MAM) TO IDENTIFY DIFFERENCES IN TRASTUZUMAB FROM 2 MANUFACTURERS.

Ferran Sanchez (1) - Chris Nortcliffe (2) - Kerstin Pohl (3) - joer Dojahn (3) - Sibylle Heidelberger (2)

SCIEX, Biologics, Barcelona (1) - SCIEX, Biologics, Warrington (2) - SCIEX, Biologics, Darmstadt (3)

Keywords: Mass Spectrometry, Biologics, Trastuzumab, MAM, Biosimilars

Introduction:

Biosimilars are a growing industry, which require comparison of the safety and efficacy of the new biotherapeutic to the original. Certain CQA's, such as high mannose content glycans, can have a detrimental effect on the function of the product. Using trastuzumab from two different manufacturers, a comparison of the biosimilars was performed, acquiring data using SWATH® and processing using BioPharmaView™ MAM workflow to identify the levels of change in the sample.

Methods:

Peptide digests of trastuzumab from two manufacturers, were run using an ExionLC™ AD with a Phenomenex® Kinetex® column C18, 100A, 1.7 µm, 2.1 x 150 mm at 60°C. A: 0.1 % formic acid in water, B: 0.1% formic acid in acetonitrile using a linear gradient of 5 to 40 over 120 min at a flow rate of 0.2 mL/min using SWATH acquisition.

Trastuzumab (intact and reduced) were acquired using a 20 min gradient.

All data was processed using BioPharmaView MAM and intact workflow.

Results:

Trastuzumab peptide mapping was acquired on the X500B using SWATH acquisition. The data was processed in BioPharmaView with the glycosylations setup as attributes for monitoring and the subsequent glycosylation percentages were calculated and compared against each other for the two manufacturers versions of trastuzumab. Differences in the glycosylations were identified at the peptide level. The same samples were acquired as intact protein and the levels of glycosylations and the variances were compared to the data acquired in peptide mapping. The result was a confirmation that some levels of glycans differed between the two samples showing how the workflow can be used to monitor for changes in biologic in production or can be used to compare biosimilar to the original biotherapeutic.

Conclusions

With the increasing number of biosimilars under development; robust, reliable workflows are required to fully characterize any Critical Quality Attributes which may differ from the originator. Certain process-specific post-translational may have a negative effect on the efficacy and clearance of the therapeutic therefore a Multiple Attribute Method allows monitoring of these in a single workflow.

Novel Aspect:

Comparison of 2 biosimilar trastuzumab using multi-attribute monitoring.

1277 - DOSE-AND TIME-DEPENDENT EFFECTS OF HEPATOTOXICANTS ON ADME PROTEINS IN 3D HUMAN LIVER SPHEROIDS BY PRM

Nathalie Selevsek (1) - Witold E. Wolski (1) - Laura Kunz (1) - Henrik Cordes (2) - Vanessa Baier (2) - Lars Kuepfer (2) - Olivia Clayton (3) - Adrian Roth (3) - Ralph Schlapbach (1)

Functional Genomics Center Zurich, ETH Zurich, Zurich, Switzerland (1) - Institute of Applied Microbiology, RWTH Aachen, Aachen, Germany (2) - Roche Pharma Research and Early Development, Roche Innovation Center Basel, Basel, Switzerland (3)

Keywords: ADME, 3D spheroids, drug toxicity, targeted proteomics, PRM

Introduction:

ADME genes (ADME: absorption, distribution, metabolism, and excretion) encode for the involved phase I-II enzymes and transporters, and they respond adaptively to xenobiotic exposure. To predict in vivo drug response in ADME proteins we applied a Parallel Reaction Monitoring (PRM)-based targeted proteomics approach to quantify the proteins in 3D human liver spheroids challenged with different dose regimes of several hepatotoxicants up to two weeks of treatment.

Methods:

After isolation from drug-treated 3D liver spheroids, proteins were digested and analyzed by Liquid Chromatography - Mass Spectrometry (LC-MS) on a Q Exactive™ HF instrument (ThermoFisher Scientific) in PRM mode. Raw MS data were directly imported into Skyline for peptide/protein quantification. Since ADME proteins are structurally represented in PBPK models the measured changes in protein abundance may be directly integrated in the corresponding models.

Results:

To design targeted PRM assays for the ADME proteins, we focused mainly on the ADME genes that are involved in the pharmacokinetics of the tested liver toxicants. MS coordinates such as precursor and retention time information were selected from spectral libraries built from MS/MS spectra acquired by data-dependent analysis experiments of protein digests isolated from pooled drug-treated 3D liver spheroids. In total, dozens of PRM assays were developed and optimized for the detection of the ADME proteins. Overall, we could identify and quantify with high confidence the different ADME proteins with either two or three proteotypic peptides across all the drug-treated 3D liver spheroids. We demonstrated high reproducibility in protein abundance between biological replicates across all time points and dose regimes. We showed that the abundance profile of ADME proteins were drug and dosage regime specific. The observed changes were integrated in the various PBPK models to describe cellular adaptation in response to xenobiotic exposure.

Conclusions:

This allowed in particular to simulate the to-be-expected effect of multiple drug administration on drug pharmacokinetic over time. As such the presented approach presents an important tool to predict in vivo drug response in ADME proteins after multiple administration in a joint approach of model-based assay design and targeted proteomics.

Novel Aspect:

We report quantitative and qualitative changes of ADME proteins in drug-treated 3D human liver spheroids by label-free PRM assays.

471 - LC-MS/MS ANALYSIS AND RAT PHARMACOKINETICS OF THE NOVEL CYCLIN-DEPENDENT KINASE INHIBITORS BP-14 AND BP-20

Jitka Šířoká (1) - Martina Čěčková (2) - Lubor Urbánek (1) - Vladimír Kryštof (1) - Tomáš Gucký (1) - Jakub Hofman (2) - Miroslav Strnad (1) - František Štaud (2)

Laboratory of Growth Regulators, Palacký University, Olomouc (1) - Faculty of Pharmacy in Hradec Králové, Charles University, Hradec Králové (2)

Keywords: cyclin-dependent kinase inhibitor; BP-14; BP-20; pharmacokinetics; tissue distribution

Introduction:

BP-14 and BP-20 are novel cyclin-dependent kinase inhibitors, structurally related to roscovitine, with potent antiproliferative activity [1]. A simple LC-MS/MS method for determining them in biological material was developed and validated following EMA guidelines. The method was applied in a pharmacokinetic study in rats following i.v. and i.d. administration including plasma pharmacokinetics, tissue distribution and excretion (renal and biliary).

Methods:

Chromatographic separation was performed on reversed phase BEH C18 column (100 x 2.1 mm, 1.7 μ m) by gradient elution with mobile phases composed of 15 mM ammonium formate pH 4.0 and methanol at flow rate 0.25 mL/min at 40 °C. The analytes were detected based on their multiple reaction monitoring transitions in positive electrospray ionisation mode m/z 473.07 > 157.93 for BP-14, m/z 499.62 > 184.2 for BP-20 and m/z 355.5 > 90.86 for roscovitine (internal standard).

Results:

The method provided good linearity within concentrations 1 - 10000 nmol/L for BP-14 and 10 - 25000 nmol/L for BP-20 in plasma and 100 - 10000 nmol/L for BP-14 and 10 - 25000 nmol/L for BP-20 in bile and urine ($R^2 > 0.9989$). The results of validation fit within the EMA acceptance limits in terms of within-run and between-run accuracy and precision. Both compounds were stable in a set of stability tests in matrices (plasma, bile and urine). Plasma concentrations of both compounds after i.v. administration followed a typical bi-exponential decline, consisting of a rapid distribution and slow elimination phase. The bioavailability after i.d. administration was determined 0.63% for BP-14 and 1.58% for BP-20. The distribution into tissues (adipose tissue, kidney, lungs, spleen, liver, muscle, brain) was the highest for the adipose tissue and the lowest for brain. The biliary excretion of the parent BP-14 and BP-20 accounted for 4.81% and 10.6% of the doses, respectively, and renal excretion for less than 0.5% in both cases.

Conclusions:

Similar pharmacokinetic profiles of both compounds were obtained after i.v. administration, with a rapid initial decrease in plasma concentrations, intensive distribution to adipose tissue and approximately 5-10% excretion of the parent drugs through urine and bile. Their bioavailability after i.d. administration was low.

Novel Aspect:

The results represent first information on pharmacokinetics of BP-14 and BP-20 in rats and will help to design a new generation of drugs with strong anticancer activity.

760 - IDENTIFICATION OF 5-FLUOROCYTOSINE AND ITS METABOLITES IN COMPLEX SAMPLES BY LIQUID CHROMATOGRAPHY COUPLED WITH MASS SPECTROMETRY.

Pavel Škvára (1) - Miroslava Matúšková (2) - Erika Ďuriníková (2) - Andrea Vojs Staňová (1)

Faculty of Natural Sciences of Comenius University, Department of Analytical Chemistry, Bratislava (1) - Slovak Academy of Sciences, Institute of Experimental Oncology, Bratislava (2)

Keywords: mass spectrometry, gene therapy, chemotherapeutics, metabolites, complex samples

Introduction

5-fluorocytosine (5FC) is an anti-mycoticum which can be used as precursor for anti-cancer drug 5-fluorouracil (5FU) in cancer treatment by the procedure "suicide gene therapy" [1]. In recent years, the use of high performance liquid chromatography (HPLC) coupled with mass spectrometry (MS) is dominated for purpose of identification and determination of 5FC and its metabolites in complex samples [2], [3].

Methods

All results were obtained by high resolution LC-MS-IT-TOF mass spectrometer (Shimadzu, Kyoto, Japan) with electrospray ionization. Chromatographic separation was performed on Ascentis C18 (100x2.1 mm; 3 µm) column (Sigma-Aldrich). The samples for analysis was prepared and delivered by the Laboratory of Molecular Oncology.

Results

The developed HPLC-ESI-IT-TOF-MS method was applied to the analysis of samples of mesenchymal stem cells, tumor cells and their control samples to which 5FC was not added. In spectra obtained by HPLC-ESI-IT-TOF-MS analysis of samples (media of tumor or mesenchymal stem cells) were present molecular ions which corresponding to the 5FC in positive ionization mode and to the 5FU and 5-fluoro-2-deoxyuridine monophosphate (5FdUMP) in negative ionization mode. The presence of 5FC's metabolites was conditional upon to presence genes which encoding excretion of enzymes cytosine deaminase (CD) or uracil phosphoribosyltransferase (UPRT). In spectra obtained from analysis of sample without addition of gene CD or CD/UPRT were present only molecular ions corresponding to 5FC and none molecular ions which corresponding to its metabolites in negative ionization mode.

Conclusions

The paper dealt with the possibilities of high performance liquid chromatography coupled with mass spectrometry for identification of 5-fluorocytosine and its major metabolites in biological samples. Developed HPLC-ESI-IT-TOF-MS method was successfully applied for analysis of mesenchymal stem cells, tumor cells and their control samples.

Acknowledgements

The research was supported by the grant of the Slovak Research and Development Agency (APVV-16-0124).

Novel Aspect

Obtained results can bring new look on the treatment efficiency of metabolic conversion 5FC during suicide gene therapy.

Contact: Lijiang.song@warwick.ac.uk, <https://warwick.ac.uk/fac/sci/chemistry/research/facilities/massspec>

Abstract

Introduction: Antimicrobial resistance poses a serious threat worldwide and new antibiotics are urgently required. Meanwhile, the pace of discovery of novel antibiotics has slowed down significantly recently due to the frequent re-discovery of known compounds. Microbial genome mining as a new approach can potentially rejuvenate the stalled antibiotics discovery pipeline. High resolution mass spectrometry provides one of the most efficient ways to carry out dereplication.

Methods: Secondary metabolites produced by producing microorganisms are extracted from spent fermentation medium and analyzed with high resolution LC-MS/MS. Molecular formulae for all major peaks identified in chromatograms are generated based on isotopic pattern and accurate measurement, these will be used for database searching, both known and potentially novel compounds can be further identified through MS/MS and UV absorbance.

Results. Rapid advances in bioinformatics enables the complete or partial structure of novel natural product to be predicted based on gene sequence, combining with genetic manipulation of bacterial strains, the final biosynthetic products can be identified through a LC-MS/MS based comparative metabolomics approach. The discovery and biosynthetic investigation of coelimycin P1, an unusual yellow-pigmented metabolic product of the cpk cryptic polyketide biosynthetic gene cluster from *Streptomyces coelicolor* M145 will be discussed.

Novel Aspects: Efficient de-replication with high resolution high accuracy Q-TOF mass spectrometry is critical for future bioactive natural product discovery.

Key words: High resolution, mass spectrometry, dereplication, drug discovery

211 - CHARACTERIZATION OF PACLITAXEL METABOLITES BY UHPLC-MS/MS: BIOMEDICAL APPLICATION OF THE STUDY IN TARGETED DRUG DELIVERY SYSTEMS

Cristina Sottani (1) - Elena Grignani (1) - Emanuele Studioso (1) - Danilo Cottica (1)

Istituti Clinici Scientifici Maugeri, Environmental Research Center, Pavia (1)

Keywords: paclitaxel, metabolite characterization, UHPLC-MS/MS, nanoparticles, new drug delivery systems

Introduction:

Recently has been proved that mesenchymal stem cells (MSCs) are able to package and deliver paclitaxel through their extracellular vesicles, suggesting the possibility of using MSCs to develop drugs with a higher cell-target specificity. The main objective of this study was to exploit the ability of mass spectrometry in order to perform structural studies on paclitaxel molecule because this drug follows a specific fragmentation pathway, which cleaves the molecules in two major fragment ions. These fragments are considered markers in biological fluids.

Methods:

The bile was collected every hour from ½ h to 3 h. An aliquot of 300 mL was picked up from every samples, diluted with acetonitrile 1:1(v:v) and then centrifuged. The supernatant was evaporated to dryness. The residue, dissolved in 100 mL with 0.02 M ammonium acetate buffer and acetonitrile 65:35 was directly injected into LC-MS/MS system. The entire effluent from the column of the control and pooled bile samples were analyzed in mass spectrometry. Product ion LC-MS/MS scans were obtained.

Results:

It is possible to take advantage of paclitaxel mass spectrometric behavior to establish the main features of drug metabolism, given that the hydroxylation process takes place on the two major fragment ions. Paclitaxel has extensively been studied both in the laboratory and in the clinic. However, its complete metabolic pathway in rats and humans have not yet been fully understood.

We concluded that the simply observation of intense molecular ions, even if well separated from the chemical noise, is not enough to determine the presence of paclitaxel analogs as well as their chemical modifications. Tandem mass spectrometry allowed to detect the presence of 9 metabolites, distinguishing them from the other endogenous contaminants.

These metabolites were recognized as three di-hydroxytaxol, four mono-hydroxytaxol, one deacetyltaxol and one containing the taxane ring.

With this methodology, we were able to identify four new metabolites of paclitaxel belonging to the di-hydroxy and mono-hydroxy series.

Conclusions

The assessment of the most important paclitaxel metabolites represents the first structured approach to pharmacokinetic studies (PKs) of this drug used in modern cancer therapy that is based on the development of new formulations. Pharmaceutical formulations such as liposome, micelle, emulsion and nanoparticles are potentially useful for drug delivery systems. The pivotal characteristics of new drug delivery systems, such as engineered nano-materials, have to include biodegradability, biocompatibility and non-toxicity for human cells [1-2].

Novel Aspect:

Paclitaxel has been recently loaded in different types of engineered nano-materials because they are demonstrated to penetrate specific tissues and reach directly the tumor site.

650 - COLLISION-INDUCED DISSOCIATION STUDY OF ANTIMICROBIAL PEPTIDE DENDRIMERS

Aura TINTARU (1) - Laurence CHARLES (1)

AIX-MARSEILLE UNIVERSITÉ - CNRS, Institut de Chimie Radicalaire UMR7273, Marseille (1)

Keywords: Antimicrobial Peptide dendrimers, Collision-induced dissociation, MS/MS sequencing

Introduction

Peptide dendrimers are non-natural branched peptides with multibranching topologies that exhibit interesting antimicrobial properties [1]. In particular, dendritic architectures composed of lysine (K) and leucine (L) were demonstrated to be active against a broad panel of multidrug-resistant pathogens [2]. The renowned efficiency of CID for MS/MS sequencing of linear peptides was evaluated for structural characterization of a KL peptide dendrimer.

Methods

High resolution MS and MS/MS experiments were performed after positive ion mode electrospray ionization (ESI), using a Synapt G2 HDMS instrument. Lysine-Leucine (KL) peptide dendrimers were dissolved in acidified methanol to promote formation of protonated species.

Results

MS/MS was previously demonstrated to be very powerful at characterizing dendritic structures [3], shown to exhibit a typical dissociation behavior consisting of iterative losses of repeating building blocks from outside branches and then internal arms down to the inside core [4]. MS/MS data recorded on the KL-peptide dendrimer suggested a different scenario, with the dissociating precursor ion to be considered as a peptidic backbone with pendant ramified segments rather than a dendritic structure. On the one hand, CID data recorded at low collision energy allowed the main backbone to be sequenced, and hence the branching points to be localized. On the other hand, raising activation energy permitted to characterize the structure of the pending peptidic segments. Moreover, charge states observed for product ions allowed some insights in the actual location of protons in the quadruply charged studied species.

Conclusions

This study showed that KL-peptide dendrimers behave as a branched peptide rather than a dendritic structure upon CID. Dissociation rules to be established from MS/MS data obtained for this first generation molecule are currently evaluated for higher generation KL peptide dendrimers.

Novel Aspect

First report of MS/MS structural characterization KL-peptide dendrimers.

Keywords: Antibody-Drug conjugates (ADCs), Cysteine-conjugation, Hydrophobic Interaction Chromatography (HIC), Mass Spectrometry

Introduction:

Antibody-Drug Conjugates (ADCs) combine the target specificity of monoclonal antibodies to the high cytotoxicity of a small molecule toxin selectively killing tumor cells while minimizing toxicity to normal tissues. ADCs are generated by covalently binding the selected toxin through a linker to specific antibody residues, usually Cysteine or Lysine, which increases the complexity of the products generating heterogeneous mixtures of isomers and isoforms

Methods:

The characterization of the ADC product is fundamental because drug loading and distribution can affect the safety and efficacy of the ADC. Mass spectrometry can be applied for the identification of the ADC modified residues and, in combination with chromatographic techniques as UV-LC or HIC, for the determination of the Drug-Antibody Ratio (DAR) and the distribution of the toxin in the different populations generated by the cysteine conjugation process

Results:

At NMS a new proprietary molecule suitable for conjugation has been developed and used to derivatize a commercial antibody to generate a cysteine conjugated ADC with an average DAR of ~3.5. The addition of the drug at the interchain cysteine residues results in a heterogeneous population of ADCs that differ in the number of drugs per antibody and in the presence of positional isomers.

The peptide mass fingerprinting strategy has been applied for the identification of the modified residues after the complete enzymatic digestion of the ADC and to characterize the ADC at the peptide level looking at primary sequence and post-translational modifications.

The DAR distribution analysis and the identification of the positional isomers present in the sample have been achieved by the combination of HIC and RPLC-MS. The intact DAR species separated by HIC on the bases of their hydrophobicity have been collected and analysed in denaturing conditions by RPLC-MS in order to separate and identify the ADC fragments composing each isomeric form

Conclusions

The application of analytical technologies, especially mass spectrometry, have been applied for the analysis of a cysteine conjugated ADC produced at NMS. These technologies represent very useful tools for the characterization of these heterogeneous products during the drug development process to guarantee the batch to batch reproducibility

Novel Aspect:

Mass spectrometry, in combination with allied separation techniques, has been applied for the characterization of an NMS proprietary drug conjugated antibody

817 - THE EFFECTS OF LOW TEMPERATURE STORAGE ON THE STRUCTURE OF HERCEPTIN®: TO FREEZE, OR NOT TO FREEZE: THAT IS THE QUESTION

Rosie Upton (1) - Kamila Pacholarz (1) - David Firth (2) - Sian Estdale (2) - Perdita Barran (1)

Manchester Institute of Biotechnology, University of Manchester, Manchester (1) - Covance Ltd., Biopharma CMC, Harrogate (2)

Keywords: IgG1, Herceptin®, cryo-stability, IM-MS, intrinsic-fold

Introduction:

For research and drug development mAbs are usually examined as fresh solutions stored between 2 – 4°C. By contrast the manufactured product is freeze-dried and stored at much lower temperatures. Here we use IM-MS and HDX-MS to probe structural differences between lots of the IgG1 mAb, Herceptin® as well as the effect of cold storage on the intrinsic conformation of this protein and its glycoforms.

Methods:

DT-IM-MS measurements were used to compare refolded mAbs against the freeze-dried API. Collision induced unfolding (CIU) measurements were performed using an RF-confining linear drift field Synapt G2 along with circular dichroism (CD) to provide stability profiles. HDX-MS analyses enabled the dynamic properties to be compared. We compare data obtained from fresh, freeze-dried and reconstituted solutions.

Results:

The fresh Herceptin® sample has a significantly broader collision cross section distribution (CCSD 45 – 100 nm²) compared with the frozen originator lots (60 – 80 nm²) despite being identical in terms of protein sequence. This is the case across 3 lots of Herceptin® as well as a lower purity ('research grade' trastuzumab) sample, which are extensively characterised with IM-MS as well as HDX-MS. Data from the renatured protein is compared with these two extreme cases in order to determine if freeze-storage fundamentally alters the protein fold. In each case the disulphide bridges are mapped. Global conformational stability is further probed using collisional activation prior to ion mobility analysis, and the profiles compared for lot-to-lot variability and storage effects. CD is used to examine the differences in secondary structure. As controls we have analysed the NIST mAb standard [1] and an intact mass check standard from Waters, using the same combination of mass spectrometry and biophysical techniques.

Conclusions:

We see significant differences in the conformational profile of Herceptin® depending on its treatment and between lots. This indicates that harsh storage conditions such as deep-freezing, do indeed restrict flexibility in the global conformation of Herceptin®. We present data that shows if complete denaturation of both the fresh and frozen mAb can be used to restore flexibility and consider the implications of these findings for drug processing following discovery.

Novel Aspect:

(150 characters max.)

Insights into the effects of cold storage upon the stability profiles, intrinsic-fold and global conformations of multiple Herceptin® lots.

153 - ASSESSING THE DRUGABILITY OF PTP1B NON-CATALYTIC SITES WITH MASS SPECTROMETRY

Ana Villar Garea (1) - Christian Buning (1) - Joerg Czech (1) - Matthias Dreyer (1) - Gerhard Hessler (1) - Stefan Matthias Petry (1) - Norbert Tennagels (2) - Stefan Welte (2)

Sanofi-Aventis Deutschland GmbH, Integrated Drug Discovery, Frankfurt am Main (1) - Sanofi-Aventis Deutschland GmbH, Diabetes Research, Frankfurt am Main (2)

Keywords: inhibitor, drug discovery, target engagement, cysteine alkylation, phosphatase

Introduction:

The identification of therapeutic inhibitors for protein tyrosine phosphatase 1B (PTP1B) is an attractive approach to treat type II diabetes, but it has failed so far due to insufficient selectivity [1]. Covalent inhibitors that target residues only present in PTP1B might overcome these limitations. We studied the reactivity of cysteines in PTP1B and designed and characterized potential ligands.

Methods:

Mass spectrometry: 2-(4'-(iodoacetamido)anilino)naphthalene-6-sulfonic acid (IAANS) was used for modification of accessible cysteine residues of PTP1B. The number and position of the reactive residues were determined by LC-MS1 and LC-MS2. Reaction of PTP1B with the designed ligands was studied in the same way. Other methods: molecular modelling, in vitro phosphatase assay, X-ray crystallography.

Results:

First, the accessibility of different cysteine residues was determined by incubating PTP1B with IAANS under native conditions and analyzing the resulting products by LC-MS. We found Cys32 as potential target for specific inhibition of PTP1B. Next, a library of molecules was designed for covalent inhibition of PTP1B and was screened with an in vitro enzymatic assay. Several inhibitors were selected for mass spectrometry experiments to evaluate their reactivity towards Cys32. Despite a having a high potency, no alkylation of Cys32 with these ligands could be detected under the same conditions as used for IAANS. X-ray crystallography analyses revealed that, although the inhibitors occupy the intended pocket, their orientation hinders the reaction with Cys32.

Conclusions:

We identified Cys 32 as potential target for PTP1B inhibition and designed inhibitors to alkylate it. Although these substances are very potent in enzymatic in vitro assays and bind the expected pocket, neither X-ray crystallography nor mass spectrometry could demonstrate covalent modification of PTP1B. Therefore we conclude that the observed activity is due to non-covalent interaction.

Novel Aspect:

Use of IAANS to test the accessibility of cysteine residues
Handling a native protein (6 reduced Cys) without reducing agent

Therapeutic drug monitoring and drug discovery:
Is it all known or are we innovative and game changing?

Author: Ron M.A. Heeren², Filip Cuyckens¹, Rob J. Vreeken^{1,2}

Janssen R&D, Beerse, Belgium
Maastricht MultiModal Molecular Imaging (M4I) institute, Maastricht, The Netherlands

Keywords: Quantitation, omics, instrumentation, drug discovery

Introduction:

Nowadays, mass spectrometry, mostly hyphenated with either GC or LC, is THE prime technology applied in therapeutic drug monitoring (TDM) and drug discovery (DD). The accurate quantitation of drugs and related metabolites are essential for personalized treatment scenario's in the clinic, while both quantitative and qualitative data of these drugs and associated metabolites or PD effects are required in drug discovery.

Methods:

In order to address all questions in both TDM and DD a wide range of instruments, spanning from single quads till high resolution MS-systems, like e.g. the orbitrap and even FTICR systems, are applied in conjunction with state-of-the-art separation sciences to provide reliable data supporting decision making in either continuation or stopping further development or treatment.

Results: Here we address several of the challenges we are facing in the two application areas and present some of the solutions. Next to small molecules, more and more larger molecules, both as proteins but also Post-Translational Modifications (PTM) need to be monitored, quantified and related to either beneficial or adverse effects from initial PK until lead optimization and further development. Also in TDM, next to the traditional small molecules, proteins, antibodies, drug-antibody complexes etc. are getting more attention in the clinic. All these new area's are relying on sensitivity, specificity and both spectral and chromatographic resolution. Hence, a diversity of applications will be addressed. Besides, the growing interest in applying not only targeted but also omics-like strategies to profile off-target effects, pharmacodynamics and drug related compounds is gaining popularity in early screening already. In TDM on the other hand, these technologies are far from routine at the moment.

Conclusions

Although, new technology, either being hardware, software is developed, there still is a need for higher sensitivity, higher acquisition speed, higher dynamic range and higher resolution in both TDM and DD. Here some examples are shown addressing some of the challenges.

Next, we show some of the novel applications rising at the horizon to further improve reliable and quantitative as well as qualitative information, required to make better and faster decisions on medication or progression of novel drugs in further development.

96 - ULTRAFAST DETECTION OF DRUGS AND METABOLITES IN URINE BY FLOW INJECTION ANALYSIS (FIA) COUPLED TO MAGNETIC RESONANCE MASS SPECTROMETRY (MRMS)

Matthias Witt (1) - Markus Godejohann (2) - Aiko Barsch (3)

Bruker Daltonik GmbH, MRMS Solutions, Bremen (1) - Bruker BioSpin GmbH, Hyphenation AIC, Rheinstetten (2) - Bruker Daltonik GmbH, Metabolomics, Bremen (3)

Ultrafast detection of drugs and metabolites in urine by Flow Injection Analysis (FIA) coupled to Magnetic Resonance Mass Spectrometry (MRMS)

Keywords: Metabolomics, Drug detection, Flow injection analysis, Screening

Introduction:

Detection of metabolites and drugs in body fluids such as plasma or urine by LCMS is a routine method in metabolomics and doping analysis. Routine UPLC-MS measurements are performed typically in 15 min. Therefore, the number of analyzed samples is highly limited. In this work, a fast method for detection of drugs and their metabolites in urine using FIA-MRMS is presented. Roughly 250 samples can be measured in 24 h using this technique.

Methods:

Six pooled urine samples were purified by SPE using Merck LiChrolutEN SPE cartridges. Samples were extracted with methanol from SPE cartridges and diluted 1 to 100 for FIA. Each sample was analyzed in 5 minutes by FIA-MRMS using a solarix 2xR (Bruker Daltonik, Bremen) in ESI using positive and negative ion mode. Analysis of data was performed with MetaboScape 3.0 (Bruker Daltonik, Bremen).

Results:

The data of the ESI(+) and ESI(-) were combined for feature analysis. More than 2100 features have been found for the pooled urine samples. More than 90% of the detected features could be assigned with a molecular formula. 300 drug candidates have been detected in the urine samples using a HMDB urine database with a mass error tolerance of only 0.5 ppm. The detected drugs have been compared with the medication of the patients. Several drugs have been found only in one or a few pooled urine samples. By comparing the relative abundances of features of all samples, possible metabolites of drugs could be identified.

Conclusions:

Drugs and their metabolites can be detected by FIA-MRMS in a few minutes. This workflow is much faster than the conventional workflow using UPLC-MS. This method could even be used for quantification when internal drug standards are added. Due to the complexity of the samples, ultra-high mass resolution as well as very accurate mass detection is a prerequisite for this workflow.

Novel Aspect:

FIA-MRMS can be used for fast detection of drugs and metabolites in urine.

Introduction:

Therapeutic drug monitoring (TDM) can improve efficacy and safety (1). Thus, we developed a liquid chromatography-tandem mass spectrometry (LC-MS/MS) method for monitoring 11 tyrosine kinase inhibitors (TKIs) used in chronic myeloid leukemia (imatinib, dasatinib, nilotinib, bosutinib, ponatinib), polycythemia vera (ruxolitinib), chronic lymphocytic leukemia (ibrutinib) and rheumatoid arthritis (filgotinib, tofacitinib, baricitinib, peficitinib).

Methods:

Only 200 μ L of human plasma was needed for the extraction of analytes and their stable isotope-labeled internal standards. μ -elution solid phase extraction was optimized and compared to simple protein precipitation. Gradient elution on Poroshell 120 EC-C18 column, flow rate of 0.6 mL/min and 60°C was applied for compounds separation. The mobile phase consisted of 0.1% formic acid in water, pH=2 (solution A) and 0.1% formic acid in acetonitrile (solution B).

Results:

Acquisition lasted for 8 minutes followed by a re-equilibration time of 4 minutes. Mass spectrometer was operating in the positive ionization mode. Dynamic multiple reactions monitoring scan was applied to improve method sensitivity. Endogenous phospholipids can strongly affect MS analysis. Therefore, the monitoring of m/z 184 > 184 (glycerophosphocholines) and m/z 104 > 104 (lysophosphatidylcholines) as common in-source collision-induced dissociation ion fragments, were included in the method. Caffeine was added to the assay as well. According to the recommendations of regulatory agencies [2,3,4], tests of precision, accuracy, recovery, matrix effect, process efficiency, stability, sensitivity (great LLOQs), and selectivity were performed and enabled us to validate the method. Sample preparation applied in the present assay showed high efficiency in phospholipids removal. More than 99% of main plasma lysophosphatidylcholines and more than 89% of glycerophosphocholines were eliminated compared to protein precipitation.

Conclusions:

This method enables simultaneous plasma monitoring of 11 TKIs, caffeine and two main plasma phospholipids. High effectiveness in endogenous phospholipids elimination ensures the reliability of the assay. Present LC-MS/MS method is currently used in our clinical practice, being applied to TDM of dasatinib, imatinib, nilotinib and ponatinib. TDM of TKIs helps to individualize dose adjustment and manage adverse effects in patients.

Novel Aspect:

The method monitors endogenous phospholipids (glycerophosphocholines and lysophosphatidylcholine) as well as caffeine in addition to 11 TKIs in a simple run.

1326 - LIQUID EXTRACTION SURFACE ANALYSIS AND DIRECT ESI/NANOESI MASS SPECTROMETRY FOR HIGH THROUGHPUT URINARY METABOLOMICS APPLIED TO MALARIA

Salah Abdelrazig (1) - Catherine Ortori (1) - David Barrett (1)

University of Nottingham, School of Pharmacy, Nottingham, United Kingdom (1)

Keywords: Liquid Extraction Surface Analysis, flow injection mass spectrometry, direct nanoESI mass spectrometry, urinary metabolomics, biomarker discovery

Introduction:

Direct electrospray/nano-electrospray ionisation mass spectrometry (ESI/nanoESI-MS) have great potential as high-throughput approaches for untargeted urine metabolomics [1-5]. Here, we compare standard liquid chromatography-mass spectrometry (LC-MS) with ambient ionisation MS methods of liquid extraction surface analysis MS (LESA-MS), flow injection ESI-MS (FIE-MS) and nanoESI-chip-based infusion for clinical urinary metabolomics.

Methods:

LESA-MS, chip-based infusion and FIE-MS using a high resolution-MS were developed and validated against a standard LC-MS method [6]. A mixture of 35 urinary metabolites were used to optimise and establish a high throughput sample preparation and data analysis protocols and the methods were then applied for biomarker discovery in malaria (n=88).

Results:

The analysis of malaria/control (n=41/47) urine samples was validated using pooled QC samples interspaced within the run. Malaria generated 7526 and 576 ions from LC-MS and FIE-MS, respectively. OPLS-DA showed clear separation and clustering of malaria from the controls with cross-validation of $R^2Y=0.810/0.993$, $Q^2=0.538/0.583$, sensitivity (80%) and specificity (77%) for LC-MS/FIE-MS, indicating comparable results. Altered levels of 30 and 17 metabolites were identified by LC-MS and FIE-MS, respectively, including pipecolic acid, taurine, 1,3-diacetylpropane, N-acetylspermidine and N-acetylputrescine and may have the potential of being used as biomarkers of malaria.

Conclusions:

The developed direct ESI/nanoESI-MS demonstrated high throughput capability combined with the ability to differentiate between urine samples in disease and health state. LESA-MS requires no sample preparation and only involves placing urine samples onto a slide surface, gives the method a further credit of being very simple and easy to use. Therefore, these methods are recommended to be considered as a fast diagnostic/screening tool in clinical practice.

Novel Aspect:

High-throughput surface analysis and direct ESI/nanoESI-MS methods for clinical biomarker discovery.

Advanced data processing for direct ESI/nanoESI-MS.

1337 - METABOLIC CHARACTERIZATION OF THP-1 MACROPHAGES POLARIZATION USING LC-MS-BASED METABOLITE PROFILING

Alaa Abuawad (1) - David Barrett (2) - Amir Ghaemmaghami (3) - Dong-Hyun Kim (2)

University of Nottingham, University of Nottingham/ Advanced Materials and Healthcare Technologies, Nottingham, United Kingdom (1) - University of Nottingham, University of Nottingham/ Advanced Material and Healthcare Technologies, Nottingham, United Kingdom (2) - University of Nottingham, University of Nottingham/Division of Immunology, Nottingham, United Kingdom (3)

Keywords: Macrophages, THP-1, metabolomics, LC-MS, polarization.

Introduction:

Macrophages are heterogeneous and plastic immune cells that change their phenotype and function in response to environmental cues. M1 and M2 macrophages represent pro and anti-inflammatory phenotypes which show distinctively different functions [1, 2]. LC-MS metabolomics study was applied to characterize the metabolic profiles of M1 and M2 macrophages. This can be translated clinically to interrogate and manipulate macrophage phenotype.

Methods:

THP-1 cells macrophages were polarized with either GC-MSF, LPS and IFN- γ or M-CSF and IL-4 to generate M1 or M2 polarised cells respectively. Unpolarised cells (M0) were set as a control. Then, LC-MS-based metabolite profiling was performed on an Accela system coupled to an Exactive (Thermo Fisher Scientific) operating with electrospray ionization (ESI), and ZIC-pHILIC (4.6 x 150mm and 5 μ m particle size, Merck Sequant) was used for chromatographic separation.

Results:

The results showed that M1 and M2 macrophages have distinctive metabolic profiles. Clear separation was shown in OPLS-DA models between M0, M1 and M2 macrophages. Moreover, various metabolic pathways were significantly disturbed upon polarization including sphingolipids and pyrimidine metabolic pathways in M1 THP-1 macrophages. Whilst arginine and proline, alanine, aspartate and glutamate metabolisms, were the most significantly perturbed metabolic pathways in M2 THP-1 macrophages. Relevant key metabolites were successfully selected as potential biomarkers for each of functional phenotype, such as [SP (22:0)] N-(docosanoyl)-sphing-4-enine, [SP (24:0)] N-(tetracosanoyl)-sphing-4-enine, [SP (16:0)] N-(hexadecanoyl)-sphing-4-enine, cytidine, cytosine, and 5-hydroxy tryptophan for M1 macrophages and N-acetyl glutamate, N-acetyl aspartate, and 4-imidazolone-5-propanoate for M2 macrophages.

Conclusions

LC-MS metabolic profiling was used to characterize M1 and M2 macrophages. This approach efficiently demonstrated the distinct metabolic profile for M1 or M2 macrophages and revealed potential biomarkers for each phenotype. These biomarkers can be translated to explain the mechanisms of macrophage polarization and consequently, manipulate the cells phenotype. For example M2 is required to resolve autoimmune diseases, where M1 is active against tumor cells.

Novel Aspect:

Discovery of biomarkers by LC-MS metabolomics can lead to understand polarization mechanism and then, development of targeted therapies for treating various diseases.

1379 - INVESTIGATING THE DIFFERENCES IN THE MOLECULAR EFFECTS OF FREE AND NANOPARTICLE LOADED METHOTREXATE ON PROLIFERATIVE AND NONPROLIFERATIVE CANCER CELLS USING ADVANCE CELL BASED METABOLOMICS

Mohammad Al-Natour (1) - Ali Alazzo (1) - Prof Amir Ghaemmaghami (2) - Dr Dong-Hyun Kim (3) - Prof Cameron Alexander (1)

University of Nottingham, School of pharmacy/Division of Molecular Therapeutics and Formulation, Nottingham, United Kingdom (1) - University of Nottingham, school of life sciences/Division of Immunology, Nottingham, United Kingdom (2) - University of Nottingham, School of Pharmacy/Division of Advanced Materials and Healthcare Technologies, Nottingham, United Kingdom (3)

Keywords:

Metabolomics, LC-MS, PLGA, Nanoparticles, Methotrexate

Introduction:

Polymer nanomedicine has drawn the attention of researchers in recent years, especially drug loaded NPs¹. However, the impact of drug loaded NPs at the molecular and cellular levels could be different from the free drugs. These discrepancies might be attributed to different levels of uptake or cellular trafficking routes, yet it is not fully understood. Metabolomics is a relevant tool for understanding such mechanisms involved in the response drug delivery systems.

Methods

Methotrexate (MTX) loaded and blank PLGA nanoparticles were fabricated using the conventional nanoprecipitation technique. The fabricated NPs in addition to free MTX were dosed to THP-1 macrophages and A549 lung epithelial cancer cells for 24 hours, after that the cellular metabolism was quenched and the intracellular metabolites were extracted. Global LC-MS based metabolic profiling was used to study the metabolic changes resulted upon different treatments.

Results

THP-1 cells were sensitive to the NPs more than to MTX and most responses can be linked to the phagocytosis process, the NPs resulted in down regulation in TCA cycle and in glycolysis, at the same time redox homeostasis impairment was recorded. A549 cells were sensitive to MTX more than to nanoparticles and the responses indicated apoptosis. MTX has resulted in nucleotide metabolism impairment, oxidative stress and shift in the energy metabolism towards fatty acid oxidation (FAO), this shift in energy metabolism leads to accumulation of acetyl CoA as end product of FAO, and because TCA cycle is malfunctioning, acetyl CoA is transformed to Acetoacetate which leads to ketoacidosis and apoptosis. The NPs did not have the same impact on A549 cells which might be due to the fact that the epithelial cells are not phagocytic. Being not proliferative might explain the resistance of activated THP-1 cells to MTX, especially because MTX is an antifolate agent that exerts its action during the S phase in proliferation process.

Conclusions

Global metabolic profiling approach was used to study the effects of MTX and MTX loaded PLGA NPs on THP-1 and A549 cells successfully. THP-1 cells were sensitive to the NPs more than to MTX and most responses can be linked to the phagocytosis process. A549 cells were sensitive to MTX more than to nanoparticles and the responses lead to apoptosis.

Novel Aspect:

This work highlights the utility of metabolomics approach in understanding the difference in the molecular activity of a therapeutic agent when dosed as in free form or in NPs.

488 - MEASURING TREHALOSE 6-PHOSPHATE (TRE6P) IN DIFFERENT PLANT MATERIALS – THE TECHNICAL CHALLENGE OF WORKING AT THE FEMTOMOLE SCALE

Regina Feil (1) - Maria Grazia Annunziata (1) - John E. Lunn (1)

Max Planck Institute of Molecular Plant Physiology, Dept. Metabolic Networks, Potsdam (1)

Measuring trehalose 6-phosphate (Tre6P) in different plant materials– the technical challenge of working at the femtomole scale

Regina Feil, Maria Grazia Annunziata, John E. Lunn

Max Planck Institute of Molecular Plant Physiology, Potsdam-Golm, Germany

Key words:Trehalose 6-phosphate (Tre6P), High-Performance Anion-Exchange Chromatography (HPAEC), Tandem mass spectrometry (MS/MS), Stable-isotope labelled internal standards (SIL-IS).

Introduction

Trehalose 6-phosphate (Tre6P) is an essential metabolite in plants. It acts as a signal of sucrose availability, thereby linking growth and development to carbon status. The amounts of Tre6P in plant tissues are extremely low (between 10 and 1000 pmol·g⁻¹FW in *Arabidopsis thaliana*), and plants contain several isomeric disaccharide monophosphates. HPLC coupled to tandem mass spectrometry (LC-MS/MS) is the most suitable technique for measuring Tre6P, offering both high sensitivity and high specificity.

Methods

Frozen plant material is extracted with chloroform/methanol(3:7, v/v) as in [1]. Each sample is spiked with a mix of [2H₂]Tre6P and other stable-isotope labelled internal standards (SIL-IS). Compounds are initially separated on an IonPac AS11-HC-4 with an alkaline eluent containing 5% methanol (ICS 5000+; Thermo Scientific Dionex). Detection and quantification is then achieved by tandem mass spectrometry (QTrap 6500; Sciex) [1,2].

Results and Conclusions

We achieve high specificity by simultaneous measurement of multiple product ions in the third quadrupole. The use of SIL-IS allows correction for ion suppression and other matrix effects in plant extracts which typically contain up to 25,000 different compounds [3]. In addition to Tre6P, we concurrently measure other phosphorylated intermediates, nucleotide sugars and organic acids, providing a comprehensive overview of central carbon metabolism.

Novel aspects

This technique allows accurate determination of low abundance signal metabolites and metabolic intermediates in plants that cannot be measured using other Methods:

Keywords: N-acylhomoserine lactone (AHL), quorum sensing (QS), C20-HSL, precursor ion scan, high resolution mass spectrometry

Introduction:

Gram negative bacterial quorum sensing (QS) is mainly regulated by an extracellularly produced N-acylhomoserine lactone (AHL). AHL consists of a lactone ring and an acyl chain, which generally varies from C4 to C18 in length. The marine photosynthetic bacterium *Rhodovulum sulfidophilum* produces extracellular nucleic acids involved in its flocculation [1], and may be regulated through AHL signaling.

Methods:

AHL extracts from cultured by *R. sulfidophilum* were obtained by TLC and analysed with liquid chromatography tandem mass spectrometry (LC-MS/MS) systems. In order to profile and detect AHLs, precursor ion scanning was performed using quadrupole-ion trap mass spectrometer. For both identification of the compounds and differential profiling analysis, high resolution accurate mass data was obtained by quadrupole-Orbitrap hybrid mass spectrometer.

Results:

AHL fraction containing long acyl-chain homoserinlactone (HSL) exceeding C10 was obtained from the reverse-phase thin layer chromatography-fractionated cultured supernatant of the marine photosynthetic bacterium *R. sulfidophilum*. We performed precursor ion scanning analysis and detected two kinds of long chain AHLs with chain length C20. By fragmentation search analysis to detect compounds with a homoserine lactone ring moiety for data dependent acquisition, a minor AHL, presumed to be 3-OH-C18-homoserine lactone, was also found. Among the detected C20-HSLs, N-(3-Hydroxyicosanoyl)-L-homoserine lactone (3-OH-C20-HSL) was structurally identified and 3-OH-C20:1-HSL was strongly suggested (paper in submission).

Conclusions:

We found that *R. sulfidophilum* produced two novel C20 long chain AHLs.

Novel Aspect:

This is the first report on structural analysis of novel AHLs with the longest yet-described acyl chain length of C20.

1238 - CHARACTERIZATION OF PHENOLIC COMPOUNDS AND DETERMINATION OF ANTI-INFLAMMATORY AND ANTI-CHOLINESTERASE ACTIVITY IN 2 COLOMBIAN FRUITS: BOROJOA PATINOI AND BACTRIS GASIPAES

Daniel Arias Ramirez (1)

Universidad de los Andes, Chemistry Departement, Bogota, Colombia (1)

Keywords: Borojoa patinoi, Bactris gasipaes, HPLC-PDA-ESI-MSn, polyphenols.

Introduction

The endemic Colombian fruits are an abundant source of secondary metabolites especially of phenolic compounds [1], [2]. Borojoa patinoi and Bactris gasipaes, two fruits from the region, are possible sources of this type of metabolites. Besides, there isn't any research focused on the identification of phenolics in these two fruits. The aim of this research is the total quantification and identification of phenolic compounds in these two fruits.

Methods:

The samples were acquired at Buenaventura's City market located at the Pacific coast of Colombia. The extraction was performed using methanol acidified with formic acid [3], [4]. The separation was carried out using a Kinetex C18 column (150 mm x 3 mm i.d., 3 μ m) [3]. The mobile phase used was 0.1% formic acid in water and methanol. The Ion Trap was operated in data-dependent, full scan and MSn mode to obtain fragment ion m/z with a collision energy of 35% and an isolation width of 2 m/z.

Results: (Limit 900 characters without spaces)

The extraction of polyphenols was previously optimized for HPLC-ESI-MS/MS analysis. The extraction was carried out according to the obtained profiles from the methanolic extracts allowing the identification of new compounds by means of data bases [5] [6]. In addition, by means of the Folin-Ciocalteu method the total content of phenolic compounds was quantified in these extracts. Additionally, the antioxidant activity was measured by the ABTS and DPPH methods. The anti-inflammatory activity by FOX method [7] and the anti-cholinesterasic activity by de Ellman method [8].

Conclusions (Limit of 400 characters without spaces)

At the structure elucidation ten new compounds were found for Bactris gasipaes among which 8 polyphenols stand out. In Borojoa patinoi nine new compounds were found eight of which are polyphenols. IC50/EC50 values were also found using quercetin as a positive control for antioxidant activities and anti-inflammatory assay. EC50 values were determined for the anticholinesterasic activity using Eserine as positive control.

Novel Aspect:

This is the first study focused on the search for polyphenols for these two Colombian fruits

Fatty acid β -oxidation fuels tricarboxylic acid cycle to sustain cell proliferation.

Matteo Audano, Silvia Pedretti, Donatella Caruso, Nico Mitro and Emma De Fabiani.

Dipartimento di Scienze Farmacologiche e Biomolecolari (DiSFeB), Università degli Studi di Milano, Milano, Italy.

Keywords: Mitochondria, mtDNA, fluxomics, β -oxidation.

Introduction: Mitochondria play a central role in energy metabolism and possess their own genome (mtDNA). Mitochondria control cell cycle and differentiation where they orchestrate and finely tune all metabolic transitions. In line with this, mtDNA is vital for cell life since it encodes for 13 OXPHOS subunits, mt-tRNAs and mt-rRNAs. The goal of this project is to identify new metabolic patterns by which cells survive to an important metabolic deficit, such as lack of mtDNA.

Methods: For this study we took advantage of p0 cells (mtDNA partially depleted cells). By LC-MS/MS, we performed steady state metabolomics and metabolic tracing. Specifically, we labelled the cells with U-13C6-glucose, U-13C5-glutamine and U-13C16-palmitate.

Results: Our results indicate that C2C12, Neuro2a, Hepa 1-6 and C3H/10T1/2 undifferentiated p0 cells have different metabolic phenotypes compared to wild type control cells with normal mtDNA levels. Specifically, steady state metabolomics and metabolic tracing analysis indicate that mtDNA downregulation differentially impairs metabolic profile of p0 cells in a cell specific fashion. Specifically, metabolomic and fluxomic analyses indicate that β -oxidation fuels the TCA cycle to replenish the reducing cofactor NADPH through the activity of the malic enzyme 1 (ME1).

Conclusions: Our data indicate that mtDNA depletion to a similar extent, differentially affects the metabolic profile, depending on the cell type.

Novel Aspect: Our findings provide new insights into undisclosed metabolic pathways activated to face important metabolic deficits. Specifically, we directly link for the first time the β -oxidation of fatty acid to NADPH, aspartate and asparagine levels and cell proliferation.

62 - DIAGNOSTIC PERFORMANCE OF METHYLMALONIC ACID TESTING BY LCMS/MS COMPARED TO HOLOTRANSCOBALAMIN BY IMMUNOASSAY FOR VITAMIN B12 DEFICIENCY

Flair Bahadory (1) - Phoebe Stanford (1) - Rita Horvath (1)

NSW Health Pathology, Prince of Wales Hospital, Department of Clinical Chemistry, Sydney (1)

Keywords: Methylmalonic acid, LC-MS/MS, Holotranscobalamin, Immunoassay, Vitamin-B12 deficiency

Introduction:

Measurement of total-B12 has been suggested to lack sensitivity to detect vitamin B12 deficiency. Methylmalonic acid (MMA) and Holotranscobalamin (Holo-TC) are recommended to be more sensitive markers for B12 deficiency. Our preliminary aim was to develop an LC-MS/MS method to measure MMA. We attempted to evaluate the diagnostic accuracy of HoloTC for the detection of B12 deficiency based on the surrogate reference criterion of a raised MMA (>500nmol/L).

Methods:

We employed a simple protein precipitation technique using acid, and a fast-chromatographic method using Ascentis RP-amide column and gradient mobile phase (3% - 90% v/v methanol with 0.1% formic acid) on Sciex 6500 QTRAP in negative mode, MRM of 117 - 73. Serum samples were tested for MMA (LC-MS/MS) and Holo-TC (immunoassay, Abbott-Architect / Roch-Cobas). Using ROC curve analysis and MMA as surrogate, the diagnostic accuracy of Holo-TC was evaluated.

Results:

We successfully developed an LC-MS/MS method for MMA measurement with an analytical range of 0.14 - 86.4 µmol/L. Serum samples, n=50 including 10 normal (>250pmol/L), 10 abnormal (<140pmol/L), 30 equivocal (140-250pmol/L) total B12 were tested for MMA and Holo-TC. Overall, we observed an increase in MMA (>500nmol/L) in 10% of patients, excluding patients with renal failure or known alternative reason for elevated MMA (1). Of this group, Holo-TC was low (<25 pmol/L) in 20% and equivocal (25-50pmol/L) in 80%. When MMA cut-off is 500nmol/L, the positive predictive value of Holo-TC<25pmol/L was 20%, and the negative predictive value of Holo-TC>50pmol/L was 100%. Compared to Abbott, results for Holo-TC by Roche was discordant in 4% of patients. All patients with low total B12 (<140pmol/L) had equivocal Holo-TC and normal MMA (<500nmol/L).

Conclusions:

Both MMA and Holo-TC have limited abilities to predict B12 deficiency. The use of these markers in combination, together with clinical details, may provide the most reliable representation of B12 status.

Novel Aspect:

To our knowledge, this is the first study that comparing several methods of measurement for detection of vitamin B12 deficiency.

768 - PYCMETRIX A FRAMEWORK FOR GAS CHROMATOGRAPHY - MASS SPECTROMETRY FOR CLINICAL DATA PRE-PROCESSING, ANALYSIS AND FEATURE EXTRACTION.

Andrei Barcaru (1) - Rebecca Heiner-Fokkema (2) - Peter Horvatovich (3)

University Medical Center of Groningen, Laboratory of medicine, Groningen (1) - University Medical Center of Groningen, Center for Metabolic and Liver Diseases, Laboratory of medicine, Groningen (2) - Rijksuniversiteit Groningen, Interfaculty of mass spectrometry, Analytical Biochemistry Group, Groningen (3)

Keywords: chemometrics, GC-MS data analysis, framework, python, Bayesian

Introduction:

Gas chromatography coupled to mass spectrometry (GC-MS) is widely used in clinical data analysis due to several major advantages: speed, resolution and available databases. Several data preprocessing tools for GC-MS are available in R [1] and C [2]. However, free open source pipelines are less common in this field. Clinical data requires often times certain specifications and code editing thus emphasizing the need of open sourcing.

Methods:

Pycmetrix is a framework build in python for preprocessing of GC-MS data and chemometrix data analysis. The package includes the possibility of deconvolution, quantification and interaction with a database via mysql.

Results:

The framework was applied to GC-MS data processing of several patients diagnosed with MCADD. The quantification feature was validated using the calibration curves and showed very good results. A feature selection method was further developed for a fast and automated diagnosis. The data from 20 healthy patients and 20 MCADD were used to create a model in a lower feature space. Using the tool described herein, we were capable to accurately quantify and classify the data.

Conclusion:

The pipeline proved to be efficient in working with multiple data sets in one run. The hardware requirements for the data analysis were reasonable, making the preprocessing and data analysis possible even on a low cost PC or laptop.

Novel Aspect:

Pycmetrix includes the features not available in other python packages such as: effect size based feature selection, supervised projection pursuit, Bayesian hypothesis testing and other useful options.

772 - PYCMETRIX A FRAMEWORK FOR GAS CHROMATOGRAPHY - MASS SPECTROMETRY FOR CLINICAL DATA PRE-PROCESSING, ANALYSIS AND FEATURE EXTRACTION.

Andrei Barcaru (1) - Rebecca Heiner-Fokkema (2) - Peter Horvatovich (3)

University Medical Center of Groningen, Laboratory of medicine, Groningen (1) - University of Groningen, Center for Metabolic and Liver Diseases, Laboratory of medicine, Groningen (2) - University of Groningen, Interfaculty of Mass Spectrometry, Analytical Biochemistry group, Groningen (3)

Keywords: chemometrics, GC-MS data analysis, framework, python, Bayesian

Introduction:

Gas chromatography coupled to mass spectrometry (GC-MS) is widely used in clinical data analysis due to several major advantages: speed, resolution and available databases. Several data preprocessing tools for GC-MS are available in R [1] and C [2]. However, free open source pipelines are less common in this field. Clinical data requires often times certain specifications and code editing thus emphasizing the need of open sourcing.

Methods:

Pycmetrix is a framework build in python for preprocessing of GC-MS data and chemometrix data analysis. The package includes the possibility of deconvolution, quantification and interaction with a database via mysql.

Results:

The framework was applied to GC-MS data processing of several patients diagnosed with MCADD. The quantification feature was validated using the calibration curves and showed very good results. A feature selection method was further developed for a fast and automated diagnosis. The data from 20 healthy patients and 20 MCADD were used to create a model in a lower feature space. Using the tool described herein, we were capable to accurately quantify and classify the data.

Conclusion:

The pipeline proved to be efficient in working with multiple data sets in one run. The hardware requirements for the data analysis were reasonable, making the preprocessing and data analysis possible even on a low cost PC or laptop.

Novel Aspect:

Pycmetrix includes the features not available in other python packages such as: effect size based feature selection, supervised projection pursuit, Bayesian hypothesis testing and other useful options.

617 - THE UTILIZATION OF TANDEM MASS SPECTROMETRY TECHNIQUES IN DIAGNOSIS OF PATIENTS WITH HOMOCYSTINURIAS.

Josef Bártil (1) - Jakub Krijt (1) - Petr Chrastina (1) - Jakub Hodík (1) - Markéta Paulová (1) - Renata Pinkasová (1) - Jitka Sokolová (1) - Viktor Kožich (1) - Karolína Peškova (1)

General University Hospital in Prague and 1st Faculty of Medicine, Charles University in Prague, Clinic of Pediatrics and Adolescent Medicine, Prague (1)

Keywords: tandem mass spectrometry, homocystinuria

Introduction:

Homocystinurias (HCYU) are rare genetic disorders characterized by accumulation of homocysteine (Hcy) in the body due to defects in a) the remethylation (RMD) pathway or b) transsulfuration pathway (cystathionine β -synthase deficiency -CBSD). Metabolism of Hcy depends also on supply, transport and intracellular metabolism of B vitamins. We developed tandem mass spectrometry methods enabling differential diagnosis of various types of HCYU.

Methods:

FIA-MS/MS newborn screening (NBS) method for amino acids (AA) in dried blood spot (DBS) and LC-MS/MS determinations of: 1) Hcy, methionine (Met) and methylmalonate (MMA) in DBS. 2) Cystathionine and other AA in plasma after derivatization with alkyl chloroformates. 3) S-adenosyl methionine (SAM) and S-adenosyl homocysteine (SAH) in plasma. 4) CBS activity in plasma using stable isotope substrate and determination of the deuterated product cystathionineD₂.

Results:

The established reference ranges were as follows: Hcy (DBS): < 12 $\mu\text{mol/L}$; Met (DBS): 7-33 $\mu\text{mol/L}$; MMA (DBS): < 5 $\mu\text{mol/L}$; Hcy (plasma): 3.5-15 $\mu\text{mol/L}$; cystathionine in plasma (P): 80-1000 $\mu\text{mol/L}$; Met (P): 12-40 $\mu\text{mol/L}$; SAM (P): 50-160 nmol/L; SAH (P): 26-80 nmol/L and CBS activity: 100-1000 nmol/hour/L plasma. By introducing new LC-MS/MS methods we diagnosed patients with CBSD presented by accumulation of Hcy and Met and decreased metabolites below the CBS block (i.e. cystathionine and cysteine), RMD including methylene tetrahydrofolate reductase deficiency and intracellular methylcobalamin synthesis defects characterized by decreased production of Met and SAM, accumulation of Hcy and an increased flux of metabolites through the transsulfuration pathway and B vitamins deficiencies presenting with elevated Hcy and MMA. Within NBS program between July 2016 and December 2017, we analyzed samples from 128531 newborns and detected 3 patients with maternal vitamin B12 deficiency and 1 patient with CBS deficiency.

Conclusions:

We developed LC-MS/MS methods approach for diagnosing patients with HCYU enabling us to discriminate between primary enzyme deficiencies and vitamin B deficiencies and distinguish between defects in the RMD and transsulfuration pathway of Hcy. Methods employing DBS are also used in NBS program and have the clinical utility for monitoring of therapy in patients with hyperhomocysteinemias due to ease of collecting and shipping DBS samples by the patients.

Novel Aspect:

The LC-MS/MS methods help to enhance efficacy in diagnosis procedure for hyperhomocysteinemias and simplify monitoring of patients under treatment.

190 - CESI-MS - A SENSITIVE AND VERSATILE APPROACH FOR METABOLOMICS

Walter Belloni (1)

Sciex, Separations, Milano (1)

CESI-MS - A Sensitive and Versatile Approach for Metabolomics

Bryan Fonslow¹; Esme Candish¹; Jim Thorn²; Walter Belloni²; Stephen Lock²

¹SCIEX, Framingham, MA; ²SCIEX, Warrington, United Kingdom;

A.08 Life sciences - Metabolomics

Keywords: CE-MS, anionic, cationic, metabolites, CESI

Introduction:

The analysis of the metabolites can present an analytical challenge, particularly those involved in the central carbon metabolism and neurotransmission. Often, structural isomers can't be differentiated by MS or MS/MS alone, making a separation crucial. Unfortunately, the LC separations prove difficult for some metabolites; some hydrophilic analytes are poorly retained by RP-LC, while column-to-column reproducibility can sometimes be more challenging with HILIC separations.

Methods:

In contrast, capillary electrophoresis (CE) is well suited towards metabolomics analyses. CESI-MS integrates CE and electrospray ionization (ESI) into a single device and this combines the benefits of a high-resolution separation with the increased MS sensitivities that result from the ultra-low flow rates. In this case, we demonstrate CESI-MS for the analysis of these challenging metabolites.

Results:

A single protocol was established for the separation and detection of both cationic and anionic metabolites. Electrophoretic separations were performed using 30 kV to generate a field strength of 333 V/cm and normal and reversed CE polarities were employed for cationic and anionic metabolites respectively. MS compatible background electrolytes (BGEs) facilitated highly efficient separations, achieved in less than 30 mins. Enhanced sensitivity was achieved using transient isotachopheresis with CESI directly coupled to either a SCIEX TripleTOF[®] 6600 or QTRAP[®] 6500+ system. Cationic metabolites were characterized using normal polarity with positive ESI while the anionic metabolites were analyzed from the same sample by simply switching the polarity of the CE and MS.

Conclusions:

The CESI-MS technology proved powerful for the targeted analysis of the central carbon metabolism, particularly the small organic acids of the tricarboxylic acid (TCA) cycle and the isobaric phosphorylated sugars of the pentose and glycolysis pathways. In addition, CESI-MS was used to detect metabolites involved in neurotransmission such as those in the tryptophan pathway. Despite an injection volume of less than 50 nL, low nanoMolar concentrations were easily detected.

Felipe Benavides (1) - Chiara Carazzone (1)

Universidad de los Andes, Chemistry Department, Bogotá D.C., Colombia (1)

ords: Lonomia, Host-plant, Secondary Metabolites, Primary Metabolites.

Introduction

The Lonomia caterpillars are venomous animals found in Latin America and Colombia owns a great variety species of this genus.[1][2] Very few works has been realized about the Lonomia caterpillars in Colombia and their host plants. The aim of this investigation is to study of the polyphenols, alkaloids, lipids and proteins content of *Ochroma pyramidale*, *Tapirira guianensis* and *Inga edulis*, host plants of the caterpillar *Lonomia descimoni*.

Methods

The specimens were collected in the Colombian Amazon jungle. The leaves were macerated with liquid nitrogen and the extraction was performed with different solvents depending on the metabolites of interest (polyphenols[3], alkaloids[4], lipids[5] and proteins[6]). The extracts were filtered and injected onto HPLC-ESI-MS/MS system. The spectra and chromatograms were analyzed for the identification of the metabolites present in the extracts.

Results

The extraction conditions for the lipids[3] and the proteins[4] were optimized previously to the analysis by HPLC-ESI-MS/MS. The alkaloids and polyphenols extraction conditions were performed according to [5] and [6], respectively. The profiles obtained of the different extracts of the leaves of the three plants under study allowed the comparison of the metabolites present. The tandem mass spectra of the metabolites were assigned and, when possible, identified. Additionally, we could establish that despite the presence of some metabolites with the same m/z relation in the three plants, these corresponded to different compounds, since the MS/MS fragments of these were different.

Conclusions

The chromatograms and the MS / MS spectra allowed us to observe differences between the polyphenol, alkaloid, lipid and protein profiles of the three plants under study. Only a few compounds are present in all plant species, therefore it would be interesting to investigate the effects of these metabolites on the diet of the caterpillar.

Novel Aspect

In spite of the Colombian biodiversity, most species remain uninvestigated. This is the first study on the host plants of *Lonomia descimoni*, a venomous caterpillar.

Keywords: solid phase microextraction, high resolution mass spectrometry, metabolomics, transplantation

Introduction:

Since successful introduction of immunosuppressants, organ transplantation is a routine procedure, which saves lives of patients with end-stage organ failure worldwide. The demand for grafts is much higher than the available pool of organs, therefore various strategies are explored to address this issue. The one presented here is metabolic profiling of organ with low-invasive method based on solid phase microextraction and high resolution mass spectrometry.

Methods:

The study of kidney grafts were performed on pig model. In one group organs were subjected to warm ischemia and in the second group kidneys were non-ischemic. Solid phase microextraction probes of ca. 0.2 mm diameter and 7 mm of coating length were selected for untargeted extraction of metabolites. Sampling was performed before organ harvesting, during preservation with normothermic perfusion and after reperfusion. Analysis were done on UPLC-Q-Exactive Focus.

Results:

The proposed analytical strategy enabled metabolomics of living organ with very low-invasiveness and tissue biopsy-free sampling. The results of LC-MS analysis revealed significant differences in metabolome of kidney obtained from donors after cardiac death (DCD, ischemic organs) and heart beating donors (no ischemia). Comparison of the data from organs subjected to warm ischemia showed increased level of lysyl residue oxidation products. The effect was most pronounced after reperfusion indicating increased risk of reperfusion injury in DCD. On the other hand, monitoring of changes during normothermic perfusion showed that level of some metabolites inducing oxidative stress peaking during ischemia drops to initial values suggesting that the used preservation strategy can successfully reverse some adverse reactions initiated by ischemia. This finding is supported by putative identification of the nephroprotective compounds reported earlier in the literature as the ones possessing anti-ischemia-reperfusion injury activity.

Conclusions

The results obtained indicate that novel analytical strategy proposed for assessment of graft quality carries a great potential for future improvement of pre-transplant diagnostics. It offers a possibility of selection of panels of biomarkers, which after required validation, could be used for fast on-site screening with SPME-MS platform in the future.

Novel Aspect:

The applicability of SPME-HRMS-based strategy for graft assessment was proven using a porcine model of kidney transplant.

246 - MULTILAYER OMICS STRATEGY FOR TRACING THE METABOLIC ROUTES EXPLOITED BY KRAS ONCOGENETIC MUTATION IN NSCLC

Laura Brunelli (1) - Elisa Caiola (2) - Francesca Falchetta (2) - Silvia Giordano (1) - Mirko Marabese (2) - Massimo Brogгинi (2) - Roberta Pastorelli (1)

IRCCS-Istituto di Ricerche Farmacologiche Mario Negri, Environmental Health Sciences, Milano (1) - IRCCS-Istituto di Ricerche Farmacologiche Mario Negri, Oncology, Milano (2)

Keywords: NSCLC, metabolism, co-occurring genetic lesions, mass spectrometry

Introduction:

NSCLC is a heterogeneous disease, with multiple oncogenic mutations (e.g. KRAS, LKB1). NSCLC patients have a variety of clinical courses, which are partly due to differences in co-occurring molecular events [1]. Since both KRAS mutation and LKB1 loss have an impact on cellular metabolism, it is fundamental to discern the metabolic effects induced by single genetic events from those induced by their co-occurrence, for novel therapeutic interventions

Methods:

We knocked-out the LKB1 gene in well-characterized NSCLC cell clones harbouring KRAS WT or mutant G12C proteins. We obtained an isogenic system in which KRAS mutation and LKB1 loss were individually or concomitantly present. The effects of these genetic makeups on cell metabolism were investigated in these NSCLC cells by means of an integrated survey of proteomics, metabolomics, ¹³C-Glucose/Glutamine flux analysis coupled with functional in-vitro strategies.

Results:

Using untargeted (FIA-LTQ Orbitrap) and targeted (p180KIT, HPLC-Triple Quad 5500) metabolomics approaches we demonstrated how isogenic NSCLC cells harbouring both KRASG12C/LKB1 loss had an impact on the same metabolic pathways (glycolysis, TCA, urea cycle) used by their single lesion counterparts, but were able to exploit these metabolic routes through a heightened metabolite production. The enhanced metabolite production triggered by the co-occurrence was not reflected in a different enzymatic asset in terms of both numbers and magnitude of enzymatic changes. Furthermore, metabolic flux analysis showed how the metabolic dynamics of glycolysis and TCA cycle differed between clones harbouring the dual lesion from those with the single lesions. The enhanced metabolic activity of cells with both genetic lesions rendered the viability of these cells susceptible to energetic stress caused by both glycolysis inhibition and by nutrients limitation (glucose/glutamine) than those harboring single oncogenic lesions.

Conclusions:

We demonstrate how the metabolic rewiring observed in presence of KRAS/LKB1 co-occurring lesions, whilst failing to improve cellular fitness, was accompanied by reduced cell growth rates compared to those of wild type or single lesion cells. Furthermore, the cells with both lesions demonstrated greater susceptibility towards survival impedance caused by 2-DG treatment or glucose/glutamine limitation.

Novel Aspect:

This observation raises the prospect that energy stress may affect NSCLC cells harbouring co-occurring lesions, which may render them more susceptible to cytotoxic drugs

479 - CONVERSION OF COENZYME A THIOESTERS BY NATIVE CHEMICAL LIGATION – A NEW APPROACH FOR CHARACTERIZING AN IMPORTANT CLASS OF BIOMOLECULES

Nevenka Cakić (1) - Heinz Wilkes (1)

Institute for Chemistry and Biology of the Marine Environment (ICBM), University of Oldenburg, Oldenburg (1)

Keywords: Coenzyme A thioesters, native chemical ligation, fragmentation patterns, chiral separation

Introduction

Acyl-coenzyme A esters (acyl-CoAs) are very important biomolecules which play a central role in different metabolic processes, including β -oxidation of fatty acids, amino acid degradation and the citric acid cycle. Although numerous techniques for the analysis of acyl-CoAs have been developed, a straightforward approach for the unambiguous characterization of isomeric acyl-CoAs is still lacking.

Methods

Transformation of CoA-thioesters has been achieved using the native chemical ligation (NCL) reaction [1]. Different acyl-CoAs were incubated with L-cysteine and sodium 2-mercaptoethanesulfonate (MESNa) in 0.05M phosphate buffer (pH 7.4) at 70 °C. Products were analyzed without further modification and after the cleavage of the disulphide bond by a reductive agent with LC-ESI-TOF in positive mode.

Results

In this research the replacement of coenzyme A from CoA-thioesters with L-cysteine by NCL is demonstrated. Initially, transthioesterification between acyl-CoAs and L-cysteine occurs to form products that further undergo an irreversible amide formation. Under the reaction conditions applied the thiol-containing amide is oxidized to a disulphide with MESNa, which results in higher water solubility. All products detected showed mass spectrometric fragmentation patterns corresponding to cleavage of the amide and disulphide bonds, which allow their straightforward identification in mixtures. After reduction of the disulphides all products showed a fragmentation pattern characteristic of cysteine derivatives. Additionally, we performed the NCL reaction on the racemate of 2-methylhexanoyl-CoA and successfully separated diastereomeric products on an achiral column.

Conclusions

The methodology described enables detailed structural characterisation of the acyl-residues in acyl-CoAs by generating transformation products through the NCL reaction which deliver more informative mass spectra. Furthermore, it provides a possibility for separation and assignment of configuration of alpha-substituted chiral compounds on an achiral column using L-cysteine as a chiral auxiliary.

Novel Aspect

Selective conversion of CoA thioesters to the cysteine containing products is a novel aspect for characterization of an important class of biomolecules.

Enhanced Metabolite Identification Using An Orbitrap Tribrid Mass Spectrometer

Kate Comstock¹; Shuguang Ma²; Seema Sharma³; Yan Chen³

¹Thermo Fisher Scientific, San Jose, CA; ²Genentech Inc., South San Francisco, CA; ³Thermo Scientific, San Jose, CA

Introduction

High resolution mass spectrometry (HRMS) is an essential tool for metabolite identification. HRMS with sophisticated data acquisition features can provide the critical information for metabolite structure elucidation and alleviate the difficulties of matrix complexity.

Here we present a study for metabolite ID using Orbitrap Tribrid MS with data acquisition features designed to significantly improve small molecule structure analysis, which include automatic background ions subtraction, inclusion/exclusion lists generation, and real-time decision-making to optimize MSn data acquisition quality and speed.

The high quality information-rich MSn data generated using this improved HRMS was processed using structure analysis and data mining software "Mass Frontier" and "Compound Discoverer".

Methods

Amprenavir, Bosentan, Lopinavir, and Ritonavir were selected as model compounds. The compounds, at concentration of (5 μ M), were incubated with human liver microsomes (HLM) in the presence of GSH and UDPGA. Incubations without drug or without NADPH were chosen purposely to test the background subtraction feature.

The LCMS analyses were performed on Vanquish Flex Binary UPLC system with DAD detector coupled to an Orbitrap Tribrid Mass Spectrometer. Mobile phases were composed of: A: H₂O/0.1% formic acid, and B: ACN/0.1% formic acid with gradient on Hypersil column (2.1X100 mm 1.9 μ m).

High resolution full scan and MSn data were collected in a data-dependent fashion with polarity switching. The data acquisition method was incorporated with features optimized for small molecule analysis.

Preliminary Data

These HIV drugs were selected because of their extensive metabolism. Using the Orbitrap Tribrid Mass Spectrometer's special features for small molecule data acquisition: the automatic background subtraction, inclusion/exclusion list generation, and real-time decision-making optimization of MSn spectra acquisition, the MS provides a wealth of information for metabolite identification. The automatic background subtraction feature is especially useful for identification of metabolites present in a complicated biologic matrix.

The new and enhanced features that use the high quality MS/MS fragments to trigger the MSn acquisition significantly improved MSn data quality, because multi-stage MS/MS (MSn) information is essential for confident metabolite structure elucidation. For example, HRAM full scan data show that Ritonavir metabolites include four mono-oxidation products, two N-dealkylation products, and four di-oxidation products. In order to determine the structure and the sites of biotransformation of these metabolites, high quality MS/MS and higher order MS/MS spectra were obtained using the novel data collection features of Orbitrap Tribrid MS.

Major and minor metabolites, both phase I and II, of these model compounds formed in the HLM microsomal incubations were quickly detected by processing the HRAM and higher level MS/MS (MSn) spectra of metabolites using Mass Frontier and Compound Discoverer.

This workflow offers significant improvements in speed and confidence of routine drug metabolite identification and other small molecule structure characterization applications.

Novel Aspect

Small molecule specific acquisition features of OrbitrapTribrid MS improve MSn data quality and increase confidence for metabolite identification.

608 - TARGETED APPROACH FOR DETERMINATION OF METABOLITES OF FLAVONOIDS AND ISOFLAVONOIDS IN BIOLOGICAL SAMPLES

Lucia Chrenková (1) - Veronika Pilařová (1) - Lenka Applová (2) - Iveta Najmanová (3) - Přemysl Mladěnka (4) - Lucie Nováková (1)

Charles University, Faculty of Pharmacy, Department of Analytical Chemistry, Hradec Králové (1) - Charles University, Faculty of Pharmacy, Department of Pharmacology and Toxicology, Hradec Králové (2) - Charles University, Faculty of Pharmacy, Department of Pharmacology and Toxicology, Hradec Králové (3) - Charles University, Faculty of Pharmacy, Department of Biological and Medical Sciences, Hradec Králové (4)

Keywords: quercetin, UHPLC-MS/MS, MEPS, μ -SPE-PT, isoflavonoids

Introduction:

Rutin is metabolized into two groups of metabolites: flavonoid type with higher molecular weight (quercetin, quercetin-3-O-glucuronide, tamarixetin and isorhamnetin) and polar weak phenolic acids (4-methylcatechol, phloroglucinol, 3,4-dihydroxyphenylacetic acid, homovanilic acid, 3-hydroxyphenylacetic acid, 3-(3-hydroxyphenyl)propionic acid). Tectoridin and tectorigenin are isoflavonoids.

Methods:

The UHPLC method with mass spectrometry (MS/MS) detection was optimized for the separation of all 13 analytes. For the pre-treatment of rat plasma samples, microscale extraction approaches including μ -SPE-PT (micro-solid phase extraction in pipette tips) and MEPS (microextraction by packed sorbent), but also non-selective PP (protein precipitation) were used.

Results:

The metabolites with significantly different physicochemical properties make the simultaneous determination quite challenging.

Considering the critical pair of isomers (tamarixetine and isorhamnetin), BEH Shield RP C18 (2.1 x 100 mm; 1.7 μ m) column and gradient elution with methanol and 0.1% aqueous solution of formic acid offered the best selectivity. The Xevo TQ-XS mass spectrometry was employed and the conditions for all compounds were also thoroughly optimized. Due to the instability of some phenolic acids (homovanilic acid, 3,4-dihydroxyphenylacetic acid) in ion source, the Xevo TQ-S mass spectrometer detector was replaced with Xevo TQ-XS. This mass spectrometer contains different type of ion optics more suitable for targeted analytes. All compounds were analyzed in the mode SRM (selective reaction monitoring), while SIM was often needed at other platforms.

Conclusions

The UHPLC-MS/MS method was optimized and validated in the terms of sensitivity, linearity and matrix effects. Using Xevo TQ-XS mass spectrometer, all analytes could be quantified with linearity range between 0.1 – 1000 ng/mL.

Novel Aspect:

Due to the instability of some phenolic acid analytes in ion optics, the Xevo TQ-S detector was replaced with Xevo TQ-XS.

This work was supported by the STARSS project (Reg. No. CZ.02.1.01/0.0/0.0/15_003/0000465) co-funded by ERDF, by SVV 260412 and by GACR 301/17/05409S.

901 - EXPLORING SERUM TARGETED METABOLOMICS MASS SPECTROMETRY PROFILE ANALYSIS TO IMPLEMENT RISK CRITERIA FOR FIRST-DEGREE RELATIVES (FDR) OF GASTRIC CANCER (GC) PATIENTS.

Giuseppe Corona (1) - Renato Cannizzaro (2) - Gianmaria Miolo (3) - Agostino Steffan (4) - Valli De Re (5)

IRCCS- National Cancer Institute, Immunopathology and Cancer Biomarkers, Aviano (PN) (1) - National Cancer Institute, Oncological Gastroenterology, Aviano (2) - National Cancer Institute, Medical and Preventive Oncology, Aviano (PN) (3) - National Cancer Institute, Immunopathology and Cancer Biomarkers, Aviano (PN) (4) - National Cancer Institute, Immunopathology and Cancer Biomarkers, Aviano (5)

Keywords: Metabolomics, Gastric cancer; first degree relatives; Biomarkers; Early diagnosis; introduce

Introduction: A positive family history is a strong and consistently reported risk factor for gastric cancer (GC)[1]. The main purpose of this study was to investigate serum metabolomic profiles to find additional biomarkers that could be integrated with serum pepsinogens and gastin test to improve the diagnosis of GC and the selection of first-degree relatives (FDR) at high risk of GC development.

Methods: The targeted serum metabolomic profile included 188 metabolites, covering amino acids, biogenic amines, acylcarnitines, phosphatidylcholines, sphingomyelins and hexoses. Metabolite profiles were performed by liquid chromatography and flow injection tandem mass spectrometry analysis. Differential metabolomic signatures among the FDR (n=54) and GC (n=71) groups were investigated by univariate and multivariate analysis.

Results: Forty metabolites mainly belong to the phospholipids and acylcarnitines classes were significantly altered between FDR and GC patients. Nine metabolites resulting from the training set were further confirmed in the validation set. Compared with FDR, GC patients were characterized by lower levels of hydroxylated sphingomyelins (SM(OH)22:1, SM(OH)22:2, SM(OH) 24:1) and phosphatidylcholines (PC ae 40:1, PC ae 42:2, PC ae 42:3) and by higher levels of acylcarnitines derivatives (C2, C16, C18:1). The sensitivity and specificity of these metabolomic biomarkers to distinguish potential cancer conditions was 73.47% and 83.78% respectively with AUC of ROC curve of 0.811 that improves to 0.90 when integrated with age and the serum level of serum pepsinogen II.

Conclusions: The results of the study for the first-time described serum metabolomic profiles that discriminate GC patients from FDR sharing the same environment and a similar genetic background. As compared with FDR, the GC patients showed specific serum metabolomic signatures characterized by an increase in specific acylcarnitines and a decrease in a distinctive subclass of sphingolipids.

Novel Aspect: The study underlines the role of the use of the individual's serum tandem mass spectrometry metabolomics profile to complement the triage of FDR at higher risk of GC development

Keywords: Fagioli Bianchi di Rotonda, FT-ICR-MS, Phytochemical Screening, Hypoglycemic Activity, Metabolomics

Introduction: The aim of this study was to evaluate the metabolome of Fagioli Bianchi di Rotonda beans (*Phaseolus Vulgaris* L.), cultivated in Basilicata (Southern Italy), labelled with DOP mark quality, in order to promote their nutraceutical properties. In this study, a metabolome untargeted analysis by HRMS was performed.

Methods: High-resolution mass spectra were acquired on a Bruker (Bruker Daltonik GmbH, Bremen, Germany) solarix XR Fourier transform ion cyclotron resonance mass spectrometer (FT-ICR-MS) equipped with a 7 Tesla superconducting magnet and an ESI source in the negative ionization mode. The nutritional compositions including starch, fat, protein and phytochemicals were analyzed.

Results: A shotgun approach, based on direct infusion negative-ion ESI ultrahigh resolution mass spectrometry (FT-ICR-MS), was employed for the rapid analysis of metabolites occurring in all extracts of Fagioli Bianchi di Rotonda beans. Such non-targeted analysis generates a tremendous amount of data and requires visualization strategies to convert lists of accurate m/z values into metabolomic context. Visualization strategy using van Krevelen diagram was adopted. This diagram displays the hydrogen/carbon (H/C) vs. oxygen/carbon (O/C) ratios of these elemental formulas and provide a qualitative description of the molecular complexity of Fagioli Bianchi di Rotonda data. This plot enabled the localization of chemical species according to class metabolites, as carbohydrates, glycosylated compounds, peptides, polyphenols and saponins. The antioxidant activity and α -glucosidase inhibition activity of extracts were evaluated. All the samples possessed strong ABTS free-radical-scavenging capacity and α -glucosidase inhibition activity.

Conclusions: In this study, an identification of different classes of secondary metabolites in Fagioli Bianchi di Rotonda, ecotypes Bianco and Tondino, was carried out. Some of these compounds are known to show bioactivities interesting for human health. Results of biological activity assays highlighted the importance of the use of such food product for nutraceutical applications.

Novel Aspect: This study shed some light on metabolic profiles of Fagioli Bianchi di Rotonda and their nutraceutical properties. Results can be used for comparative studies.

1133 - TWO-DIMENSIONAL GAS CHROMATOGRAPHY AS A POWERFUL TOOL FOR DISCRIMINATING VOCs IN MONOVARIETAL AND COMMERCIAL EXTRA VIRGIN OLIVE OIL

Alessio Da Ros (1) - Silvia Carlin (1) - Domenico Masuero (1) - Samantha Riccadonna (1) - Fulvio Mattivi (2) - Nadia Mulinacci (3) - Urska Vrhovsek (1)

Fondazione Edmund Mach, Food quality and Nutrition, San Michele all'Adige (TN) (1) - Fondazione Edmund Mach, University of Trento, San Michele all'Adige (TN) (2) - NEUROFARBA, University of Florence, Florence (3)

Keywords: GCxGC-TOF-MS, EVOO, VOCs, oils quality, LOX pathways, terpenes.

Introduction:

The unique and special flavour of Extra Virgin Olive Oil (EVOO) can be attributed to VOCs such as the C6 and C5 aldehydes, which are responsible for green aromatic notes, but also terpenes and sesquiterpenes, which tend to generate greater aromatic complexity in quality oils. The identification of the compounds responsible for flavour or off-flavour attributes is considered one of the keys for EVOOs quality control and a good indicator of olive oil quality changes.

Methods:

Sixteen monovarietal EVOOs produced from different cultivars (purchased directly from producers) were compared with 25 blended commercial EVOOs (purchased in national grocery stores).

EVOO VOCs were analysed with HS-SPME-GCxGC-TOF-MS[1]. A total of 1254 putative compounds were detected, with 123 being significantly different in monovarietal and commercial oils. Compound identity was confirmed with Kovats retention index and by comparing spectra compounds to NIST 2.0, Wiley 8 FFNSC 2 (Chromaleont, Messina, Italy).

Results:

Principal component analysis (PCA) showed clear separation between the two classes of samples. Specifically, commercial samples were more influenced by compounds such as alcohols, acids (acetic acid and formic acid) and other acetates frequently responsible for certain unpleasant notes. The monovarietal samples were more influenced by compounds deriving from LOX pathways (aldehydes C6 and C5), as well as terpenes and sesquiterpenes, such as valencene, copaene and ocimene for example, which generally generate pleasant wood, green and lemon notes. Furthermore, differences in the composition of monovarietal samples were evaluated. Two varieties (Casaliva and Tonda Iblea) were clearly distinguished from the rest of the monovarietal samples, underlining that the cultivar and pedoclimatic conditions can influence VOC composition.

The preliminary results show that HS-SPME-GCxGC-TOF-MS is a fast and very powerful tool for revealing differences between the aroma of different classes of EVOO products.

Conclusions:

The present investigation demonstrates that volatile compounds can be used as reliable indicators of Extra Virgin Olive Oil quality. In detail, between commercial and monovarietal oils, significant qualitative differences were found in a large number of volatile compounds, highlighting the possibility to use terpenes, sesquiterpenes and aldehydes how markers for quality olive oil aroma.

Novel Aspect:

Two-dimensional gas chromatography is a novel method to discriminate EVOOs quality and aroma. Its applicability can reveal the differences of a large number of volatile compounds, analyzing the macro and micro differences in this matrix.

Keywords: pancreatic cancer stem cells; pancreatic cancer; metabolomic and proteomic approaches; pancreas; deregulated pathways.

Introduction:

Pancreatic ductal adenocarcinoma (PDAC), one of the most aggressive solid tumours of the pancreas, is characterized by a remarkable resistance that also depends on the presence of the so-called cancer stem cells (CSCs) [1,2]. It is evident that, to make an impact on pancreatic cancer, it is necessary to eradicate CSCs with targeted therapies and, for this reason, a complete molecular characterization of CSC biology is fundamental.

Methods:

The MIAPaCa-2, PaCa3 and Panc-1 CSCs and relatives parental cells were cultivated and subjected to metabolomics and proteomic analyses. Different protocols have been evaluated to improve the identification of metabolites from adherent and suspended cell lines. Different extraction approaches and different derivatization approaches have been evaluated and compared.

Results:

The results obtained indicate that CSCs are characterized by downregulation of succinate, fumarate, and malate and by upregulation of glutamate, in comparison to the parental cell lines. A reduction of Krebs cycle intermediates and an increase of a Krebs cycle-related metabolite may suggest a switch to a less oxidative metabolism. The results of the proteomic analyses are still in the collection phase. Preliminary data suggest that a total of 121, 188 and 186 proteins are modulated in Panc-1, PaCa-3 and MIA PaCa-2 CSCs as compared to the parental cells with p-value ≤ 0.05 and fold change ≥ 1.5 , respectively.

Conclusions

Altogether our findings may clarify some critical aspects of the metabolic network signature of PDAC and may serve as a relevant pool of metabolites and proteins from which biomarkers and therapeutic targets can be identified. Further analysis of biological replicates and validation of results are required to confirm our preliminary data.

178 - A TARGETED METABOLOMICS ASSAY TO INVESTIGATE STEROID HORMONES IN WOMEN DURING PREGNANCY AND EARLY POSTPARTUM PERIOD

Serena Di Palma (1) - Endre Laczko (1)

Functional Genomics Center Zurich, University of Zurich/ETH, Zurich (1)

Keywords:

Steroid hormones, saliva, pregnancy, targeted metabolomics, SRM

Introduction:

In this study, we want to set up a targeted assay to measure the concentration of six steroids from salivary samples of pregnant women, beginning from the first trimester of pregnancy to a few weeks postpartum.

Saliva has potential clinical applications in maternal monitoring and represents a less invasive alternative to serum or plasma for the measurement of steroid hormones. However, little information is available regarding the range of salivary steroid concentrations during pregnancy [1, 2].

Steroid hormones in saliva derive primarily from free steroid present in the general circulation and their concentrations can be regarded as the bioavailable fraction. Our aim is to establish an accurate MS-based assay for quantification of six steroids in saliva, reaching great sensitivity and precision.

Methods:

Steroid hormones are extracted from the biological matrix employing a methanol extraction protocol. After reconstitution in an aqueous buffer containing an internal standard, they are analyzed using a targeted approach by SRM technology on a nanoLC-MS system (Thermo TSQ-Quantiva coupled to a Waters M-class UPLC). Our targets include cortisol, cortisone, estradiol-17 β , estriol, progesterone, dehydroepiandrosterone (DHEA), and testosterone. A minimum of three transitions are selected per each target compound, with optimized collision energy, to ensure high selectivity and great sensitivity. The LC is set up in RP mode, with a C18 column (200 μ m x 5cm), a flow rate of 2 μ L/min and a gradient of 10 minutes. Calibration curves are included in the analysis for accurate quantification. The data will be investigated using a combination of Xcalibur Quan Browser and TraceFinder.

Results:

We have fully developed and optimized an SRM assay to include our six steroid targets in the analysis. For the purpose, commercially available reference compounds were directly infused into the MS to select the best precursor ion and three to four fragment ions, optimizing collision energy (among other parameters) per each fragment. Also, the LC gradient was optimized to have each peak, corresponding to each compound, chromatographically well resolved.

Calibration curves containing all our compounds simultaneously, plus an internal standard to normalize for instrument variations, were built ranging from 0.4 to 400 nM. The curves showed good linearity and, for most of the compounds, the LLOQ was below 1 nM.

A test phase was conducted on saliva samples (100 μ L) collected from pregnant women upon awakening at different stage of pregnancy. These test samples were employed to refine the extraction procedure and evaluate sample recovery.

We will expand the analysis to hundreds of saliva samples collected from pregnant women participants, monitoring the full range of steroid hormone concentration across pregnancy. After completing the acquisition, we will build quantitative plots of our targeted steroid compounds per each woman.

Conclusions

Targeted metabolomics employing SRM assays allows us to investigate a broad panel of steroid hormones in biological fluids, such as saliva sample. The study will shed light on the course of the steroid concentrations in saliva across pregnancy and into the early postpartum period.

Novel Aspect: (Limit of 150 characters without spaces)

Our MS assay will represent a fast and reliable tool to measure steroid concentrations in the saliva of pregnant women.

459 - ECOMETABOLOMICS OF ROOT EXUDATES IN GERMAN GRASSLAND COMMUNITIES

Sophie Dietz (1) - Stefanie Döll (1) - Karin Gorzolka (2) - Dierk Scheel (1)

Leibniz Institute of Plant Biochemistry, Stress and Developmental Biology, Halle-Saale (1) - Leibniz Institute of Plant Biochemistry, Stress and Developmental Biology, Halle Saale (2)

Keywords: Life Science, Metabolomics, LC-MS, untargeted profiling

Introduction: Rhizosphere: the belowground black-box

The plant roots are embedded in a multiple organism network: the rhizosphere. For reactions towards different abiotic stresses [1, 2] or to interact with the microbial soil communities and neighboring plants [3-7], roots release metabolites called exudates. Until now, there is little known about these chemicals in natural habitats. Therefore, we applied non-targeted metabolomics combined with ecology to analyze exudate patterns in natural grassland communities.

Methods: Exudate analysis under field condition

Ten common European grassland species were grown under field conditions, exudates were directly collected from roots and subjected to non-targeted metabolite profiling by UPLC coupled to ESI-Q-TOF mass spectrometry and the combination of different software. Selected compounds were chemically classified on the level of metabolite families by the use of MetFamily. The method for exudate isolation was proven to be appropriate by control experiments.

Results: Exudates: species specific and environmentally influenced

Using our approach, more than 2800 compounds from samples of field grown plants were annotated. Different statistical tools revealed the release of semi-polar metabolites in a growth form dependent manner with species-specific compound patterns. This is more distinct in forbs than in grasses, which showed a less differentiated metabolite composition. In order to identify the main factors responsible for the exudate patterns, the species itself, plant functional traits, neighboring plants and environmental conditions were considered. In case of the five forbs, target species identity was determined as the main driver for exudate composition, while environmental conditions are decisive in case of the five grasses. Nevertheless, there are no specific metabolite classes released by single species. Rather, most of the detected specific metabolites could be putatively classified as members of the typically defense related metabolite families of flavonoids, coumarins, isoprenoids and phenylpropanoids, but also sugar related metabolites.

Conclusions: MS exudate analysis under field condition is feasible

Our analysis demonstrates the possibility to obtain and analyze root exudates in field experiments. The species specificity of root exudate patterns appears either to be driven by interspecific differences or by the environmental conditions, depending on the investigated growth forms. The putative classification on the level of metabolite families delivered a broad spectrum of metabolites of the secondary metabolism.

Novel Aspect: Novel method collection for analyzing exudates

We demonstrate the feasibility of analyzing exudates under field conditions by mass spectrometry and the benefits of EcoMetabolomics study.

906 - A NOVEL LABELED METABOLOMICS WORKFLOW APPLYING ISOTOPE RATIO OUTLIER ANALYSIS (IROA) AND SWATH® ACQUISITION FOR UNAMBIGUOUS COMPOUND IDENTIFICATION

Papan Cyrus (1) - Chris Beecher (2) - Felice A. de Jong (3) - Baljit Ubhi (4) - Joerg Dojahn Dojahn (5)

SCIEX Germany GmbH, Sciex, Darmstadt (1) - IROA Technologies, University Florida, Bolton MA (2) - IROA Technologies, University Florida, Bolton, MA (3) - SCIEX USA, Sciex, Redwood City (4) - SCIEX Germany (5)

Introduction

Metabolomics focuses on the chemical processes central to cellular metabolism. Mass spectrometry and specifically data dependent workflow tend to be the choice for the measurement of these metabolites. Data independent techniques such as SWATH® Acquisition are different in that they allow for unbiased data collection and MSMS of every single mass precursor can be collected allowing for information rich datasets. However, unambiguous metabolite identification can be increasingly challenging due to the lack of databases, chemical noise and isobaric compounds. The SWATH analysis of the Isotope Ratio Outlier Analysis (IROA) labeled Internal Standard (IS) provides the first mechanism for simultaneous and unambiguous compound identification and quantitation for unbiased metabolomics analysis.

Methods

A biochemically complex Internal Standard (IS) which contains 100's of biochemicals, each with an IROA isotopic pattern, was added to clinical samples to accurately identify and quantitate complex mixtures without the need for baseline separation, and overcome variances introduced sample-to-sample or by ion suppression. SWATH fragmentation of the IROA peaks completely differentiates fragments, and artifacts. The identification of all IROA compounds and their fragments by ultra-high-resolution mass measurement make it possible to determine the empirical formula for all fragments. Data were collected a TripleTOF® 6600 System in SWATH® Acquisition using a variable window strategy which defined windows of varying mass ranges to be applied in areas of the chromatogram where there are many ions co-eluting.

Preliminary data

Applying a variable window SWATH Acquisition strategy to an IROA Internal Standard (IS) spiked sample made it possible to unambiguously identify and accurately quantify hundreds of biochemicals in a single unbiased metabolomics analysis using a TripleTOF® high resolution mass spectrometer. The IS contains 500+ well characterized compounds, which migrated in an HPLC separation with their natural abundance isotopomers, to provide for both identification and standard quantities for accurate measurement even in a non-baseline separated, "unbiased" metabolomics separation. Using traditional DIA, all compounds with the same retention time are fragmented without selection. SWATH DIA subjects all ions within a discrete m/z window to fragmentation allowing specific precursor ions to be selected, making it easier to analyze fragmentation spectra. However, a corresponding spectral library of metabolites is required for accurate identification. Here, we present SWATH-IROA DIA whereby uniquely-labeled IROA metabolites were captured within discrete SWATH windows, and subjected to fragmentation. IROA fragments and adducts were shown to have the identical labeling patterns of their precursor ions, with defined formulae. All artifactual (non-IROA) peaks from the SWATH window were eliminated and data was quantitated based on MSMS peaks. The combination of IROA and SWATH allow a path in which a basic metabolomic-style system may be used for the accurate clinical quantitation of several hundred compounds in a single sample without the need for a base-line separation. Specific software was developed to automatically find, quantitate and identify all natural-abundance peaks that corresponded to their known IROA isotopomers. The identification of compounds of unknown identity is simplified because all fragments are identified by their complete formula making the mode of fragmentation of the parent compound clear. Fragments are identified as they share the daughter fragments of their parent compounds.

395 - UNTARGETED METABOLOMICS IN PLANT BIOCHEMISTRY

Stefanie Döll (1) - Hendrik Treutler (1) - Steffen Neumann (1) - Dierk Scheel (1)

Leibniz Institute of Plant Biochemistry, Stress and Developmental Biology, Halle (1)

Keywords: Untargeted metabolomics, LC-MS, plant science, substance annotation, functional genomics

Introduction: Search for differentially accumulated metabolites in plant science

A frequent task not only in plant science is to find biomarkers for certain conditions ("treatment vs. control"), find chemical differences and similarities between cultivars, subspecies or species and to aid functional genomics by determining the effects of single mutations on the metabolome. This is done by untargeted metabolomics, a technique that works without prior knowledge to the metabolites' identity.

Methods: Experimental setup for UPLC-HR-Q-ToF MS

For this task, we established a work flow starting from an appropriate experimental setup including numerous quality checks for liquid chromatography coupled to High Resolution Q-ToF MS and MS/MS. This is followed by data analysis with XCMS[1] and MetaboScape (Bruker) including appropriate statistical Methods: A combination of tools is applied for substance annotation and identification.

Results: A combination of tools is a start to a nearly comprehensive annotation

Our approach extracts substances of significance with a very high confidence. Limited by the extraction protocol and LC method, the focus is on semipolar compounds. After determining relevant features, the challenge is the identification of these unknown metabolites: In-house libraries are the basis for batch processing of whole feature tables in MetaboScape. This batch search is extended by publicly available databases (Massbank [2], GNPS [3], ReSpect). Further annotation is done using the in-silico fragmentation tool MetFrag[4]. It is clear that most of the estimated 200,000 metabolites in the plant kingdom are not yet included in databases and therefore, cannot be annotated easily. But, in many cases it is already sufficient to know the compound classes of differentially accumulated metabolites. MetFamily [5] groups features with available MS/MS information according to common fragments or neutral losses and allows a survey of regulated compound classes.

Conclusions: A workflow for automated annotation of known and clustering of unknown metabolites

Advances in processing large metabolomics data sets, the growing wealth of publicly available databases and the development of customized tools for metabolite annotation largely facilitates the batch annotation of previously known and unknown metabolites of biological relevance.

Novel Aspect:

A comprehensive approach to annotate metabolites of biological relevance.

³Department of Pediatrics, College of Medicine, University of Saskatchewan, Saskatoon, SK, Canada

Introduction: Asthma and COPD are chronic inflammatory conditions of the respiratory airways. Their differential diagnosis can be hampered by overlapping clinical presentations. Currently, physicians rely on patient history and trials of therapy. Therefore, there is a need for new diagnostic tests. A recent untargeted exploratory ¹H-NMR metabolomic study [1] suggested 50 urinary metabolites as candidate biomarkers for the differentiation of asthma and COPD.

Methods: The 50 metabolites were divided into 4 groups. Groups 1 and 2 (37 targets) contain amine and carboxylic acid-containing metabolites. Two LC-MS/MS methods for their quantification were developed using differential isotope labelling (DIL) with dansyl chloride and dimethylaminophenacyl bromide, respectively. Group 3 contains 7 metabolites of diverse structures. Therefore, HILIC-MS/MS method was developed. All methods were fully validated for clinical testing.

Results: All methods were fully validated according to the FDA and European Medicines Agency (EMA) guidelines [2, 3]. While almost all of the validation criteria were still applicable, in some situations, the guidelines were insufficient to drive the validation process. Accordingly, uncommon analytical or statistical approaches were adopted. In addition, the use of DIL with 2 mass unit difference between the derivatized analyte and its internal standards necessitates the optimization of the analytical methods to account for isotopic interferences. Non-blinded patients' samples with asthma and COPD were analyzed and the data was processed using partial least square discriminant analysis. A set of fifteen metabolites was found to differentiate asthma from COPD with high accuracy (R^2 0.935 Q^2 0.864). The constructed model was then tested using a blinded subset of subjects, where an accuracy of diagnosis of 80% for asthma was achieved. However, COPD had modest accuracy; examination of clinical information suggested misdiagnosis for some of these patients.

Conclusions: Novel validated analytical methods were developed for clinical application. Promising clinical results were obtained which may improve the management of airway diseases. Of the 15 metabolites identified by statistical analysis from the mass spectrometry data, eight metabolites were common, as critical for disease diagnosis, to the previously reported ¹H-NMR study [1]. Therefore, this work also validates the diagnostic importance of these metabolites.

Novel aspects: New LC-MS targeted methods are developed, providing insights into targeted metabolomics method validation. 15 urine biomarkers are identified for respiratory illnesses.

A method for group 4 metabolites is currently under development.

1246 - INFORMED UNTARGETED METABOLOMICS USING LC-MS/MS

Julica Folberth (1) - Olaf Jöhren (2) - Markus Schwaninger (1) - Alaa Othman (3)

University of Luebeck, Institute for Experimental and Clinical Pharmacology and Toxicology, Luebeck, Germany (1) - University of Luebeck, Center of Brain, Behavior and Metabolism (CBBM), Luebeck, Germany (2) - University of Luebeck, Bioanalytic Core Facility, Center of Brain, Behavior and Metabolism (CBBM), Luebeck, Germany (3)

Keywords: untargeted metabolomics, data-dependent acquisition, LC-MS/MS, Orbitrap, library

Introduction:

Metabolite identification is the main challenge in untargeted LC-MS based metabolomics. Although there are libraries available, they suffer some limitation. Therefore an LC-MS² standards library of high resolution and accurate mass spectra was generated. Another aspect is the inevitable bias in every metabolomics study, due to the diversity of the metabolome. To assess this bias the LC-MS² standards library can be used (Informed unTargeted Metabolomics).

Methods:

An automated flow injection/t-SIM/ddMS² method was developed to generate various MS² spectra of more than 600 synthetic standards of metabolites (MS² library). Chromatographic data was acquired under different conditions (LC library). Using a hybrid quadrupole-orbitrap mass spectrometer (Q-Exactive™, Thermo scientific™) allows high-resolution and accurate-mass detection. Data analysis was performed by using FreeStyle, Library Manager and Tracefinder.

Results:

We developed a method to acquire MS² spectra at different collision energies without the need for manual injection. Data-dependent acquisition proved superior to other scan modes as it offers high-quality MS¹ and MS² spectra. Due to flow injection, several different MS² spectra could be acquired for every metabolite. Using this flow injection/t-SIM/ddMS² method, we generated about 4000 MS² spectra for over 500 metabolites. LC data was acquired for 295 metabolites in 139 unique conditions. Chemical properties of the metabolites will be included in the LC-MS² library as well. To further expand the library, more compounds, LC conditions and also extraction methods will be tested. By utilizing a certain extraction and LC method, an analysis is shifted to a subset of metabolites, that can be estimated by comparing features of metabolites already detected using this workflow and documented in the library. Informed unTargeted Metabolomics can be adjusted to cover the highest number of metabolites possible or to analyze specific metabolites of interest.

Conclusions:

For unambiguous metabolite identification high mass accuracy, high-quality MS² spectra and retention times under specific chromatographic conditions are essential – information that is included in the LC-MS² standards library together with chemical properties of the metabolites. Informed unTargeted Metabolomics uses this information to assess or determine the bias that goes along with the impossibility to cover the whole metabolome with a single workflow.

Novel Aspect:

Using a novel flow injection/SIM/ddMS² method on a hybrid quadrupole-orbitrap instrument we developed a LC-MS² library, that can be used for Informed unTargeted Metabolomics.

303 - AN INVESTIGATION OF BIOMARKERS IN THE SERUM OF DEVELOPMENTAL DISORDERS USING AN INTELLECTUAL DISABILITY MODEL MOUSE, WHICH SHOW IMPAIRED SOCIAL BEHAVIOURS

KEIJI GAMOH (1) - MAI NISHIMURA (1) - TAKUMI AKASHI (1) - YOSHINORI NISHIWAKI (1) - TAIKI KASHIO (2) - SHINICHI MITSUI (2)

KOCHI UNIVERSITY, CHEMISTRY DEPARTMENT, KOCHI (1) - GUNMA UNIVERSITY GRADUATE SCHOOL OF HEALTH SCIENCES, DEPARTMENT OF REHABILITATION SCIENCES, MAEBASHI (2)

Keywords: Developmental Disorder Model, Motopsin Knockout (KO) Mice, Biomarkers, Serum, High Resolution LC/MS

Introduction:

Our aim is identifying biomarkers of developmental disorders by a liquid chromatography/mass spectrometry (LC/MS). In the present study, serum samples of motopsin KO mice were used for the exhaustive analysis of biological metabolites-amino acids. We demonstrated the exhaustive analysis of mouse serum using a reversed-phase separation mode and an electrospray ionization method of the LC/MS, and compared metabolites between motopsin KO and wild-type (WT) mice.

Methods:

Acetonitrile and 1% acetic acid, as well as 15N-glutamic acid as an internal standard, were added to serum samples of motopsin KO and WT mice, and the solution was centrifuged. After the solid-phase extraction of the supernatant using a ODS cartridge, the eluent was injected to the Intra Amino Acid column (Imtakt). The high resolution LC/MS system is composed by Accela (LC) and Orbitrap Exactive (Thermo Fisher Scientific).

Results and Discussion:

Various kinds of amino acids, neurotransmitters, and their metabolites were simultaneously separated and detected by the LC/MS method using standard reference materials. To analyze the effects of genotype and sex, we performed two-way analysis of variance to compare serum concentrations of those substances between KO (male, n=5; female, n=3) and WT mice (male, n=4; female, n=5). Serum concentrations of Glu, Gly, and Asn were significantly higher in KO mice than WT mice ($p=0.016$, $p=0.028$, $p=0.010$, respectively), whereas that of DOPAC was lower in KO mice than WT mice ($p=0.003$). Interestingly, post hoc analyses revealed that such difference was significant in males, but not females. Asp, Ser, dopamine, and DOPAC showed higher concentration in males than females ($p=0.006$, $p=0.044$, $p=0.000$, $p=0.000$, respectively). Glu and Gly are neurotransmitters and Asn affects the metabolism control of the cell function of the nervous system and the brain tissue. DOPAC is a metabolite of the neurotransmitter dopamine and is degraded to form HVA. Interestingly, the current result is consistent with our previous research demonstrating significantly higher concentration of Glu in saliva of autism children compared to typically developing children. According to the above results, possible biomarkers of developmental disorders are suggested. It will be necessary to increase the number of subjects for identifying biomarkers with statistical reliability.

This work was supported in part by JSPS KAKENHI Grant No.17K18650.

Novel Aspect:

We demonstrated a possible strategy to find biomarkers of a developmental disorder based on a comparative LC/MS analysis of serum samples between motopsin KO and WT mice.

187 - ELECTROCHEMICAL OXIDATION OF PRIMARY BILE ACIDS: SIMULATION OF ENDOGENOUS METABOLISM

Laura Gau (1) - Lea Brückner (1) - Sascha Rohn (1)

Hamburg School of Food Science, University of Hamburg, Hamburg (1)

Keywords: Electrochemistry, Oxidation, Bile Acids, EC-MS

Introduction:

Electrochemical oxidation is a rapid, relatively inexpensive approach to simulate natural metabolic redox events and potential subsequent reactions in vitro [1,2]. This makes it possible to study biologically relevant oxidative and reductive processes in an organism and thus, to replace animal studies within the meaning of the directive 2010/63/EU [3]. In this case, coupling of an electrochemical and a mass spectrometric system should simulate phase I and phase II metabolism of bile acids.

Methods:

Electrochemical oxidation was performed using a ROXY™ EC system (equipped with a μ -Prep cell consisting of a BDD working electrode, a titanium counter electrode and a Pd/H₂ reference electrode). A solution containing 100 μ M CA/CDCA was injected into the EC-system. First scan mode was applied (0 V to 3 V in 0.3 V steps). Afterwards a constant potential was used. Detection of oxidation products was performed with an ESI-MS ion trap mass analyzer in positive ion mode.

Results:

First, the applicability of an electrochemical oxidation for transforming bile acids was evaluated. Simulation of endogenous metabolism of primary bile acids was successful. It was shown that it is possible to oxidize cholic acid and chenodeoxycholic acid under various conditions. Best parameters were acidic pH values and a constant potential (DC-mode). It was also shown that switching to pulse-mode (as mentioned in literature [4]) did not increase the yield. Moreover, it was possible to generate mg-amounts of the oxidized products with a SynthesisCell™ and a general comparison to mass spectra of commercially available bile acids standards.

Conclusions:

Electrochemical oxidation using a ROXY™ EC system coupled to a mass spectrometric system is suitable to simulate phase I and phase II metabolism of primary bile acids. It is possible to investigate biosynthetic pathways without using animals or animal tissues.

Novel Aspect:

Applicability of an electrochemical oxidation of cholic acid and chenodeoxycholic acid using a ROXY™ EC system was successfully demonstrated.

257 - TARGETED ON-LINE BREATH ANALYSIS SUPPORTS THE HYPOTHESIS OF ALTERED COLLAGEN TURNOVER IN IDIOPATHIC PULMONARY FIBROSIS

Martin Thomas Gaugg (1) - Anna Engler (2) - Pablo Martinez-Lozano Sinues (3) - Lukas Bregy (1) - Yvonne Nussbaumer-Ochsner (2) - Lara Eiffert (1) - Tobias Bruderer (1) - Renato Zenobi (1) - Malcolm Kohler (2)

Swiss Federal Institute of Technology, Department of Chemistry and Applied Biosciences, Zurich (1) - University Hospital of Zurich, Department of Pulmonology, Zurich (2) - University of Basel, Department of Biomedical Engineering, Basel (3)

Keywords: on-line breath analysis, idiopathic pulmonary fibrosis, biomarker, secondary electrospray ionization – mass spectrometry

Introduction:

On-line breath analysis is a powerful technique to obtain insights into the metabolism of a person. Idiopathic pulmonary fibrosis (IPF) is a chronic and poorly understood lung disease. Following a recent study that reports increased levels of collagen related amino acids in lung tissue of IPF patients using GC-MS profiling [1], we hypothesized that these altered amino acid levels might be mirrored in exhaled breath, which would allow for a non-invasive screening of IPF.

Methods:

Breath analysis was performed on-line using secondary electrospray ionization-high resolution mass spectrometry (SESI-HRMS). For all previously reported target compounds where a signal was detected at the accurate mass in real-time, UHPLC-MS measurements of exhaled breath condensate (EBC) were performed, to confirm their identity. Their classification performance was estimated using 1 million leave-one-out cross-validations.

Results:

On-line breath spectra were recorded for 21 IPF patients and 21 healthy controls, matched in terms of age, gender and smoking history. Within these, we could detect robust signals for proline, 4-hydroxyproline, alanine, valine, leucine/isoleucine, allysine, phenylalanine and pyroglutamic acid, most of which could also be confirmed in EBC. Six of the eight compounds showed significantly increased signal levels ($p < 0.05$) in exhaled breath of IPF patients. Additionally, we observed a strong signal correlation across subjects, and those amino acids with a higher abundance in collagen or elastin showed the most pronounced effect. This is consistent with altered collagen and elastin turnover being the underlying metabolic processes. Using the signals of all detected amino acids, we were able to obtain a cross-validated area under the receiver operating characteristic curve of 0.86.

Conclusions:

Using targeted on-line breath analysis with SESI-HRMS, we could detect increased amino acid levels in IPF patients, which allowed for a good discrimination from healthy controls. This is consistent with previous metabolomic findings from lung biopsies, strongly reducing the probability of false discoveries. However, we were able to capture this information in a non-invasive and rapid fashion, underlining the strength of real-time breath analysis.

Novel Aspect:

Our results suggest that on-line breath analysis using SESI-HRMS might be a valuable tool for screening of IPF, thereby reducing the time of diagnosis as well as medical costs.

949 - LOW INVASIVE METABOLOMIC PHENOTYPING: A POTENTIAL ALTERNATIVE FOR GENOTYPING OF GLIOMAS

Paulina Zofia Goryńska (1) - Krzysztof Goryński (1) - Kamila Chmara (1) - Jacek Furtak (2) - Dariusz Paczkowski (2) - Marek Harat (2) - Barbara Bojko (1)

Faculty of Pharmacy Collegium Medicum, Department of Pharmacodynamics and Molecular Pharmacology, Nicolaus Copernicus University in Toruń, Bydgoszcz (1) - 10th Military Research Hospital, Department of Neurosurgery, Bydgoszcz (2)

Keywords: Glioma, SPME, diagnostic method, mass spectrometry

Introduction:

Diagnostic of human brain tumors has developed greatly in the recent few years. Proper classification of tumor type plays significant role in prediction of the response to a given treatment, but histology often fails in this regards and genotyping is used instead. However, several mutations can affect therapy efficiency and identification of molecular biomarkers could be useful complement to current testing.

Methods:

In the current study, described approach was applied to human brain tumors. To provide minimal tissue damage ca. 0.2 mm diameters probe had been used to extract metabolites from brain tumor sample. For chromatographic analysis two types of stationary phase had been used: pentafluorophenyl (PFP) and underivatized silica (HILIC). The samples were analyzed on Q-Exactive Focus mass spectrometer and Compound Discoverer 2.1 were used for data processing and statistical analysis.

Results:

Metabolomics studies with SPME-LC-HRMS showed that there are several compounds which discriminate tumors of different origin as well as gliomas of different malignancy. Identification of these features revealed involvement of creatine, hypotaurine, cystathionine, etc. in cancerogenesis of gliomas, which was already reported in the literature based on cell line study. It was investigated, that higher concentration of other from those above mentioned naturally produced in the body amino acids and its homologues indicates the presence of high grade of malignancy glioma in examined patient. Moreover in current study it has been shown that there are several endogenous metabolites that differentiate high grade of malignancy glioma in patients with genetic mutations (IDH1, IDH2, methylation, deletion 1p19q) from those without that mutation. Comparison of the data obtained from genotyping and metabolomics profiling (phenotyping) exhibited very good correspondence.

Conclusions

According to performed experiments in the current study, the use of SPME fibers for extraction and separation via liquid chromatography coupled to high resolution mass spectrometer provided an appropriate workflow for comprehensive brain tumor metabolomics analysis. The simplicity of the approach when compared to routinely used diagnostic methods indicates a great potential of the method to serve as an intra-operative tool in the future.

Novel Aspect:

The experimental results obtained using low invasive sample preparation method coupled with LC-MS provide new insight into the diagnostic options of human brain tumors.

384 - ^{13}C ISOTOPE LABELLING OF ARABIDOPSIS THALIANA: TRACKING LABELLED CARBON IN METABOLITES FROM LEAVES TO ROOTS TO EXUDATES

Karin Gorzolka (1) - Gerd Balcke (2) - Hendrik Treutler (1) - Steffen Neumann (1) - Dierk Scheel (1)

Leibniz Institute of Plant Biochemistry, Stress and Developmental Biology, Halle, Saale (1) - Leibniz Institute of Plant Biochemistry, Cell and Metabolic Biology, Halle, Saale (2)

Keywords: ^{13}C isotope labelling, metabolites, Arabidopsis thaliana tissues, GC-MS, LC-MS

Introduction: How fast is carbon transferred from leaves to roots and exuded?

Plants interact with their belowground environment by the secretion of compounds, a process called exudation [1]. Little is known about this exudation process, exudate biosynthesis and upstream metabolic dynamics. To resolve metabolite origins, we used ^{13}C to track labelled carbon in metabolites from fixation by photosynthesis via transport into roots down to exudation with respect to time dependent dynamics covering light and dark phases.

Methods: ^{13}C labelling and spatio-temporal metabolite profiling of Arabidopsis thaliana

Arabidopsis thaliana plants were pulse labelled in a ^{13}C atmosphere. Aerial plant parts, roots and exudates were collected 3, 6, 9, 20 and 23 hours after labelling and analyzed for primary and secondary metabolites using GC-MS and HPLC-MS. Metabolite labelling was quantified by the investigation of shifts in the isotope pattern in the MS. An XCMS based analysis pipeline was developed for the detection and quantification of isotopes in GC-MS and LC-MS data.

Results: Arabidopsis thaliana - Labelling dynamics of metabolites

In GC-MS, up to 14000 peaks were detected and clustered in isotopes, resulting in more than 1000 isotope patterns for approximately 350 peak groups (metabolites). Fast labelling was observed in mono- and disaccharides, amino acids and organic acids. Tissue distinction and time-scale harvesting demonstrated that labelling often followed a time dependent delay from leaves (early labelling) to roots to exudates (late labelling); however, spatio-temporal labelling dynamics were still metabolite specific. Especially in saccharides, interesting labelling patterns were observed during the dark phase.

In LC-MS, up to 15 000 peaks were clustered in about 500 peak groups that contained more than 1500 isotope patterns. Labelling was observed in many metabolites, e.g. glucosinolates and related compounds in leaves, roots and exudates, providing the opportunity to compare labelling between tissues and metabolites. Co-labelling dynamics pointed to common biosynthetic pathways and metabolite classes and facilitated metabolite identification.

Conclusions: ^{13}C tracking in metabolites from leaves to exudates: Biosynthetic connections

This dataset provides insight into the dynamics between ^{13}C fixation in the aboveground plant, transportation into the roots and exudation of metabolites. The comparison and correlation of labelling patterns revealed biosynthetic connections and consequently facilitated metabolite identification (e.g. fatty acid amines). Time dependent sampling resolved changes in metabolite labelling after switches from light to dark phase and back to light.

Novel Aspect: The first MS based study of ^{13}C tracking through leaves, roots and exudates in Arabidopsis

We applied MS based ^{13}C labelling analysis of Arabidopsis plant tissues and exudates using GC-MS and LC-MS for a comprehensive profiling of primary and secondary metabolites.

389 - METABOLOMIC APPROACH TO INVESTIGATE METABOLITE ALTERATIONS ATTRIBUTED TO A 25-HYDROXYVITAMIN D IN HEALTHY KOREAN ADULTS

Mi-Ri Gwon (1) - Bo Kyung Kim (2) - Boram Ohk (2) - Seungil Cho (3) - Sook Jin Seong (4) - Young-Ran Yoon (5)

Cell and Matrix Research Institute, Department of Biomedical Science, School of Medicine, Kyungpook National University, DAEGU (1) - Department of Biomedical Science, School of Medicine, Kyungpook National University, DAEGU (2) - Molecular Diagnostics and Imaging Center, Department of Biomedical Science, School of Medicine, Kyungpook National University, DAEGU (3) - Clinical Trial Center, Kyungpook National University Hospital, DAEGU (4) - Department of Biomedical Science, School of Medicine and Clinical Trial Center, Kyungpook National University and Hospital, DAEGU (5)

Keywords: 25-hydroxyvitamin D [25(OH)D], UHPLC-QTOF/MS, untargeted metabolomics analysis

Introduction: Vitamin D deficiency is prevalent in Korean adults, affecting up to 80% of them [1]. Vitamin D deficiency, which impairs bone mineralization, may induce many diseases including chronic autoimmune, infectious diseases, cancer, cardiovascular disease, and diabetes. This appears to be associated with levels of the main metabolite, 25(OH)D [2]. We examined the association between serum levels of 25(OH)D and metabolite alterations in healthy Korean adults.

Methods: Forty-five healthy Korean adults were divided into two groups based on serum levels of 25(OH)D (23.0 and 10.4 ng/mL on average for high (n=21) and low (n=24) group, respectively). Demographic, anthropometric, and blood profile parameters were measured. Metabolic profiling was performed using UHPLC-QTOF/MS and multivariate statistical analysis. The candidate metabolites were tentatively identified through the search of web databases.

Results: No significant differences were observed in demographic, anthropometric, and blood profile parameters between two groups. For untargeted metabolomic analysis, 47,499 spectral features were detected from UHPLC-QTOF/MS data using XCMS software. Score plots, obtained from principal component analysis and orthogonal projections to latent structures-discriminant analysis (OPLS-DA), showed a tendency that two groups were separated. R² (goodness of fit) and Q² (predictability) were 0.654 and 0.125, respectively. Metabolites which had the variable importance in projection value ≥ 1.0 and p-value ≥ 0.05 were identified using web databases such as Human Metabolome database (HMDB) and ChemSpider. These results suggest that serum levels of 25(OH)D are related to metabolic alterations in healthy Korean adults. And we will further study to identify putative metabolites and assess their association with synthetic mechanism of 25(OH)D.

Conclusions: This research suggests that serum levels of 25(OH)D have influence on metabolic alterations in healthy Korean adults. However, further research with larger sample sizes and other clinical trial designs (e.g., administration of 25(OH)D to osteoporotic or elderly populations) is required before solid conclusion can be reached.

Novel Aspect: First untargeted metabolomic approach to investigate the influence of serum levels of 25(OH)D on metabolic alterations in healthy Korean adults

942 - AN ANALYTICAL FRAMEWORK FOR THE EXPLORATION OF ENDOGENOUS PEPTIDES INTEGRATING PEPTIDE STRUCTURE PREDICTION AND TANDEM MASS SPECTROMETRY

Chihiro Kawano (1) - Eisuke Hayakawa (1) - Hiroshi Watanabe (1)

Okinawa Institute of Science and Technology, Okinawa Institute of Science and Technology, Okinawa (1)

Keywords: Peptidomics, EndogenousPeptide, Tandem Mass Spectrometry, Structure Analysis

Introduction:

Peptidomics, an analytical workflow for systematic identification of short, native and endogenous peptides, has been widely used to study peptides in a wide variety of biological matrices. The workflow of peptidomics is largely diverted from proteomics, including LC-MS/MS and spectrum matching algorithm. However, sensitive and reliable identifications for endogenous peptides are still difficult even with recent mass spectrometry instruments.

Methods:

To overcome the difficulties in the conventional peptidomics technologies, we have developed an analytical framework dedicated to the exploration of naturally occurring endogenous peptides. We created an analytical workflow combining tandem mass spectrometry and a series of dedicated informatics modules that enables highly sensitive exploratory search for endogenous peptides.

Results:

One of the modules creates potential forms of peptides based on user-defined structural properties such as substructures, motifs, potential cleavage sites, post-translational modification and other molecular properties. The predicted forms of peptides can be used as a target sequence dataset of MS/MS peptide search in a top-down fashion. This approach effectively reduces the search space of MS/MS peptide search, therefore increasing the sensitivity of identification. Moreover, in-silico fragmentation spectra of predicted peptides are generated and their spectral similarities are searched against the experimental fragment spectra acquired from sample. This allows “fuzzy” matching to identify peptides with unexpected post-translational modifications or amino acid substitution with high-sensitivity.

Conclusions:

Our analytical framework is built in a modular together with other informatics, data analysis tools, and therefore is flexible and applicable to any kind of peptides in a wide variety of matrices. We discuss the effectiveness and flexibility of our framework by demonstrating identifications of novel endogenous peptides.

Novel Aspect:

A novel analytical workflow to improve identification of endogenous peptides by combining tandem mass spectrometry and a series of dedicated informatics tools.

Trypanosoma cruzi (*T. cruzi*), a kinetoplastid protozoan parasite, is the etiologic agent of Chagas disease. The disease affects millions of people and represents a major burden for the socio-economic development of affected countries (mainly Latin America). The mobility of patients infected with Chagas disease makes it a global public health burden. So far, no vaccine exists and current drugs suffer from significant drawbacks, which limit their use in disease endemic areas. In the foreseeable future, the very few drugs currently in clinical development do not offer new alternatives to patients. Thus, there is a need to identify and develop novel drug candidates with new mechanisms of action to overcome the current situation and eventually feed the Chagas clinical trials pipeline.

The objectives of our study were to identify metabolites and proteins markers of the efficacy of an experimental drug, S205, and to determine the related metabolic pathways to formulate hypotheses on its unknown mode of action. To this aim, we focused on uninfected and *T. cruzi* infected rat myoblast cells, in presence or not of the drug targeting intracellular amastigotes form of the parasite (intracellular phase in the life-cycle of trypanosomes). The drug effect on cells was analyzed after 24h of exposition. We analyzed polar extracellular metabolites by 600 MHz NMR and intracellular lipids and proteins were determined by LC-HRMS using a Q-Exactive (Thermo) and a Q-TOF (Bruker Maxis HD), respectively.

Through our profiling approach, we identified potential markers for infection and drug mode of action. Indeed, the GAPDH (glyceraldehyde-3-phosphate dehydrogenase) protein of *T. cruzi* was identified as a potential target of the drug S205 by proteomics and metabolomics has shown that the drug affects the energy metabolism and hence, through the impact on Acyl-CoA synthesis, the formation of lipids. Thus, S205 seems to act through a specific target and both technologies applied (proteomics and metabolomics) complement each other in the description of the mechanism.

We have shown the relevance of proteomics and metabolomics approaches to contribute to the elucidation of drug mechanism of action as a complement to classical Methods: The methods are applicable even to complex systems such as mammal cells infected with parasites.

1398 - LC-MS ANALYSIS OF NONRIBOSOMAL PEPTIDOME FROM A BRAZILIAN CYANOBACTERIUM NOSTOC SP. CENA543

Jouni Jokela (1) - Heinilä Lassi (1) - Tânia Keiko Shishido (1) - Matti Wahlsten (1) - David Fewer (1) - Marli Fátima Fiore (2) - Esa Haapaniemi (3) - Perttu Permi (4) - Kaarina Sivonen (1)

Keywords: Nostoc, cyanobacterium, nodularin, pseudospumigin, namalide

Introduction

Nostoc is a cosmopolitan genus of cyanobacteria found in soils and in symbiotic associations and a prolific producer of bioactive natural products. Nodularin (NOD) is a cyclic nonribosomal pentapeptide, hepatotoxic protein phosphatase inhibitor and tumor promoter. Spumigins are small linear nonribosomal peptide protease inhibitors. Anabaenopeptins are cyclic nonribosomal hexapeptides. Namalides are a cyclic tetrapeptide structurally as anabaenopeptin.

Methods

LC-MS analyses were performed with an Agilent 1100 Series LC/MSD Ion Trap XCT Plus System (Agilent Technologies, Palo Alto, CA, USA). High accuracy mass was measured by UPLC-ESI-QTOF mass spectrometer Synapt G2 Si HDMS (Waters Corp.).

Results

In this study we analyzed non-ribosomal peptidomes with LC-MS methods from 18 cyanobacterial genera that had been collected from Brazilian saline-alkaline lakes of the Nhecolândia, Pantanal wetland area. Our objective was to discover novel bioactive compounds. We found a cyanobacterium strain Nostoc sp. CENA543 which produced 18 different peptide variants from which 13 were novel. Peptides belong to four different peptide families namely nodularins[1], pseudospumigins[1], anabaenopeptins[2] and namalides[2]. Pseudospumigins constitute a novel trypsin inhibiting peptide family. Pseudospumigin A inhibited trypsin (IC₅₀ 4.5 μM after 1 h). Hepatotoxic nodularin was produced at exceptional high amounts, at same levels as many Nodulariaspumigena strains isolated from blooms from different geographical locations produces nodularin. Together our results demonstrate that the nonribosomal peptidome of Nostoc sp. CENA543 analyzed at gene and metabolite level is strikingly similar to N. spumigena but contains also clear differences.

Conclusions

Natural products are an important source of antimicrobial, antifungal, anticancer, immunosuppressant and other bioactive molecules. We demonstrate that Nostoc sp. CENA543 produces one phosphatase inhibitor peptide group and three protease inhibitor peptide groups pseudospumigins, anabaenopeptins and namalides with 13 novel peptide structures.

Novel Aspect

Complete genome contains biosynthetic gene cluster only for anabaenopeptin so namalides are a module skipping products from the anabaenopeptin biosynthetic pathway.

Keywords: Bloodstain, Elapsed time, Forensic, HPLC Q-TOF, Metabolite

Introduction:

Bloodstain is created by the blood left at the crime scene, and it has a lot of information including genetic information. [1] It is very meaningful because it can identify the time of the attack at the incident. Although various methods have been studied to estimate the age of bloodstain, it has not been applied to forensic field. [2-6] In this study, we identify the metabolites that have changed as time passed to discover markers that we can determine the age of bloodstain.

Methods:

The bloodstains were prepared using filter paper over a 21-day period. Metabolites were extracted from bloodstain and analyzed using high-performance liquid chromatography-mass spectrometry (HPLC Q-TOF). We performed multivariate analysis, Venn diagrams and partial least squares discriminant analysis (PLS-DA).

Results:

We chose 62 candidate molecular features and analyzed partial least squares discriminant analysis (PLS-DA) that the group have been classified with an accuracy of 75.0%, and R² and Q² were 0.7513 and 0.6998, each. Ten metabolites were identified matching of METLIN database. Ten of Two metabolites, vitamin D₃/cholecalciferol and 1-palmitoyl-2-glutaryl phosphatidylcholine (PGPC), are up-regulated as time passed, whereas ergothioneine is decreased.

Conclusions:

We identified several candidate metabolites that are up- or down-regulated over time so that we are able to measure the age of the bloodstain.

Novel Aspect:

In this study, we aimed to discover metabolites markers so that we can determine the elapsed time of bloodstain.

Keywords: persistent organic pollutants, organochlorine pesticides, polychlorinated biphenyls, metabolic syndrome, UHPLC-QTOF/MS, untargeted metabolomics

Introduction: Humans are widely exposed to persistent organic pollutants (POPs) such as organochlorine pesticides (OCPs) and polychlorinated biphenyls (PCBs). Because of their high lipophilicity, POPs are known to bioaccumulate mainly in adipose tissue and to be resistant to biodegradation [1]. Low-dose exposure to OCPs and PCBs is related to metabolic syndrome [2]. Here, we investigated alterations of endogenous metabolites in human plasma caused by OCPs and PCBs exposure.

Methods: A total of 203 subjects (age ≥ 60) participated in this research and serum POPs levels were measured. All subjects were categorized into quartile based on serum concentration levels of OCPs or PCBs. Plasma samples were analyzed using ultra-high performance liquid chromatography (UHPLC)-quadrupole time-of-flight (QTOF)/mass spectrometry (MS), then multivariate statistical analysis was performed. The metabolite features of variable importance in projection value (VIP) ≥ 1.0 were compared with web databases.

Results: A total of 37 POPs, 4 OCPs and 6 PCBs were selected and considered in this study. Through the untargeted metabolic profiling, the 32,301 ion peaks were detected. Score plots obtained from principal component analysis (PCA) and partial least squares-discriminant analysis (PLS-DA) accounted for the relationship among variables, especially Q1 and Q4. The PLS-DA results showed a tendency to divide that Q1 group is separated from Q4 groups by OCPs concentration, not by PCB's. The 4,491 ion peaks were acquired (VIP ≥ 1.0), and considered to contribute separation of two groups. Thirty three compounds were obtained which had a possibility to consider the accurate mass fragmentation pattern. These results suggest that serum OCPs levels can cause metabolic alterations in human. And we will further study to identify putative metabolites that contribute to metabolic changes caused by OCPs exposure.

Conclusions: Through this study, we will show UHPLC-QTOF/MS-based metabolomics research can be a useful tool to evaluate the effects of POPs exposure by characterizing the metabolic alterations in general population by serum OCPs levels and figuring out the relation of POPs exposure and metabolic syndrome.

Novel Aspect: The large scale untargeted metabolomics approach with human plasma to characterize metabolic alterations associated POPs exposure and metabolic disease.

Keywords: Metabolomics, Lipidomics, Rapid Phenotyping, UPLC-QToF.

Introduction:

Metabolic phenotyping has been employed in large epidemiological studies in the effort to discover more about human health and disease [1 & 2]. UPLC and hybrid mass spectrometers have been essential tools in analyzing the matrices chosen for these studies [3]. However, long acquisition times per sample (15 – 30 mins) have meant large batches can take days to analyse [2]. Here we have developed a suite of rapid profiling methods reducing acquisition time to ~3 mins per sample.

Methods:

Rodent urine and human plasma extracts (1:4 v/v IPA) were analysed using Waters Acquity I-class UPLC system coupled to a Synapt G2-Si QToF capable of ion mobility separation. Urinary metabolites were chromatographically resolved through HILIC separation with lipids by reversed-phase, both utilizing 5.0 cm X 1 mm i.d. columns. Mobile phases consisted of water, acetonitrile for HILIC and the addition of IPA for lipid, both with ammonium formate.

Results:

Standard LC-MS methods for metabolite and lipid profiling using 2.1 mm i.d. columns were geometrically scaled down, reducing column i.d., cutting analysis times, injection volumes and mobile phase flow rate ultimately increasing the linear velocity. Each method scaling resulted in a reduced overall acquisition time to approximately 1/3 of the original method. Compound standard mixtures were used to confirm that chromatographic performance and analyte retention was not compromised with the method scaling. The relative retention time of 3 marker compounds between the standard HILIC separation and the rapid method were comparable, demonstrating a preservation of the HILIC mechanism. When analyzing biological matrices, the potential peak capacity of the assay was 28, however, enabling the ion mobility function, this increased to 51 with the overall number of compound ions detected doubled. The inclusion of ion mobility separation and resulting CCS values enabled an additional confirmatory database search for compound identification.

Conclusions

A set of rapid LC-MS methods have been successfully employed in profiling polar and non-polar molecules in rodent urine and human plasma from breast cancer patients. A reduction in analytical run time has enabled large batch data acquisition to be reduced by 60%, eliminating the need for multiple sample batches and the risk of inconsistent results. The inclusion of ion mobility has provided an additional dimension to the data and improved compound identification.

Novel Aspect: (Limit of 150 characters without spaces)

Rapid 3 minute long discovery phenotyping assays in conjunction with high resolution accurate mass and ion mobility spectroscopy.

Keywords: exhaled breath condensate (EBC) samples, amino acids, derivatization step, LC-MS/MS, bariatric treatment

Introduction

The analysis of free amino acids (AAs) in biological samples is important for diagnosing the health of individuals, because their concentrations are known to vary with various diseases [1-4]. In this study, reliable and high-throughput analytical method for AAs analysis in different biological matrices was proposed and applied to assess their concentration in noninvasively collected breath condensate samples obtained from patients before bariatric treatment.

Methods

A robust and sensitive method for identification and quantification of free amino acids in exhaled breath condensate, plasma, saliva and urine samples, based on liquid chromatography-electrospray ionization-tandem mass spectrometry (LC-ESI-MS/MS) has been developed. Due to the presence of highly polar groups (-NH₂, -OH, -COOH) and their non-volatile nature, amino acids need to be derivatized with methyl chloroformate before LC-MS/MS analysis.

Results

To evaluate the efficiency of the present method, the method was applied to human exhaled breath condensate, urine, plasma and saliva samples collected from obesity patients qualified for surgical bariatric treatment. Adequate preoperative preparation and postoperative care of patients requires profiling of amino acids to control of diet and search potential biomarker of obesity-related diseases. In our developed method, the separation of 23 of physiological amino acids was achieved in 18 min. It was observed that arginine, glutamine, serine, proline, hydroxyproline, glycine, threonine, alanine, proline, methionine, aspartic acid, histidine, lysine, norvaline, glutamic acid, tryptophan, leucine, phenylalanine, isoleucine, asparagine, cystine, cysteine and tyrosine levels are higher in plasma and saliva with reference to breath condensate samples. Only valine concentration are comparable in both saliva and EBC samples.

Conclusions

Methyl chloroformate derivatization followed by LC/MS/MS analysis provides an effective platform for quantitative analysis of amino acids in complex biological samples such as plasma, urine, saliva and exhaled breath condensate samples. The proposed method is rapid, sensitive and can easily be performed in aqueous media. Further it does not require any pre-purification, cleanup and/or lyophilization steps before analysis. The method developed has wide applications for the routine analysis of amino acids in non-invasive breath samples, without the need for blood collection.

Novel Aspect:

A sensitive and direct analytical method has been proposed for the first time for simultaneous determination of twenty-free amino acids in non-invasive EBC samples.

1368 - COMPARATIVE EVALUATION OF DIFFERENT GINSENG BERRY SPECIES BASED ON UPLC-QTOF/MS AND HR-MAS NMR METABOLITE PROFILES

Dae Young LEE (1) - Jae Won lee (1) - Bo-Ram Choi (1) - Dahye Yoon (2) - Young Chang Kim (1) - Suhkmann Kim (2)

National Institute of Horticultural and Herbal Science, Department of Herbal Crop Research, Eumseong, Korea, Republic Of (1) - Center for Proteome Biophysics and Chemistry Institute for Functional Materials, Pusan National University, Busan, Korea, Republic Of (2)

Keywords: ginseng berry, ginsenoside, UPLC-QTOF/MS, HR-MAS NMR

Introduction

Many studies have previously reported the pharmacological activities of ginsenosides from *Panax ginseng* C.A. Meyer. The interests in therapeutic potential of ginsenosides also have increased. Ginsenosides are distributed in several parts of *P. ginseng*, including not only root but also leaf and berry. Different parts of *P. ginseng* may contain distinct composition of ginsenosides and pharmacological activities [1]. Recent studies have indicated the utility of ginseng berry as a good ingredient for various ginsenosides [2,3]. Thus, in the herbal market and food industry, it is critical to evaluate and control the quality of ginseng berry. The profiling of ginsenosides and primary metabolites will be applicable for this purpose.

Methods

The ginseng berry samples were obtained from four different *P. ginseng* species (i.e. Sunone (SW), Gumpoong (GP), Yunpoong (YP), Gopoong (GoP)). From the extract mixture, ginsenosides were separated by using UPLC system with ODS column. Exact mass measurements based on QTOF/MS were also effective for the reliable identification of individual ginsenosides. Also, different species samples of *P. ginseng* berry were analyzed through global metabolite profiling by HR-MAS NMR spectroscopy.

Results

In the negative ion mode of MS, ginsenosides were detected as $[M+COOH]^-$ ions. As a result, 35 ginsenosides were profiled from the four ginseng berries. The raw data of many metabolites including ginsenosides from four ginseng berries were subjected into the principal component analysis (PCA). In the PCA score plot, the four ginseng berries were well separated. The PCA loading plot also represented several ginsenosides as the major variables to discriminate the four ginseng berries. 16 primary metabolites of *P. ginseng* berry were identified by 1H NMR spectra. The PLS-DA clearly distinguished *P. ginseng* berry extract according to the four ginseng berries.

Conclusions

These results demonstrated that contents of ginsenosides differ depending on the species of ginseng berry, and UPLC-QTOF/MS and NMR based profiling method can be a good tool to evaluate the metabolites contents of ginseng berry. This method will help the quality control and effective use of ginseng berry in the food industry.

Novel Aspect

This study indicated that the proposed method based on the UPLC-QTOF/MS and NMR can be an effective tool for characteristics of Korean ginseng varieties.

Keywords: Bloodstain, Forensic science, Internal standard, Metabolite

Introduction:

Bloodstains obtained from crime site provide important information for scene reconstruction. Various researches have been conducted to obtain information of the crime by analyzing bloodstain components. However, the components vary with bloodstain volume and other unpredictable factors. In this study, we identified internal standard metabolites that having stable volume even long after its deposition for standardize bloodstains.

Methods:

Blood was collected from six subjects. Bloodstains were kept until following time points: day 0, day 7, day 14, day 21 and day 28. The metabolite profiling was conducted by using aliquid chromatography-tandem mass spectrometry (LC-MS/MS). Coefficient of variation (CV) of molecular features was calculated for each criterion: time point, subject, all data. Fold change and statistical analysis were performed to select suitable candidates for internal standard.

Results:

Five molecular features with average of CVs \leq 5% were selected as candidates for internal standard. Partial least squares discriminant analysis (PLS-DA) and principal component analysis (PCA) shows well grouping of time condition. This results indicated the candidates unrelated to elapsed time. Fold change value of those candidates' abundances was calculated to each time points versus day 0. The stigmaterol had the most stable pattern and the L-methionine remained stable until day 14 and after day 21. Therefore, two metabolites of candidates were suitable for internal standard.

Conclusions:

In this study, we selected the candidates of internal standard to obtain the information of initial volume of bloodstain for more accurate analysis. Further studies should be conducted to validate the candidates using more samples and conditions associated with the real field situation. This study provides the basic data to obtain absolute quantitative information and proposed the possibility of bloodstain standardization method using the internal standard.

Novel Aspect:

The internal standard metabolites will contribute to establish standardization of bloodstains and help to perform accurate bloodstain analysis in the field.

959 - AN INFUSION “SHOTGUN” APPROACH FOR HIGH-THROUGHPUT UNTARGETED METABOLOMICS

Mariateresa Maldini (1) - Cyrus Papan (1) - Zuzana Demianova (1) - Joerg Dojahn, (1) - Baljit K Ubhi (2)

SCIEX, SCIEX, Darmstadt (1) - SCIEX, SCIEX, Redwood City (2)

Keywords: MSMS all, metabolomics, high resolution, DIA

Introduction:

Metabolomics studies the complexity and large variety of various chemical compounds. Mass spectrometry-based untargeted metabolomics requires approaches to collect data in an unbiased fashion. Current LC approaches are biased to the column chemistry and metabolites which can be retained on such chemistries. The main goal of researchers in the untargeted metabolomics field is to analyze a large number of samples and obtain the most information in the shortest time with limited sample preparation. Here we evaluate the direct infusion or “shotgun” approach to such analyses by using a technique, Infusion MS/MSALL Acquisition, for untargeted metabolomics. This data-independent technique allows the MS/MS of all possible candidates, improve identifications significantly, allows to have quantitative data and enables retrospective analysis of the data.

Methods:

Data were acquired using a TripleTOF® 6600 System (SCIEX) coupled to a high flow liquid chromatography system (Shimadzu) and employing the Infusion MSMSALL Acquisition to collect one survey scan and then MS/MS of every single precursor within a given mass range. Mass ranges were evaluated from 50 to 900 in varied sizes to optimize the number of MS/MS and time needed to collect the data. Data were collected on a small case study of urine extract and statistical analyses was performed.

Data were processed using MasterView™ Software and the accurate mass metabolomics spectral library for fast metabolite identification and confirmation. Statistical analysis was completed in MarkerView™ Software and any quantitation results were generated by MultiQuant™ Software.

Results:

By optimizing for mass range, MSMS ALL method was developed to capture all relevant metabolites per ionization mode (positive and negative mode). Metabolites are extracted from several biological samples and directly infused by using the developed method. The Total Ion chromatogram shows the presence of a large number of separate peaks. The extracted ion chromatograms show that most peaks represent, as expected, different metabolite classes, which are characteristic for each sample. Preliminary, by using the fragment filter tool, metabolites classes occurring in the different samples, were identified on the basis of their diagnostic fragment peaks and/or neutral loss. Statistical analysis is successively performed to differentiate samples and highlight rapidly marker compound in each sample. Using the high quality of MS/MS spectra thanks to SWATH acquisition, identification of marker and occurring metabolites is obtained together with the relative amount.

“Shotgun” approach for Metabolomics results a powerful and rapid tool to obtain huge and complementary data of numerous samples even if metabolites present only at very low levels in biological samples.

Post-acquisition data processing software, allows the user to have rapidly structural information and/or identification and quantification of metabolites occurring in complex samples to derive important biological conclusions.

Conclusions:

By using Infusion MSMSALL with SWATH acquisition, a rapid metabolic fingerprint of each biological sample can be captured. The optimized method is able to capture all relevant metabolites per ionization mode (positive and

negative mode). Verifying the method through a simple biological extract case study highlighted the metabolites responsible for differentiating the different sample groups.

Novel Aspect:

An Infusion “Shotgun” Approach for High Throughput Untargeted Metabolomics

draft

400 - SWATH® ACQUISITION IMPROVES METABOLITE COVERAGE OVER TRADITIONAL DATA DEPENDENT TECHNIQUES FOR UNTARGETED METABOLOMICS

Mariateresa Maldini (1) - Zuzana Demianova (1) - Cyrus Papan (1) - Joerg Dojahn (1) - Baljit K. Ubhi (2)

SCIEX, SCIEX, Darmstadt (1) - SCIEX, SCIEX, Redwood City (2)

Keywords: Untargeted metabolomics, SWATH®, Data Dependent Acquisition

Introduction:

Data independent acquisition (DIA) workflows are well adopted in quantitative discovery proteomics¹, but still not commonly used in discovery metabolomics. Data dependent acquisition (DDA) techniques are heavily employed in the field of metabolomics and workflows on mass spectrometers have been adapted so that as much data as possible can be captured. Researchers were limited by the speed of their QTOF mass spectrometers meaning a multiple injection workflow. Also, the stochastic nature of data dependent workflows often means MSMS of low abundant metabolites are often missed. Here, we describe how DIA enables the identification of a higher number of metabolites for untargeted metabolomics workflows compared to traditional DDA approaches thus enabling a broader profile of the metabolome.

Methods:

Urine and plasma were processed according to standard extraction protocols. Urine was diluted with water at a ratio of 1:4 (v/v) and centrifuged for prior analysis, whilst plasma was extracted 1:4 (v/v) with ice-cold methanol allowing for protein precipitation. Separation was performed on reverse phase chromatography.

DDA and DIA specific settings were chosen and evaluated. The data were acquired on a QqTOF mass analyzer. For the DDA acquisition, we selected the top 5, 10, 15, 20 and 25 precursor ions for MSMS. For DIA, we applied 15, 20 and 30 mass windows with either fixed window (fw) or variable window (vw) widths. Results were evaluated by the highest number of identifications and coverage of metabolites in plasma and urine extracts.

Results:

At the DDA level, the data demonstrate a significant improvement of metabolite coverage at the MSMS level when comparing the top5 to the top25 DDA method. We show over 100% increase of metabolite coverage in plasma extracts by increasing the number of selected precursor ions for DDA acquisition from top5 to top25. This result highlights the capability of the QqTOF mass analyzer for fast MSMS acquisition, which allows for the fragmentation of a large number of precursors in a single DDA cycle, leading to a larger number of metabolites identified.

In the second part of this study, we evaluated the DIA strategy with various fixed (fw) and variable window (vw) sizes with similar cycle time in a plasma extract. Increasing the number of fixed windows resulted in ~30% gain in metabolite coverage. Using the variable window method resulted in a ~70% gain in metabolite coverage.

We finally applied these experimental approaches to common matrices used in metabolomics studies, namely urine and extracted plasma. We show that a DIA approach applying 20 variable windows can identify up to 55% more metabolites than a traditional top20 DDA acquisition (in a urine extract). More confident MSMS based identifications lead to higher quantifiable metabolites in a metabolite expression experiment, which at the end allows better understanding of the biology. When comparing the performance in extracted plasma it can be observed that applying a DIA approach with 20 variable windows allows significant gains in metabolite coverage (around 55%) versus the top20 DDA acquisition, similar gains as seen in the urine extract.

Conclusions

Data Independent Acquisition allows to quickly obtain a comprehensive identification and quantification of the metabolites in your sample since is able to acquire full scan (MS1) and MS/MS of every single metabolite in a single injection. Variable Window Calculator can be used to optimize Q1 isolation window pattern to achieve the right balance of metabolite coverage and specificity.

Novel Aspect:

Data Independent Acquisition Improves Metabolite Coverage over Traditional Data Dependent Techniques for Untargeted Metabolomics.

FELIX Laboratory, Radboud University, Nijmegen (1) - Translational Metabolic Laboratory, Radboud University Medical Centre, Nijmegen (2)

Keywords: Infrared ion spectroscopy, metabolite identification

Introduction:

Small molecule identification is a key component of many areas of the(bio)analytical sciences, including metabolomics and drug development. Here, we demonstrate how infrared (IR) ion spectroscopy is being used for small molecule identification by metabolomics labs. We present technological developments that enable separation by (ultra) high pressure liquid chromatography followed by structural identification by IR spectroscopy of the mass-selected ions¹.

Methods:

The experimental setup is based on a modified commercial ion trap mass spectrometer in combination with the tunable infrared radiation of the FELIX infrared free electron laser. Resonant absorption of multiple infrared photons leads to dissociation. Relating the extent of dissociation as a function of the laser frequency gives the infrared spectrum of any mass-selected ion that can finally be matched to reference (or calculated) IR spectra.

Results:

The majority of clinical metabolomics laboratories rely on mass spectrometry to identify the presence of abnormal levels of specific small molecules in common body fluids that correlate with diseases, drug treatments, and environmental factors. In a first example, we focus on the differentiation of N-acetylmannosamine, a recently discovered biomarker for NANS-deficiency (a new inborn error of metabolism in sialic acid metabolism, from other possible N-acetylhexosamines found at the same m/z ². This differentiation is not possible using standard LC-MS protocols available in most metabolomics laboratories. Here, we demonstrate the use of IR ion spectroscopy to cleanly distinguish these three N-acetylhexosamines directly from urine and cerebrospinal fluid (CSF). Finally, we show how IR ion spectroscopy has been used to partially identify a previously detected but yet unidentified biomarker of antiquitin deficiency. This peak "X" is thought to be associated with intellectual disability that persists despite current treatment strategies.

Conclusions:

The results presented here show how IR ion spectroscopy compares very favorably against alternative techniques, such as NMR spectroscopy, for small molecule identification³. It maintains the sensitivity (low nanomolar) and (mass) selectivity inherent to mass spectrometry while providing orthogonal identification on the basis of retention time, mass-to-charge ratio, MS/MS fragmentation patterns and the IR spectral fingerprint.

Novel Aspect:

1396 - UNTARGETED METABOLOMICS WITH PARALLEL ACCUMULATION – SERIAL FRAGMENTATION (PASEF) ON A NOVEL TRAPPED ION MOBILITY MASS SPECTROMETER

Florian Meier (1) - Catherine Vasilopoulou (1) - Karolina Sulek (2) - Andreas-David Brunner (1) - Ulrike Schweiger Hufnagel (3) - Sven Meyer (3) - Aiko Barsch (3) - Matthias Mann (1)

Max Planck Institute of Biochemistry, Proteomics and Signal Transduction, Martinsried, Germany (1) - NNF Center for Protein Research, University of Copenhagen, Copenhagen, Denmark (2) - Bruker Daltonik GmbH, Bremen, Bremen, Germany (3)

Keywords: metabolomics, lipidomics, ion mobility spectrometry, TIMS, PASEF

Introduction:

The metabolome is a highly dynamic network of small molecules that represent not only the end-product of cellular metabolism, but also regulate and catalyze key biological processes. Here, we integrate Trapped ion mobility spectrometry (TIMS) and “Parallel Accumulation – Serial Fragmentation” (PASEF) [1, 2] to multiply the speed and sensitivity of MS² acquisition in untargeted liquid chromatography – mass spectrometry-based lipidomics and metabolomics.

Methods:

High-flow and nano-flow liquid chromatography was coupled online to a hybrid TIMS quadrupole time-of-flight mass spectrometer (Bruker timsTOF Pro) via electrospray ionization. Complex lipid and metabolite extracts from tissue and plasma sample were measured in PASEF mode. Raw LC-TIMS-MS data were processed with MetaboScape (Bruker) using on four-dimensional feature recognition and ion mobility-enhanced compound identification from spectral libraries.

Results:

IMS can separate even isobaric ions within ~100 ms, compatible with LC and TOF time scales. In TIMS this happens by the opposing forces of an electric field and the drag of a gas flow. In PASEF, the quadrupole switches rapidly within a single TIMS scan to capture as many precursors as possible for fragmentation without diminishing sensitivity. We found that in crude metabolite extracts, we could fragment up to 17 precursors in 100 ms TIMS scans, which increased the total number of data-dependent MS² scans by more than an order of magnitude. This extreme sequencing speed can be used in part to increase spectral quality for low-abundance precursors by re-sequencing. In terms of its physical principle, TIMS closely resembles conventional drift-tube IMS. This allows straightforward determination of collisional cross sections (CCS). We measured CCS values for a set of metabolites comprising vitamins, hormones, and lipids, which were in good agreement with literature values and highly reproducible with median coefficients of variation below 1%.

Conclusions:

TIMS literally adds a novel dimension to conventional metabolomics LC-MS workflows that is only beginning to be explored. The speed of PASEF enables very high sample throughput. We anticipate that the accurate and precise measurement of CCS values in conjunction with highly sensitive PASEF acquisition will allow a deeper metabolomics and lipidomics characterization of, for example, clinical samples.

Novel Aspect:

Robust high-speed and high-sensitivity metabolomics with online PASEF

Keywords: microflow, HILIC, MRM, metabolomics, cancer

Introduction:

Identification of metabolites from biological matrices is necessary for studying potential disease biomarkers and to further understand their biological implications. Liquid chromatography–tandem mass spectrometry (LC-MS/MS) analysis is an essential tool for identification and quantitation of metabolites in complex sample matrices. Here, we present HILIC method using a μ flow LC-MRM to evaluate the assay performance on a colon cancer study.

Methods:

Metabolite extracts from urine, plasma and an MDCK cell line samples were analyzed with both analytical and μ flow rate on SCIEX ExionLC™ AD HPLC and M3 MicroLC system. HILIC separation was performed using Luna- NH 2 columns (Phenomenex). MRM analysis with pos/neg polarity switching was completed on a QTRAP® 6500+ system. A total of 363 positive and negative ion mode MRM's for a total 312 unique polar metabolites were monitored.

Results:

While μ flow LC in general has become increasingly popular, it has not been readily employed in metabolomics because the typically used sample solvent does not allow for injecting larger volumes of samples without sacrificing HILIC chromatographic resolution. However, by simply reconstituting the sample in an organic solvent (95% acetonitrile, pH9), we could inject up to 5 μ L sample, while maintaining good peak shape. Using this single injection workflow we identified 263 unique metabolites out of 312 from all three matrices, covering all major metabolic pathways. This μ flow HILIC-MRM method on average provided 10 times more sensitivity compared to similar high flow methods. The μ flow HILIC LC-MRM method improved the S/N ratio by up to 60 times for some polar metabolites such as uridine 5'-diphosphate, hippuric acid and cytidine. Excellent chromatographic separation of improved sensitivity and resulted in higher number of detections with a 50% improvement in MDCK cell line, 35% in urine and 11% in plasma when compared to high flow Methods:

Conclusions

For the colon cancer study the previously classified healthy and diseased (Cancer) samples were clearly differentiated by data acquired using this microflow method and data analysis with the multivariate data analysis techniques in MarkerView™ Software. This method identifies the metabolites responsible for the differentiation of the sample grouping (healthy vs cancer), which is clearly being driven by 14 metabolites profile changing due to these conditions.

Novel Aspect:

A single microflow targeted metabolomics method allowing detection of over 300 polar metabolites across multiple biochemical pathways.

1314 - AUTOMATED PARALLEL DERIVATIZATION STRATEGY WITH BROAD METABOLITE COVERAGE COUPLED TO SWATH/MS DATA ACQUISITION FOR QUALITATIVE AND QUANTITATIVE ANALYSIS

David Ruskic (1) - Maria Fernanda Cifuentes Girard (1) - Renzo Piconi (2) - Mario Francesco Mirabelli (2) - Günter Böhm (2) - Gérard Hopfgartner (1)

Keywords: Parallel derivatization, QUAL/QUANT, dansyl-derivatives, SWATH/MS, automation

Introduction:

Diversity in metabolite polarity and electrospray ionization efficiency challenge the development of a single method. Chemical derivatization can significantly improve chromatographic retention time and MS response. We propose a workflow including an automated fast parallel derivatization of amines, phenols, aldehydes, alcohols and ketones followed by QUAL/QUANT SWATH/MS analysis for broad metabolite coverage.

Methods:

Dansyl-chloride (DanCl), dansyl-hydrazine (Dan-N₂H₃) and their ¹³C label analogs were used as derivatization agents. Samples (49 analyte mix and urine) were derivatized with ¹²C reagents while standards were derivatized with ¹³C labeled reagents using PAL RTC autosampler (CTC Analytics). The two fractions were mixed and injected onto a column-switching LC system. MS acquisition was performed on a TTOF6600 (Sciex) using SWATH acquisition.

Results:

Polar metabolites are converted to more hydrophobic products (DanCl and Dan-N₂H₃ derivatives), enabling them to be separated on reverse phase liquid chromatography. The presence of a basic p-amino group on both reagents increase the electrospray response factor by a factor of 10 to 200. Primary alcohols, phenols, primary and secondary amines are derivatized with DanCl and Dan-N₂H₃ transforms ketones and aldehydes to hydrazones. The automated parallel derivatization enables reproducible derivatizations in a single workflow including light labeling of sample and heavy ¹³C labeling of metabolite mix in 15 minutes during the LC analysis of the previous sample. Collision induced dissociation generates fragments specific for the analyte, and for the light and heavy derivatized analytes and for tags (XIC m/z=171 and m/z=173). LC-SWATH/MS which collects all precursors and all fragments allowed the screening and the relative and absolute quantification (n=45) of metabolites in urine.

Conclusions:

Labelled reagents enable to generate adequate standards for amines, phenols, aldehydes, alcohols and ketones. Automation was found to be key for reproducibility and is performed on-line prior LC analysis. In a batch, sample preparation and sample analysis are overlaid resulting in a significant gain of time. Dansyl-chloride and dansyl-hydrazine were found to be ideal for light/heavy labeling, improved LC retention, improved MS response and MS/MS tag

Novel Aspect:

Automated parallel heavy || light derivatization of sample || standard mix using dansyl-chloride and dansyl-hydrazide for improved metabolites coverage with LC-SWATH/MS.

Nico Mitro (1) - Donatella Caruso (1)

Università degli Studi di Milano, Department of Pharmacological and Biomelecular Sciences, Milano (1)

Keywords: steady-state metabolomics, fluxomics, energy metabolism, peripheral neuropathy, diabetes.

Introduction:

Metabolomics is a powerful tool to gain new insights contributing to the identification of complex molecular mechanisms in human and animal cells. Our aim is to understand how metabolism is rearranged during the development of age-related diseases. In particular, we focused our attention on the role of mitochondria that represents the energy-generating hubs of the cell in the context of two pathologies related to age: the peripheral neuropathy and type 2 diabetes.

Methods:

We used ESI-LC-MS/MS metabolomics of more than 500 metabolites involved in energy metabolism to investigate changes in the sciatic nerve of an experimental model of peripheral neuropathy. The same analyses were also used to characterize a novel mitochondrial regulator in vitro and in humans. In these latter cases, we also determined the rates of metabolic reactions by culturing cells with uniformly ¹³C-labeled nutrients (glucose, palmitate and glutamine).

Results:

Mice lacking the master regulator of de novo lipogenesis Sterol Regulatory Element Binding Factor (SREBF-1cKO) developed peripheral neuropathy. Metabolomics indicated that SREBF-1cKO peripheral nerves experienced decreased fatty acid synthesis and glycolytic flux, but increased fatty acid catabolism and mitochondrial function. These alterations were the result of local accumulation of two endogenous PPAR α ligands, specifically identified by mass spectrometry [1].

We have identified Zinc finger CCCH-type containing 10 (Zc3h10) as novel mitochondrial regulator. Depletion of Zc3h10 results in mitochondrial dysfunction and blunted Krebs cycle flux. We have also identified a loss-of-function mutation of Zc3h10 in humans (Tyr105 to Cys105) that is associated with increased body mass index and hyperglycemia. Isolated peripheral blood mononuclear cells from Cys105 homozygotes display reduced oxygen consumption rate and decreased levels of some Krebs cycle metabolites, which all together derive in mitochondrial dysfunction [2].

Conclusions:

Collectively, our results contributed to elucidate metabolic pathways modulated by two specific proteins, namely SREBF-1c and Zc3h10. Specifically, we identified changed energetic metabolites when both proteins were experimentally knock-down or functionally altered. Further, stressing the physiologic relevance of our findings, we demonstrated the key role of SREBF-1c and Zc3h10 in peripheral neuropathy and mitochondrial dysfunction development.

Novel Aspect:

Steady-state and dynamic metabolomic analyses are powerful analytical methods to unravel metabolic re-wiring in the transition from physiology to pathophysiology.

351 - HIGH-THROUGHPUT LC-MS/MS-BASED CHIRAL METABOLIC PROFILING FOCUSING ON AMINO ACIDS AND RELATED METABOLITES

Yosuke Nakano (1) - Moyu Taniguchi (1) - Eiichiro Fukusaki (1)

Osaka university, Advance Science and Biotechnology, Osaka (1)

Keywords: d-amino acid, chiral metabolomics, enantioseparation, LC-MS/MS

Introduction:

Metabolomics has been an evolving science with a wide range of applications in various fields. However, previous studies have rarely focused on metabolite chirality. We previously developed analytical methods for the simultaneous analysis of eighteen chiral proteinogenic amino acids[1, 2]. In this study, to achieve metabolic profiling of chiral amino acids and related metabolites, we developed a high-throughput method using LC-MS/MS.

Methods:

LC-MS/MS analysis was performed using the Nexera HPLC System (Shimadzu Corporation, Kyoto, Japan) connected to an LCMS-8060 (Shimadzu) with dual ion source of electrospray ionization and atmospheric pressure chemical ionization in MRM mode. Chromatographic separation was achieved with CROWNPAK CR-I(+)/CR-I(-) (3.0 mm i.d., 150 mm, 5 μ m) and CHIRALPAK ZWIX(-) (4.0 mm i.d., 150 mm, 3 μ m) (Daicel CPI, Osaka, Japan).

Results:

The combination of two types of chiral columns (with binaphthyl-based crown ether and cinchona alkaloid-derived zwitterionic stationary phases) enabled the analysis of 115 chiral and non-chiral metabolites. By finely optimizing MS/MS parameters, the method allowed the highly sensitive (0.001-50 nmol/mL) and wide dynamic range detection (100-50,000) of target analytes in a standard solution without derivatization. We applied the method to food samples (cheese), and successfully quantified trace levels of metabolites such as d-amino acids in samples. Additionally, we performed principal component analysis (PCA) on the metabolome data and obtained unique profiles that reflected metabolite chirality.

Conclusions:

This method highlights the highly sensitive detection of trace amounts of targeted metabolites without the need for derivatization. Moreover, we demonstrated the usefulness of our system by simultaneously analyzing both chiral and non-chiral metabolites in samples. According to the profiling, some d- and l-amino acids showed different behaviors in the PCA plot, which could not be observed by conventional methods that rarely consider separation of enantiomers.

Novel Aspect:

We anticipate that this method will enable comprehensive profiling to provide novel insights into the discovery of molecular markers utilized in various fields.

1242 - TARGETED METABOLOMICS APPLIED TO HEART FAILURE PATIENTS – A PILOT STUDY

Ralf Nilsson (1) - Lars Löfgren (1) - Filippos Michopoulos (2) - Maria Ryaboshapkina (1) - Pia Davidsson (1) - Cecilia Linde (3) - Bengt Persson (4)

Astrazeneca, Translational science, Mölndal, Sweden (1) - Astrazeneca, Oncology IMED Biotech Unit, Cambridge, United Kingdom (2) - Karolinska University Hospital,, Department of Cardiology, Stockholm, Sweden (3) - Danderyd Hospital, Cardiology, Stockholm, Sweden (4)

Keywords: Targetedmetabolomics, heartfailure, reducedejectionfraction (HFrEF), preservedejectionfraction (HFpEF)

Introduction:

Targetedmetabolomicswasperformedat AstraZeneca on a pilotstudy with plasma samples from heartfailure (HF) patients in the 4D heartfailure PREFERS project for improvement of heartfailure management and research in Stockholm, initiated by the Karolinska Institute and Stockholm County. The patientsweredivided in threegrups: HF with reducedejectionfraction (HFrEF, n=13), HF with preservedejectionfraction (HFpEF, n=22) and a HF control (n=41) group. All 76 patientshadcoronaryartery bypass surgeryperformed.

Methods:

The effectiveanalysis of polarionicmetabolites by LC-MS, represents an analyticalchallenge for metabolicprofiling. Ion-pair-chromatography (IPC) coupled to negative-electrospray-ionizationtandem-mass spectrometry (1) wasused to profile100+ endogenousmetabolicintermediates in human plasma. A complementarymethodbased on hydrophilicinteractionchromatography (HILIC) positive-electrospray-ionizationtandem-mass spectrometrywasdevelopedcoveringanother 70+ metabolites. By combiningthesetwoplatformsmetabolitesrepresenting amino acids, phosphorylatedsugars, citric acid cycleintermediates, glycolyticintermediates,acylcarnitines, lysophospholipids, and nucleosideswererecovered.

Results: There was no clear metabolite phenotype separation between normal, HFpEF and HFrEF patients based on targeted metabolomics but two metabolites were differentially abundant between HFrEF patients and controls and survived adjustment for multiple testing. There wasalso significant pair-wise separation between groups for more than 15 metabolites.

Conclusions:

In conclusion, targeted metabolomics was successfully applied to the heart failure pilot study. Results were in-line with published data, confirming the capability of the platform to support future work on an expanded cohort aiming at identifying dysregulated metabolic pathways to advance the understanding of heart failure pathophysiology in search for new treatments and biomarkers.

Novel Aspect: The application of combined targeted metabolomic platforms on samples from heart failure patients with preserved or reduced ejection fraction.

1044 - STUDY OF AUXIN BIOSYNTHESIS USING IN VIVO LABELLING

Ales Pencik (1) - Petr Vonka (1) - Martin Kubes (2) - Karin Ljung (3) - Ondrej Novak (1)

Institute of Experimental Botany AS CR & Palacky University, Laboratory of Growth Regulators, Olomouc (1) - Centre of the Region Haná for Biotechnological and Agricultural Research, Palacky University, Department of Chemical Biology and Genetics, Olomouc (2) - Swedish University of Agricultural Sciences, Department of Forest Genetics and Plant Physiology, Umea (3)

Keywords: tandem mass spectrometry, in vivo labelling, auxin, metabolism, *Arabidopsis thaliana*

Introduction:

The phytohormone auxin (indole-3-acetic acid; IAA) plays a fundamental role in various processes of plant growth and development. Crucial for auxin action is the interplay between its transport, biosynthesis, degradation and conjugation. The use of heavy isotope labelling of intermediates in conjunction with mass spectrometry analysis has proven to be a powerful tool for monitoring fluxes through IAA metabolic pathways.

Methods:

7-day-old seedlings of *Arabidopsis thaliana* were incubated with 10 μ M [¹³C]indole. Seedlings were harvested after 1, 2, 4, 6 and 24 hours, then extracted and subsequently purified by solid phase extraction (SPE) as described by Novák et al. [1]. Incorporation of [¹³C]indole and its metabolisation in planta were monitored by LC-MS/MS with multiple reaction monitoring transitions and quantified by isotopic dilution method with appropriate internal standards [2].

Results:

We performed a feeding experiment using ¹³C labelled indole in *Arabidopsis* wild type (Col-0) and several IAA biosynthetic and metabolic mutants to investigate auxin metabolism. Incorporation of the ¹³C from labelled precursor into most abundant IAA biosynthetic intermediates (tryptophan, indole-3-pyruvic acid (IPyA), indole-3-acetamide (IAM) and indole-3-acetonitrile (IAN)) as well as metabolites (IAA-aspartate (IAAsp), IAA-glutamate (IAGlu), 2-oxoindole-3-acetic acid (oxIAA), IAA-glucose and oxIAA-glucose) was monitored by mass spectrometry. Our results are in consistence with published role of particular enzyme in *Arabidopsis* metabolism [3]. Applied isolation procedure and LC-MS/MS method showed sufficient sensitivity for in vivo labelling studies. Therefore, our developed approach allows to monitor phytohormone metabolic pathways in extremely small samples (<1 mg), such as root tips, meristems or embryos.

Conclusions:

Obtained results provide us with important information about the rates of IAA biosynthesis and degradation and the relevance of individual IAA precursors, catabolites and conjugates. Combined with mutant line screening [4], the developed approach can improve our knowledge about auxin metabolic pathways in different plant species.

Novel Aspect:

Using heavy isotope labelling and mass spectrometry, we have developed a new functional bioanalytical approach for studying IAA biosynthesis and metabolism in *Arabidopsis*.

Keywords: breath analysis, secondary electrospray ionization, obstructive sleep apnea, biomarkers, metabolomics

Introduction:

Since breath analysis shows a high potential as a non-invasive diagnostic tool, many explorative case-control studies investigating different diseases have been carried out in the recent years. However, only very few results have been validated in a larger cohort later on. Here, we present a blinded validation study for the diagnosis of obstructive sleep apnoea (OSA) by analyzing exhaled breath with secondary electrospray ionization mass spectrometry (SESI-MS).

Methods:

Subjects with suspected OSA (n=150) were diagnosed by conventional in-laboratory respiratory polygraphy. In addition, they underwent exhaled breath analysis using SESI-MS. Metabolic breath patterns were analyzed and the diagnosis of OSA was predicted for the subjects using a panel of biomarkers found to be characteristic for the presence of OSA in our previous pilot study [1]. The person analyzing the data was blinded regarding clinical diagnosis.

Results:

Between the pilot study and the validation study, some technical improvements on our SESI-MS setup were made. We upgraded to a commercial SESI source making the data challenging to compare. In a preliminary data analysis of 130 subjects measured so far, we were able to render the old and the new dataset comparable using empirical Bayes methods[2]. Thus, the data from the pilot study can be used for training the classification model for predicting the validation cohort.

Conclusions:

A positive outcome of this study will strengthen real-time breath analysis by SESI-MS as a diagnostic tool tremendously and bring it a step closer to its application in clinical routine.

Novel Aspect:

This is the first validation study for any biomarkers found in exhaled breath using secondary electrospray ionization mass spectrometry.

881 - A DUAL SEPARATION/HIGH RESOLUTION ACCURATE MASS SPECTROMETRY SYSTEM FOR IMPROVED METABOLOME COVERAGE AND INCREASED THROUGHPUT

Ioanna Ntai (1) - Martin Samonig (2) - Aran Paulus (1) - Ralf Tautenhahn (1) - Amanda Souza (1) - Andreas Huhmer (1)

Thermo Fisher Scientific, Marketing, San Jose (1) - Thermo Fisher Scientific, Marketing, Germering (2)

Keywords: metabolomics, high-throughput, untargeted metabolomics, metabolite profiling, beer

Introduction:

Complete coverage of a metabolome of interest can be challenging due to the diversity of small molecules. Here, we integrated reverse phase (RP) and hydrophilic interaction chromatography (HILIC) to maximize throughput and metabolome coverage. This dual separation system was coupled to an Orbitrap™ mass spectrometer and used for untargeted metabolomic analysis of beer samples, identifying compounds important in discriminating flavor and indicating spoilage.

Methods:

Sixteen beers were purchased from retail stores. For each beer, samples were collected at time of purchase and after storage at room temperature or 4°C for 6 and 18 weeks. A Thermo Scientific™ Vanquish™ UHPLC system equipped with an autosampler with two injection units, was coupled to a Thermo Scientific™ Q Exactive™ HF mass spectrometer. Data were processed with Thermo Scientific™ Compound Discoverer software for unknown identification and differential analysis.

Results:

We developed a dual liquid chromatography/mass spectrometry (LC/MS) system that combines RP and HILIC separation and we evaluated it for its reproducibility and separation capabilities of complex samples. Small polar metabolites from beer, like malate and succinate, were not retained during RP, but showed good reproducibility of retention times and MS signal during HILIC separation. Hydrophobic metabolites, such as apigenin and isoxanthohumol, were reproducibly retained only during RP. By combining the two complementary separation techniques, we were able to reproducibly analyze a larger number of metabolites.

Two independent UHPLC pumps were incorporated into the system to allow independent control of the two columns (RP and HILIC). This enabled the use of different solvents, additives and pH ranges and resulted in broader metabolite coverage. By equilibrating one column, while separation was carried out on the other, analysis time was decreased by 30% and the overall throughput of the method increased.

Conclusions:

The increased throughput of the dual LC/MS system described above, did not compromise reproducibility or compound detection. It was successfully employed for the differential analysis of beer and provided robust indicators of flavor profiles and degradation. One can envision extending its application to any metabolomics application, where increased throughput is needed.

Novel Aspect:

Innovative integration of RP and HILIC separations leads to improved metabolome coverage while simultaneously increasing throughput of untargeted metabolomic workflow.

884 - INTELLIGENT MSN WORKFLOW FOR IMPROVED METABOLOME COVERAGE AND INCREASED CONFIDENCE IN UNKNOWN IDENTIFICATION

Ioanna Ntai (1) - Iman Mohtashemi (1) - Ralf Tautenhahn (1) - Graeme McAlister (1) - Seema Sharma (1) - Vlad Zabrouskov (1) - Amanda Souza (1) - Andreas Huhmer (1)

Thermo Fisher Scientific, Marketing, San Jose (1)

Keywords: metabolomics, compound identification, untargeted metabolomics, multi-stage fragmentation, data-dependent acquisition

Introduction:

Compound identification is a bottleneck in untargeted metabolomics, hindering biological interpretation of results. Here, we describe a data-informed workflow that maximizes the number of metabolites interrogated by MS/MS and MS_n, while minimizing the acquisition of uninformative spectra. This workflow was used to analyze human plasma resulting in high confidence identifications, deeper metabolome coverage and enhanced biological knowledge generation.

Methods:

Human plasma was purchased from NIST. Metabolites were extracted with methanol and injected on a Thermo Scientific™ Hypersil GOLD™ column. Instrumentation included a Thermo Scientific™ Vanquish™ UHPLC system and a Thermo Scientific™ Orbitrap Tribrid™ Mass Spectrometer with modified instrument control and data acquisition software. Data were analyzed using Thermo Scientific™ Mass Frontier software and Thermo Scientific™ Compound Discoverer™ software.

Results:

During data-dependent MS/MS, ions are selected based on abundance, without any knowledge of biological relevance or type of ion. In a typical DDA experiment, we determined, that >40% of MS/MS spectra could be attributed to background ions. By enabling the automatic generation and implementation of a background exclusion list based on real-time feature detection in LC-MS data, background ion MS₂ spectra were practically eliminated (<0.1%), allowing for the analysis of more true sample components.

Small molecules form different types of adducts and cluster ions during electrospray ionization. Highly abundant compounds may prevent the fragmentation of metabolites of lower abundance. By populating the inclusion list with the preferred ion for each metabolite, more compounds can be sampled by MS/MS and MS_n in a single run. Additionally, by automatically updating inter-run inclusion and exclusion lists during analysis, we can ensure that compounds not selected for MS/MS and MS_n will be prioritized during a subsequent injection.

Conclusions:

The combination of MS_n and automatically generated inter-run inclusion and exclusion lists resulted in fragmentation of more unique metabolites and a greater number of metabolites confidently annotated. Application of this innovative workflow addresses the identification bottleneck of untargeted metabolomics studies and enables confident biological interpretation of the results.

Novel Aspect:

Automated workflow for information-rich fragmentation data acquisition, designed to minimize irrelevant spectra and maximize metabolome coverage.

763 - NON-TARGET METABOLOMIC ANALYSIS OF PEPERONI DI SENISE PEPPERS IGP (CAPSICUM ANNUUM L.) AND EVALUATION OF THEIR NUTRACEUTICAL PROPERTIES

Keywords: Capsicum Annuum L., Peperoni di Senise, FT-ICR-MS, Phytochemical Screening, hypoglycemic activity

Introduction: Peperoni di Senisepeppers (*Capsicum Annuum* L.), a typical food product cultivated in Basilicata (Southern Italy), protected with a PGI quality mark, are known for their unique taste. A Mass Spectrometry-based phytochemical screening was performed to promote their functional food properties.

Methods: Direct injection negative-ion ESI-UltraHigh Resolution Mass Spectrometry was used to obtain a metabolic fingerprint of the sample. High-resolution mass spectra were acquired on a Bruker (BrukerDaltonik GmbH, Bremen, Germany) solarix XR Fourier transform ion cyclotron resonance mass spectrometer (FT-ICR-MS) equipped with a 7T superconducting magnet and an ESI source. Moreover, antioxidant activity of the extracts was evaluated.

Results: UltraHigh Resolution Mass Spectrometry data obtained from analysis of the extract of Peperoni di Senisepeppers were used to perform a rapid analysis of metabolome by converting accurate m/z values in putative elemental formulas in order to better understand the chemical composition of the sample. Molecular formula maps were obtained by making Van Krevelen diagrams, that lead to a direct visualization of different classes of metabolites. As expected, the most abundant compounds were polyphenols and carotenoids. A significant antioxidant activity was assessed also.

Conclusions: The results of the present study shed some light on metabolic composition of Peperoni di Senisepeppers and highlighted their health-promoting properties.

Novel Aspect: This study improved the knowledge of metabolites occurring in Peperoni di Senise fruits and it can be used for comparative studies with other types of *Capsicum Annuum* L. fruits.

Keywords: UPHLC/MSMS, auxin, fluorescence, in planta stability

Introduction:

Auxin is an indole-derived plant hormone which significantly contributes to plant growth and development [1]. Using a fluorescent label to visualize auxin natural distribution in different physiological processes will provide new insights into auxin biology [2]. Here we present one-step purification and quantification methods used to determine the chemical stability of the new fluorescent derivatives and their potential *in vivo* metabolization in plant system.

Methods:

The purification procedure based on liquid-liquid extraction was developed using hexane:water:methanol (1:1:1) as an extraction solution. After isolation step, an Acquity UPLC[®] I-Class System coupled to a triple quadrupole mass spectrometer Xevo[™] TQ-S MS (Waters) was employed for detection of the analytes. Concentrations of all compounds were then calculated by an isotopic dilution method using the stable isotope labelled standards by deuterium and ¹³C.

Results:

Applying the presented method, time-dependent uptake and metabolization dynamics of two new fluorescent auxin derivatives in roots of *Arabidopsis thaliana* seedlings was determined. After the treatment of 5-d old plants by 10 μ M exogenous application of tested compounds, both fluorescent conjugates showed similar metabolization rate *in vivo* yielding 20-28 pmol/50 roots of free auxin in 3 h (5 % of their total content). Furthermore, the detected amount of free auxin analogue in short-term treatment (30 min) was close to the detection limit of the UHPLC-MS/MS method (in range 5.8-9.5 pmol/50 roots representing just 2% of the total content of fluorescent analogues). Despite a slight metabolization on the background, the evidences of biological activity of the whole fluorescent compounds were provided in various auxin-related bioassays.

Conclusions:

A new detection method was developed to determine stability of two fluorescent analogues of plant hormone auxin in planta. Our analytical approach helped to reveal the time-dependent metabolization of new fluorescent auxin derivatives in plant tissues. Furthermore, the detected amount of free auxin analogue was proven not to be sufficient to cause the biological response.

Novel Aspect:

A developed purification method is applicable for determination of a stability of various plant hormone derivatives and presents a useful analytical tool for plant research.

666 - METABOLOMIC APPROACHES TO INVESTIGATE THE ROLE OF THE MITOCHONDRIAL REGULATOR ZC3H10 IN ADIPOCYTES

Silvia Pedretti (1) - Matteo Audano (1) - Emma De Fabiani (1) - Donatella Caruso (1) - Nico Mitro (1)

Università degli Studi di Milano, Department of Pharmacological and Biomolecular Sciences, Milan (1)

Metabolomic approaches to investigate the role of the mitochondrial regulator Zc3h10 in adipocytes.

Silvia Pedretti, Matteo Audano, Emma De Fabiani, Donatella Caruso and Nico Mitro

Dipartimento di Scienze Farmacologiche e Biomolecolari (DiSFeB), Università degli Studi di Milano, Milano, Italy.

Keywords:

Zc3h10; LC-MS/MS; metabolism; mitochondria; adipocytes;

Introduction:

Mitochondria play a crucial role in many cellular processes and they are essential organelles for the health of the cell. Beyond their contribution to energy production, they are key regulators of tissue development and cell differentiation. We recently isolated the new mitochondrial regulator zinc finger CCCH-type containing 10 (Zc3h10) [1] and here, we validated its role during adipocytes differentiation.

Methods:

C3H/10T1/2 cell line (mesenchymal stem cells) can be differentiated into white adipocytes using a specific adipogenic cocktail. Quantification of different metabolites was performed with a liquid chromatography/tandem mass spectrometry (LC-MS/MS) on an API-4000 triple quadrupole mass spectrometer coupled with a HPLC system using a C18 column for amino acids and cyano-phase LUNA column for metabolites.

Results:

Zc3h10 protein levels increase during C3H/10T1/2 differentiation. Zc3h10 silencing significantly affects adipocyte differentiation and mitochondrial activity. To demonstrate that Zc3h10 plays a role in energy metabolism we evaluated the intracellular levels of by-products belonging to the main metabolic pathways (i.e. glycolysis, tricarboxylic acid (TCA) cycle and pentose phosphate pathway (PPP), amino acids) using LC-MS/MS. Steady-state metabolomics indicated that lack of Zc3h10 led to decreased AMP, ADP, ATP and NADH levels. We also observed reduced levels of acetyl-CoA, α -ketoglutarate (α -KG), citrate, and succinyl-CoA and increased levels of glutamate. We also used metabolic tracers ([U-13C6]-glucose, [U-13C16]-palmitate or [U-13C5]-glutamine) to confirm that the flow of energy substrates into the TCA is affected by Zc3h10 silencing.

Conclusions:

Our results indicate that Zc3h10 expression increases during murine white adipocyte differentiation. Further, Zc3h10 silencing in white preadipocytes and adipocytes deeply impaired mitochondrial function, decreased adipogenic potential and altered metabolic profile.

Novel Aspect:

These data annotate Zc3h10 as a new regulator of mitochondrial function and cell differentiation in adipocytes.

349 - LC-MS/MS QUANTIFICATION OF THIOL-CONTAINING METABOLITES WITHIN THE DE NOVO GLUTATHIONE SYNTHESIS PATHWAY OVER THE LIFESPAN OF CAENORHABDITIS ELEGANS

Gavin Ferguson (1) - Russell Pickford (2) - Wallace Bridge (1)

University of New South Wales, School of Biotechnology and Biomolecular Sciences, Sydney (1) - University of New South Wales, Bioanalytical Mass Spectrometry Facility, Sydney (2)

Keywords: glutathione, thiol, quantification, LC-MS/MS, aging

Introduction:

A consistent underlying index of aging is declining cellular levels of the tripeptide glutathione (GSH). This could be due to either limited cysteine availability or a decrease in the activity of the rate-limiting enzyme glutamate cysteine ligase (GCL). Insight into the availability of cysteine levels and the regulatory control of GCL will inform the development of therapeutic strategies aimed to overcome age-related dysregulation of the GSH synthesis pathway.

Methods:

We have developed a rapid and sensitive LC-MS/MS method that can simultaneously quantify each thiol in the de novo GSH synthesis pathway (Cys, γ -GC and GSH together with GSSG) using a relatively unexplored thiol-derivatizing reagent, 4-(dimethylaminoethylaminosulfonyl)-7-chloro-2,1,3-benzoxadiazole (DAABD-Cl). This method was applied to a nematode model to determine if the dysregulation in GSH homeostasis is due to cysteine availability or GCL activity.

Results:

The nematode, *Caenorhabditis elegans*, which has a median lifespan of approximately 17 days, presents a potentially useful model to investigate the age-related decline in GSH homeostasis, due to the presence of the metabolites and orthologues of the mammalian GSH synthesis pathway enzymes.

Work to date has validated the LC-MS/MS method as having the dynamic range, sensitivity and selectivity to be suitable for the analysis of age-dependent changes of all the thiol and disulfide levels in nematode tissue samples.

Using this method, thiol and disulfide levels were monitored in aged-matched wild-type cohorts. It was observed that γ -GC and GSH levels significantly declined over the first 10 days of adulthood. The GSH:GSSG molar ratio followed an age-related oxidizing shift, declining from 115:1 in day 1 old worms to

25:1 in day 10 old worms. Cysteine levels did not appear to show any age-dependent trends, indicating that factors other than the availability of cysteine are perhaps causing this age-related decline in GSH synthesis.

Conclusions:

The age associated decline of the GSH pool is likely due to a progressive lowering of GCL activity. The corresponding decline in the GSH/GSSG ratio may be a function of a decline in the activity of the GSH recycling enzyme, glutathione reductase, or a depletion of its NADPH cofactor pool. Future work will expand the assay and quantify other key thiol metabolites to further our mechanistic understanding of the aging process in relation to glutathione homeostasis.

Novel Aspect:

We developed a strategy using LC-MS/MS coupled with derivatization for the quantitative measurement of labile low molecular weight thiols in biological tissue.

1132 - INTEGRATION OF TANDEM MASS SPECTROMETRY MOLECULAR NETWORKING AND GAS-PHASE FRAGMENTATION REACTIONS FOR STRUCTURAL ANALYSIS OF FLAVONOID GLYCOCONJUGATES

Alan Cesar Pilon (1) - Fausto Carnevale Neto (1) - Hawei Gu (2) - Daniel Raftery (2) - Vanderlan da Silva Bolzani (3) - Norberto Peoporine Lopes (1) - Ian Castro Gamboa (3)

Keywords: Molecular Networking (GNPS), Dereplication, O-glycosyl-flavonoids, Gas-phase Fragmentation

Introduction:

Gluconjugated flavonoids (GF) are important natural products in plants [1]. Their identification in the different isomeric forms, stereochemistry and positions still represent a great challenge. HPLC-MS/MS combined with bioinformatics proved to be efficient in analyzing and organizing large datasets of MS2. For this work, we integrate the Molecular Network (MS2) and the fragmentation patterns to the GF annotation in Chrysobalanaceae species.

Methods:

Our approach uses massive molecular networks that embeds chemical - glycosylation type and position, nature of their aglycones, and the structure/linkage information of their glycan moieties -, and biological information layers to highlight the flavonoid composition through structural-based organization. We exemplify this workflow by identifying the glycoconjugated flavonoids present in six Chrysobalanaceae species analyzed using LC-ESI-QToF-MS.

Results:

The combination of Molecular Network capabilities, gas-phase fragmentation patterns with detailed taxonomical knowledge on flavonoid biochemistry allowed a rapid screening and annotation of several glyconjugate flavonoids including those with different glycosylation type and position, nature of their aglycones and the structure/linkage information of their glycan moieties. According to the literature, more than fifty flavonoids have been described, so far, from Chrysobalanaceae species, with a predominance of flavonol glycosides [2]. Based on the systematic inspection of all MN nodes related to the flavonoid groups, sixty-four metabolites were identified in the Chrysobalanaceae plant species, with a predominance of flavonol 3-O-glycosides. This is also the first report of methoxyl, O-di- and tri-O-glycosyl flavonols for this family.

Conclusions:

The application of this strategy using LC-MS in automatic data-dependent acquisition (DDA) capability combined to molecular networking allowed the visualization and data comparison not only for known compounds but also provided information for the determination of correlated analogues of glycoconjugated flavonoids described for the first time in the Chrysobalanaceae family.

Novel Aspect:

This is first time molecular networking, fragmentation pattern and chemotaxonomic information is combined to annotate glyconjugate flavonoids considering glycosylation type and position, aglycones and linkage information of their glycan moieties

Keywords: colorectal cancer, pattern recognition, metabolomics workflow, data processing methods

Introduction:

As mentioned in recent research in USA about 50000 deaths have happened from colorectal cancer (CRC), also authors postulate the need to create a method for screening CRC in the early stages [1]. The comprehensive workflow for pattern recognition of three group CRC patients based on UPLC-MS with fully comprehensive algorithm for optimization methods of preprocessing and data acquisition were reported here.

Methods:

All morning fasting urine samples (on an empty stomach, immediately after sleep) of control group volunteers (8 pcs.), colorectal cancer patients before surgical operation (20 pcs.) and after surgical operation (12 pcs.) were collected for this research.

The HPLC separation was conducted on a C18 column. The separation was carried out in a gradient elution mode with MS detection in a positive ion (TIC mode). "Dilute and shoot" technique was used for sample preparation.

Results:

Three types of signal drift correction were used for reduction unwanted variations [2]: total ion current, quantile, median and without any method. ANOVA was applied, to test correction Methods: Two methods for metabolites concentration normalization were examined [3]: mass spectrometry total useful signal, creatinine concentration and without normalization. Log transformation and three type of scaling methods (auto, mean, Pareto and without scaling) were tested.

So, the dataset was applied to assess all possible 48 permutations of normalization, correction, transformation and scaling followed by PLS-DA and sPLS-DA. Analyzing sPLS-DA result, we found that using a log transformation, regardless of the application of any other data processing methods, the first 10 features with the maximum values of their loadings were the same for all permutations. After an extraction from the entire set of data set only the top features, in all cases samples groups were fully resolved from each other by PCA, sPLS-DA, PLS-DA, RF, dendrograms and heat map.

Conclusions

We propose the pragmatic decision procedure for selection and evaluation of preprocessing methods in metabolomics studies. This algorithm is based on the estimating of the influence each stage using multivariate and univariate statistical analysis. Extraction selected features from raw data set will led to appropriate pattern recognition if the model is built right.

Novel Aspect:

This LC-MS workflow with algorithm of evaluation, optimization and scheme for performing statistical analysis operations can be applied in other relatively short studies.

1264 - PHOSPHOLIPID REMOVAL BY SOLID PHASE EXTRACTION FOR UNTARGETED METABOLOMICS: IMPROVED SENSITIVITY FOR POLAR METABOLITES IN BRAIN

Päivi Pöhö (1) - Anu Vaikkinen (1) - Elena Scurti (1) - Mikko Airavaara (2) - Tapio Kotiaho (1) - Risto Kostiainen (1)

University of Helsinki, Division of Pharmaceutical Chemistry and Technology, Helsinki, Finland (1) - University of Helsinki, Institute of Biotechnology, Helsinki, Finland (2)

Keywords: Untargeted metabolomics, HILIC, solid phase extraction, phospholipid

Introduction:

Untargeted UHPLC-ESI-HRMS metabolomics of polar brain tissue metabolites is challenging because brains contain large amounts of phospholipids. As phospholipids ionize easily, they cause signal suppression of polar metabolites and detector overloading at large injection volumes. Here we compare four solid phase extraction cartridges for phospholipid removal from brain extracts.

Methods:

Rat brain proteins were precipitated with methanol, and supernatants subjected to phospholipid removal by pass through SPE. Non-encapped, octadecylfunctionalized silica (C18), zirconia coated silica (HybridSPE), and two types of hydrophilic-lipophilic balance polymer cartridges (HLB and PRiME HLB) were compared for the lipid removal. The analytes were separated by HILIC with BEH Amide column, and detected in negative ion mode with ESI-Q-TOF-HRMS.

Results:

Amount of phospholipids was significantly reduced with all sorbent materials, and subsequently, concentration and injection of larger volumes of sample was enabled. However, the removal was less efficient with PRiME HLB compared to the other cartridges. The C18 and HLB sorbents removed efficiently also other lipid types from the samples, such as fatty acids, sulfatides, and ceramides. This is expected based on their non-polar retention mechanisms. PRiME and HybridSPE showed variable removal efficiency for the lipid classes that do not contain the phosphate group. In addition to lipids, some analytes of interest were retained in the sorbents. For example, in the case of HybridSPE, lactic acid, glucose, the dipeptide neurotransmitter N-acetylaspartylglutamic acid, and its precursor N-acetylaspartate were not recovered from the samples, while the C18 sorbent retained GABA completely. Extraction RSDs were mainly below 20 % for C18 and HLB, whereas PRiME and HybridSPE showed larger variance.

Conclusions:

All tested sorbent materials are able to reduce the amount of phospholipids in methanolic brain extracts with very simple pass through protocols and thus improve sensitivity towards polar metabolites. However, some metabolites are lost in the process. The HLB sorbent provided best combination of lipid removal efficiency, repeatability, and metabolite recovery for brain metabolite analyses.

Novel Aspect:

Systematic evaluation of solid phase extraction sorbents for phospholipid removal for the untargeted metabolomics of polar brain metabolites.

Keywords: Metabolomics, coffee, mass spectrometry, molecular networking

Introduction: Coffee is one of the most appreciated beverages in the world. It has a unique flavor and aroma, resulted from a complex chemical composition of the beans and influenced by several factors [1]. The beverage quality is directly related to the chemical composition of the beans and studies about quality x chemical composition have been carried out for decades. However, they usually focus on a small number of metabolites, not covering the complex chemical composition of the beans.

Methods: Raw (unroasted) coffee beans with different beverage qualities were extracted comprehensively and exhaustively using a two-step solvent extraction and analyzed using a non-target method by liquid chromatography-data dependent high-resolution mass spectrometry (LC-HRMS ddMS2) in the Thermo QExactive Plus. The obtained files were converted to the mzXMLopen format and submitted to target and non-target metabolomic analysis as well as to molecular networking using the GNPS online platform [2].

Results: Sixty-four substances from different chemical classes including xanthines, chlorogenic acids, diterpenes, serotonin amides, among others, were identified using the m/z value with high accuracy (ppm error < 5ppm), fragmentation profile and isotopic pattern as the criterion for identification. The GNPS online platform allowed the creation of molecular networks containing molecular families according to the similarities in their chemical structure, helping in the better understanding of the chemical composition of the beans. By PCA and PLS-DA multivariate data analyses sucrose and the lipid fraction showed high correlation with beans of better quality, while substances in coffee wax were correlated to low quality coffees.

Conclusions: With this work it was possible to develop a comprehensive methodology based on metabolomics to study and better understand the chemical composition of coffee beans and its relation to the quality of the beverage. So, it may help coffee growers, cooperatives and other professionals in the coffee chain to produce better quality products.

Novel Aspect: We have developed a comprehensive metabolomic study identifying a large number of coffee compounds from the non-volatile fraction together with the creation of molecular networks based on tandem mass spectrometry data.

Keywords: metabolomics, metabolite profiling, urine, mass spectrometry, cancer

Introduction

Cancer is one of the leading causes of morbidity and mortality worldwide and the number of new cases is expected to rise significantly in the future. Improvements in early detection and therapeutic evaluation are essential to decrease cancer mortality [1]. Metabolomics is increasingly applied for the identification of biomarkers for disease diagnosis, prognosis and risk prediction. The metabolic analysis in non-invasive biofluids such as urine may help to obtain a complete functional molecular picture of the biochemistry and ultimately the discovery of new cancer biomarkers [2].

Methods

The different properties of the huge diversity of chemical compounds mean that the complete metabolic analysis of urine is practically impossible with a single analytical method. Therefore, multiple analytical approaches have been used such as capillary electrophoresis-mass spectrometry (CE-MS), liquid chromatography-mass spectrometry (LC-MS) and gas chromatography-mass spectrometry GC-MS.

Results

A urinary metabolic fingerprinting analysis has been performed in an animal model in order to detect potential biomarkers that could help in the early detection of prostate cancer, which is the second most frequent type of cancer in men [3]. The comparison between healthy and diseased mice was carried out analyzing urine samples from Wild-Type (WT) mice and Transgenic Adenocarcinoma of the Mouse Prostate (TRAMP) mice of C57/BL6 strain. The experimental design offers a wide range of metabolites with a significant chemical diversity, due to the different platforms applied: very polar (CE-MS) non-volatile (LC-MS) or volatile metabolites (GC-MS). This strategy produces large amounts of complex datasets that must be handled with powerful computational analysis. An unsupervised method, such as principal component analysis (PCA), reduces the complexity of the data obtaining plots of easier interpretation. This approach is useful to see whether the two groups (TRAMP and WT) can be discriminated by their characteristics.

Conclusions

To summarize, we have a preliminary study that permits the detection of a wide range of metabolites, some of which could be possible biomarkers because it allows the discrimination of the tumour progression. Those compounds are identified based on the capabilities of mass spectrometry.

Novel Aspect

The search for biomarkers as an alternative to the analysis of the prostate-specific antigen (PSA) which has been questioned due to a lack of specificity at this cancer diagnosis [4].

1182 - A NOVEL INTEGRATIVE STRATEGY TO PREVENT COLORECTAL CANCER WITHIN THE DIET-HOST-MICROBIOTA TRIANGLE: FROM ORGANOID TO HUMAN IN VIVO REALITY

Josep Rubert (1) - Fulvio Mattivi (2) - Andrea Lunardi (1)

Centre for Integrative Biology (CIBIO), University of Trento, Trento, Italy (1) - Center Agriculture Food Environment (C3A), University of Trento, Trento, Italy (2)

Keywords: metabolomics, microbial metabolites, gut microbiota, cancer, organoids

Introduction:

Currently, colorectal cancer (CRC) is the second cause of death in EU[1]. In EU, the Czech Republic and Slovakia showed the highest rates. By contrast, Greece presented the lowest rates across Europe[2, 3]. This incidence is postulated to reflect risk factors associated to socioeconomic status, including poor dietary habits and obesity. However, emerging evidence also implicates gut microbiota as an important effector in the relationship among diet, human health and cancer[4].

Methods:

A novel integrative strategy to deepen understanding of CRC is vital. To accomplish this, a real-life scenario is needed. In this context, colon organoids/tumoroids will be established. Afterwards, an apple will be digested/fermented in vitro using a batch culture colonic model inoculated with feces from lean/obese healthy donors. In the end, such polyphenol metabolites will be tested in colon organoids/tumoroids and the mechanisms of action will be revealed by metabolomics and organoids assays.

Results:

In summary, the results from TRIANGLE through the integration of polyphenols (diet), gut microbiota and colon organoids (host), will be highly multidisciplinary, and will undoubtedly set the stage towards the identification of mechanisms contributing to CRC understanding and will ultimately pave the way to phytochemical treatment and prevention. First, it is still unknown how apple phytochemicals are affected by lean and obese microbiotas, and it must be understood in order to comprehend chemopreventive efficacy of polyphenols and to be able to give nutritional recommendations related to functional-group class therein. Secondly, tumor organoids (tumoroids) and organoids can bridge the gap between human 2D cancer cell lines and animal-based models. Lastly, metabolomics analysis and 3D cell assays of colon organoids/tumoroids will provide valuable new insights into the mechanisms by which nutrient-gene interaction influences colon stem cell niche and CRC, and will open up new possibilities for CRC understanding and prevention.

Conclusions

TRIANGLE will provide novel insights towards CRC prevention by (1) using a new in vitro model based on colon organoids, (2) considering both gut microbiota composition and microbial metabolites, and (3) applying novel techniques. By implementing this, colon organoids will clearly mimic human real-life scenario. Secondly, the manner how polyphenols are affected by microbiotas will reveal the type and quantity of polyphenol metabolites, which could be correlated to the chemoprevention of CRC.

Novel Aspect:

Metabolomics will provide a holistic signature in organoids and, together with organoid assay data can generate new hypotheses regarding underlying the mechanisms by which polyphenol-gene interaction influences CRC.

Indolome analysis for nutraceutical and physiological studies.

Keywords: isotope dilution, liquid chromatography, melatonin, tandem mass spectrometry, tryptophan ethyl ester

Introduction: Biotransformation products of tryptophan are gaining an increasing multi-faceted interest as nutritional supplements to cope with environmental and lifestyle related stressors. Their identification and measurement in nutritional and biological matrices mandates for flexible, yet accurate and precise analytical methods based on mass spectrometry and adapted to studies with stable isotopic labels. Fragmentation studies are necessary to fulfil this aim.

Methods: An API3000LTQ LC-MS system is used for extensive tandem MS fragmentation studies on 3tryptophan amino-acids, 4 tryptamines and 3 N-acetyl-tryptamines. A stable-isotope analogue of melatonin is custom synthesized. LC separation and quantification parameters are optimized for the detection by MRM of 8analytes and 3 internal standards in four different biological and food matrices.

Results: Spectroscopic studies highlight key fragmentation pathways for the identification and measurement of 8 target analytes. The study of the fragmentation pattern[1] allowed designing and synthesizing[2] an under-considered isotope-labelled form of melatonin [3],to improve quantification by ID-MS-MS, with respect to previously employed isotopologues. Furthermore, the discrimination of the critical pair of isobaric melatonin and isomeric tryptophan ethyl ester, that also yield very similar fragmentation, could be accomplished with a scan function that addresses a triplet of consecutive fragments, only a pair of which are specific for each compound. With this method, the levels of melatonin and of its metabolic pathway are measured in human fluids fromseveral unique conditions, as well as from nutraceutical and pharmaceutical formulations and food matrices.

Conclusions Accurate fragmentation studies of biological indole compounds supply information to design a new internal standard for isotope dilution measurement of melatonin, and identification and quantification methods suitable for the measurement of the indolome in different natural matrices of interest for biological and technological applications.

Novel Aspect: An innovative internal standard to measure melatonin by ID-MS-MS and a method to discriminate isomers and isobars of melatonin are proposed.

International Agency for Research on Cancer (IARC), Biomarkers Group, Nutrition and Metabolism Section, Lyon, France (1)

Keywords: Exposome, biomarkers, metabolomics, diet, cancer risk

The exposome, defined as all exposures to which an individual is subjected along life course, involves chemicals or metabolites that can be directly measured in biospecimens such as blood or urine. Hundreds of these chemicals or metabolites, derived from diet, drugs, pollutants and other environmental factors, can affect health and risk of diseases. High-resolution mass spectrometry (MS) techniques, combined with biostatistics and bioinformatics in metabolomic studies, are increasingly used to measure these chemicals and metabolites, in order to discover new biomarkers of exposure or new risk factors for diseases in exposome-wide association studies. These MS techniques are particularly adapted to the measurement of a large diversity of biomarkers of exposure and to assess complex exposures such as diet. Each food is indeed characterized by a specific chemical profile, with compounds often specific for a particular food or food group that are eventually absorbed during digestion. These compounds found in the systemic circulation constitute the 'food exposome'. Examples will be presented on the identification of novel biomarkers of food intake in dietary intervention and cross-sectional epidemiological studies and on the study of their associations with cancers in recent case-control studies nested in large cohort studies, thus providing new evidence on the role of the diet in disease risk. The same metabolomic studies also provide new data on associations between exposures and the host metabolism shedding new light on mechanisms linking exposures to diseases as will be illustrated for diet, air pollution, overweight or birth weight.

Development of these studies also faces a number of challenges. These include a more comprehensive annotation of the exposome, the measurement of components of the exposome present at low concentrations, the development of quantitative, high throughput and robust methods (targeted metabolomics) for large epidemiological studies. Recent progress in this rapidly moving field will be presented. It should contribute to the identification of novel disease risk factors and to the improvement of our understanding of disease aetiology.

607 - RAPID ANALYSIS OF NCI60 PANEL METABOLIC AND LIPID PROFILES WITH AN AUTOMATIC WELL PLATE READER USING LASER ASSISTED REIMS

Waters Research Center, R&D, Budapest (1) - MTA-TTK, Research Centre for Natural Sciences, Budapest (2) - Waters Corporation, R&D, Wilmslow (3) - Imperial College London, South Kensington Campus, London (4)

Keywords: Cell line, metabolic profile, REIMS

Introduction:

In this study, we present an automated, fast and effective way to identify different cell cultures based on their metabolic profile using laser assisted rapid evaporative ionization mass spectrometry (REIMS [1]). The aim of this study was to create an integrated workflow for the automatic analysis of cell line samples from well plates, and the building of a NCI60 cell line database based on the metabolic and lipid fingerprints of the samples.

Methods:

The technology is based on the direct analysis of aerosol generated by a laser sampling device through thermal ablation of the samples. OPOTEK Opolette IR 532 tunable laser was combined with 3 stages (Thorlab NRT) for 3 dimensional sample movements. This stage prototype was coupled to a XEVO G2-XS QTOF MS and used on a number of different liquid and dried cell line samples from the NCI60 lines. Different multivariate statistical models were used to characterize cell lines.

Results:

A total of 30 different cell lines were analyzed in both dried and liquid form in the mass-to-charge range of 50-2000. Number of parameters such as sample format (dried and liquid in different solvent, cell number per well), laser parameters (wavelength, pulse energy, frequency) and sampling methods (e.g.: aerosol intake) were optimized. The results showed that best signal was achieved with 2900 nm, 20Hz and a minimum of 3mJ energy was applied on 1 Million cells / well. As the acquired mass spectra featured partly different species in liquid form compared to the dried samples, thus a different database was built for the two sample format after lock mass correction, background subtraction and normalization. Testing different classification models created with numerous artificial intelligence algorithms (Support Vector Machines, Neural Networks, Random Forests and Principal Component Analysis followed by Linear Discriminant Analysis) showed us a > 98.0% correct classification rate based on phospholipids, plasmalogens and sphingolipids.

Conclusions:

The results demonstrate that our technology was capable of a rapid, fully automatic LA-REIMS based well plate reading and identification of different cancer cell lines. This method is suitable to analyze lipid and metabolic compounds of different cell lines. Our future plan is to finish the analysis of all cell lines within the NCI60 panel, and to identify the effect of perturbation of cell culturing environment on the metabolic and lipid profile of the cells.

Novel Aspect:

Automated high throughput well plate analysis of NCI60 cell line metabolic fingerprint by OPO laser based ambient MS technique.

Keywords: metabolomics, QTRAP®, microLC, dried blood spot, polar metabolites

Introduction:

LC-MS/MS is an essential tool for identification and quantitation of metabolites in complex samples to investigate the affected metabolic pathways in dietary assessment studies and precision medicine. Self-testing is on the rise as people are interested in monitoring their health. Here, we have analyzed dried blood spots (DBS) with microflow LC coupled to QTRAP® 6500+ system for a wellness study and monitored polar metabolites covering all major metabolic pathways.

Methods:

Metabolite extracts from a 6-mm dry blood spot disk at three metabolic states; fasted, fed and active were analyzed in 5 replicates on a M3 MicroLC system with HILIC separation at pH9 using Luna- NH2 columns (Phenomenex). MRM analysis performed in positive/negative polarity on a QTRAP® 6500+ system with IonDrive™ Turbo V source. 187 positive and 176 negative ion mode MRM's were combined into a single experiment to monitor polar metabolites across metabolic pathways.

Results:

A total of 312 polar metabolites were monitored for this wellness study across the three metabolic states (fasted, fed and active). The PCA analysis of these groups in MarkerView™ Software clearly shows that these three groups are differentiated based on their metabolic profile. It is known that during exercise protein degradation occurs, releasing amino acids (AA) into the body including Tyr which is released from human skeletal muscle in the presence of insulin hence we observed the spike in Tyr concentrations in the samples after cycling activity was completed. This release of AAs from protein breakdown also releases branched chain AAs such as Ile and Leu, which are differentiating the active group. Technical replicate analyses of the DBS extracts shows there is insignificant variation between sampling which does not interfere with ability to differentiate these metabolic conditions. The method provides accuracy and precision across each of the different DBS extracts. DBS is a minimally invasive way of collecting blood samples with low cost.

Conclusions:

The microflow targeted metabolomics analysis of DBS shows to be a rapid, sensitive, and accurate method for profiling polar metabolites in a variety of biofluids and could be utilized for monitoring these targeted polar metabolites in other wellness-based studies as the method successfully differentiated these three different conditions we monitored during this wellness study.

Novel Aspect: A sensitive microflow targeted metabolomics method allowing detection of over 300 polar metabolites across multiple biochemical pathways for studying wellness.

256 - FECAL METABOLOMICS OF A MOUSE MODEL OF AUTISM

Emily Sekera (1) - Troy Wood (1) - Heather Rudolph (1) - Stephen Carro (1)

University at Buffalo, Department of Chemistry, Buffalo (1)

Fecal Metabolomics of a Mouse Model of Autism

Keywords: Metabolomics, MALDI, autism, biomarkers, FT-ICR

Introduction: (Limit of 400 characters)

Autism spectrum disorders (ASD) are a group of neurodevelopmental disorders lacking a clinical biomarker for diagnosis. In preliminary studies from our group, it was observed that the level of stercobilin, a metabolite produced in heme catabolism, is depleted in the fecal material of an animal model of autism. Here, we discuss creating an isotopologue standard for quantitation by MALDI FT-ICR MS.

Methods: (Limit of 400 characters)

Utilizing labelled stercobilin synthesized by adding 18-O water to our standard and heating it at 70°C for several hours, it is possible to create an isotopologue to quantify stercobilin levels. Fecal samples are chosen in pairs between the ASD model group and gender-matched controls. Stercobilin is then extracted and prepared for MS analysis. Analysis is completed by MALDI FT-ICR MS (n=5).

Results: (Limit 900 characters)

Although the initial 18-O isotopologue of stercobilin used was shown to be stable through 20 days of storage, back labelling was observed for longer storage. By incubating the sample a second time under the same conditions, labelling efficiency of stercobilin was comparable but more labelling was observed at the labile sites with a lower amount of unlabeled material. Once a new batch of isotopologue was prepared, a new calibration curve was generated to quantify stercobilin within the fecal samples. It is from this work that an observed depletion of stercobilin was observed in the fecal material in a mouse model of ASD. An average depletion of 45% has been observed with a p-value of less than 0.001 (n=14). A less dramatic depletion was also observed with stercobilinogen; more samples will need to be analyzed to determine the statistical significance of the results.

Conclusions (Limit of 400 characters)

The 45% depletion of stercobilin in the fecal material of an ASD mouse model relative to controls at a greater than 99% confidence level suggests that depletion of fecal stercobilin may serve as a potential ASD biomarker in humans. While less statistically significant, it appears that stercobilinogen, the precursor to stercobilin, is also depleted in the fecal samples of ASD mouse models.

Novel Aspect: (Limit of 150 characters)

Quantitative analysis of stercobilin, a putative autism biomarker, in mouse excrement utilizing isotopologue standards and MALDI FT-ICR MS.

965 - URINARY METABOLIC PROFILE OF NEWBORNS WITH TRANSPOSITION OF GREAT ARTERIES UNDERGOING CARDIAC SURGERY WITH CARDIOPULMONARY BYPASS

Manuela Simonato (1) - Luca Vedovelli (1) - Massimo Padalino (2) - Giovanni Stellin (2) - Stefania Carollo (3) - Andrea Bandini (3) - Virgilio Carnielli (4) - Paola Cogo (5)

Istituto di Ricerca Pediatrica "Città della Speranza", PCare Laboratory, Padova (1) - Padova University Hospital, Pediatric and Congenital Cardiac Surgery Unit, Department of Cardiac, Thoracic and Vascular Sciences, Padova (2) - Padova University Hospital, Department of Medicine DIMED, Anesthesia and Resuscitation Institute, Padova (3) - Polytechnic University of Marche and Azienda Ospedaliero-Universitaria Ospedali Riuniti, Division of Neonatology, Department of Clinical Sciences, Ancona (4) - University of Udine, Department of Medicine, Udine (5)

Keywords: transposition of great arteries; cardiopulmonary bypass; untargeted metabolomics; newborns

Introduction:

Complete transposition of the great arteries (TGA) is a common cyanotic congenital heart defect. Surgical correction, with the use of cardiopulmonary bypass (CPB), should be performed within the first month of life. CPB-assisted open heart surgery results in brain hypoperfusion and in a powerful systemic inflammatory response and oxidative stress [1,2].

Methods:

Thirteen TGA newborns undergoing arterial switch operation with the use of CPB were recruited. Urine samples were collected before and after CPB and were analyzed using an untargeted metabolomic approach based on UHPLC-high resolution mass spectrometry.

Results:

Since the post CPB metabolic spectra could be heavily "contaminated" by metabolites derived from administered drugs, we have constructed a library with drugs used during surgery and the relative metabolites retrieved from urine samples. This library was applied to our samples and a total of 2163 drug metabolites were correctly identified and excluded from the analysis. Afterward we detected over 14000 unique features in urine and 67 metabolites were significantly differentially abundant between pre and post CPB samples ($p < 0.02$; $FDR < 0.10$). Multivariate PCA classification model was established to differentiate between pre and post CPB urine samples.

Conclusions:

This is the first report on the metabolic response to cardiac surgery in TGA newborns. Using UHPLC-high resolution mass spectrometry we identified metabolites whose concentrations appeared to be associated with clinical outcome. Metabolic profiling could be useful for patient stratification and directing investigations of clinical interventions.

Novel Aspect:

We developed a high coverage metabolomic approach that has potential for biomarker discovery in CPB related damage.

788 - VOLATILOME ANALYSIS FOR PARKINSON'S DISEASE DIAGNOSTICS

Eleanor Sinclair (1) - Drupad Trivedi (1) - Yun Xu (1) - Camilla Liscio (2) - Phine Banks (2) - Joy Milne (1) - Monty Silverdale (3) - Tilo Kunath (4) - Royston Goodacre (1) - Perdita Barran (5)

University of Manchester, Chemistry, Manchester (1) - Anatune, Analytical Chemistry, Cambridge (2) - University of Manchester, Neurology, Manchester (3) - University of Edinburgh, Biological Sciences, Edinburgh (4) - University of Manchester, Chemistry, Manchester (5)

Keywords: Parkinson's disease, biomarker, sebum, volatilome, super-smeller

Introduction:

Parkinson's disease (PD) is the 2nd most common age-related neurodegenerative disorder. The onset of symptoms such as tremor, slowed movements and muscle rigidity do not present in the early stages; however do form the basis of clinical diagnosis [1]. This often results in late diagnosis and treatment, highlighting an urgent need to identify a biomarker. Evidence from a super-smeller has shown there is a characteristic odour released from the skin of PD sufferers [2].

Methods:

Sebum was collected non-invasively using gauze swabs from the upper back of 63 participants; 20 control subjects and 43 PD patients. Dynamic headspace was measured directly from swabs using thermal desorption-gas chromatography-mass spectrometry (TD-GC-MS). For three samples the instrument was interfaced with an odour-port allowing our super-smeller to highlight regions of interest within the GC chromatogram.

Results:

Headspace analysis was performed in two groups; firstly a discovery cohort consisting of 30 subjects was used to build a classification model in which metabolites of interest were identified. Partial least squares discriminant analysis was performed and validated with 5-fold cross validation alongside 26 permutation tests. The variables ($n=17$) which contributed to classification were selected using variable importance in projections (VIP) scores, where $VIP > 1$. The volatile components of the second group, a validation cohort of 30 different subjects, were targeted for the presence or absence of these identified biomarkers. Out of 17 metabolites, 9 were found within the validation dataset and subsequent statistical testing was performed. Further to this, regions of interest were identified by superimposing olfactogram data with the corresponding TD-GC-MS chromatograms. A 2 minute window associated with a strong PD-like scent in all 3 samples correlated to the elution time of 3 differentially expressed volatiles identified in both cohorts.

Conclusions:

We demonstrate there is a characteristic volatile profile associated with the scent of Parkinson's disease. Several potential volatile biomarkers have been found to be statistically significant in the differentiation between disease and non-disease subjects and also associated to the PD-scent detected by a super-smeller.

Novel Aspect:

A non-invasive method of sampling has enabled volatilome analysis of sebum produced from the skin of Parkinson's disease sufferers and produced a panel of putative biomarkers.

1309 - UNTARGETED METABOLOMICS OF NATIVE TASMANIAN PLANTS: COMPARISON WITH THEIR MEDICINALLY-KNOWN RELATIVES

Karolina Skraskova (1) - Richard Wilson (1) - Jason Smith (1)

University of Tasmania, School of Chemistry, Hobart, Australia (1)

Keywords: High resolution mass spectrometry, Liquid chromatography, Multivariate statistics, Plant analysis, Chemical map

Introduction:

Scientific knowledge of chemistry and medicinal properties of native Australian flora is sparse and only occasionally applied in practice. This is especially valid for Tasmania where the information on the Aboriginal use of herbal medicine was poorly documented. This project compares the chemistry of selected native Tasmanian plants (NTP) and their taxonomical medicinal "relatives" as a first step towards a chemical map of Tasmanian flora.

Methods:

Seven plants from three genera were included in this study. Each genus was represented by one (or two) NTP species and one non-native species. Extracts of plants were prepared using ultrasound aided extraction and subsequently analyzed by UHPLC coupled to an LTQ-Orbitrap. High resolution LCMS data were mined using multivariate statistics and targeted metabolomics approaches to compare chemical differences / similarities between the plants from the same genera.

Results:

Principal component analysis and agglomerative hierarchical clustering helped to visualize the chemical relations between the different plants. Interestingly, all native/non-native plant pairs (from the same genera) showed a high degree of chemical similarity. The greatest similarity was detected between the two *Epilobium* spp. By searching for compounds previously detected in their non-native counterparts, targeted data mining provided insight into the chemistry of the native plants. We determined, for example, that both *Epilobium* spp. were rich in polyphenolic compounds. Some of these compounds were previously found to have neuroprotective, anti-inflammatory, antioxidant, anti-proliferative, and other pharmacological properties [1]. This finding suggests that native Tasmanian *Epilobium* species may hold promise for medicinal uses.

Conclusions:

We demonstrate that high resolution LC-MS combined with multivariate statistics is a powerful analytical approach to explore the chemistry of previously unmapped plant species. This is the first comparative study of native Tasmanian & non-native medicinal plants from the same genera.

Novel Aspect:

Novel experimental design and analytical approach based on ultrasonic extraction, UHPLC & HRMS was used to create a proof-of-concept chemical map of native Tasmanian plants.

717 - DETECTION OF METABOLIC SIGNATURES OF CROHN'S DISEASE USING AN INTELLIGENT MSN-BASED DISCOVERY WORKFLOW

Ioanna Ntai (1) - Amanda Souza (1) - Ralf Tautenhahn (1) - Gina Tan (1) - Andreas Huhmer (1)

Thermo Fisher Scientific, Chromatography and Mass Spectrometry, San Jose (1)

Keywords: Crohn's disease, untargeted, metabolomics, biomarker, identification

Introduction: (396/400 characters without spaces)

Crohn's disease is a chronic inflammation of the gastrointestinal tract where the etiology remains largely unknown. LC-MS profiling of serum metabolites has become a powerful tool for biomarker detection. Here, an untargeted metabolomics approach using high resolution accurate mass (HRAM) Orbitrap™ technology with dynamic acquisition for automatic data dependent MS/MS and multistage fragmentation was used to analyze serum from healthy and disease donors.

Methods: (399/400 characters without spaces)

Metabolites were extracted using cold methanol from 18 serum samples consisting of healthy donors and disease donors with or without infliximab treatment. Supernatant was dried and re-suspended in acidified water and separated with a C18 column. Samples were analyzed by an Orbitrap Tribrid™ mass spectrometer with modified acquisition software. Differential analysis and compound annotation were applied using Thermo Scientific™ Compound Discoverer™ software.

Results: (892/900 characters without spaces)

In this study, we explored the use of an intelligent LC-MSn untargeted metabolomics workflow for the identification of potential discriminant markers of Crohn's disease. We analyzed serum samples from three different populations.

Accurate m/z measurements determined molecular formula and putative annotation of thousands of metabolites by searching against ChemSpider. To increase annotation confidence, MS/MS data was searched against the mzCloud library. Multistage fragmentation (MSn) enabled structural elucidation of unknowns. The modified instrument control software automated inter-run inclusion and exclusion lists, facilitating MSn acquisition for more unique metabolites.

Differential analysis detected metabolite perturbations in the urea cycle and catabolism of amino acids in serum from disease donors when compared to that of healthy donors; these metabolic changes are often associated with inflammation. Some of those inflammation driven changes were minimized when disease donors were treated with infliximab.

Conclusions (359/400 characters without spaces)

The combination of an untargeted metabolomics profiling approach with intelligent high resolution MSn acquisition described here, addresses the identification bottleneck in untargeted metabolomics. This strategy presents a

promising and facile workflow for the discovery and identification of novel disease biomarkers that could lead to further biochemical insights in disease progression and treatment outcome.

Novel Aspect: (146/150 characters without spaces)

Combination of HRAM Orbitrap technology with automated MSn acquisition strategy for untargeted metabolomics enables detection of Crohn's disease metabolic signature.

652 - MONOAMINE MAPPING BY MASS SPECTROMETRY IDENTIFIED BRAIN NUCLEI REGULATING ANXIETY IN A SEROTONIN DEFICIENCY MODEL

Yuki Sugiura (1) - Eiji Sugiuyama (1)

Keio University, School of Medicine, Tokyo (1)

Keywords: Imaging MS, on tissue derivatization, neuroscience, monoamines

Introduction:

In the brain, monoamines, dopamine (DA), norepinephrine (NE), and serotonin (5-hydroxytryptamine, 5-HT), act as neuromodulators, diffusing from the nuclei to affect slow-acting receptors of many neurons. Levels of monoamines are important not only for cognitive functions, including memory and learning, but also mood, appetite, and sleep. However, the relationship between actual monoamines' concentrations within the nuclei and behavioral output remains unclear. Here, utilizing imaging mass spectrometry (IMS), we generate a 3-dimensional mouse whole brain atlas of serotonin (5HT), dopamine (DA) and norepinephrine (NE), consisted of 30 coronal slice images.

Methods:

After euthanasia, the mice brains were isolated, immediately frozen and sliced into 8µm sections. 5HTd4 solution was sprayed on them as an internal standard with an automated sprayer(SunCollect). To perform on-tissue derivatization of monoamines, DPP solution and then DHB solution were manually sprayed. Imaging were performed by a MALDI-FT-ICR MS (Bruker Daltonics). Three dimensional images was constructed using SCiLS lab software.

Results:

Using the atlas, we unexpectedly found several brain nuclei co-contain 5HT and a catecholamine (DA or NE) at high levels; among these, paraventricular nucleus of the thalamus (PVT) was 2nd 5HT rich nuclei in the brain. This novel observation suggests that 5HTergic system was integrated into catecholaminergic system by sharing several major nuclei.

Moreover, we attempted to reveal which 5HT-rich nuclei regulates mice behavior. Here, we used acute tryptophan deficient model (ATD) which exhibits decreased total brain 5HT followed by anxiety behavior. By generating and comparing two 3D monoamine-atlas of control and ATD-model brains, we successfully visualized specific reduction of 5-HT in PVT, which correlates anxiety-like behavior.

Furthermore, we show that the abnormal behavior and brain 5HT level were recovered by injecting [¹³C][¹⁵N]Trp into the ATD model. By visualizing [¹³C][¹⁵N]Trp conversion into [¹³C][¹⁵N]5HT, it is demonstrated that several brain nuclei including PVT have surprisingly high turnover of de novo 5-HT synthesis.

Conclusions:

These results proved usefulness of brain-monoamine mapping by imaging MS to study relationship between monoamine concentrations within small brain nuclei and animal behavior.

Novel Aspect:

3D brain atlas of monoamines created by imaging MS was utilized to study relationship between monoamine concentrations and animal behavior.

397 - CONSTRUCTION AND APPLICATION OF A HIGH-RESOLUTION MS/MS LIBRARY INCLUDING RETENTION TIME INFORMATION FOR RAPID IDENTIFICATION OF ENDOGENOUS METABOLITES

Matthias Szesny (1) - Shuang Zhao (2) - Xian Luo (2) - Wan Chan (2) - Ulrike Schweiger-Hufnagel (1) - Aiko Barsch (1) - Liang Li (2)

Bruker Daltonik GmbH, Metabolomics, Bremen (1) - University of Alberta, Department of Chemistry, Edmonton (2)

Keywords: HMDB; metabolite identification; QTOF-MS; MS/MS library; RT correction

Introduction:

High-resolution LC-MS is an important platform for metabolite detection and quantitation. However, for untargeted Metabolomics rapid, unambiguous and universal compound identification is still challenging. In this work, we report the construction of a library for relevant endogenous metabolite and its' successful application to human biofluids.

Methods:

Standards were obtained from the Human Metabolome Database (HMDB). They were injected into an Intensity Solo C18 column via an Elute LC system and detected by a QTOF-MS (impact QTOF, all Bruker Daltonics) for acquiring MS/MS library spectra and the retention time determination (RT). For the analysis of biofluids the same setup was used following a standard operating protocol (SOP) for consistency.

Results:

In this study a library from over 800 endogenous metabolites was created. It contains MS/MS spectra of 635 compounds acquired in positive mode and 474 negative mode spectra. Up to 5 collision energy levels were applied for each standard giving more than 6000 MS/MS spectra in total. For each metabolite, library fragment spectra were manually curated by confirming each fragment via a molecular formula. For unambiguous identification we determined the RT of each standard. Automatic metabolite identification was performed in the MetaboScape software based on matching of multiple parameters: precursor mass accuracy and isotopic pattern, RT, and MS/MS spectrum quality.

Conclusions

The established SOP and library was applied analyze to biofluids, e.g. plasma and urine, and metabolite identification results will be presented. Finally, we have examined the portability of this library for different instrumental conditions and for different labs.

Novel Aspect:

Development of a high-confidence and rapid metabolite identification method by combining a high-resolution MS/MS library and RT information.

1350 - HYDROPHILIC INTERACTION LIQUID CHROMATOGRAPHY – FIELD ASYMMETRIC WAVEFORM ION MOBILITY SPECTROMETRY – MASS SPECTROMETRY AS A PLATFORM FOR UNTARGETED METABOLOMIC STUDIES

Katarzyna Szykula (1) - Matthew Turner (1) - Colin Creaser (1) - James Reynolds (1)

Centre for Analytical Science, Department of Chemistry, Loughborough University, Loughborough, United Kingdom (1)

Keywords: Liquid chromatography mass spectrometry, field asymmetric waveform ion mobility spectrometry, untargeted metabolomics

Introduction: (Limit of 400 characters without spaces)

The challenge of metabolic profiling requires the use of analytical platforms that maximize the peak capacity. Previous studies have shown that the hyphenation of highly orthogonal methods such as hydrophilic interaction liquid chromatography (HILIC) with field asymmetric waveform ion mobility spectrometry (FAIMS) and mass spectrometry (MS) increased the number of peaks detected [1,2].

Methods:

The developed workflow included one-step sample preparation by protein precipitation with acetonitrile which was followed by a 13 minutes chromatographic run on a HILIC column. The elute from the column was ionized by positive ion ESI and separated by FAIMS with the compensation field (CF) scanned from -0.5 to 3.5 Td (DF 240 Td) in 1 second at an MS scan rate of 20 scans per second, resulting in the acquisition of 19 MS across each CF scan, with one scan for re-initialization.

Results:

The described workflow was applied to the analysis of fresh and aged (72 hours) urine samples. The method has shown good reproducibility for LC retention times (%RSD 0.13-0.87) and peak areas (%RSD 4.46-11.31). Principal component analysis (PCA) demonstrated a clear separation of fresh and aged urine at different CFs. Several biomarkers (up- and down-regulated) were found and identified for aging of urine by the presented method. The highest change in abundance was observed for m/z 121.072 (urea dimer) which increased in concentration with the age of the sample.

Conclusions

The combination of HILIC with fast scanning FAIMS and MS was applied to the analysis of urine samples. This rapid method including a simple sample preparation shows the potential for untargeted metabolomics and biomarker discovery.

Novel Aspect:

For the first time, the hyphenation of FAIMS with LC-MS was applied to untargeted metabolomic studies of urine samples.

1 NUS Graduate School for Integrative Sciences and Engineering, National University of Singapore, Singapore

2 Cardiovascular Research Institute, National University Health System, Singapore

3 Translational Laboratory in Genetic Medicine, Agency for Science, Technology and Research, Singapore

4 Department of Surgery, Yong Loo Lin School of Medicine, National University of Singapore, Singapore

Introduction

Plasma samples are commonly used for biomarker screening by LC-MS. However, pre-analytical variability in processing blood can lead to spurious results [1]. Our previous experience with thymosin beta-4 as biomarker interest us in the problem of residual platelets in plasma [2]. Proteomics-based markers however may not be conveniently incorporated into a metabolomics-only workflow, hence a panel of metabolic markers for sample quality control is ideal.

Methods

Alipidomic-focused screen for markers that is consistently higher in platelet rich compared to platelet poor plasma was conducted. Plasma was extracted using a single-phase method [3], then analyzed on a UPLC-QTOF system. Lipid identification and shortlisting was done using Lipid Data Analyzer 2.6.2 (LDA) [4].

A systematic literature search was also conducted to identify other reported pre-analytical sample quality issues and markers proposed for them.

Results

Molecular features 774.54 m/z and 746.51 m/z are the most consistently elevated in platelet rich plasma compared to platelet poor plasma. Base on tandem ms spectrum matching on LDA, these had been tentatively identified as plasmalogen phosphatidylethanolamine (P-PE) 36:4 and P-PE 38:4 respectively. Further validation are underway.

Common sample quality issues identified in the literature are: inappropriate use/non-use of anticoagulant, pre-centrifugation time delay, freeze-thaw cycles, hemolysis, sample handling, and sample storage. Markers for markers pre-centrifugation delays are the best studied: Sphingadienine-1-phosphate [5], ornithine/arginine ratio [6], ascorbic acid/lactic acid [7], cytokine levels [8], gamma-glutamyl-transferase and lactate dehydrogenase [9] have been proposed as markers. Gamma-glutamyl-transferase and lactate dehydrogenase [7] also marks for excessive freeze-thaw cycles. Hemolysis can be detected by hemoglobin or discoloration.

Conclusions

P-PE 36:4 and P-PE 38:4 are candidate markers for residual platelets in plasma samples. Because P-PE is a major constituent of cell membrane, we suspect it may be "housekeeping" in platelet membrane. We intend to further characterize whether these markers can normalize for residual platelet content in plasma. Through validating the existing plasma quality markers in the literature, we hope to put together a robust LC-MS panel for assessing plasma sample quality.

Novel Aspect:

Standardized protocols can reduce variability, however compliance may be infeasible. A LC-MS panel for plasma quality check would be transformative for biomarker screening.

502 - REVEALING THE HIDDEN PART OF BACTERIAL METABOLISM

Marion THOMAS (1) - Ekaterina DAIRII (2) - Pierre Loïc SAAIDI (3) - Alain PERRET (4) - Marcel SALANOUBAT (3)

CEA - Genoscope, 2, Rue Gaston Crémieux, Evry (1) - CEA - GENOSCOPE, Université Paris Saclay, Evry (2) - CEA - Genoscope, Université Paris Saclay, Evry (3) - CEA-Genoscope, Université Paris Saclay, Evry (4)

Keywords: Structural elucidation, metabolism, Mass Spectrometry, Nuclear Magnetic Resonance

Introduction:

We studied the metabolic adaptation of the bacterium *Acinetobacter baylyi* ADP1 (ADP1) after a biotic stress that consisted in shifting the carbon source from succinate to quinate (1). Quinate metabolism in ADP1 has been investigated for decades (2). Yet, we spotted unexpected and unknown metabolites in quinate-grown cells(1). These orphan metabolites (OM) may participate in new pathways and represent entry points into the dark part of bacterial metabolism.

Methods:

100 µg of a first metabolite of $m/z = 211$ (M211) was purified by preparative HPLC and its structure was analyzed by NMR. The interpretation of the ¹H, COZY, HSQC-HMBC (¹H-¹³C), ROESY, ¹³C and ¹H-¹⁵N spectra, recorded on a 600 Hz NMR fitted with a cryoprobe.

Results:

NMR analyses led us to conclude that the molecule was a (3-aminopropyl)-amine-hydroxybenzoic acid. Because of the small quantity of purified material, NMR data acquired did not allow us to unambiguously conclude on the position of the alcohol and carboxylic acid groups on the benzene ring of the molecule. To overcome this uncertainty, the compounds corresponding to the different six possible structures were chemically synthesized (Synthenova.com). Comparison of the NMR signal on one hand and high resolution (LTQ-Orbitrap Elite) LC/MS/MS data on the other hand between the purified metabolite and the reference standards led us to assign the structure of the compound of interest as 3 (3-aminopropyl) amine 4-hydroxybenzoic acid. This is a previously undescribed compound that is missing from all interviewed databases.

Conclusions

The identification of a second metabolite (M193) is under way. These structural elucidations are a first step in deciphering pathways that take place during quinate metabolism. We would next identify genes involved in their synthesis. We are using the complete library of deletion mutants of ADP1 (3) for determining their molecular phenotype (2600 metabolomes) and seek mutants in which OM are absent. In such mutants, the deleted genes thus participate in MO synthesis.

Novel Aspect:

We solved the structure of a novel metabolite and investigate the genes involved in its biosynthesis for deciphering previously unreported metabolic pathways.

852 - ASSESSMENT OF THE THS EXPOSITION IN ANIMAL MODELS BY MULTIPLATFORM METABOLOMICS ANALYSIS

Sonia Torres (1) - Sara Samino (1) - Pere Rafols (1) - Neema Adhami (2) - Manuela Martins-Greens (2) - Xavier Correig (3) - Noelia Ramirez (4)

Rovira y Virgili University, Department of Electronic, Electrical and Automatic Control Engineering, Tarragona (1) - University of California, Department of Cell Biology and Neuroscience, Riverside (2) - Spanish Biomedical Research Centre in Diabetes and Associated Metabolic Disorders, Rovira y Virgili University, Barcelona (3) - IISPV, Rovira y Virgili University, Tarragona (4)

Keywords: LC/MS-based metabolomics, NMR-based metabolomics, MS imaging, multiplatform metabolomics, thirdhand smoke exposure

Introduction:

Thirdhand tobacco smoke (THS) is a novel and poorly understood pathway of tobacco exposure produced by the accumulation of secondhand smoke (SHS) on environmental surfaces that ages with time, becoming progressively more toxic[1]. Although the emerging evidence of THS harm, the molecular mechanisms of THS exposure are still unclear. Here, we present a multiplatform metabolomics approach for the characterization of metabolic disorders in liver of mice exposed to THS.

Methods:

C57BL/6 mice were exposed for 24 weeks to THS, under conditions that mimic exposure of humans in homes of smokers. Aqueous and lipid liver extracts were analyzed by ¹H NMR and UHPLC-MS. AMIX and Chenomix programs were used to process NMR data and XCMS to LC-MS. Statistics and pathway enrichment were performed using the Metaboanalyst platform tools. Mass spectrometry images of liver were acquired by laser desorption-ionization MS, and processed with MSI software[2].

Results:

Analysis of the lipid extracts by NMR confirmed that THS exposure increases the levels of triglycerides, polyunsaturated and monounsaturated fatty acids, which can lead to the development of fatty liver disease, as previously described[3]. UHPLC-MS analysis of the extracts allowed the identification of more than 30 triglycerides and 10 phosphocholines elevated in liver of THS-exposed mice. MS images showed lipid accumulation and increased lipid droplets due to THS-exposure. Statistically relevant ions in the images were further identified as 14 triglycerides. Untargeted metabolomics analysis of the aqueous extracts allowed the identification of 48 statistically significant metabolites. Pathways analysis showed that 19 of these metabolites are involved in the glutamate, glutathione and nicotine/nicotinamide metabolism pathways, which are related to nucleic acid and protein synthesis among others[4],[5],[6]. Furthermore, the dysregulation of these pathways confirms the oxidative stress nature of THS exposure health effects[7]

Conclusions:

The combination of three different analytical platforms allowed the identification of more than 80 metabolites relevant for the health assessment of THS exposure. NMR provided reliable identifications and quantifications and UHPLC-MS was key for the identification of many dysregulated metabolites and the identification of lipids,

whereas MSI allowed us to enrich the biological interpretation by the mapping of lipids in control and THS-exposed livers.

Novel Aspect:

First metabolomics characterization of dysregulations in liver from THS-exposed mice, by MS and NMR multiplatform approach, including extracts analysis and tissue MS images.

56 - SIMULTANEOUS QUANTITATIVE ANALYSIS METHOD FOR HYDROXYPROLINE AND 4-HYDROXYGLUTAMIC ACID USING ISOTOPOLOGUE-SRM TO CLARIFY HYDROXYPROLINE METABOLISM.

Makoto Tsuji (1)

Daiichisankyo RD Novare Co., Ltd., Pharmaceutical and Biomedical Analysis, Tokyo (1)

Keywords: 4-Hydroxyglutamic acid, HILIC, isotopologue-SRM, Hydroxyproline metabolism

Introduction:

The main component of kidney stones is calcium oxalate. Oxalic acid is synthesized from hydroxyproline (HP) in vivo in addition to those from diet. We examined intermediate metabolites on HP metabolic pathway to clarify HP metabolism. 4-hydroxyglutamic acid (4HG) was found to be a marker of HP metabolism, and an simultaneous analysis method for HP and 4HG was established.

Methods:

Culture media were acidified and deproteinized with acetonitrile and then centrifuged. The supernatant were injected into LC-MS/MS operated in ESI-positive mode. Chromatographic separation was achieved with Acquity BEH Amide column. HP and 4HG were quantified using 2H3-HP and 2H3-Lys as internal standards.

Results:

Chromatographic separation of HP from other amino acids such as Met, Leu, Ile and Asp was achieved. The range of calibration for HP and 4HG were from 0.5 to 1000 microM and from 0.05 to 100 microM, respectively. Isotopologue-SRM (iSRM)[1] enabled to quantitate HP and 4HG simultaneously improving the linearity of calibration. 4HG concentration was elevated after adding HP to culture medium of human hepatocytes.

Conclusions

Although 4HG analysis method with derivatization have already been reported[2], the developed method is highly sensitive in addition to excellent operability not requiring derivatization. This method is considered useful for the study of HP metabolism.

Novel Aspect:

Simultaneous quantitation of metabolite at lower concentration and substrate at higher concentration using iSRM.

Keywords: metabolomics, untargeted analysis, aspirin, urine profile

Introduction: Pharmacometabolomics aims to highlight metabolic signatures after drug exposure. Although the canonical cyclooxygenase-1-mediated effect of Acetylsalicylic acid (ASA) is well defined, a substantial variability in drug response exists and the mechanisms at the basis of this variability are still poorly understood [1-2]. Applying an untargeted metabolomics approach, we aimed to reveal novel information about biochemical pathways modified by ASA treatment.

Methods: In this study we have developed an untargeted liquid chromatography-mass spectrometry method to define the urine metabolic profile of healthy subjects (n=7) before and 7 days after 100 mg once-daily ASA treatment.

Results: Through this untargeted method, we detected 2007 features: among them, 64 metabolites significantly differed ($p < 0.05$) after ASA assumption. Pathway analysis, performed on identified metabolites, revealed low levels of those metabolites involved in histidine, alanine, aspartate and glutamate and purine metabolisms, after ASA treatment. In addition, we observed the decrease of several short- and medium-chain acylcarnitines.

Conclusions: The data here reported reveal unusual pathways affected by ASA treatment, in particular, the decrease in urine acylcarnitines levels indicates an increase in fatty acid β -oxidation process. This observation may suggest non-canonical use of ASA in clinical situations characterized by energy depletion.

Novel Aspect:

This study demonstrates the pivotal role of the untargeted metabolomics approach in exploring new clinical application of drugs.

720 - EVALUATION OF HIGH SPEED, HIGH RESOLUTION DATA INDEPENDENT ACQUISITION FOR THE ANALYSIS OF METABOLOMIC FLUX, KINETICS AND PATHWAY MAPPING

Zuzana Demianova (1) - Baljit K Ubhi (2) - Loren Olson (2) - Jean-Baptiste Vincendet (3)

SCIEX, Omics, darmstadt (1) - SCIEX, Omics, Redwood City (2) - SCIEX France (3)

Keywords: metabolomics, flux, SWATH, data independent acquisition, quantitation

Introduction:

Scientists across many disciplines are looking at metabolomics to answer challenging questions. Quantitative studies have focused on the steady-state metabolite levels where experimental variability can mask the true degree of metabolic regulation. Herein, we evaluate the merits of high resolution approaches to the measurement of the flux heavy isotopes in a metabolic pathway shows great potential to elucidate the regulation / kinetics of metabolic pathways.

Methods:

MDCK cells were cultured under sterile conditions. A control and ¹³C labeled time course were created (0,1,2,5,10 and 20 min). Controls was fed with normal media and flux samples were fed with stable isotope labeled ¹³C6-glucose media. Samples were washed 2x with ³⁷C PBS lysed in icecold 70% MeOH. Cell supernatant was injected onto weak anion exchange chromatography. Acquisition was performed on TripleTOF 6600 in positive and negative mode with DDA or DIA.

Preliminary Data:

Samples were analyzed by multiple means to create a library of observed metabolites. Careful creation of control samples (unlabeled) was important for the discovery of metabolites as well as the confirmation of species by mass accuracy, isotope ratio and MS/MS fragment pattern. Multivariate analysis (PCA and PLS-DA) of perturbed samples was particularly useful for identifying species that were undergoing significant flux of heavy atoms into a pathway. Major differences in the degree of kinetic flux were apparent between labeled controls and treatments that received pathway inhibitors.

Simple unit resolution data dependent MS/MS, which is the most traditional style of LC/MS data collection, was employed for basic confirmation of metabolites. In addition, DIA and some targeted MS2 modes were also employed to evaluate their utility for kinetic measurements. The results support that the traditional DDA workflows were adequate for identifying and doing some basic quantitation of metabolites.

Conclusions:

The stochastic nature of data dependent MS2 data collection limits the use of MS2 to identification only. Measurement of flux kinetics and identification of the locale of heavy atom incorporation is made possible by using targeted "scheduled" analyses as well DIA.

This work demonstrates the combining high levels of resolution and scan speed at the MS and MS2 level. Level of performance can generate information rich targeted and DIA datasets for metabolomics flux studies.

Novel Aspect:

The use of data independent acquisition (vs. traditional DDA) to elucidate the structure and kinetics of metabolomics flux.

347 - UTILIZING A STANDARDIZED AND TARGETED QUANTITATIVE ASSAY COUPLED TO HRAM MS FOR THE ANALYSIS OF SERUM METABOLITES OBTAINED FROM DIABETIC STUDY SUBJECTS

Anastasia Kalli (1) - Sally Webb (2) - Manuel Kratzke (3) - Markus Langsdorf (3) - Stephen Dearth (3) - Hai Tuan Pham (3) - Therese Koal (3) - Andreas Huhmer (2)

Keywords: targeted metabolomics, standardization, quantitation, reproducibility

Introduction: Type 2 Diabetes, T2D, is a metabolic disorder characterized by decreased insulin sensitivity and abnormal hepatic glucose production. Metabolomics creates new capabilities for understanding metabolic disorders as it enables gaining insights into physiological and pathophysiological processes. We employed a standardized, quantitative method for targeted metabolic profiling of 408 metabolites in serum samples from T2D study subjects and healthy controls.

Methods: Sample preparation was performed with the AbsoluteIDQ® p400 HR Kit (Biocrates Life Sciences, AG). Briefly, 10 µl of plasma samples were pipetted onto the 96-well plate containing the internal standards. Following derivatization, metabolites and internal standards were extracted and diluted for subsequent analysis. Mass spectrometric analysis was performed on a Vanquish™ UHPLC system coupled to a Thermo Scientific™ Q Exactive™ HF Orbitrap mass spectrometer.

Results: We aim to monitor changes in metabolite concentrations in serum samples obtained from T2D study subjects and healthy controls. We have identified several metabolites that were significantly altered between the two study groups (p values $< 9.97E-04$). For instance, we observed increased concentrations of acylcarnitine AC(2:0), cholesterol ester CE(22:6), diglycerides DG(41:1), DG(36:4), sphingomyelins SM (36:1), SM(42:3), and phosphatidylcholines PC(38:6), PC(40:6) in the T2D serum samples versus the healthy controls. The concentration of serotonin, trilecyrinide TG(52:6), and phosphatidylcholines PC(40:4) were lower in the T2D serum samples. Acetylcarnitine AC(2:0), phosphatidylcholines PC(38:6), PC (36:6) and PC(40:6), serotonin and Ile, have been previously reported to be associated with higher likelihood of T2D, obesity, or they have shown differential changes in response to oral glucose tolerance test [1-4] in agreement with our findings. In terms of the method reproducibility, for 90% of all metabolites the % RSD was $< 20\%$.

Conclusions: By employing a standardized and quantitative analytical method and high resolution accurate mass (HRAM) mass spectrometry we were able to monitor metabolite changes in serum samples obtained from T2D study subjects and healthy controls. Overall, our results demonstrate that the method provides standardized and accurate quantitation for monitoring and quantifying changes between different study groups, while, providing high reproducibility.

Novel Aspect: Combining a standardized analytical method with high resolution mass spectrometry for targeted metabolic profiling of T2D serum samples

167 - DEVELOPMENT OF A SIMULTANEOUS ANALYSIS OF THE FAT-SOLUBLE VITAMIN USING THE LITHIUM ION

Naohito Yamada (1) - Takuya Matsui (1) - Hideyuki Kuno (1)

JAPAN TOBACCO INC., Toxicology Research Laboratories, Hadano (1)

Keywords: Lithium ion, Fat-soluble vitamins, Simultaneous analysis

Introduction:

In drug development, it is frequently demanded to investigate the fat-soluble vitamins when malabsorption of the fat-soluble vitamins is suspected as a side effect of treatment. Despite the need for a high sensitive analysis with a limited sample volume especially in a non-clinical study, a quantification of the fat-soluble vitamins using LC-ESI-MS/MS has been difficult because of the low ionization efficiency and fragmentation reaction. The aim of the work was to develop a high sensitive simultaneous analysis of the fat-soluble vitamins in a biological sample using a post column infusion of a lithium ion.

Methods:

Lithium ion was added post-column and the fat-soluble vitamins were analyzed by the multiple reactions monitoring (MRM) method. The transition of the MRM method used was m/z 286 (M)⁺ to 255, 300 (M)⁺ to 255, 384 (M)⁺ to 118, 400 (M)⁺ to 118, 423 (M+Li)⁺ to 387, 431 (M+H)⁺ to 165 and 451 (M+H)⁺ to 187 for vitamin A, retinoic acid, vitamin D3, 25OH-vitamin D3, 1,25(OH)₂-vitamin D3, vitamin E and vitamin K1, respectively.

Results:

When vitamins A and D3 were ionized in the presence of the lithium ion, the (M)⁺ as well as (M+Li)⁺ was detected as a precursor ion. Furthermore, the MS/MS spectrums pattern obtained from (M)⁺ or (M+Li)⁺ significantly differed from the MS/MS spectrums pattern obtained from the (M+H)⁺. Surprisingly, when the standard sample of the fat-soluble vitamins was measured using a MRM method in the presence of the lithium ion, the intensity and S/N ratio of the peak of the vitamins A and D3 were much higher than those measured without lithium ion. The magnitude of their increase was 5 to 10 times.

Conclusions:

In a simultaneous analysis of the fat-soluble vitamins, the ionization efficiency and fragmentation pattern were improved using a post column infusion of a lithium ion. The sensitivity and S/N ratio increased because the product ion from (M)⁺ or (M+Li)⁺ significantly differed from the product ion from (M+H)⁺.

Novel Aspect: (Limit of 150 characters)

A quantitative fat-soluble vitamins analysis with improved sensitivity and specificity in the presence of the lithium ion and detecting (M)⁺.

1227 - HUMAN METABOLITE IDENTIFICATION BY SEARCHING A HIGH QUALITY AND COMPREHENSIVE TANDEM MASS SPECTRAL LIBRARY

Xiaoyu Yang (1) - Pedatsur Neta (1) - Stephen Stein (1)

NIST, Mass Spectrometry Data Center, Gaithersburg, United States (1)

Human Metabolite Identification by Searching a High Quality and Comprehensive Tandem Mass Spectral Library

Xiaoyu Yang, Pedatsur Neta, Stephen E. Stein

Mass Spectrometry Data Center, NIST, Gaithersburg, MD, USA

Keywords: Tandem mass spectral library; Human metabolite identification; Data analysis; LC/MS/MS; In-source fragmentation.

Introduction:

LC/MS/MS is a routine technique for compound identification in metabolomic studies. However, accurately identifying metabolites from millions of mass spectra is critical for data analysis. We applied an extended high quality and comprehensive reference tandem mass spectral library with >17,000 compounds, >141,000 precursors, and >671,000 spectra to identify human metabolites from LC/MS/MS data.

Methods:

Mass spectra (MS₂, MS₃, MS₄) of each authentic compound were acquired in positive and negative modes at different collision energies for major ions including isotopic precursors and in-source fragment ions with Orbitrap Elite and Lumos instruments (HCD, FT-IT, IT) for extending a tandem mass spectral library. Human metabolites were identified by searching this library with MS Search program 2.3.

Results:

The extended tandem mass spectral library [1, 2] contains 671,473 spectra, 141,927 precursor ions from 17,631 compounds. Of these, 4,005 are human metabolites. This library has been examined and applied in metabolite identification in human plasma, urine, and milk samples that were run on an Orbitrap Fusion Lumos HCD mass spectrometer. For example, 325 metabolites and 154 in-source fragments from these metabolites by various neutral losses (e.g. [M+H-NH₃]⁺ from tryptophan) were identified in a urine sample by searching the library. Over 700 human metabolites were identified with positive and negative precursor ions (e.g. [M+H]⁺, [M+Na]⁺, [M+2H]²⁺, [M-H]⁻). The in-source fragments were also identified in ~50% of the identified metabolites. Although the structures of the in-source fragments can be easily deduced from the original compounds, these sub-structures may not exist in the sample.

Conclusions:

The high-quality reference tandem mass spectral library (17,631 compounds, 141,927 precursor ions, and 671,473 spectra) can be used for comprehensive metabolite identification. The spectra of in-source fragments can identify common fragmentation artifacts and high duplicate "unknown" spectra, confirm metabolite identification and help identify metabolites that are not in the library.

Novel Aspect:

A high-quality reference tandem mass spectral library, including 4,005 human metabolites, facilitates accurate identification.

214 - IN VIVO REAL-TIME MONITORING SYSTEM FOR METABOLITES IN A LIVING MOUSE BRAIN USING PROBE ELECTROSPRAY IONIZATION/TANDEM MASS SPECTROMETRY (PESI/MS/MS)

Kei Zaitso (1)

Nagoya University, In Vivo Real-time Omics Laboratory, Institute for Advanced Research, Nagoya (1)

Keywords: In vivo real-time monitoring, Metabolites, PESI/MS/MS, Real-time metabolomics

Introduction:

Recent improvements in ambient ionization techniques have achieved real-time monitoring of biogenic compounds in organisms. Here, we developed a novel analytical system for in vivo real-time monitoring of metabolites in a living mouse brain [1]. It consists of a manipulation system and a probe electrospray ionization unit, which uses an extremely thin solid needle (tip dia.: 700 nm) for direct sampling and ionization, coupled to a tandem mass spectrometer [1-3].

Methods:

The system consists of a LCMS-8040 equipped with PESI (Shimadzu) and the manipulation system (Shimadzu). To validate the system, a mouse was anesthetized and ca. 4 mm-dia. hole was drilled at the center of the skull to expose the intact brain surface. A special sample cup was fixed onto the skull, and 8 metabolites were analyzed by the system. A CB1 agonist, which also acts as an inhibitor of TCA-cycle activity, or vehicle were administered 3 min after the analysis started.

Results:

Eight metabolites including TCA-cycle intermediates were successfully monitored in real time in a living mouse brain for 3 hours. Glutamic acid levels immediately decreased after the analysis started for both CB1 agonist-administered and vehicle mice. For CB1 agonist-administered mouse, glucose rapidly decreased 30 min into the analysis. At the same time, citric/isocitric acid increased remarkably. ADP and TCA-cycle intermediates, succinic, fumaric and malic acids, maintained its level or weakly increased, while α -ketoglutaric acid level slightly decreased. This state continued for about 30 min, then returned to their initial levels. During these dynamics observations, glucose and citric/isocitric acids seem to fluctuate coordinately. On the other hand, these phenomena were not observed in the vehicle mouse. Additional experiments demonstrated that the extracellular glutamic acid changes monitored by microdialysis showed the opposite profile, suggesting that the present system may be capturing intracellular metabolic changes.

Conclusions:

We developed a novel in vivo real-time monitoring system for a living mouse brain by combinational use of PESI/MS/MS and a manipulation unit. We applied the system to real-time monitoring of metabolites in a living mouse brain, successfully capturing the metabolic dynamics in mouse brain over 1 hour with 20-second intervals. The systems is highly expected to be expanded to real-time metabolomics in the near future.

Novel Aspect:

The newly-developed analytical system achieved in vivo real-time monitoring of the metabolites in a living mouse brain.

1214 - TiO₂ ASSISTED LASER DESORPTION/IONIZATION MASS SPECTROMETRY FOR RAPID PROFILING OF CANDIDATE METABOLITE BIOMARKERS FROM ANTIMICROBIAL RESISTANT BACTERIA

Rutan Zhang (1) - Qin Qin (2) - Baohong Liu (1) - Liang Qiao (1)

Fudan University, Fudan University/Department of Chemistry, Shanghai, China (1) - Changhai Hospital, The Second Military Medical University/Changhai Hospital, Shanghai, China (2)

Keywords: TiO₂ P25, LDI-MS, Drug-resistant bacteria, Metabolomics, ROC analysis

Introduction:

Antimicrobial resistance (AMR) is one of the most severe problems affecting public health and safety.¹ It is crucial to understand the mechanism of antimicrobial resistance from molecular level. Herein, we presented an innovative TiO₂ enhanced LDI method, which is able to recognize different types of bacteria at both species and strains level based on metabolites profiling by MVA analyses.

Methods:

The workflow mainly involves sample preparation, data acquisition and MVA analyses. Briefly, P25 TiO₂ was utilized as LDI matrix. And then, a step by step procedure was applied with formic acid and 1-butanol acting as lysis solution together with salicylic acid and dopamine serving as charging additives in positive and negative mode respectively. Mass peaks were then aligned using an open source R package "MALDIquant" and normalized by total peak areas.²

Results:

This TiO₂-LDI MS based metabolomics method can easily type four species of bacteria, including *E. coli*, *K. pneumoniae*, *P. aeruginosa* and *S. aureus*, based on PCA and PLS-DA models. The robustness for bacteria taxonomy was demonstrated by iterative validation using 48 species of clinical bacteria.

It is worth noting that this method also achieved fast bacterial AMR recognition, which possesses promising clinical diagnostic values. A multivariate ROC curve was obtained based on all obtained 11 potential biomarkers by Monte-Carlo cross validation (MCCV)³ with an AUC of 0.955. Pseudo-unknown bacteria test further confirmed AMR recognition capacity of our method.

In the end, pathway and metabolites network analysis were also performed to find responsible metabolites and mechanisms for AMR formation of ESBL+ *E. coli* at molecular level. Cysteine and methionine metabolism, purine metabolism, arginine and proline metabolism, glyoxylate and dicarboxylate metabolism, as well as peptidoglycan biosynthesis were found in disorder in ESBL+ *E. coli*.

Conclusions:

This research presented an innovative TiO₂LDI-MS method with good performance in the applications of bacteria identification, rapid AMR recognition and metabolomics analysis, which may provide an alternative to traditional LC-MS and/or NMR based metabolic analysis strategies.

Novel Aspect:

This method presented a new metabolomics method based on LDI-TOF technique, which solved some crucial problems involving complexed background interferences, peaks alignment and normalization.

1212 - A SIMPLE AND RAPID EXTRACTION OF LIPIDS IN PLASMA USING SPIN COLUMN WITH SUPERABSORBENT POLYMER BEADS

Geul Bang (1) - Jung Hoon Choi (1) - Young Ja Hwang Park (2) - Jeong Ah Kim (1) - Young Hwan Kim (1)

Korea Basic Science Institute, Biomedical Omics Group, Cheong-ju, Korea, Republic Of (1) - Korea University, College of Pharmacy, Sejong, Korea, Republic Of (2)

Keywords: lipid extraction, superabsorbent polymers, spin column, liquid chromatography, mass spectrometry

Introduction:

A fast and straightforward lipid extraction method from plasma is introduced in this study. Lipids are one of the major components of biological cell membranes, and they participate in many biochemical functions and metabolic processes, such as intercellular signaling, secretion, and energy storage [1]. The aim of our study was to develop a lipid extraction using a spin column with superabsorbent polymer beads (mSAPs). Although our previous study about fast lipid extraction method using SAPs has been reported [2], it is still challenging to realize quantitative analysis. Thus, a newly developed a simple and reliable lipid extraction method using a spin column filled with SAPs was built to shorten the time of extraction. We evaluated the extraction efficiency and the reproducibility of this method using liquid chromatography-mass spectrometry (LC/MS) analysis to compare properties of our method with the modified Folch method. The modified SAP method was applied to lipid extracts from the plasma sample, demonstrating that it can be powerfully utilized for high-speed (<10 min) preparation for lipid extraction.

Methods:

The ten microliter of plasma was dropped into the spin column with SAP beads and left for 30 s to complete absorption of aqueous solutions. Then, mixture of organic solvents, MTBE:MeOH, 2:1 (v/v) were loaded to the SAP beads, and the samples were incubated for 2–3 min. For obtaining extracts, the spin columns are followed by centrifugation at 6,000 rpm for 2 min. The organic phase was collected and dried with nitrogen gas. The extracted lipids were dissolved in 200 μ L of IPA:ACN:DW (65:30:5 v/v) for storage at 4 °C before MS analysis. Then, they were analyzed using ultra-performance liquid chromatography–mass spectrometry (UPLC/MS).

Results:

There is an urgent requirement of a quantitative lipid extraction method for plasma sample especially in the area of clinical research. For the conventional lipid extraction, arduous supernatant transfer and large volume organic solvents need to be repeated twice. Hence, we have to adopt a spin column with SAPs. After its improvement, time-consuming reduces about 95 % for lipid extraction. For the qualitative lipid profiling after extraction using the modified SAPs method, plasma samples were analyzed using LC-ESI/MS. The results of the LC/MS chromatograms and MS/MS spectra indicated that the modified SAPs method successfully extracted lipids from plasma. Also, we found that LOD of the modified SAPs method (0.035pmol) was approximately about seven times lower than that of the modified Folch method (0.243pmol), indicating that modified SAPs method is more sensitive than the modified Folch method in positive-ion mode. For the possibility tests of the lipid extraction using the spin column with SAPs, lipid extracts in another biological sample such as CSF were analyzed for lipid profiling. These results similarly corresponded with modified Folch Methods:

Conclusions:

Generally, conventional lipid extraction demands multiple steps, including drying, incubation, partitioning, and centrifugation, which results in tedious labor and low performance. However, the extraction of lipids using the spin column-based SAP is much simpler and faster because it eliminates the complicated processes. Therefore, we firmly

conclude that the modified SAPs method is a very easy, fast, and quantitative method that is especially important due to its use of small amounts of samples from complex biological specimens, such as plasma/serum for clinical use.

Novel Aspect:

A newly high-speed and quantitative lipid extraction method was developed; this method has extensive application prosperity in the clinical field.

331 - NOVEL SKIN LIPID BIOMARKERS ASSOCIATED WITH ATOPIC DERMATITIS

Evgeny Berdyshev (1) - Elena Goleva (2) - Irina Bronova (1) - John Jung (2) - Max A Seibold (2) - Donald YM Leung (2)

National Jewish Health, Department of Medicine, Denver (1) - National Jewish Health, Department of Pediatrics, Denver (2)

Keywords: Atopic dermatitis; skin tape strips; sphingolipids; lysophosphatidylcholines

Introduction: Allergic skin diseases severely impair the quality of life of affected patients. Atopic Dermatitis (AD) is linked to a damaged skin barrier function that can precede clinical AD manifestations by many months. There are no effective tools to predict the development of AD or to characterize the efficacy of applied therapy. Therefore, novel approaches to advance mechanistic understanding of AD as well as clinical management of AD and related skin diseases are needed.

Methods: A novel protocol for simultaneous assessment of lipids and filaggrin breakdown products in skin stratum corneum using tape stripping and liquid chromatography tandem mass spectrometry was employed. Targeted analyses with scheduled MRM algorithm were employed for precise quantitation of analytes. The hallmark of our approach is in the ability to normalize targeted mass spectrometric data per sample total protein content that was never done before.

Results: Lesional and non-lesional stratum corneum of 30 AD subjects was compared with 25 healthy individuals. In addition to the known redistribution of ceramide molecular species in AD, our study provided novel findings. Thus, the levels of sphingomyelins, and especially those with short chain fatty acids, increased several fold in atopic lesional skin. Most strikingly, lysophosphatidylcholines demonstrated a profound redistribution towards the prevalence of short chain species not only in lesional but also in non-lesional skin of AD subjects. RNAseq analysis performed on stratum corneum from same subjects revealed the downregulation of the expression of fatty acid elongases ELOVL3 and ELOVL6 that may explain the observed global redistribution of the long chain and short chain lipids. The modeling of the effect of type 2 cytokines on sphingolipids using human differentiated keratinocytes in vitro along with stable isotope pulse labeling confirmed the ability of type 2 cytokines IL-4 and IL-13 to provoke similar changes in sphingolipids.

Conclusions: Our ongoing studies further validate the power of the developed methodology and the value of lysophosphatidylcholines as biomarkers of atopic disease. Furthermore, skin tape stripping in conjunction with our unique processing protocol and targeted mass spectrometric methodology opens novel possibilities in clinical research by unveiling novel biomarkers of skin diseases and by allowing clinical studies in the skin using minimally invasive methodology.

Novel Aspect: Previously unrecognized association of sphingomyelins and lysophosphatidylcholines in skin stratum corneum with atopic dermatitis.

191 - QUANTUM CHEMICAL MASS SPECTROMETRY AS A TOOL FOR THE PREDICTION OF MASS SPECTRA AND THE IDENTIFICATION OF FRAGMENTATION PATHWAYS - PEPTIDES AND LIPIDS

Frank Blockhuys (1) - Julie Cautereels (1)

University of Antwerp, Department of Chemistry, Antwerp (1)

Keywords: Quantum Chemical Mass Spectrometry, Tandem Mass Spectrometry, Density Functional Theory, Tripeptides, Lipids

Introduction

A new computational tool for the prediction of mass spectra based on quantumchemical calculations is being developed, called Quantum Chemical Mass Spectrometry for Materials Science (QCMS2). It was benchmarked by predicting the EI fragmentation pathways of a number of organics with a variety of functionalities. The main features in the mass spectra were correctly reproduced and new fragmentation routes proposed by QCMS2 were confirmed by MS/MS measurements [1].

Methods

QCMS2 is based on DFT/B3LYP/6-311+G* calculations and selects fragmentation pathways based on the relative values of bond orders, and reaction (for bond cleavages) and transition-state energies (for rearrangements). Known peptide-specific fragmentation mechanisms such as the Mobile Proton Model for His, confirmed by quantum chemical calculations, have been implemented into the method [2].

Results

QCMS2 has been applied to predict the fragmentations of tripeptides in ESI/MALDI CID MS, focusing on the influence of inter-side-chain (ISC) interactions on initial protonation and subsequent fragmentation. The fragmentations of non-cyclic tripeptides consisting of His as the central amino acid (AA) have been studied and a number of observations illustrate the importance of strong ISC interactions between the AAs; as a result, QCMS2 outperforms common tools such as PEAKS and Prospector in the assignment of tripeptide mass spectra [3].

Given the more recent interest in lipidomics QCMS2 is currently being used to predict the fragmentations of lipids. Common tools such as LipidXplorer and LipidBlast generally perform poorly due to the limitations of the models (e.g., the absence of McLafferty rearrangements). The results obtained for compounds such as sphingosylphosphorylcholine will be presented: fragmentation pathways in both positive- and negative-ion mode ESI/MALDI CID MS have been calculated and compared to the experimental spectra.

Conclusions

QCMS2 reproduces the main features in the mass spectra of tripeptides, i.e., the traditional backbone cleavages resulting in a-, b₂- and y₁-ions, but, significantly, also predicts fragments resulting from ISC interactions. Likewise, it provides superior assignments of lipid spectra by taking a considerably larger number of fragmentation pathways into account. QCMS2 surpasses common tools in terms of insight into fragmentation and assignment of spectra.

Novel Aspect

QCMS2 assigns up to twice the number of signals in peptide/lipid spectra assigned by common mass spectral assignment software, and generates detailed fragment structures.

996 - A NEW UHPLC/MS-QTOF METHOD TO EVALUATE EFFECTS OF ENVIRONMENTAL METABOLIC DISRUPTORS ON HEPATIC LIPIDOMIC PROFILE

Fabrizia Carli (1) - Melania Gaggini (1) - Veronica Della Latta (1) - Sabrina Tait (2) - Francesca Maranghi (2) - Roberta Tassinari (2) - Cinzia La Rocca (2) - Amalia Gastaldelli (1)

National Research Council (CNR), Institute of Clinical Physiology, Pisa (1) - Istituto Superiore di Sanità, Toxicology Unit, Roma (2)

Keywords Ultra-High Pressure Liquid Chromatography Quadrupole Time of Flight (UHPLC/MS-QTOF), di-2-ethylhexyl phthalate (DEHP), hepatic lipidomic profile

Introduction

DEHP is a phthalate used in many consumer products. It is metabolized in the liver to MEHP, MEOHP and MEHHP. These compound are known to alter organ lipid metabolism acting as metabolic disruptors[1]. Since the liver is a key organ in whole body metabolism and waste handling, the aim was to quantify DEHP metabolites in liver by UHPLC/MS-QTOF and relate them to alteration in organ lipid profile[2,3].

Methods

We evaluated the effect of 28 day exposure to DEHP on hepatic lipidomic profile. We studied 3 groups of rats (n=4 each, 2F/2M) exposed to low, medium and high dose vs non exposed. Lipids and DEHP metabolites were extracted from liver tissues (10-20mg) and analyzed with ZORBAX Eclipse Plus C18 and ZORBAX SB Phenyl 2.1x100mm 1.8 μ m columns respectively. Concentrations were quantified using labeled internal standards added before the preparation.

Results

Hepatic concentrations of unconjugated DEHP metabolites (that reflects exposition) were increased after exposure. Male rats had significantly higher hepatic accumulation of both DEHP metabolites and lipids. Different lipid composition was found in rats exposed to DEHP vs non exposed: Ceramide CER(18:1/24:0) and CER(18:0:24:1) known to be involved in apoptotic pathway, were significantly higher (p<0.05) in exposed rats indicating tendency to hepatic damage, while CER(18:2/20:0) was lower than in non-exposed rats (p<0.05). These ceramides were synthesized more in proportion to total hepatic accumulation of DEHP metabolites. After DEHP exposure we also observed decreased hepatic phosphocholine PC(32:2) and phosphoethanolamine PE(38:2) (p<0.05) and increased saturated triacylglycerols (TAGs) and diacylglycerols (DAGs), compounds known to be lipotoxic.

Conclusions

Rats exposed to DEHP showed a different hepatic lipid composition compared control rats, in particular in lipids involved in lipotoxicity and apoptosis.

Novel Aspect

We set up a new method by UHPLC/MS-QTOF to quantify DEHP metabolites and evaluate their metabolic effects from small amounts of livers of rats exposed to different doses of DEHP.

241 - A QUANTUM CHEMICAL TOOL FOR THE IDENTIFICATION OF FRAGMENTATION PATHWAYS: ADDITIONAL INSIGHT INTO LIPID-SPECIFIC FRAGMENTATION MECHANISMS

Julie Cautereels (1) - Frank Blockhuys (2)

/, University of Antwerp/Departement of Chemistry, Antwerp (1) - /, University of Antwerp, Antwerp (2)

Keywords: Quantum Chemical Mass Spectrometry (QCMS2), Density Functional Theory (DFT), Tandem Mass Spectrometry, Tripeptides, Lipids

Introduction

A new computational tool for the prediction of mass spectra based on quantum chemical calculations is being developed, called Quantum Chemical Mass Spectrometry for Materials Science (QCMS2). It was benchmarked by predicting the EI fragmentation pathways of a number of organics with a variety of functionalities. The main features in the mass spectra were correctly reproduced and new fragmentation routes proposed by QCMS2 were confirmed by MS/MS experiments [1].

Methods

QCMS2 is based on DFT/B3LYP/6-311+G* calculations and selects fragmentation pathways based on the relative values of bond order, reaction energies (for bond cleavages) and transition state energies (for rearrangements). Known peptide-specific fragmentation mechanisms such as the Mobile Proton Model (MPM) for His, confirmed by quantum chemical calculations, have been implemented into the method and the code omits the breaking of irrelevant bonds [2].

Results

QCMS2 was applied to predict the fragmentation patterns of tripeptides focusing on the fragmentation of the side chain and the influence of inter-side-chain (ISC) interactions on the fragmentation. Therefore, it is able to predict not only the traditional backbone cleavages but also side chain fragmentations and, as a result, convincingly outperforms common tools such as PEAKS [3].

Currently, QCMS2 is being used in the prediction of the fragmentations of lipids. Since the interest in lipidomics is more recent, there is not much known about their fragmentation and, therefore, the shortcomings of their methods are more pronounced than with peptides: none of the available methods can be used for all eight lipid classes and major fragmentation pathways such as McLafferty rearrangements are missing. The results of a number of sphingolipids including sphingosylphosphorylcholine will be presented: fragmentation pathways in both positive- and negative-ion mode ESI CID MS/MS have been calculated and compared to the experimental spectra.

Conclusions

QCMS2 correctly reproduces the main features in the mass spectra of lipids. Furthermore, QCMS2 associates, in contrast to literature, multiple (new) fragmentation pathways with the most prominent fragment ion, m/z 184 corresponding to phosphocholine in positive ion mode. In addition, QCMS2 predicts considerably more fragments in negative ion mode. Therefore, QCMS2 represents a considerable leap forward with respect to the available tools.

Novel Aspect

QCMS2 assigns a significantly higher percentage of signals in lipid mass spectra than the common tools, and provides detailed insight into the fragmentation behaviour.

1232 - LIPIDOMIC APPROACH FOR ALGAL OIL CHARACTERIZATION BY FTICR MASS SPECTROMETRY

Stefano Chiaberge (1) - Roberta Miglio (1) - Davide Deriu (1) - Sara Perucchini (1) - Andrea Siviero (1)

eni s.p.a., Renewable Energy & Environmental R&D, Novara, Italy (1)

Keywords: Microalgae, Bio-Fuels, FTICR-MS, Lipidomics, Lipid Extraction

Introduction:

Microalgae *Nannochloropsis salina* provides high lipid yields and, therefore, it can be used as feedstock for bio-fuel production. The solvent extraction of apolar lipids (mainly triglycerides-TAGs) from microalgae must be optimized for the transformation of these lipids into a bio-fuel through hydrotreating. The entire process optimization needs a detailed characterization of the microalgae extract (algal oil). A lipidomic [1] approach must be developed.

Methods:

Algal oils were separated by solid phase extraction (SPE) using an amino based cartridge, obtaining two fractions: neutral compounds were eluted using a solvent mixture of chloroform and 2-propanol, polar compounds were obtained eluting with methanol. The fractions were then analyzed by flow injection with Electrospray ion source (ESI+) on a 7T-FTICR Mass spectrometer. The mass spectra were then elaborated [2] and the main peaks were attributed to a molecular formula.

Results:

The algal oil was separated by SPE in two fractions which were dried and weighted. Starting from about 12 mg of algae ethanol extract, about 9.1 mg were collected as neutral lipids (74%), 1.6 mg as polar lipids (13%). Therefore, a fraction of about 13% was lost in the sample loading step or bonded to the solid phase of the cartridge. The apolar fraction was first analyzed by GC-MS for the quantitation of the main apolar lipid compounds. The starting extract and the two fractions were then analyzed by direct flow ESI+ FTICR MS for the semiquantitative determination of the main species (TAGs, Phospholipids and Glycolipids) mainly ionized as adducts with sodium. Thanks to the high resolution and mass accuracy of the FTICR mass spectrometer, the main species can be separated and most of the peaks can be attributed to a molecular formula. Tandem mass spectrometry allowed fatty acid identification for the main species.

The lipidomic approach developed provides a molecular fingerprint of the algal oil that is extremely useful for the optimization of the whole process.

Conclusions:

A detailed characterization of algal oil was performed employing a lipidomic approach. Even if the SPE fractionation did not provide a total recovery, it allowed to obtain a preliminary quantification of apolar lipids (mainly TAGs) in the algal oil, by simple weighting of the extract. Finally, the detailed molecular characterization of lipid classes allowed the determination of the more suitable process conditions for the valorization of TAGs into a fuel-like mixture.

Novel Aspect:

A novel analytical approach was developed for the direct quantification of apolar and polar lipids obtained by microalgae.

515 - ROBUST AND SENSITIVE LC-MS/MS BASED PLASMA LIPID PROFILING ON A THERMO SCIENTIFIC™ Q EXACTIVE™ HF-X MASS SPECTROMETER

Array Tabiwang N. (1) - Sokol Elena (2) - Criscuolo Angela (1) - Clairey Dauly (3) - Harder Alexander (4)

Thermo Fisher Scientific, CMD, Bremen (1) - Thermo Fischer Scientific, CMD, Hemel Hempstead (2) - Thermo Fisher Scientific, CMD, Villebon sur Yvette (3) - Thermo Fischer Scientific, CMD, Bremen (4)

Keywords: Lipidomics, Q Exactive™ HF-X, Profile Analysis

Introduction:

Lipid profiling can be compromised by their extraction from biological samples, chromatographic separation, ionization and detection by mass spectrometry. The Thermo Scientific™ Q Exactive™ HF-X is a new Orbitrap based mass spectrometer with increased scan speed and sensitivity, which should both benefit lipid profiling experiments. In this study, we optimized a complete workflow for plasma lipidomics with improved sensitivity and quantitative performances.

Methods:

Human plasma samples were spiked with known concentrations of SPLASH™ Standard (Avanti) and extracted with varying sample amounts. Lipids were separated on a 15 cm Accucore™ C30 column and analyzed on the Q Exactive HF-X. Several instrument parameters were tested, including detection mass range, ion source conditions, ion transfer and data dependent parameters. LipidSearch™ software was used for identification and quantification of molecular lipid species.

Results:

Different plasma extraction volumes were tested in order to maximize the number of lipid species which could be detected and quantified with good precision. This evaluation was conducted by extracting the ion signals for the 14 spiked isotopic labeled lipid standards representing all major lipid classes present in plasma. Replicate extractions confirmed the reproducibility of the method with coefficient of variations below 20% for all standards. Further optimizations included the limitation of in-source fragmentation of labile lipids and improvement of MS1 detection across the studied lipid classes. Calibration curves were generated to determine the linearity of detection and limits of quantification. Finally, data dependent parameters were evaluated in order to maximize the number of high quality MS2 spectra generated in view of the higher scan rate and sensitivity of the instrument.

Conclusions:

This method optimization resulted in the confident identification and quantification of several hundreds of lipids from a human plasma sample. For Research Use Only.

Novel Aspect:

Development of a robust and sensitive mass spectrometry based workflow for large-scale plasma lipidomics profiling studies.

Introduction

There are about 150,000 different lipid molecular species present across the biological spectrum. 'Shotgun' lipidomics is an established non-targeted approach for broad-based lipidomic analysis but it can suffer from inherent ion suppression and ambiguous identification. Herein we introduce a targeted lipidomics workflow with the combination of HILIC LC separation and multiple reaction monitoring (MRM) mass acquisition. HILIC LC chemistry provides reproducible isomer separation based on lipid classes. The Scheduled MRMTM type data acquisition provides high sensitivity and wide coverage (over 1200 lipid species) for lipids screening and relative quantitation with 24 min run time. The method was extensively verified and is a robust solution for a targeted lipidomics workflow.

Methods

Standards and samples Lipids standards (SPLASH heavy isotopic labeled standards, 17:1 standards and regular light standards) and bovine heart extract were purchased from Avanti and SCIEX. They were diluted with 50%:50%/MeOH: dichloromethane containing 10mM ammonium acetate before injection. LC-MS Bovine heart extract samples were subjected to LC-MS/MS analysis with a QTRAP® 6500+ mass spectrometer coupled with Exion HPLC system. A Waters XBridge Amide 3.5 µm, 4,6 x 150 mm column was used for HILIC based LC separation. A Scheduled MRM TM method was implemented to provide screening and relative quantification of over 1200 lipids with 24 min run time.

Preliminary Data

Isomer interference minimization Isomer interference among different lipid classes is known as one of major challenges for LC-MS/MS method development for lipidomics analysis. Very commonly, one lipid molecule can have multiple isomers in other lipid classes sharing the identical precursor and product masses. This cross-class crosstalk could be troublesome because mass spectrometers cannot differentiate these isomers based on MRM transitions. To overcome this issue, a HILIC chromatographic method is implemented to provide good LC separation based on lipid classes. In order to confirm separation efficiency, lipids standards as natural lipids extracts distinguished by lipid class (one class per standard) were injected individually to confirm that there was no isomer crosstalk among different lipid classes. Retention time reproducibility improvement Retention time on a HILIC chromatography is very sensitive to changes of LC condition. A minor pH difference or organic composition change in the mobile phase might induce retention time shifts of analytes. To minimize retention time drift, extensive evaluation on mobile phase preparation was performed. A standard LC preparation protocol was developed to achieve optimal retention time reproducibility, which is especially critical for the Scheduled MRM TM method. Internal Standard Selection Lipid standards from 19 different classes, which are either heavy isotopic labeled lipids or odd chain lipids, served as internal standard. This method provided extensive lipid class coverages including, CE, CER, DCER, HCER, LCER, TAG, DAG, MAG, LPC, PC, LPE, PE, LPG, PG, LPI, PI, LPS and PS.

Novel Aspect

HILIC-MS/MS by QTRAP® system provides a reliable solution for targeted lipidomics workflow with maximum sensitivity, wide coverage and high throughput.

1001 - STRUCTURE ELUCIDATION OF GRAM-NEGATIVE MICROBIAL GLYCOLIPIDS BY ENERGY-RESOLVED TANDEM MASS SPECTROMETRY

Agnes Dornyei (1) - Viktor Sandor (2) - Aniko Kilar (2) - Nikolett Eros (3) - Bela Kocsis (4) - Ferenc Kilar (2)

University of Pecs, Department of Analytical and Environmental Chemistry and Szentagothai Research Centre, Pecs (1) - University of Pecs, Institute of Bioanalysis, Pecs (2) - University of Pecs, Department of Analytical and Environmental Chemistry, Pecs (3) - University of Pecs, Department of Medical Microbiology and Immunology, Pecs (4)

Keywords: bacterial lipid A, structure elucidation, fragmentation pathway, energy-resolved tandem mass spectrometry

Introduction:

Gram-negative bacteria are responsible for a variety of foodborne diseases and healthcare-associated infections. The outer leaflet of their outer membrane is composed of lipopolysaccharides (LPSs) of diverse structure and composition. The beneficial (immune-stimulatory) and/or adverse (e.g., pro-inflammatory) effects of these molecules released from the bacteria depend mainly on the structure of the lipidA, the lipophilic anchor constituent of the LPS.

Methods:

The HPLC-MS/MS measurements were performed on an Infinity 1290 UHPLC system coupled to a 6530 Accurate Mass Q-TOF mass spectrometer (Agilent) equipped with a Jet Stream ESI ion source. The separation was achieved using a core-shell Kinetex™ C18 column. The collision energy dependence of the low-energy CID fragmentation pathways was followed both in negative- and positive-ion modes. LipidA samples obtained from *Escherichia coli* strains were used as “training sets”.

Results:

Recently, we have established a new RP-HPLC method combined with ESI-QTOF MS/MS for the simultaneous determination and structural characterization of complex and heterogeneous lipid A samples [1-3]. We have also investigated the effects of the application of different eluent additives on the separation and on the ionization. The fragmentation pathways of the adduct ions and of the protonated lipid-A molecules in the positive-ion mode and those of the deprotonated molecules in the negative-ion mode were explored and compared. Phosphorylation site-specific diagnostic fragment ions were identified in the positive-ion mode. By a comprehensive analysis of the fragmentation pathways of numerous lipidA variants, a full structure elucidation method was proposed.

Conclusions:

The overall structural analysis of lipid A samples is of high importance, because this knowledge is essential to describe any structure-function relationship related to Gram-negative bacterial endotoxins. Energy-resolved tandem mass spectrometry proved to be a valuable method to mapping trends in fragmentation relative to the collision energy applied during the activation.

Novel Aspect:

We present an energy-resolved tandem mass spectrometry based strategy to characterize the microbial membrane lipidA structures.

931 - DEVELOPMENT OF A COMPREHENSIVE PANEL OF EICOSANOIDS AND RELATED FATTY ACID METABOLITES FOR HIGH-SENSITIVITY AND QUANTITATIVE LC-MS/MS ANALYSIS

Yuka Fujito (1) - Masaki Yamada (1) - Huan Lin (1) - Setsuko Fujita (2)

Shimadzu Corporation, Global Application Development Center, Kyoto (1) - Ono Pharmaceutical Co., LTD., Discovery Technology Research Laboratories, Osaka (2)

Keywords: Eicosanoid, lipid mediator, omega-3 fatty acid, MRM, ionization polarity switching

Introduction

Eicosanoids or omega-3 fatty acids metabolites are attractive targets to understand physiological roles. Comprehensive and quantitative monitoring methods using LC/MS has been developed in last decades. Here we report a novel method consisted of 300 MRM transitions packed in a 20 minutes' chromatographic condition for 200 targets. From 30 μ L human serum, 75 targets were assigned by the consistence of retention time or intensity ratio with authentic standards.

Methods

Authentic standards were purchased from Cayman Chemical (Ann Arbor, MI). Human serum and blood were obtained from Sigma-Aldrich Co. LLC. and from Bioreclamation IVT, US, respectively. STRATA-X (Phenomenex, Torrance, CA) cartridge were used for solid phase extraction. An LC/MS system consisting of Nexera UHPLC system and LCMS-8060 (Shimadzu Corp.) was used. A Kinetex C8 column (2.1 x 150 mm, 2.6 μ m) was used for target separation.

Results

A new method consisted of over 300 MRM transitions for 186 eicosanoids and related fatty acid metabolites and of 14 deuterium labeled analogs as internal standards. Expected retention times were confirmed by analyzing authentic standards with a 20 minutes' chromatographic condition using 0.1% acetic acid and acetonitrile as elution buffers. More than one MRM transitions were applied for over 100 targets. The most of MRM transitions were negative ion mode without 27 transition with positive ion mode. When 5 msec dwell time and 1 msec pause time were set, lower limit of quantifications were sub-pg for the majority of targets. The quantitative profiling of human serum resulted that 75 targets were assigned by the consistence of retention time within 3 seconds or that of the intensity ratio detected in multiple MRMs with corresponding authentic standards. Major eicosanoids PGE2 and PGD2 were not detected. An arachidonic acid metabolite 11-HETE was observed with the highest intensity close to saturation of the detector.

Conclusions

We have developed a new LC/MS method for comprehensive quantification of over 180 eicosanoids and related fatty acid metabolites. The method was applied to 30 μ L of human serum sample to assign 75 targets including 30 arachidonic acid metabolites, 13 DHA metabolites, 9 EPA metabolites. The method will be detectable over 100 targets which covers wide range of fatty acid metabolites. We believe the method is useful to study physiological functions or biomarker discovery.

Novel Aspect

We successfully developed a comprehensive MRM panel of 186 eicosanoids and related fatty acid metabolites for high-sensitivity and quantitative LC-MS/MS analysis.

1294 - DUAL MASS SPECTROMETRY AS A TOOL TO IMPROVE ANNOTATION AND QUANTIFICATION IN TARGETED PLASMA LIPIDOMICS

Liang Gao (1) - Amaury Cazenave-Gassiot (2) - Bo Burla (1) - Markus Wenk (2) - Federico Torta (2)

National University of Singapore, Life Sciences Institute, Singapore, Singapore (1) - National University of Singapore, Department of Biochemistry, Singapore, Singapore (2)

Keywords: Dual MS, lipidomics, glycerophosphocholines, sphingomyelins

Introduction

Lipidomics is rapidly developing as one of the most important areas in biomedical research[1-2]. New technologies and analytical approaches are advancing a field that is defining new guidelines and standards. High quality data, based on reliable quantification and clear identification of the reported lipid species, are required for the clinical translation of human plasma lipidomic studies[3-4].

Methods

As a tool to improve the quality of targeted lipidomics studies, we established a Dual MS platform by simultaneously coupling a reversed-phase liquid chromatography (RPLC) separation to a triple quadrupole (QqQ) and a quadrupole-time of flight (Q-ToF) mass spectrometers. In one single experiment, this platform allows to correctly identify, by high resolution MS/MS, the peaks that are quantified by MRM.

Results

Glycerophosphocholines (GPCs) and sphingomyelins (SMs) play important biological roles in various cellular functions and physiological processes and are highly abundant in plasma. Quantification of GPCs and SMs can be efficiently performed on QqQ mass spectrometers in targeted multiple reaction monitoring (MRM) mode. A series of issues encountered when aiming at the identification and accurate quantification of GPC and SM in MRM were solved with the Dual MS platform, including (i) resolving peaks of GPC polyunsaturated species, (ii) discriminating between plasmanyl-, plasmenyl- and odd chain GPCs and (iii) resolving the isotopic overlap between GPC and SM co-eluting species.

Conclusions

Our platform provides a higher level of confidence in the quantification and identification of phosphocholine-containing lipids in human plasma. Our work is aligned with several new initiatives in the lipidomic field with the aim to establish better methodologies and standard procedures to generate high quality lipidomic data.

Novel Aspect

This new methodology might have a great potential in comprehensive studies that want to achieve an acceptable specificity in the quantification of lipids.

Keywords: pathogen identification, rapid, polymicrobial, antibiotic

Introduction: Microbial identification relies on bacterial culture followed by biochemical testing, which generally takes overnight. Protein analysis by MALDI-TOF MS has become a prominent player in clinical microbial diagnosis. Identification is nearly instantaneous, but requires overnight growth to produce the required pure colony. We recently published (1,2) a method for microbial identification direct from biofluid without the need for culture.

Methods: Bacterial membrane glycolipids were extracted as published (1) and reconstituted in chloroform/methanol/water (3: 1.5: 0.25, v/v/v) for LC-MS/MS analysis on a SYNAPT G2 (Waters). Signature ions from each ESKAPE species were selected and fragmented. Suitable transitions were determined for each ESKAPE pathogens. The existing MALDI library (1) was used to confirm LC-MS results after deconvolution and manual inspection used for polymicrobial analysis.

Results: Previously we published use of microbial lipids for identification of bacteria and fungi direct from specimen using the Bruker Biotyper platform (1, 2). Here we present development of a pseudo-MRM assay for the ESKAPE pathogens (1) on a SYNAPT MS. A new extraction protocol that takes less than one hour is also introduced. Individual glycolipid preparations were analyzed by direct infusion to generate mass spectra for each ESKAPE species. Signature lipid ions, which are those unique to a given microbe, were selected for tandem MS fragmentation and their unique transitions, attributable to loss of various fatty acids, noted. For example, precursor ions at m/z 1744, 1824, and 977 ($z=2$) were found to be unique to *Enterobacter cloacae*. After successfully generating tandem mass spectra for each individual ESKAPE pathogen, mixed samples containing multiple pathogens were tested to demonstrate the method could distinguish and detect each organism in a simulated polymicrobial sample and where appropriate antibiotic resistance (3).

Conclusions ESKAPE pathogens, *Enterococcus faecium*, *Staphylococcus aureus*, *Klebsiella pneumoniae*, *Acinetobacter baumannii*, *Pseudomonas aeruginosa*, and *Enterobacter* spp., were targeted due to their high incidence of nosocomial infections and multidrug resistance. Here we present initial work to develop a rapid (< 1 hour) pseudo-MRM assay targeted at detection of these microbes that are sensitive and resistant to antibiotic therapy.

Novel Aspect: Rapid identification of ESKAPE pathogens by LC-MS/MS points toward a targeted clinical assay that may be carried out on triple quadrupole systems rather than MALDI-TOF MS.

242 - BIOMARKER RESEARCH AND SHORT TIME CHROMATOGRAPHY: A UTOPIA?

Lisa Hahnefeld (1) - Gerd Geisslinger (1) - Nerea Ferreirós (1)

Goethe University Frankfurt, Institute of Clinical Pharmacology, Frankfurt (1)

Keywords: LC-HRMS, lipidomics, biomarker research

Introduction:

In biomarker research short analysis times are preferred, which are limited by problems like matrix effects and coelution of isobaric compounds. For this reason, run-times often exceed 30 or even 50 minutes. Our aim is to implement an untargeted method for high-throughput screening, reducing drifts in instrumental response, retention time shifts and improving sample stability.

Methods:

We developed a chromatographic method with a sub 2 micrometre C8 column and a binary gradient to cover the lipidome ranging from polar lipids to highly apolar triacylglycerides and cholesteryl esters in biological samples after liquid-liquid extraction. The chromatographic system was coupled with quadrupole-time-of-flight mass spectrometry for lipid identification.

Results:

The obtained chromatographic resolution allowed the separation of isobaric lipids and reduced ion suppression effects. Combined with high resolution mass spectrometry we could identify lipids from over 15 different lipid classes. The resulting acquisition time was 17 minutes per sample and polarity, simplifying the measurement of large sample numbers and improving system stability. Hence we achieved a coefficient of variation (CV) below 15% for the peak area of 220 lipids in human plasma at repeated extractions, with 205 of these having a CV below 10%. Additionally, the average CV of the retention times was 0.1%. We successfully applied the method on plasma, serum and cell culture samples as well as several different mouse tissue types. For the latter, we could show the importance of the sampling location of mouse kidney, heart and liver for the reproducibility of the lipid profile.

Conclusions:

The developed method can be applied for high-throughput lipidomics and biomarker discovery research in biological samples.

Novel Aspect:

LC-HRMS analysis of biological samples in 17 minutes with low matrix effects, adequate peak resolution, lipid identification and method reproducibility.

322 - INVESTIGATION INTO THE BLEACHING OF VEGETABLE OILS USING HIGH RESOLUTION MASS SPECTROMETRY

Andrew Hambly (1) - Jeroen Van Duijneveldt (1) - Paul Gates (1)

University of Bristol, School of Chemistry, Cantock's Cl, Bristol BS8 1TS, Bristol (1)

Keywords: HPLC-MS, vegetable oils, bleaching, adsorbents

Introduction:

The refining of lipid-based oils is important to the food and pharmaceutical industries in the production of food supplements and excipients. 'Bleaching' refers to one step in the process where the oils are mixed with adsorbents to remove contaminants such as; lipid peroxides, pigments and soaps. This project uses high resolution mass spectrometry to study the bleaching of vegetable oils.

Methods:

Various techniques including reverse-phase UHPLC-MSn and MALDI MS were used to analyse crude and refined versions of sesame, olive and fish oils, as well as synthetic poly(ethylene glycol) (PEG) and polysorbate based products. A rapid method for processing spectra was built using software package Knime.

Results:

Refined versions of vegetable oils saw lower levels of lipid oxidation products and pigments as predicted from drops in peroxide value and removal of colour after processing. Refined oils also showed lower levels of soaps, metals and phospholipids. Compounds seeing the greatest removal saw a drop in abundance by factor 20.

Surprisingly, refined oils also showed lower concentrations of diglycerides. This was suggested to be due to presence of the glyceryl hydroxyl group.

Conclusions:

Combination of high resolution mass spectrometric methods with computer processing can provide a high throughput means of studying the removal of compounds during edible oil processing. Data confirmed removal of typical contaminants during oil processing. It also highlighted change of otherwise unknown compounds during bleaching.

Novel Aspect:

Use of high resolution mass spectrometric methods as a means of rapid study of bleaching processes in edible oil refinement.

506 - ANALYSIS OF A COMPLEX LIPID PROFILE IN HUMAN SEBUM BY USING GCXGC-HRTOFMS

Masahiro Hashimoto (1) - Koji Okuda (2) - A. John Dane (2) - Robert B. Cody (2) - Bram van der Meer (3)

JEOL(EUROPE)SAS, European Application Group, Croissy-sur-Seine (1) - JEOL USA Inc., Application Group, Peabody, MA (2) - JEOL (Europe) B.V., Sales Executive Science and Measurement Instruments, Nieuw-Vennep (3)

Keywords: Lipid analysis, High resolution, High mass accuracy

Introduction: (Limit of 400 characters)

Sebum is a complex mixture of lipids that are typically measured by using GC-FID. However, these methods are often unable to separate the individual components from each other which makes it difficult to definitively identify each of them. Conversely, GCxGC-HRTOFMS is a powerful tool for identifying analytes in complex mixtures. In this work, we measured lipids in sebum by using GCxGC-HRTOFMS.

Methods: (Limit of 400 characters)

The sample was collected onto square aluminum sheets wiped across a human forehead. The lipid compounds were then extracted from the aluminum sheets using a 50 / 50 volume solution of methanol / dichloromethane with sonication. Next, the extraction solution was centrifuged and concentrated. Afterwards, the final solution was analyzed using GCxGC-HRTOFMS.

Results: (Limit 900 characters)

A lot of lipid compounds such as free fatty acids, wax esters, diacylglycerols and triacylglycerols were observed, and these lipid compounds were separated by GCxGC perfectly. Obtained peaks were comprehensively identified using a combination of accurate mass measurements and library searches. As an example, the peaks detected at retention time 18.684 minute (1st column), 6.756 seconds (second column) was matched to oleic acid using a NIST library search. Furthermore, this mass spectrum showed a molecular ion that coincided with the calculated accurate mass of oleic acid (error of 1.4 mDa). The results for the other compounds present in the sebum sample will be presented in this work.

Conclusions (Limit of 400 characters)

Low boiling point fatty acids up to high boiling triglycerides were observed in a single sebum measurement. The cholesterol esters and triacylglycerols, which are difficult to separate by 1D GC, showed high chromatographic separation by GCxGC-HRTOF. Additionally, the peaks were comprehensively identified by using a combination of accurate mass measurements and library searches.

Novel Aspect: (Limit of 150 characters)

Analysis of a complex lipid profile in human sebum by using GCxGC-HRTOFMS.

1316 - NEW PEAK ALIGNMENT SOFTWARE: METABOALIGN IMPROVING ISSUES OF LC-MS/MS LIPIDOMICS ENABLES HIGHTHROUGHPUT DATA ANALYSIS FOR THOUSANDS OF LIPIDS IN BIOLOGICAL MATERIALS.

Akio Hayashi (1) - Takashi Matsuzaka (2) - Hitoshi Shimano (2)

ONO Pharmaceutical Co.,LTD., Minase Research Institute, Mishima-gun, Japan (1) - University of Tsukuba, University of Tsukuba, Faculty of Medicine, Tsukuba, Japan (2)

Keywords: ELOVL6, insulin resistance, targetedlipidomics, software, automatic-annotation

Introduction:Up to now many quantification softwares for targeted LC-MS/MS analysis using triple quadrupole mass spectrometer have been developed, but any of them could not be completely sufficient in peak alignment because of the difficulty to correct for any drift in retention time. Furthermore, it is difficult to identify the fatty acid composition of phospholipids (PLs) by simultaneous MS/MS assay using a thousand of polar head group MRM transitions because of the limitation of MS/MS cycle time in one assay. Therefore, we developed a new software for targeted lipidomics (TL) to improve these issues. Then we applied this software to lipidomics in liver of liver specific ELOVL6 knockout (LKO) mice, and found a lipid which was correlated with insulin sensitivity scores.

Methods:The liver tissues of LKO mice were homogenized in 1% acetic acid methanol solution on ice cold water. Then the whole lipid extraction and TL were performed by the method previously reported. TL and non-TL raw data were obtained by 4000QTRAP (Sciex) and QExactive HF (Thermo Fisher Scientific). The lipid identification data set including the information of PLs fatty acid analysis were made by Lipid Search (LS) software (Mitsui Knowledge Industry Co., Ltd.) from non-TL data. TL raw data analysis was performed by newly developed lipidomics software: MetaboAlign beta version with automatic peak annotation by means of merging with the LS identification data set.

Results: MetaboAlign was allow to align peaks independent of peak shape and peak width. All Lyso-PL regio isomers of sn-1 form and sn-2 form could be separated, as for example LPCacyl (18:1) of sn-1 and sn-2 were separated accurately and partially LPCacyl (cis-Vaccenyl) and LPCacyl (Oleyl). LPCacyl (cis-Vaccenyl, sn-2) was correlated well with LPCacyl (16:1, sn-2). N-Acylethanolamine (18:1) (AEA) was separated into two peaks which were considered AEA (Oleyl) and AEA (cis-Vaccenyl). Liver PCs with a variety of fatty acids were separated by high resolution C18 reverse phase column, aligned, quantified, and identified about fifty PC species automatically by MetaboAlign. ELOVL6 is an enzyme which can elongate fatty acid chain from C16 to C18. LKO mice showed lower levels of C18 fatty-acyl PCs in liver than WT mice under high sucrose diet condition. Then we found a lipid_Y which was correlated with insulin sensitivity scores which might be involved in improvement of insulin resistance.

Conclusions:We successfully developed a new software MetaboAlign beta version for LC-MS/MS lipidomics to enable to align, quantify and identify thousands of lipid peaks. Both four isomers of LPCacyl (18:1) and two isomers of AEA(18:1) were aligned and quantified adequately. We found a lipid_Y which was correlated well with insulin sensitivity.

Novel Aspect: Successful development of a new software MetaboAlign beta version for LC-MS/MS lipidomics to enable to align, quantify and identify thousands of lipid peaks.

Separation of four isomers of LPCacyl (18:1) and two isomers of AEA (18:1).

Finding of a lipid_Y which was correlated with insulin sensitivity scores which might be involved in improvement of insulin resistance.

735 - RELATIVE QUANTIFICATION OF PHOSPHOLIPID SN-ISOMERS USING POSITIVE DOUBLY CHARGED LIPID-METAL ION COMPLEXES

Sven Heiles (1) - Simon Becher (1) - Patrick Esch (1)

No company affiliation, Justus Liebig University Giessen/ Analytical Chemistry, Giessen (1)

Sven Heiles, Simon Becher, Patrick Esch

Keywords: UVPD, FTMS, Lipidomics, Tandem MS

Introduction:

Phospholipids are ubiquitous in living organisms and are involved in a plethora of biochemical processes.[1] For glycerophospholipids assignment of double bond positions and sn fatty acid isomers is often not possible with routine tandem MS Methods: Especially untargeted assignment of sn isomers is challenging. Here, we present a simple tandem MS strategy that allows phospholipid sn isomer assignment by phospholipid metal ion complex fragmentation.

Methods:

All experiments were performed using a LTQ-FT Ultra or a Q Exactive (Thermo Fisher Scientific) mass spectrometer equipped with heated ESI sources. An in-house developed 213 nm UVPD setup [2], CID and HCD were used for tandem MS experiments. Lipid extracts were prepared according to Schwudke et al.[3] and phospholipase A2 digestion was performed as described by Ekroos et al.[4] Samples were mixed in alcohol/water and corresponding complexes were produced by ESI.

Results:

Abundant lipid-metal ion complexes (LM2+) complex formation was observed for phosphatidylcholines (PCs) and sphingomyelins (SMs) but not for other lipid classes. Upon LM2+ activation by CID, HCD or UVPD, lipid head group and fatty acid ester bond dissociation were detected. The relative abundances of the fragment ions depended on the metal ion identity. Only for iron(II) LM2+ complexes, head group dissociation was suppressed and only fatty acid ester bond dissociation occurred. One singly charged ion containing the dissociated deprotonated fatty acid together with Fe2+ ([FA-H+Fe]+) and the complementary singly charged PC fragment ion were observed. For PCs containing two different fatty acid moieties, activation of LM2+ resulted in preferential dissociation of FAs located at sn2-position. PLA2 digestion revealed that fragment ions upon CID and UVPD are sn2-specific but for HCD sn-scrambling occurs. LM2+ ions were utilized in MS2 CID or UVPD experiments to quantify the relative abundance of PC sn-isomers in mouse organ lipid extracts.

Conclusions:

Abundant ion adduction of Fe(II) to neutral PCs in ESI mass spectrometry was observed and optimized. Tandem MS experiments of these LM2+ complexes allow to assign fatty acid moieties and to assign sn-isomer in one-step tandem MS experiments. Under low energy activation conditions, relative quantification of sn-isomers is possible and this method can readily be applied to complex lipid mixture in a shotgun approach and potentially be coupled to LC-MS experiments.

Novel Aspect:

Simple MS2 method to quantify the relative abundance of phosphatidylcholine sn-isomers in complex lipid mixtures using positive ion mode.

A.09 Life science-Lipidomics

Introduction:

Bacteria, regardless of whether they are beneficial or pathogenic all contain a large diversity of lipids with various structures and functions in the cells; and the structures are complex and difficult to define. Herein, we report LIT MSn method to identify the lipid structures from *R. opacus*, *Cordyceps sinensis*, *P. gingivalis*, *L. monocytogenes* and *Corynebacterium stratum*, which contain unique lipids different from those in eukaryotic and other prokaryotic cells.

Methods:

Cells were homogenized and lipids were extracted using a modified Bligh & Dyer method. Preparative HPLC experiments were carried out using a Thermo TSQ Vantage MS with Accela UPLC. Separation of lipids was achieved by a Supelco C-8 column. High resolution LIT MSn experiments were performed on a LTQ Orbitrap Velos. Peptidolipids collected from HPLC separation were dried, re-dissolved in CHCl₃/CH₃OH, and continually infused into the ESI source.

Results:

In addition to the lipids commonly seen for other bacteria, *R. Opacus* contains two novel families of peptidolipids; *Cordyceps sinensis* contains extremely rich linoleic acid containing phospholipids; *P. Gingivalis* and *L. monocytogenes* contain odd chain methyl branch iso-fatty acid containing phospholipids, with the former also contains dihydroceramides, including EPC, IPC, GPC, and GS-peptidolipid, and the latter also contains plasmalogen PG and lysyl-CL; *C. stratum* contains a novel glucuronosyl diacylglycerol family. All the fatty acyl substituents in EPC, IPC, and GPC belong to the β -OH fatty acid family, and the structure is readily identifiable by CID MS₂.

Conclusions:

We found three new lipid families (peptidolipid, glycine-lipid, 18:1/16:0-glucuronosyl diacylglycerol) that have not been previously reported for these bacteria. ESI LIT CID/HCD MSn with high resolution mass spectrometry revealed the complexity of microbial lipid structures, including many isomers. The MSn capability of LIT adds additional dimensions in segregating ions, thereby, accelerating and simplifying data interpretation and structural characterization.

Novel Aspect:

LIT MSn with high resolution MS unravels the structural details of novel lipids including many minor isomers that would be very difficult to define using other analytical Methods:

1343 - JOINT APPLICATION OF ESI AND MALDI LIPIDOMIC PROFILES FOR CLASSIFICATION OF BRAIN TUMORS

Keywords: brain tumors, lipidomics, molecular profiling, classification

Introduction:

Analysis of molecular profiles is one of the promising approaches to determine malignancy of brain tissues. Different ionisation methods could be used for molecular profiling: online extraction with ESI is better for fast intraoperative analysis, while MALDI more suitable for histological investigation. The purpose of this study is to quantify ability to construct a joint classifier of brain tumors, working with MALDI and direct spray MS profiles simultaneously.

Methods:

Set of molecular profiles of different brain tumor tissues was obtained by online extraction with ESI and MALDI Imaging experiments. Discriminating features for the malignancy level of tumor determination were identified individually for each ionisation method[1], and two brain tissue classifiers were created, followed by the comparison of selected features for each classifier.

Results:

The molecular profiles that were obtained by direct ionisation and MALDI show the high level of correlation between each other for the same type of tissue especially in a mass range of common lipids. MALDI brain tissue classifier and direct spray classifiers were able to determine features to quantify the ratio of malignancy, and a number of these features were presented in both classifiers. Since we use high-resolution mass analysers for measuring direct-spray molecular profiles, for some of the common features we predict the molecular origin of these ions.

Conclusions

It was demonstrated that the classifiers build on the molecular profiles from direct-extraction MS and MALDI MS contain signals of the same compounds so both types of data could be used for the creation of joint classifier. The analysis of features, used in the classifiers, will allow optimising the parameters of experiments to improve the efficiency of classification and visualization of the spatial structure of the samples.

Novel Aspect:

This work shows principal ability to use heterogeneous data to construct the classifier which works with online extraction and MALDI imaging experiments together.

1312 - DEVELOPMENT AND APPLICATION OF AN ENHANCED LIPIDOMIC PROFILING METHOD USING LC-MS

Malak Jaber (1) - David Barrett (1) - Dong-Hyun Kim (1)

University of Nottingham, University of Nottingham/Advanced Materials and Healthcare Technologies, Nottingham, United Kingdom (1)

Malak Jaber, David Barrett and Dong-Hyun Kim

Keywords

Lipidomics, Variations, ^{13}C in vivo labeling, Normalisation

Introduction

Quantification is a critical task in comprehensive lipidomics studies. Liquid chromatography-mass spectrometry (LC-MS)-based technique can provide a valuable tool for monitoring lipid changes as well as to identify specific biomarkers. A key limitation of this technique is the nonlinear responses due to stability, matrix effect, instrumental variations and others. However, those can be overcome by our novel method using ^{13}C -labelled organism extracts (1).

Methods

The lipidome profiles of five different microorganisms were compared to obtain the most coverage of human lipids leading to comprehensive compound-specific normalisation in quantitative mass spectrometry assays. An in vivo labelling strategy was used to produce a wide range of isotopically labelled lipid species from the selected microorganism grown on uniformly ^{13}C -labelled glucose, which have similar physico-chemical properties of unlabelled lipids (2, 3).

Results

Comparison of the lipid profiles of five different species including *E. coli*, *Spirulina*, *S. cerevisiae* CEN.PK 113-7D, *S. cerevisiae* BY4741, and *P. pastoris* NCYC 175 showed that there were marked differences in the relative amount of the identified lipid species as well to their labelling pattern. *P. pastoris* provides the highest number of common lipids with human metabolome database with good labelling efficacy. Therefore, *P. pastoris* was selected as a source of isotopically labelled internal standards (IS).

Then, the lipidomic extract of *P. pastoris* used to normalise variations introduced during samples preparation, storage and LC-MS analysis. The labelled yeast extract was successfully used to correct variations in LC-MS response in long analysis time (230 injections over 3.5 days) and reduction in CV% of the identified lipids was achieved (from 8.4 to 4.9). Also, the extract was able to reduce batch to batch variations successfully (from 17.2 to 6.2) without the need for quality control samples (QC) and thus decrease the analysis time.

Conclusions

P. pastoris proved to be the ideal source for production of labelled IS with more coverage for higher eukaryotic lipids. Normalisation using the ^{13}C -labelled extract could successfully correct for instrumental variation and batch to batch variations without the need for QC samples. These results show the high potential of the use of in vivo labelling strategy in quantitative measurement of a wide range of lipids especially in more complex matrices.

Novel Aspect

To use labelled organism extracts as a source of IS to develop more reproducible, quantitative untargeted lipidomic analysis that can be applied to a variety of clinical studies

Title: Applicability of MALDI-Orbitrap-MS for the early diagnosis of renal cell carcinoma based on the lipidomic analysis of blood and urine samples

Introduction:

Renal cell carcinoma (RCC) is the most common type of kidney cancer. The RCC incidence and the mortality rate have been increasing globally during the last decade. Up to date, there are still no recommended screening tests for early diagnosis. In our work, the matrix-assisted laser desorption/ionization coupled with Orbitrap mass spectrometry (MALDI-Orbitrap-MS) is used for the clinical study of patients with RCC and healthy volunteers.

Methods:

All samples were spiked before the extraction with the appropriate internal standard mixture. Lipidomic extracts of human plasma were prepared by modified Folch method, while reversed-phase solid phase extraction was applied for urine samples. The LTQ Orbitrap instrument was operated in the negative-ion mode over a mass range m/z 400 - 2000 and the mass resolution was set to 100,000. 9-aminoacridine was used as MALDI matrix.

Results:

First, lipid species are identified using high mass accuracy full scan and tandem mass spectra. Subsequently, the optimization and method validation for semiquantitative measurement is performed. The optimized methodology is finally used for the analysis of all studied body fluid samples. Each measurement is represented by one average MALDI-MS spectrum with thousands of m/z peaks. The automatic peak assignment is subsequently performed and particular m/z peaks of various intensities are matched with deprotonated molecules from a database created during the identification procedure using the Excel macro script for each sample. Multivariate data analysis methods, i.e., unsupervised principal component analysis and supervised orthogonal partial least square discriminant analysis, are further used for the visualization of differences between studied sample groups.

Conclusions:

Most upregulated and downregulated lipids in blood and urine samples of RCC patients are finally visualized using particular boxplots. Significant differences in lipid abundance between RCC patients and healthy volunteers proved potential of MALDI-Orbitrap-MS for early diagnostic of RCC, but further testing is still necessary. This work was supported by the Czech Science Foundation (project No. 18-12204S).

Novel Aspect:

Applicability of MALDI-Orbitrap-MS for the early diagnosis of renal cell carcinoma based on the lipidomic analysis of blood and urine samples.

764 - CHANGES OF SPECIFIC SPHINGOMYELINS DEPENDING ON THE SEVERITY OF NONALCOHOLIC FATTY LIVER DISEASE

Youngae Jung (1) - Geum-Sook Hwang (1) - Jungju Seo (2)

KBSI, Western Seoul Center, Seoul (1) - Scientific Instruments Reliability Assessment Center, Korea Basic Science Institute (2)

Keywords: Nonalcoholic fatty liver disease, lipidomics, sphingomyelin

Introduction:

Nonalcoholic fatty liver disease (NAFLD) is one of common causes of chronic liver disease that involve hepatic accumulation of triglycerides. The clinical-histologic spectrum of NAFLD extends from a nonalcoholic fatty liver (NAFL) to nonalcoholic steatohepatitis (NASH). NASH is divided from NAFL according to the presence of ballooning and lobular inflammation [1]. Although NAFLD is closely correlated with obesity, 5-8% of lean subjects also have NAFLD [2].

Methods:

Total 361 serum samples from patients with biopsy-proven NAFLD were classified in six groups on the basis of BMI (25 kg/m²) and liver histology (No NAFLD, NAFL and NASH). Lipidomics study for all serum samples were performed using ultra-performance liquid chromatography/quadrupole time-of-flight mass spectrometry (UPLC/QTOF MS).

Results:

The diverse lipid metabolites identified in serum samples showed a characteristic alterations depending on the severity of NAFLD between non-obese and obese groups. Most of all, specific sphingomyelins (SMs) had distinct increase patterns according to the stage of steatosis, lobular inflammation, and ballooning except for fibrosis only in non-obese NAFLD. Moreover, the receiver operator characteristic (ROC) analysis for determining the progression degrees of NAFLD produced higher the area under the curve (AUC) values in non-obese group than in obese.

Conclusions

These results presented that disease mechanism is different between non-obese and obese NAFLD, and these specific SMs might be used as markers to predict the severity and/or progression of NAFLD.

Novel Aspect:

Specific SMs were clearly associated with liver histology including steatosis, lobular inflammation, and ballooning in non-obese NAFLD patients.

284 - A COMPREHENSIVE METHOD FOR TOTAL LIPID ANALYSIS IN BIOLOGICAL MATRICES BY HYDROPHILIC INTERACTION LIQUID CHROMATOGRAPHY ELECTROSPRAY IONIZATION MASS SPECTROMETRY HILIC/ESI-MS

Spiro KHOURY (1) - Stéphanie CABARET (1) - Elodie A.Y. Masson (1) - Olivier Berdeaux (1)

UMR CSGA - INRA - CNRS, University of Bourgogne Franche-Comté, Dijon (1)

Keywords: Lipids, Extraction, liquid chromatography, Mass spectrometry, Ion suppression

Introduction: (Limit of 400 characters)

Lipid analyses are increasingly used for determining the development of several diseases. Because of their extremely heterogeneous structures, analysis of lipids is challenging. LC/ESI-MS, the major tool used to analyze complex lipidomes, is very sensitive towards the composition of lipid extract. Therefore, a complete analytical strategy is proposed in this work in order to efficiently extract, purify and analyze lipids in different biological matrices.

Methods: (Limit of 400 characters)

Lipids were extracted from rat brain and plasma samples with an optimized method using a mixture of solvents of increasing polarity. The efficiency of this method was compared to other reference Methods: Then, lipids of low relative abundance were purified by several methods (C18 solid-phase, phase partition [1] or Phree phospholipid removal columns). LC-MS (Triple quadrupole and Orbitrap FUSION) methods were developed for targeted and global analyses of lipids.

Results: (Limit 900 characters)

The optimized monophasic extraction method enabled a fast and efficient extraction of all lipids from the matrices. A better recovery of lysophospholipid and ganglioside (GG) classes, whereas similar recovery of other phospholipids (PL), ceramides, fatty acids and sterol, was obtained compared to other extraction Methods: The HILIC conditions allowed the separation of PL and GG classes, including acetylated forms, according to their increased polarity. Analyses conducted by LC-ESI-HRMS/MS enabled the identification of a large diversity of lipid molecular species. Quantification of lipids by MS tuned to specific acquisition modes showed high levels of phosphatidylcholine and phosphatidylethanolamine classes. Different purification methods of GG were evaluated in order to overcome some analytical challenges in LC/ESI-MS like ion suppression phenomenon [2] after co-elution with the more abundant PL of similar polarity. Therefore, an increase in quantification of all GG classes was observed after removing PL prior to analysis.

Conclusions (Limit of 400 characters)

Polar and complex lipids in biological samples usually present very low extraction yield with the most popular Folch-type procedures. In this work, we propose a monophasic extraction method adapted to extract lipids of a large range of polarity. A method in tandem MS was optimized and coupled to an HILIC system to separate, characterize and quantify all lipids. In this respect, powerful purification tools were used to avoid ion suppression effect for ESI-MS analysis.

Novel Aspect: (Limit of 150 characters)

Our complete analytical strategy offers an efficient extraction of both polar and non-polar lipids from complex biological matrices followed by an accurate LC-MS analysis.

118 - GRAPHICAL IDENTIFICATION OF LIPIDS USING THREE-DIMENSIONAL KENDRICK MASS PLOTS

Ansgar Korf (1) - Christian Vosse (1) - Heiko Hayen (1)

University of Münster, Institute of Inorganic and Analytical Chemistry, Münster (1)

Keywords: Lipidomics, Kendrick mass defect, High-resolution mass spectrometry, Liquid chromatography

Introduction:

Recent technical advances regarding liquid chromatography (LC) and HRMS enable the mapping of the lipidome of an organism with short data acquisition times. However, interpretation and evaluation of resulting multidimensional datasets are challenging and this is still the bottleneck regarding overall analysis times. Therefore, we present a novel adaption of Kendrick mass (KM) plot analysis.

Methods:

Separation of lipids by their respective head group was achieved via hydrophilic interaction liquid chromatography (HILIC) coupled to a HRMS instrument (Q Exactive). The resulting LC/HRMS datasets were processed to a list of chromatographically separated features by applying an optimized MZmine 2 workflow.[1] All features were plotted in a 3DKM plot for graphical lipid identification.

Results:

To demonstrate the novel adaption of KM plot analysis, occurring phospho- and glycolipid classes of the green alga *Chlamydomonas reinhardtii* have been separated using HILIC. Phospho- and glycolipid species have been identified by exact mass database matching and graphical 3DKM plot analysis according to [2]. LC-HRMS/MS datasets have been processed utilizing an optimized MZmine 2 workflow for feature list generation. Database matching was achieved by extending the already existing MZmine 2 module 'glycerophospholipid search' by adding missing phospho- and glycolipid classes. Furthermore, graphical analysis has been carried out by implementing a new visualization module in MZmine 2, which adds chromatographic characteristics, such as retention time, to a classic KMplot in form of a heat map. The developed visualization module is part of the MZmine 2 toolbox since version 2.31.

Conclusions:

The use of the novel adaption of the KM plot has accelerated the identification of the relevant lipid species in the green alga *Chlamydomonas reinhardtii*. 106 species were identified within the lipid classes: phosphatidylserine, phosphatidylethanolamine, phosphatidylglycerol, phosphatidylinositol, monogalactosyldiacylglycerol, digalactosyldiacylglycerol, and sulfoquinovosyldiacylglycerol.

Novel Aspect:

A tool for graphical analysis of HRMS/MS has been developed, using the Kendrick mass defect in combination with chromatographic characteristics.

Keywords: polyglycerophospholipids, (trimethylsilyl)diazomethane, nanoflow UPLC-ESI-MS/MS, Lipidomics, neurodegenerative disease

Introduction:

Polyglycerophospholipids include phosphatidylglycerol (PG), bis(monoacylglycerol)phosphate (BMP), Hemi BMP, and bis(diacylglycerol)phosphate (BDP) having two glycerols, and cardiolipin (CL), monolysocardiolipin (MLCL), and dilyocardiolipin (DLCL) having three glycerols [1]. These polyglycerophospholipids are generally synthesized from PG as a precursor and closely related to each other. Therefore lipidomic analysis of these lipids is important.

Methods:

Polyglycerophospholipids were methylated with (trimethylsilyl)diazomethane (TMSD) under an acidic condition. Deuterated reagents with DCI were used for relative quantitation by isotope-labeled methylation (ILM) method [2]. Efficacy of ILM for polyglycerophospholipids were evaluated using reversed-phase nanoflow UPLC-ESI-MS/MS.

Results:

The molecular structures of methylated polyglycerophospholipid standards were investigated with the CID experiments during nUPLC-ESI-MS/MS. The degree of methylation varied with the number of phosphate groups (1 for PG, BMP, Hemi BMP, and BDP, 2 for CL, MLCL, and DLCL). The efficiency of methylation for polyglycerophospholipids was found to be > 97% for most classes. Over-methylation in the free hydroxyl group of glycerol moieties were detected with less than 4.6%. PG and BMP which are geometrical isomers, and three isomers of BMP can be well resolved from each other after methylation by nUPLC-ESI-MS/MS. Furthermore, isomeric structures among Hemi BMP, MLCL, and DLCL can be well separated.

Conclusions:

In this study, analysis of polyglycerophospholipids were investigated with ILM method using TMSD. As a result, ILM method with nUPLC-ESI-MS/MS enhanced the capability of analyzing polyglycerophospholipids qualitatively and quantitatively. The developed method can be utilized to analyze urinary polyglycerophospholipids from neurodegenerative diseases such as Parkinson's and Alzheimer's diseases.

Novel Aspect:

Analysis of polyglycerophospholipids can be improved by using Isotope-labeled methylation (ILM) method in nanoflow UPLC-ESI-MS/MS.

751 - PLASMA LIPIDOMIC PROFILING OF FIVE DIFFERENT TYPES OF CANCER BY NUPLC-ESI-MS/MS

Gwnagbin Lee (1) - jongcheol Lee (1) - Myeonghee Moon (1)

Yonsei Univ./Chemistry, Yonsei Univ./Chemistry, Seoul (1)

Keywords: cancer, biomarker candidate, lipids, nUPLC-ESI-MS/MS

Introduction:

Lipids are the substances that play key roles in the metabolism of human bodies and are known to be related to cancer genesis pathways [1]. In this study, plasma lipids from 5 different cancer types (liver, stomach, lung, colorectal, and thyroid cancer) were investigated in order to discover potential lipid biomarkers of each cancer.

Methods:

Lipids were extracted from patient's plasma using the modified Folch method with MTBE/methanol [2], and the extracted lipids were analyzed by nUPLC-ESI-MS/MS. Due to the study that blood lipid metabolites are affected by hormones in women after menopause, only male plasma samples were used in this study.

Results:

As a result of analyzing the extracted lipids from patient's plasma with liver, stomach, lung, colorectal, and thyroid cancers along with that of healthy controls, a total of 357 lipid structures (58 PCs, 39 PEs, 26 PGs, 37 PIs, 26 PAs, 31 sphingo, 150 glycerol) were identified. Based on identified lipids, a total of 241 lipids (55 PCs, 58 PEs, 19 PGs, 24 PIs, 17 PAs, 21 sphingo, 47 glycerol) were quantified. Lipids showing significant changes (high abundance, >2-fold change, and one-way analysis of variance (ANOVA) with Bonferroni post hoc test with p -value < 0.05) in each cancer type were selected: 31 liver, 16 stomach, 23 lung, 24 colorectal, and 16 thyroid cancer. Statistical analyses of these selected lipids were performed with logistic regression and receiver operating characteristic (ROC) curve and the area under the curve values (AUC) of each cancer were more than 0.8 except for thyroid cancer.

Conclusions:

A total of 357 from patient's plasma with liver, stomach, lung, colorectal, thyroid cancer, and controls, were identified by nUPLC-ESI-MS/MS and among them 241 lipids were quantified by multiple reaction monitoring (MRM). Selected lipids showing significant differences from healthy controls can be utilized to develop characteristic biomarkers of cancers in the future.

Novel Aspect:

Lipidomic profiles of five different types of cancer patient's plasma were systematically examined by nUPLC-ESI-MS/MS with MRM along with statistical evaluations.

Keywords: Lipidomics, HepG2 cells, oxidative stress, LC/MS, multivariate analysis

Introduction:

Liver is the primary organ for glucose metabolism and regulation; therefore it is interesting to elucidate the effects of hyperglycemia in cultured liver cells. HepG2 cell, the human hepatoma cell line, has been used extensively to study hyperglycemia in vitro as evidenced by several reports [1,2]. HepG2 cells treated with glucose exhibited an upregulation of the transcription of human apolipoprotein A-II gene which causes a rise in plasma triglyceride level and glucose intolerance, resulting in hyperglycemia [3]. High glucose exposed HepG2 cells exhibited inhibition of 50AMP-activated protein kinase (AMPK) which plays a role in cellular energy homeostasis, and increased accumulation of lipids which were prevented either by metformin or by expressing the constitutively active AMPKa [4]. The high concentration of glucose also leads to oxidative stress, which plays an important role in the glucose-induced cellular dysfunction in diabetes complications [5]. Oxidative stress is defined as an imbalance between free radical production and antioxidant defense in a biologic system. It has been reported that irregular cellular metabolism in diabetes leads to generation of free oxygen radicals and reduction of antioxidant capacity [6].

In cells, lipids have functions as structural membrane components, sources of energy, and signaling molecules. As hormones and cellular messengers, lipids are particularly involved in many intracellular and intercellular signaling processes [7]. Furthermore, lipids adjust membrane fluidity and support diverse cellular processes [8]. Thus, it is critical to determine the cellular lipid metabolism correlated with oxidative stress.

Recently, liquid chromatography coupled to tandem mass spectrometry (LC-MS/MS) has been used as an effective tool to analyze various lipids from biological samples [9]. An ultraperformance LC (UPLC) enables the rapid and effective separation of individual lipid species [10]. Multiple reaction monitoring (MRM) based on triple quadrupole (QqQ)/MS is also applicable for the sensitive analysis of target compounds [11]. Optimal lipidomics based on UPLC-QqQ/MS has been widely applied to shed light on many biological events [12]. In this study, UPLC-QqQ/MS-based lipidomics was used to elucidate the altered lipid metabolism of HepG2 cells affected by the oxidative stress. We also treated anti-oxidative compound and extracts to the high glucose induced HepG2 cells and assessed the altered levels of lipids. The detailed characterization of lipids in HepG2 cells having oxidative stresses may provide a good understanding of the lipid metabolism correlated with oxidative stress.

Methods:

MTT and Lactate dehydrogenase (LDH) assay

Cell viability was determined by the quantitative colorimetric assay using MTT reagent. The cytotoxicity was also measured by lactate dehydrogenase (LDH) assay using commercial LDH detection kit for detection the leakage of soluble cytoplasmic LDH into the extracellular medium.

Lipid extraction

First, the cell pellet was added to 990 μ L chloroform/methanol (1:2, v/v) and 10 μ L 1 μ g/mL of lipid standards. The sample was incubated for 10 min on ice with vortexing for 30 s. After centrifugation (13,800 \times g, 2 min at 4°C), 950 μ L supernatant were transferred to a new Eppendorf tube. Second, the remaining pellet was resuspended in 750 μ L chloroform/methanol/37% (1N) HCl (40:80:1, v/v/v) and incubated for 15 min at room temperature with vortexing. The tube was transferred to ice, and 250 μ L cold chloroform and 450 μ L cold 0.1 M HCl were added followed by 1 min of vortexing and centrifugation (6,500 \times g, 2 min at 4°C). The lower organic phase was added to the tube, and subjected into LC/MS.

UPLC-QqQ/MS analysis

Lipid profiling was performed using the 6490 Accurate-Mass Triple Quadrupole LC-MS coupled to a 1200 series HPLC system (Agilent Technologies, Wilmington, DE, USA) with a Hypersil GOLD column (2.1 × 100 mm ID; 1.9 μm, Thermo Science). Solvent A consisted of an acetonitrile–methanol–water mixture (19:19:2) with 20 mmol/L ammonium formate and 0.1% (v/v) formic acid, and solvent B consisted of 2-propanol with 20 mmol/L ammonium formate and 0.1% (v/v) formic acid. The flow rate was 250 μL/min, and total run time was 30 min for each analysis. MRM conditions including transition and MS/MS collision energy were optimized to analyze target lipids in individual samples.

Data processing and multivariate analysis

LC/MS data were obtained and processed using Agilent Mass Hunter Workstation Data Acquisition software. The MRM data of target lipids, including m/z of precursor ions, m/z of product ions, and retention time (RT), were exported using Qualitative Analysis B.06.00 software (Agilent Technologies, USA). Next, the Skyline software package (MacCoss Laboratory, University of Washington, USA) was used as an in-house database to determine the peak area of each assigned lipid from replicate raw data. The extracted areas of lipid peaks were normalized to the appropriate IS. Multivariate analyses such as principal component analysis (PCA), the sparse projection to latent structure discriminant analysis (sPLS-DA), and analysis of variance (ANOVA) were performed using the MetaboAnalyst website.

Results:

Effects of ALM16 on high glucose-induced cell death and cytotoxicity in HepG2 cells

To determine the protective effects of the ALM16 on high glucose-induced cell death and cytotoxicity, HepG2 cells were pre-treated with the ALM16 for 2 h, and then treated with high glucose (30 mM) for 24 h.

The ALM16 (10–200 μg/mL) did not show significant cytotoxic effects. While treatment of the HepG2 cells with high glucose (30 mM) significantly reduced the cell viability to approximately 64.0% compared with the untreated control cells (100%), pre-treatment with the ALM16 (50, 100, and 200 μg/mL) for 2 hours before exposure to high glucose (30 mM) dose-dependently reduced the high glucose-induced cell death to 70.2%, 73.3%, and 78.5%, respectively. In addition, pre-treatment with silymarin (50 μg/ml), as a positive control, reduced the cell death to approximately 83.0%. The effect of the ALM16 on the high glucose-induced hepatotoxicity in HepG2 cells was confirmed by the LDH assay. Whereas an approximately 2.89-fold higher LDH activity was observed from the high glucose-treated cells compared with the untreated control cells (1.00 fold), HepG2 cells pre-treated with the various concentrations of ALM16 were reduced in a dose-dependently manner by 2.78-, 2.40-, and 2.23-fold increases in LDH activity, respectively. The cells pre-treated with silymarin (50 μg/ml) were also reduced LDH activity to 2.53-fold increase.

Lipid profiling of high glucose induced HepG2 cells treated with the mixture of Astragalus membranaceus and Lithospermum erythrorhizon extracts

Next, six samples of HepG2 cells (normal control (Con), Con + glucose 30 μg/mL (Glu30), Glu30 + silymarin 50 μg/mL (Sil50), Glu30 + ALM16 50 μg/mL (Alm50), Glu30 + ALM16 100 μg/mL (Alm100), Glu30 + ALM16 200 μg/mL (Alm200)) were subjected into lipidomic analysis. For the profiling of various lipids from these HepG2 cells, we used a previously constructed method using UPLC-QqQ/MS [13]. Lipid standards were used to optimize the MRM conditions for the analysis of TG, DG, MG, ChE, cholesterol, PC, PE, PS, PG, PI, PA, LPC, LPE, LPS, LPG, LPI, LPA, SM, Cer, dCer, So, Sa, Cer1P, So1P, and Sa1P. In particular, TMSD was used to methylate several highly acidic lipids, such as PS, PI, PA, LPS, LPI, LPA, Cer1P, So1P, and Sa1P. By using an octadecylsilyl silica column, various lipid species were separated according to their total carbon chain length (Cn) and total degree of unsaturation (Un). In the MRM data, the RT of each lipid was increased with a higher Cn and a lower Un. In this study, the skyline software was used to assign each lipid peak in the basis of RT and to calculate its peak area in the MRM data. Finally, in the HepG2 cell, a total of 336 lipid species were identified as follows: 23 TGs, 37 DGs, 8 MGs, 16 ChEs, cholesterol, 62 PCs, 28 PEs, 15 PSs, 5 PGs, 16 PIs, 34 PAs, 17 LPCs, 13 LPEs, 5 LPSs, 7 LPGs, 4 LPIs, 15 LPAs, 11 SMs, 11 Cers, 2 dCers, So, Sa, 2 Cer1Ps, So1P, and Sa1P. Furthermore, in the data processing of each lipid class, the calculated peak area of individual lipid species was normalized by the peak area of the IS. And then, the normalized datasets were subjected to statistical analysis.

Statistical analysis of lipid datasets obtained by the profiling of six HepG2 cells

The six datasets of lipids analyzed from Con, Glu30, Sil50, Alm50, Alm100, and Alm200 were subjected into multivariate analyses. Assays were carried out in triplicate (n = 3) for each sample. First, we applied the multiple pattern recognition methods such as PCA and sPLS-DA for visualizing the general clustering trends among the six groups. In the PCA score plot, the six groups were not sufficiently distinguished. For well discriminating the six

groups, we also applied the sPLS-DA that reduce the number of variables in the data to produce robust and easy-to-interpret model. In the score plot, points of Con were firstly separated with those of Glu30. Furthermore, other four groups including Sil50, Alm50, Alm100, and Alm200 were scattered between Con and Glu30 in the basis of Component 1. These indicated that cell lipid profiles differ depending on normal control, high glucose induced cells, and high glucose induced cells treated with silymarin or ALM16. In the sPLS-DA score plot, Sil50s were getting closer to Cons. This indicated that the lipid profiles of Sil50 are similar with those of Con comparing to Glu30. Furthermore, the points of Alm200, Alm100, and Alm50 were in order getting closer to those of Con. When the treatment amounts of ALM16 were increased, their points were closer to Cons than others. This indicated that ALM16 treatment is effective to suppress the cellular oxidation and recover the lipid metabolism. In the loading, we also presented the variable importance in projection (VIP) plot of 25 lipids (VIP scores Top 25) that were differently regulated among the six samples of HepG2 cells. Next, ANOVA test was performed to find the differentially regulated lipids (DRLs), which were statistically different lipids among the six groups. As a result, the p-values of 142 lipids were below 0.05 by using the Student's t-test, and we selected several lipids that have the lowest p-values to find the alteration of their relative levels in the six groups.

Conclusions

In this study, UPLC-QqQ/MS-based lipidomics was used to elucidate the altered lipid metabolism of HepG2 cells affected by the oxidative stress. In the cell experiments, we confirmed that high glucose treatment causes the cellular oxidation. Then, ROS may give effects on the metabolism of various metabolites including lipids. Silymarin is a well-known drug for the anti-oxidation activity. Thus, the treatment of silymarin may suppress the oxidation of high glucose induced cells. Alm treatment also showed the biological activity to suppress the oxidative stress. Thus, the treatment of silymarin or Alm may suppress the severe alteration of lipid metabolism in high glucose induced HepG2 cells. To detail characterize the lipid alterations of HepG2 cells affected by oxidative stress and treatment of silymarin or Alm, six samples of Con, Glu30, Sil50, Alm50, Alm100, and Alm200 were subjected into lipidomic analysis. Furthermore, multivariate analyses such as PCA, sPLS-DA, and ANOVA were applied to characterize the lipid alterations in these six groups. As a result, sPLS-DA well differentiated the lipid profiles of these six groups. In the ANOVA tests, 142 DRLs were identified to find the alteration of their relative levels in the six groups. Finally, we assessed the altered levels of lipids by oxidative stress, and suggested these lipids as the biomarker candidates associated with oxidative stress. Furthermore, we assessed the lipid alteration in the high glucose induced HepG2 cells treated by silymarin or Alm. When silymarin or Alm suppresses the damage of oxidative stress, it can decrease the degree of lipid alteration occurred by oxidative stress. With these results, it was possible to more understand how lipid metabolism of HepG2 cells was affected by oxidative stress. In future aspect, identified DRLs can be used as biomarker candidates to evaluate the oxidation of liver cells.

Novel Aspect:

This study firstly attempted to perform the LC/MS-based lipidomics analysis of high glucose induced HepG2 cells which were damaged by oxidative stress. Various lipids including glycerol lipids (i.e., TG, DG, MG), sterol lipids (i.e., ChE, cholesterol), phospholipids (i.e., PC, PE, PS, PG, PI, PA), lysophospholipids (i.e., LPC, LPE, LPS, LPG, LPI, LPA), and sphingolipids (i.e., SM, Cer, dCer, So, Sa, Cer1P, So1P, Sa1P) were profiled in the HepG2 cells, and their levels were assessed in six samples of Con, Glu30, Sil50, Alm50, Alm100, and Alm200. We also found how the pretreatment with silymarin or Alm before exposure to high glucose dose dependently attenuated the high glucose induced hepatotoxicity and altered lipid metabolism. The DRLs identified by multivariate analyses can be used as biomarker candidates to evaluate the oxidation of liver cells.

221 - MALDI-TOF/MS ANALYSES DETERMINED URINARY PHOSPHOLIPIDS AS A POTENTIAL BIOMARKER FOR PROSTATE CANCER

Xin Li (1) - Kenji Nakayama (2) - Takayuki Goto (1) - Shusuke Akamatsu (1) - Koji Shimizu (3) - Osamu Ogawa (1) - Takahiro Inoue (1)

Department of Urology, Kyoto University, Kyoto (1) - Support Center for Precision Medicine, Shimadzu Techno-Research Inc., Kyoto (2) - Clinical Research Center for Medical Equipment Development, Kyoto University Hospital, Kyoto (3)

Keywords: MALDI-TOF/MS; Urine; Prostate cancer; Phosphatidylcholine; Lysophosphatidylcholine.

Introduction:

The variations of phospholipids in plasma or tissues have been reported in several cancers, however they have not been elucidated in prostate cancer (PCa) especially in the non-invasive source of urine[1]. Matrix-assisted laser desorption and ionization time-of-flight mass spectrometry (MALDI-TOF/MS) is increasingly used in the lipid research which enables a rapid screening of phospholipids[2].

Methods:

Urinary lipidomic screening was performed by MALDI-TOF/MS (AXIMA Performance, Shimadzu) in the urine samples collected from 20 PCa and 20 benign prostatic hyperplasia (BPH) patients after digital rectal examination (DRE). Lipids were identified by MALDI-TOF/MS² analyses. The compositions of phosphatidylcholine (PC) and lysophosphatidylcholine (LPC) were compared between the PCa and BPH groups.

Results:

In this study we have focused on the DRE urine. The samples contain many kinds of lipids secreted from prostatic microenvironment, which enable the detection of secreted prostate products as potential sources of PCa specific biomarkers. The lipids were extracted from the DRE urine by the Bligh-Dyer method[3]. The urinary phospholipids including PC, LPC, phosphatidylethanolamine (PE) and phosphatidylglycerol (PG) species were detected by MALDI-TOF/MS and identified by MALDI-TOF/MS² in a reflectron positive mode. Among them, PC and LPC species were relatively abundant and with good reproducibility in the DRE urine samples. The peak intensities of the synthetic PC and LPC molecules spiked in the urine were detected by MALDI-TOF/MS and linearly correlated with their concentrations. The compositions of PC and LPC in the urine samples were significantly different between the PCa and BPH groups.

Conclusions:

The urinary phospholipids are detectable by MALDI-TOF/MS and identified by MALDI-TOF/MS². The relatively quantitative analyses of PC and LPC concentrations in the DRE urine samples are feasible and with good reproducibility. The MALDI-TOF/MS analyses determined the alteration of the compositions of urinary PC and LPC and it may be used as a simple and non-invasive biomarker for the PCa.

Novel Aspect:

We revealed the variations of urinary PC and LPC detected by MALDI-TOF/MS in PCa which may offer a simple and non-invasive method for PCa diagnosis.

726 - INVESTIGATION OF ONE NOVEL OXIDIZED 1-PALMITOYL-2-ARACHIDONOYL-SN-GLYCERO-3-PHOSPHOCHOLINE MOLECULE ON HUMAN AORTIC ENDOTHELIAL CELLS BY LC-MS/MS

Yu-Qing Chen (1) - Hsin-Pai Tsou (2) - Ying-Tzu Shieh (1) - Mine-Yine Liu (1)

National Changhua University of Education, Department of Chemistry, National Changhua University of Education, Changhua (1) - National Changhua University of Education, Department of Chemistry, NCUE, Changhua (2)

Keywords: Phospholipids, oxidation, human aortic endothelial cell, LC-MS/MS.

Introduction:

Phospholipids are the major components of cell membranes. Among them, 1-palmitoyl-2-arachidonoyl-sn-glycero-3-phosphocholine (PAPC) is especially important since oxidized PAPC products are closely associated with atherosclerosis. PAPC is composed of a polyunsaturated fatty acyl chain at the Sn2 position, and is highly susceptible to oxidation. Many of the oxidized PAPC products are bioactive.

Methods:

An LC-MS/MS method was developed to analyze one specific ox-PAPC molecule ($m/z=846.5$) in human aortic endothelial cells [1-5]. The optimal HPLC mobile phase compositions and flow rate were selected. For MS/MS, the optimal sheath gas pressure, capillary temperature, collision energy and injection time were chosen. Endothelial cells were treated with oxidized LDLs, extracted by liquid-phase and solid-phase extractions and then analyzed by LC-MS/MS.

Results:

Elucidation of the chemical structure of $m/z = 846.5$ was based on the MS2 and MS3 spectra [1-5]. Quantitation of $m/z = 846.5$ in HAECs was based on the reconstructed ion chromatogram (RIC) and selected multiple-reaction monitoring (SRM) of LC-MS/MS analysis. An internal standard was used to construct calibration curves for measuring the concentration of $m/z = 846.5$ in endothelial cells under oxidative stress.

Conclusions:

An LC-MS/MS method in conjunction with liquid-phase and solid-phase extractions has been developed to separate and identify a specific ox-PAPC molecule ($m/z=846.5$) in human aortic endothelial cells. The most possible structure of the ion is PAPC_5-epoxy_8-E/D-IsoP_14-epoxy which is elucidated from its MS2 and MS3 spectra. This new ox-PAPC molecular species has never been reported by other researchers so far.

Novel Aspect:

A novel ox-PAPC molecule ($m/z=846.5$) in human aortic endothelial cells has been found. Its chemical structure has been identified by LC-MS/MS analysis.

749 - EXPANDING THE LIPIDOME BY DATA-INDEPENDENT OZONE-INDUCED DISSOCIATION TO PROFILE COMPLEX LIPID ISOMERS

David Marshall (1) - Berwyck Poad (1) - Reuben Young (1) - Stephen Blanksby (1)

Queensland University of Technology, Institute for Future Environments, Brisbane (1)

Keywords: lipidomics, ozone-induced dissociation, data-independent analysis, plasma

Introduction:

Human plasma contains over 1500 different lipids at the sum composition level.[1] Yet the number of unique lipids present is surely higher, once isomeric contributions from double bond location and fatty acyl regiochemistry are considered. To close this gap, ozone-induced dissociation (OzID) is incorporated into data-independent lipidomics workflows, thus enabling complex extracts to be profiled for unsaturation and regioisomerism by construction of 2D maps.

Methods:

Ozone-induced dissociation was implemented on a Thermo Fisher Scientific LTQ Orbitrap Elite high-resolution mass spectrometer, equipped with an ESI source operating in positive ion mode. The instrument is modified such that nitrogen is replaced by ozone (~15% in oxygen) as the HCD collision gas. Lipid standards and complex extracts were introduced into the ESI source by direct infusion (Advion TriVersa NanoMate).

Results:

OzID performance was benchmarked using glycerolipid standards containing unsaturated fatty acyl chains. Isolation of lipid ions in the linear ion-trap, followed by interaction with ozone in the HCD cell yielded diagnostic ions for each double bond position and sn position in the resulting MS/MS spectrum. The increased ozone concentration in the HCD cell (compared to a single stage ion-trap instrument[2]) significantly improved ozonolysis efficiency. This advance translates into increased lipidome coverage, and improvements in duty cycle for data-independent MS/MS analysis using shotgun workflows. Grouping all precursor ions with a common OzID neutral loss enables straightforward classification of the lipidome by unsaturation position (with respect to the methyl terminus). Glycerolipids exhibiting common HCD/OzID product ions were classified according to the fatty acyl carried at the sn-1 position. 2-dimensional maps provide a straightforward visualization of the data.

Conclusions:

Resolving ambiguity in the molecular structure of lipids is the next frontier in contemporary lipidomics.[3] OzID provides access to this detailed level of molecular characterization. Global profiling of fatty acyl unsaturation within a biological extract provides a snap-shot of enzymatic biosynthesis and could potentially provide indicators of health and disease.

Novel Aspect:

First demonstration of a data-independent strategy combined with ozone-induced dissociation for comprehensive profiling of unsaturation in complex lipid samples.

Keywords: Lipidomics, translational research, coronary atherogenesis, asymptomatic patients, intermediate Framingham risk score, mass spectrometry.

Introduction: The appropriate management of subjects classified as intermediate Framingham risk score of cardiovascular events is challenging and uncertain [1,2]. The prospection of lipid markers in patients with non-calcified plaque is relevant for better disease monitoring, as a complementary technique to re-stratification and development of more efficient molecular diagnostic method [3,4]. Through a pilot conceptual design, using molecular qualifiers of the global lipid profile in noninvasive liquid biopsies, we evaluated possible markers involved in the process of coronary atherogenesis, in asymptomatic patients with intermediate Framingham. Comparing the global profile between patients with non-calcified plaque and calcified coronary plaques, against the control patient without plaque, we present discriminant features of the presence of coronary artery plaques and their composition.

Methods: Three subjects in each scenario classified as intermediate coronary artery disease according to Framingham risk score, asymptomatic, with myocardial perfusion scintigraphy negative for ischemia and normal left ventricular fraction on transthoracic echocardiography, were recruited into three groups according to coronary computed tomographic angiography (CCTA) results: (1) control patient without plaque (CTRL); (2) calcified coronary plaques (CCP); (3) non-calcified coronary plaques (nCAP). The lipid profile of the patients in each group, in triplicates, was analyzed by MALDI-MS in a Bruker Autoflex III MALDI-TOF/TOF mass spectrometer equipped with a 334 nm intelligent beam laser. The nonparametric statistical analysis was used to reveal the discriminant lipid profile through of the MetaboAnalyst software and analyzes of PCA and PLS-DA were performed.

Results: The selection of the most discriminants lipid ions was performed for VIPSCORE analyzes of PLS-DA, $p < 0.05$, showed differences between the three phenotypes (CTRL x CCP x nCAP) and distance between these phenotypes with VIPSCORE values between 1.5 - 2.7. The lipid profiles of the analyzed tomographic phenotypes can also be compare with the molecular findings, reinforcing the phenotypic stratification. Lipid profiles was statistic correlated with clinical golden patterns as calcium score, carotid intima-media thickness (ITCT), high sensitivity C-reactive protein (hs-CRP), and a family history of atherosclerotic disease in plaque prediction ability. The group of control patient without plaque (CTRL) displayed a diverse molecular feature, with high reproducibility within patients, when compare to other groups (calcified coronary plaques – CCP and non-calcified coronary plaques - nCAP), regardless their equal clinical stratification.

Conclusions: The global lipid profile of asymptomatic subjects at Framingham intermediate risk of coronary artery disease may be useful as a complementary molecular marker when correlated with the presence of plaque and its composition, presenting a possible good discriminant power between the different tomographic phenotypes. The implementation of this high performance analysis by mass spectrometry in clinical applications forward to an important future impact in the prevention of clinical events focusing on patients whose traditional risk markers were not able to predict the presence of coronary atherosclerosis.

Novel Aspect: Use of mass spectrometry in Cardiology as a high performance analytical tool to additional screening with other risk clinical stratifications.

643 - LIPID PROFILING OF NON-STEROIDAL ANTI-INFLAMMATORY DRUGS (NSAIDS) ON PROSTATE CANCER CELL LINES WITH TOF-SIMS AND DESI-MS

Danielle J McDougall (1) - Emrys Jones (2) - Claire Hart (3) - Michael Brown (3) - Adam McMahon (4) - Nicholas Lockyer (1)

University of Manchester, Division of Chemistry, Manchester (1) - Waters Corporation, Research and Development, Wilmslow (2) - University of Manchester, Division of Molecular and Clinical Cancer Sciences., Manchester (3) - University of Manchester, Division of Informatics, Imaging and Data Sciences, Manchester (4)

Keywords (5/5): Prostate Cancer, SIMS, DESI, NSAIDs

Introduction:

Prostate cancer (PCa) is the prime cause of cancer related death in Western men.¹ It is not possible to distinguish indolent and aggressive disease, leading to overtreatment and associated complications. NSAIDs can potentially prevent growth of PCa cells, offering an alternative treatment approach.² The response of NSAIDs on PCa cell lines varying in clinical aggression was studied using MSI.

Methods:

The lipidomic fingerprint was explored post NSAID treatment at a series of concentrations and time points. For DESI (Waters, Xevo-G2-SX), 95% methanol was used at a spatial resolution of 50 μm . For ToF-SIMS (Kore Technology Ltd), the samples were analysed using micro-focussed Au³⁺ clusters. Due to the hypoxic nature of the prostate, this was repeated under different levels of oxygenation.

Results:

The cell lines used for this study were LNCaP, LNCaP-C42 and LNCaP-C42B, which respectively increase in aggression. Post drug treatment, the proliferation assays demonstrated that trifluorinated ibuprofen (TFIB), ibuprofen (IBP), and orlistat, lead to a decrease in cell growth above 1 mM of IBP concentrations and 10 μM of Orlistat. ToF-SIMS and DESI analysis of the untreated cell line samples highlighted a number of differences in the ratios of lipid classes, including more abundant cholesterol species in the less aggressive LNCaP cells with phospholipids generally being more abundant in the more aggressive cell lines. After drug treatment, multivariate analysis highlighted further differences. Under varying levels of hypoxia, the untreated samples separate with principle component analysis, suggesting future work identifying which more accurately represents the prostate in vitro.

Conclusions:

The administration of NSAIDs leads to a decrease in PCa cell growth irrespective of their phenotype. Untreated PCa cell lines can be differentiated using ToF-SIMS and DESI with multivariate data analysis of the lipid fingerprint. NSAIDs alter these profiles suggesting lipid involvement in the drug pathway. Here we show the potential of MSI technologies to generate therapeutic mechanistic data.

Novel Aspect:

Using imaging MS techniques to examine the lipid profile of PCa cells with differing metastatic properties post drug treatment.

839 - DEFINING STRUCTURAL DIFFERENCES IN CARDIOLIPINS FROM AN ACTINOMYCETE MARINE SPONGE SYMBIONT AND *S. AUREUS*

Benjamin Oyler (1) - Courtney Chandler (2) - Fan Zhang (3) - Robert Ernst (2) - Russell Hill (3) - David Goodlett (4)

University of Maryland, Baltimore, School of Medicine, Baltimore (1) - University of Maryland, Baltimore, School of Dentistry, Baltimore (2) - University of Maryland Center for Environmental Science, Institute of Marine and Environmental Technology, Baltimore (3) - University of Maryland, Baltimore, School of Pharmacy, Baltimore (4)

Keywords: cardiolipin, mass spectrometry, ion mobility, symbiont, actinomycete

Introduction:

Marine sponges harbor complex microbiomes and novel bacteria associated with these sponges have been isolated and classified by 16S rDNA sequencing [1]. Sponge-symbiont relationships are not yet well understood. It is clear, however, that symbionts are responsible for a portion of the production of bioactive metabolites previously isolated from sponges. Some membrane lipids also have been shown to play a vital role in bacterial recognition by host cells.

Methods:

An actinobacterium (R45601) was isolated from *X. muta* and cultured in ISP2 medium. Cells were lysed and cardiolipins (CLs) were extracted according to the method described by El Hamidi, et al [2] for extraction of LPS. Extracts were dissolved in a 2:1:0.1 solution of chloroform, methanol, and water. Samples were analyzed first by MALDI-TOF using norharmane as matrix. Tandem mass spectra with ion mobility separation were acquired on a Q-IMS-TOF mass spectrometer.

Results:

A comparison of broadband mass spectra of extracted lipids, filtered by drift time in the ion mobility cell and m/z , from a clinical isolate [3] of methicillin-resistant *S. aureus* (MRSA-M2) and a recently discovered [4], marine sponge-associated actinomycete (R45601) showed that R45601 produces a pool of CLs with greater mean mass and possibly a higher degree of unsaturation than those produced by MRSA-M2. To identify fatty acyl groups incorporated into CLs from each species, MS/MS experiments were performed. The fatty acyl groups from CLs were released in the gas phase upon collisional activation as ionized free fatty acids with a single negative charge. These data show that ions observed in the single stage mass spectra which differ by multiples of 2 Da correspond to CLs with unsaturated fatty acyl groups. CLs from MRSA-M2 contained mostly saturated fatty acyl groups, whereas many CLs from R45601 contained at least one unsaturation. A possible explanation for this difference is that the mechanisms for CL synthesis differ between bacterial phyla.

Conclusions:

Comparisons of molecular classes from different organisms can be useful for generation of testable hypotheses. In this study, there were clear observations of differences in CL structure between representatives from two bacterial phyla. These structural differences may have implications with regard to bacteria-host interactions. CLs may play a role in sponge recognition of microbes. Differences in CL structure will also affect bacterial phenotype and behavior.

Novel Aspect:

Direct comparison of cardiolipins from a terrestrial firmicute and a marine actinomycete.

Untargeted lipidomics for the assessment of arsenic exposure in rice (*Oryza sativa japonica*)

Miriam Pérez-Cova^{1*}, Joaquim Jaumot¹, Romà Tauler¹

¹IDAEA-CSIC, Department of Environmental Chemistry, Barcelona, Spain

*mpcqam@cid.csic.es

Keywords: untargeted, lipidomics, LC-MS, arsenic, rice.

Introduction:

There is an increasing interest in how arsenic is assimilated and metabolized in plants-based foods such as rice (*Oryza sativa japonica*), due to the potential health risk that its accumulation might cause through food chain [1]. Lipidomics is a powerful approach to study lipid species present in rice, with the aim of determining the affected metabolic pathways.

Methods:

Two treatments were applied to rice crops: As was applied by irrigation (1 or 1000 μM), and directly to the soil before planting (5 or 50 ppm). LC-MS analysis was conducted using a Waters Acquity UPLC system connected to a Waters TOF mass spectrometer. A Kinetex C8 column (100 x 2.1 mm, 1.7 μm) was used for chromatographic separation. Multivariate tools (PCA, PLS-DA, ASCA) were employed in data analysis.

Results:

In watering treatment, the lower concentration was set at 1 μM , as it is the limit of acceptable As concentration in water by European legislation, whereas the higher concentration was chosen at 1000 μM , because it is expected to induce changes in plants without causing their death [2]. In soil treatment, the lower As limit was set at 5 ppm, as an average concentration of this element in Earth's crust, and the higher As limit at 50 ppm, as soil is considered to be contaminated by this element above 10 ppm [1].

Results obtained after chemometric analysis show that there are significant differences between treatments and concentrations, when compared with control samples (without arsenic treatment), especially in the case of the higher concentrations of this element.

The principal lipid families that were affected by As treatments were glycerophospholipids and acylglycerides.

Conclusions:

Only the highest As concentration levels (both in irrigation water or settled in soil) allowed the differentiation between samples. This complies with the European legislation, with permitted levels of the As exposure not showing relevant effects.

As a general lipidomic conclusion, glycerophospholipids and acylglycerides are the main families of lipids that were affected by the arsenic exposure.

Novel Aspect:

A lipidomic approach giving a better understanding of the metabolic pathways affected by arsenic exposure, and able to identify possible biomarkers.

High-Resolution Multiple Reaction Monitoring Method Development for Quantification of Steroidal Hormones in Plasma

Keywords: Lipidomics; MRM-HR; LC-MS/MS; Steroids; Chronic Stress

Introduction:

Advances in MS enabled development of HR-MRM and became the analysis of target analytes more specific in lipidomics approach, contributing in the medical and pharmaceutical fields. Hence, HR-MRM it is a sensitive and very specific virtual modes of acquisition that allows the simultaneous steroidal hormones quantification in low concentrations, such as observed in biological samples.

Methods:

HR-MRM method included cortisol, cortisone, corticosterone, 11-DHC, progesterone and aldosterone. Analytical validation was conducted according to the ANVISA guidelines. Specificity, linearity, intraday and interday precision and accuracy, and the LLOQ were evaluated. Plasma real samples of 129sv male mice exposed to chronic unpredictable stress were used to validate the quantification method.

Results:

The method was conducted according to the ANVISA normative, adopting a coefficient of variation (CV), as well as relative standard deviation (RSD) and relative error (RE) lower than 15% in linearity, intraday and interday precision and accuracy. For cortisol, corticosterone, and their inert metabolites (cortisone and 11-DHC), the LLOQ was 3.9 ng/mL, while those for progesterone and aldosterone was 7.8 and 15.6 ng/mL, respectively. The linearity of the method was between LLOQ-500 ng/mL for each analyte. HR-MRM analysis showed that animals submitted to stressors have 4.5 times more corticosterone in their serum than non-stressed mice and the levels of 11-DHC does not vary significantly in both groups. The development method showed adequate selectivity and sensibility for quantification of target analytes and can be used in several studies according the observed validation parameters.

Conclusions:

The results indicate that the method can be applied for quantification of steroids in several biological samples, such as human or animal plasma with selectivity and confidence. Thereby all studies that involve the balance of the target analytes can be conducted using this method for quantification.

Novel Aspect:

The HR-MRM method allows the monitoring of different steroids from human/animal origin, facilitating its application in several biological situations.

Keywords: microflow liquid chromatography, high-throughput screening, lipidomics

Introduction:

In the presentation we will describe the Micro-UPLC-MS system based on Vanquish Focused+ LC (Thermo) and TSQ Altis Triple Quadrupole Mass spectrometer (Thermo) for lipid analysis.

Methods:

Replacing conventional tubing of the system with micro ID tubing, adding a second pump and optimizing the injection strategy allows us to convert conventional system to micro with parallel chromatography capabilities. Run time using a 5 cm length column was less than one min per injection.

Results:

This system was successfully used for affinity screening of biomarkers from lipid pathways. This strategy is valuable when highly sensitive biomarker quantification in large sample set (library screening) is required.

Conclusions:

In the poster we will demonstrate performance of the micro-LC-MS system using endogenous sphingolipid biomarkers from cell extracts at sub ng/ml (limit of quantitation is 0.05ng/ml) concentration. We have evaluated Acclaim C8 0.3mm ID and BEH C18 1mm ID columns using gradient and isocratic chromatography. C8 was found to be more rugged but C18 enabled us to discriminate isobaric lipids.

Novel Aspect:

We have developed LC-MS based screens using microflow chromatography.

254 - CERAMIDOME PLASTICITY THROUGH ISO-ENERGETIC PRECURSOR AND NEUTRAL LOSS DISCOVERY SCANS.

Ceramidome plasticity through iso-energetic precursor and neutral loss discovery scans.

Keywords: Ceramide, epidermoside, collision-induced dissociation, screening, triple quadrupole,

Introduction: Mass spectrometric methods of identification and measurement are pivotal to investigate the multi-faceted biological role of ceramides and the dose-effect relationship of pharmaceuticals that modulate ceramide flux. Triple-quadrupole tandem MS embodies the highest flexibility to discover, identify and measure expected and unexpected molecular species, and an unprecedented scan mode is presented[1].

Methods: An API3000LTQ LC-MS system is operated under manufacturer's instructions to perform extensive tandem MS fragmentation studies on standard ceramides with C6-C24 fatty acids, lipid extracts of animal tissues and of nutraceutical seeds and nuts. LC separation and MS operation is optimized for the separation, detection, identification and quantification of expected and unexpected ceramides.

Results: The equation linking instrumental to center-of-mass collision energy (CoM-CE) in collision-induced dissociation is rearranged to calculate laboratory-frame inter-quadrupole potential drop (LF-CE) corresponding to distinctive positions, such as that of the CoM-CE maximum fragment yield, in the breakdown curves for protonated ceramides with molecular masses up to 1,000 Th. The value of the CoM-CE for distinctive fragments is calculated for representative ceramide FA homologs from accurate recordings of the spectra in the 0 to 90 DV interval of LF-CE. A scan function of the q2 collision cell is synchronized with the Q1 scan in the precursor ion mode and with the Q1 and Q3 scans in the Neutral Loss mode. Several lipid extracts containing ceramides are examined by infusion and by LC, and unexpected components, such as Z-ceramides in nut extracts are tentatively identified.

Conclusions Precursor and Neutral Loss scans with iso-energetic CID in the triple quadrupole MS allow to characterize ceramide mixtures that contain unexpected components with a common substructure to known ones. Individual response factors for (semi)-quantification of unexpected components can be calculated from the fractional intensity of the reporter fragment in the spectra of known components.

Novel Aspect: A novel scan function of a triple quadrupole instrument allows to measure tandem mass spectra at a constant center-of-mass collision energy.

1062 - SERUM LIPIDOMIC CHANGES IN ZIKA AND DENGUE VIRUS INFECTION REVEALS POTENTIAL TARGETS FOR ASSERTIVE CLINICAL DIAGNOSIS

Fabio Santos (1) - Aline Martins (2) - Kelly Magalhães (2) - Marcos Eberlin (3)

University of Campinas, Analytical Chemistry, Campinas (1) - University of Brasilia, Cell Biology, Brasilia (2) - University of Campinas, Organic Chemistry, Campinas (3)

Keywords: Zika virus, Dengue virus, lipidomic, serum

Introduction:

The Zika (ZKV) and Dengue (DENV) Virus have been a major public health challenge in the world due to large number of underreporting, inaccurate and false diagnoses. The lipidomic-based method to detect biomarkers of the physiological variations at all stages of the infection and immunological responses. Herein we showed that lipidomics-based mass spectrometry can be applied for molecular diagnostic of Zika and Dengue and co-infection of infected serum [1,2].

Methods:

The serum samples were separated in four groups through ELISA (IgG and IgM) protocol: 30 ZKV, 30 DENV and 30 controls. The method of metabolites extraction from 50 μ L serum infected was Bligh-Dyer. The upper phase was collected for lipidomic analysis using an Agilent 1290 Infnit LC-MS system coupled with an Agilent 6550 Q-TOF/MS mass spectrometer equipped with an electrospray source, in positive and negative modes.

Results:

The chromatograms were processed by XCMS software and multivariate analysis was made in the Metaboanalyst 3.0 software. The PLS-DA was applied to classify the serum samples according to the type of virus infection. Based in different class of lipids, the serum infected by ZKV and DENV were clearly distinguishable into two clusters by PLS-DA plot. The majors lipids identified as responsible for the differentiation of the two clusters, by variable importance in projection (VIP plot), were phosphatidylcholine (PC), lysophosphatidylcholine (LysoPC), phosphatidylinositols (PI), glycolipids and glycosphingolipids. The Gangliosides, particularly GM1, GM2, GD1a, GD1b, and GT1 were upregulated only under infection of the ZKV.

Conclusions:

Our study identified altered lipids phosphatidylcholine (PC), lysophosphatidylcholine (LysoPC), phosphatidylinositols (PI), glycolipids and glycosphingolipids of Zika and Dengue infection. The identification of specific biomarkers of the Zika and Dengue virus infections can perform the differential diagnosis of these arboviruses and closer to the actual clinical state of the patient.

Novel Aspect:

The lipids identified allude to possible novel diagnostic targets, pharmacological studies and advance our understanding on the mechanisms of arbovirus pathogenesis.

Migal--Galilee Research Institute, Laboratory of Vascular Signaling Research, Kiryat Shmona (1) - Migal--Galilee Research Institute, Oxidative Stress and Human Diseases Laboratory, Kiryat Shmona (2)

Keywords: LC-MS, lactones, PON1, polyunsaturated fatty acids (PUFA), structure determination

Introduction:

PON1 is an anti-atherogenic HDL-associated lactonase, whose native substrates remain unknown. PON1 knockout mice have low blood pressure and high levels of arachidonic acid (AA) metabolite 5,6-EET [1]. Under physiological conditions, 5,6-EET transforms to the δ -lactone 5,6- δ -DHTL [2], a PON1 substrate [3]. We hypothesize that additional lactone PUFA metabolites are potential PON1 substrates.

Methods:

To identify and characterize these lactones, we react lipid extracts from mouse kidneys with an amine to convert lactones to lactams that can be isolated using solid phase cation exchange. We apply high resolution liquid chromatography-mass spectrometry to determine the molecular formula of the original lactones. Molecular databases are used to find potential structures, and standards will be used to confirm or negate these structures.

Results:

The selective chemical reaction was developed using standards of different lipid functional groups (free fatty acid, ester, and two lactones of different ring size). Conditions were optimized to achieve reaction of the lactones and not of the ester. However, reaction of the fatty acid did occur. LC-MS analysis of similarly reacted lipid extracts from w.t. and PON1KO mice provided over 60 different chemical formulae of potential lactones, most of which were present in all samples ($n = 3$ pools of 5 kidneys for each strain). Using molecular databases, hundreds of potential lactone structures were identified. We are currently investigating ways to limit the search results to the most biologically relevant and likely structures. Standards of those structures will then be subjected to the same chemical reaction, extraction, and LC-MS method in order to confirm the structures of the unknowns in the biological samples. MS/MS experiments may be applied. It will then be investigated whether the confirmed structures are PON1 substrates.

Conclusions:

Chemical formulae of potential lactones were repeatedly identified in separate mouse kidney samples using LC-MS, while their precise structures are not yet known. Presently, further repetitions are underway to determine the differences between w.t. and PON1KO and pinpoint PON1 substrates. We hope that this research will shed light on the potential role of PON1 in blood pressure regulation.

Novel Aspect:

PON1 has been thoroughly studied in relation to atherosclerosis, yet the substrates of PON1 linking the enzyme to blood pressure regulation remain unknown.

Challenges of lipid isomers and isobars in mass spectrometry-based biomarker research
Ulf Sommer¹, Hai Tuan Pham¹, Therese Koal¹

¹ Biocrates Life Sciences AG, Innsbruck, AUSTRIA

Keywords: Isobars and isomers, lipidomics, high-resolution accurate-mass (HRAM) spectrometry, multiple-reaction monitoring (MRM)

Introduction

Interfering isobaric & isomeric species still constitute a major issue in the unambiguous attribution of lipid biomarkers to disease. MRM scanning allows to distinguish the main lipid classes, but not always isobaric subclasses. HRAM spectrometry (MS1) allows the distinction of these isobaric species but is not able to distinguish isomers. We are comparing two flow-injection analysis Methods:

Methods

Two commercially available kits using MRM or HRAM screening are being compared. They are used to measure a range of small molecules & lipids and have been validated for human plasma & serum, the AbsoluteIDQ[®] p180 Kit (1-3) for Waters Xevo TMTQ-S, Sciex QTrap[®] 5500 or ThermoScientific TSQ Vantage[™], and p400 HR Kit (2017) (ThermoQ Exactive[™] systems) (both Biocrates Life Sciences AG).

Results

Derivatization removes especially most phosphatidylethanolamines, the main interfering species, leading to more specific detection of PCs.

All realistically possible species covered by a result should be listed. The given name of the signal should refer to the most relevant species; lists with isobaric / isomeric species being provided.

In both cases, chromatography will assist the separation of species, but is limited due to high throughput requirements and the need for internal standards for different sections of the chromatogram to correlate with suppression effects.

The reliable quantitation of additional lipid classes can be achieved, e.g. as a service (4), but requires additional effort compared to the single high-throughput methods discussed here.

Conclusions

Screening using HRAM and low-resolution MRM will by their nature give somewhat different results due to different isobaric & isomeric compounds. The AbsoluteIDQ[®] p180 and p400 HR Kits provide standardized procedures for the fast and efficient detection and annotation of the major lipid classes. Use of HRAM increases coverage through complementary quantitative high-resolution measurements.

Novel Aspect

New guidance on how to interpret the different results obtained by lipid biomarkers screening via MRM versus HRAM.

407 - APPLYING TRAPPED ION MOBILITY SEPARATION (TIMS) IN COMBINATION WITH PARALLEL ACCUMULATION SERIAL FRAGMENTATION (PASEF) FOR ANALYSIS OF LIPIDOMICS SAMPLES

Matthias Szesny (1) - Sebastian Götz (1) - Sven Meyer (1) - Ulrike Schweiger-Hufnagel (1) - Aiko Barsch (1) - Ningombam Sanjib Meitei (2)

Bruker Daltonik GmbH, Metabolomics/Lipidomics, Bremen (1) - Premier Biosoft, Lipidomics, Palo Alto (2)

Keywords: PASEF; Ion mobility; Lipidomics; timsTOF PRO; Plasma

Introduction:

Untargeted lipidomics workflows are aimed at profiling changes in the lipidome which can lead to the discovery of lipids as potential biomarkers. We present an improved lipidomics identification workflow that is based on the combination of LC-MS and TIMS separation together with a data dependent MS/MS fragmentation (PASEF).

Methods:

LC separation was performed using a Bruker Elute UHPLC system. Data acquisition was performed with separate positive and negative ionization methods on a Bruker timsTOF PRO instrument. The instrument was in TIMS mode while acquiring MS/MS fragmentation (PASEF). The data sets were processed in MetaboScape 4 using 4-dimensional feature finder. Features were annotated using SimLipid software.

Results:

The TIMS technology adds an additional dimension of separation. To evaluate this effect on lipidomics analyses a direct infusion method was applied to critical pairs of isobaric and close isobaric lipids. A pair of isobaric phosphocholines (PC 18:1) differing only in the position of the unsaturation (9Z vs 6Z) could be separated with a mobility peak resolution of 175. A second almost isobaric pair (phosphoethanolamine&phosphocholine) could be fully baseline separated with a mobility resolution of 180.

LC-TIMS-MS measurements in PASEF mode were performed on extracts of commercially available plasma samples from different species (bovine, chicken, pig and human). The 4-dimensional feature finder in MetaboScape was used to extract the features from all analyses. The main precursor mass and the most intense fragment spectrum were exported to SimLipid software for identification.

Conclusions:

First results show 200-400 unique lipid IDs (depending on animal species). Compared to analyses performed without TIMS/PASEF an increase of 30-50% in identifications can be observed. Additional measurements will be presented to further highlight the benefit of PASEF.

Novel Aspect:

Lipidomics workflow combining positive/negative ion data using PASEF mode on an LC-TIMS-QTOF instrument.

300 - HOW TO ENSURE QUALITY IN THE ANALYSIS OF ENDOGENOUS COMPOUNDS IN BIOLOGICAL SAMPLES

Dominique Thomas (1) - Stefanie C. Fleck (2) - Robert Gurke (1) - Gerd Geisslinger (1) - Nerea Ferreirós (1)

Goethe University, Institute of Clinical Pharmacology, Frankfurt (1) - Fraunhofer IME, Project Group TMP, Frankfurt (2)

Keywords: endogenous compounds, quality assurance, validity of results

Introduction:

The mass spectrometric analysis of lipid mediators and other endogenous compounds remains challenging and rich in pitfalls. Variations between runs and even within runs impairing the validity of the data are hard to identify. We established a systematic approach to ensure the quality of data in the analysis of prostanoids in plasma samples by evaluating control samples using a control chart.

Methods:

A mass spectrometric method for the quantification of PGE₂, PGD₂, TXB₂, PGF₂α and 6-keto-PGF₁α in human plasma was validated according to EMA and FDA guidelines. After successful validation, a control chart was set up: blank plasma was spiked with prostanoids and aliquots were stored at -80 °C. In every analytical run, one control plasma aliquot was analysed in the beginning and one at the end of the batch, in addition to six freshly prepared quality control samples.

Results:

After analysis of 24 control samples over six weeks, for all analytes alert limits and control limits were defined depending on mean value and corresponding standard deviation. Exemplarily, results for PGE₂ were: MV 93.2 pg/mL, SD 8.7 pg/mL, alert limit $\pm 2 \cdot SD$ (75.8 pg/mL or 110.6 pg/mL), control limit $\pm 3 \cdot SD$ (67.1 pg/mL or 119.3 pg/mL). After six more weeks, a tendency of increased concentrations of all prostanoids in the control samples was observed, indicating instability of the analytes in plasma samples at -80 °C after 12 weeks. During validation, stability had been proven for 8 weeks.

Surprisingly, concentrations went back to the initial level after 10 more weeks. Detailed investigation revealed that the slopes of the calibration curves of the runs with increased concentrations of control samples differed from the slopes during the validation. These variations cannot be discovered when using only quality control samples. Thus, the control chart revealed difficulties in the preparation of calibration and quality control standard solutions.

Conclusions:

Due to lack of interlaboratory surveys for lipid mediators and other endogenous compounds, alternative tools for quality assurance are urgently required. Monitoring of control samples using control charts is a useful tool to ensure the constancy of the analytical results. Careful evaluation can reveal systematic errors, problems concerning stability of samples or analytical standards, lack of robustness and other issues relevant to quality.

Novel Aspect:

A systematic approach to ensure quality and validity in the analysis of endogenous compounds.

344 - STUDY OF ACETOGENINS IN A NATURAL EXTRACT USING SFC-HRMS/MS AND POST-COLUMN METAL CATIONISATION

Laboureur Laurent (1) - Champy Pierre (2) - David Toubou (1)

CNRS, ICSN, Gif-sur-Yvette (1) - CNRS UMR 8076 BioCIS, Pharmacy Faculty, Chatenay-Malabry (2)

Keywords: supercritical fluid chromatography, high resolution tandem mass spectrometry, post-column metal cationisation, lipid.

Introduction:

Acetogenins, lipids from the polyketide class and specifically found in plants from the Annonaceae family, are food toxins suspected to be responsible of atypical Parkinsonian syndromes. Acting as an inhibitor of mitochondrial complex I, acetogenins are also proposed as potential anti-cancer molecules. Previous dereplication studies highlighted some limitations of the HPLC-MS approach including long analysis time and low chromatographic resolution.

Methods:

Nowadays, supercritical fluid chromatography (SFC) can be considered as an alternative to LC for the study of hydrophobic compounds. Indeed, physicochemical properties of supercritical CO₂ allow excellent solubility of such analytes and give analytical performances above that of LC. However, examples using SFC-HRMS/MS to analyze natural extracts are poorly developed in the literature.

Results:

Due to the rarity of standards, a SFC-HRMS/MS method was directly developed using a crude seed extract of *Annona muricata* L. with a reduced analysis time by a factor of 4. Nevertheless, the fragmentation of protonated or sodium/potassium cationized species only led to limited structural information. For the first time, post-column lithium cationisation was fully optimized after SFC in order to form ion fragments of structural interest but of very low intensity. Finally, copper salt was employed allowing the detection of intense odd and even ion fragments related to unique radical-driven fragmentation pathways.

Conclusions

The final SFC-HRMS/MS method significantly improved the structural characterization of acetogenins highlighting the power of SFC-HRMS/MS in the field of natural products.

Novel Aspect:

For the first time, SFC-HRMS/MS including post-column cationization was implemented for the structural characterization of natural lipids.

1031 - MODELLING CANCER LIPOGENESIS USING LA-REIMS METABOLIC FLUX ANALYSIS IN BREAST CANCER CELL LINES

Seyma Turkseven (1) - Nikolaos Koundouros (2) - Renata Soares (1) - Luisa Doria (1) - Alvaro Perdones- Montero (1) - Simon Cameron (1) - George Poulogiannis (2) - Zoltan Takats (1)

University, Imperial College London / Department of Surgery and Cancer, London (1) - Institute, Institute of Cancer Research / Division of Cancer Biology, London (2)

Keywords: [U-13C]-palmitic acid, LA-REIMS, metabolic flux analysis, breast cancer, lipogenesis

Introduction:

Understanding alterations in the lipid metabolism of cancer cells is important due to the role that lipids play in membrane fluidity, energy storage and signalling processes. Using U-13C-labelled palmitic acid, biosynthetically incorporated into fatty acids, provides a further understanding of lipogenesis in in vitro studies. Here, laser assisted rapid evaporative ionisation mass spectrometry (LA-REIMS) was performed to monitor metabolic flux during cell proliferation.

Methods:

SkBr3 cells were grown in DMEM containing 1% fatty acid free-BSA, and treated with [U-13C]-palmitic acid under normoxic conditions for 24h. After centrifugation, cell biomass pellets were analysed directly with LA-REIMS analysis without further sample processing steps. LA-REIMS spectra were obtained in the mass range m/z 50-2500 in positive and negative ion modes and putative identification was performed using the LIPID MAPS database

Results:

LA-REIMS analysis of cell lines resulted in specific lipidomic profiles that enabled the identification of different cell lines. Common adduct formations such as [M-H]⁻ and [M-H₂O]⁻ in negative mode and [M+H-H₂O]⁺, [M+H]⁺ or [M+Na]⁺ in positive mode were detected in the metabolic flux experiment for SkBr3 cells. [U-13C]-palmitic acid was detected with m/z 271.2 in negative ion mode in SkBr3 cells. From the data obtained, the labelled lipid composition of SkBr3 cells in negative mode was observed to consist of phosphatidylethanolamines (e.g. PE (P-38:6) at m/z 746.5), sphingomyelins (e.g. SM (34:1) at m/z 701.5), and phosphatidylserines (e.g. PS(36:0) at m/z 790.5). In positive mode, diacylglycerides (e.g. DAG(32:1) at m/z 549.4) and ceramides (e.g. Cer(42:0) at m/z 634.6) were found in the cell line material

Conclusions:

The use of stable-isotopically labelled palmitic acid in conjunction with LA-REIMS analysis allowed specific biochemical information to be collected. This approach will help to further understand how palmitic acid is being incorporated into the lipid biosynthesis pathway in a rapid and sample preparation free approach. This preliminary data demonstrates the applicability of LA-REIMS for the characterization of metabolic flux experiments using labelled metabolites.

Novel Aspect:

LA-REIMS analysis can be used in metabolic flux analysis experiments in rapidly proliferating cells to model breast cancer lipogenesis – potentially identifying novel diagnostic markers and drug targets.

1215 - LIPIDOMICS ANALYSIS OF CELLS AND TISSUES IDENTIFIES THERAPEUTIC TARGETS

Michael Wakelam (1) - An Nguyen (1) - Qifeng Zhang (1) - Roberto Solari (2)

Babraham Institute, Signalling, Cambridge, United Kingdom (1) - Imperial College, Imperial College, London, United Kingdom (2)

Keywords: Mass spectrometry, lipidomics, pathway analysis, colorectal cancer, rhinovirus

Introduction:

Theoretically mammalian cells can contain many thousands of individual lipid molecular species, whilst it is unlikely that all are present in a single cell, lipidomic experiments have demonstrated the presence of more than a thousand species. The integrated regulation of changes in lipid species that occur that can regulate cell functions, including signalling and metabolism, highlights the need for bioinformatics analysis to fully interpret lipidomics data.

Methods:

We have adopted two experimental systems: lipids extracted from colorectal tumour tissue and rhinovirus-infected human bronchial epithelial cells, were identified by LC-MS/MS. Pathway analysis of lipid metabolising enzymes coupled to network optimising Prize-collecting Steiner tree problem methodology was adopted to identify key enzymatic changes which could be considered as therapeutic targets.

Results:

Lipidomic analysis that compared colorectal tumour tissue of defined stage with matched normal tissue showed changes in more than 700 lipid species, this also demonstrated changes in acyl chain saturation and chain length accompanying tumour progression. In the rhinovirus-infected cells there were temporal-associated changes in a number of lipids including PIP, cardiolipin, PC and DG, there were also clear changes in the acyl chains of neutral and phospholipids.

Pathway analysis highlighted key changes in sphingolipid metabolising enzymes in both systems including sphingosine kinase and ceramide synthase activities. Further, adopting the network optimising Prize-collecting Steiner tree problem methodology, we were able to identify fatty acid synthases, acyl transferases and ceramidases as potential therapeutic targets. The importance of a number of these activities in viral infection was confirmed by observing inhibitory effects of selective inhibitors upon infection of human bronchial epithelial cells by rhinoviruses.

Conclusions

The lipidomics-determined changes identify potential novel therapeutic targets, they additionally suggest roles for remodelling of membrane lipid acyl chains thus changes in membrane fluidity, protein binding or curvature may have important roles in infection and disease progression.

Novel Aspect:

Lipidomics with appropriate bioinformatics analysis can point to key enzyme activities that are responsible for disease-associated change. This can therefore point to novel therapeutic targets that can be subsequently explored.

537 - IMPROVED LIPID ANNOTATION UTILIZING POSITIVE AND NEGATIVE ION MS2 / MS3 HCD AND CID SPECTRA

David Peake (1) - Reiko Kiyonami (2) - Daniel Gachotte (3) - Yasuto Yokoi (4) - Sally Webb (1) - Andreas Huhmer (5)

Thermo Fisher Scientific, CMD Life Sciences Research, San Jose (1) - Thermo Fisher Scientific, Thermo Fisher Scientific, San Jose (2) - Dow AgroSciences, Dow AgroSciences, Indianapolis (3) - Mitsui Knowledge Industry, Mitsui Knowledge Industry, Tokyo (4) - Thermo Fisher, CMD Life Sciences Research, San Jose (5)

Improved Lipid Annotation Utilizing Positive and Negative Ion MS2 / MS3 HCD and CID Spectra

David A Peake¹, Reiko Kiyonami¹, Daniel Gachotte², Yasuto Yokoi³, and Andreas Hühmer¹

¹Thermo Fisher Scientific, San Jose, CA, United States

²DOW AgroSciences, Indianapolis, IN, United States

³Mitsui Knowledge Industry, Atago, Tokyo, Minato-ku, Japan

Introduction:

We present improvements to Thermo Scientific LipidSearch software. New algorithms are introduced to reduce false positives, improve quantitation and to automate searching of LC-MSn data obtained by higher collisional energy (HCD) and linear ion trap collisional induced dissociation (CID) fragmentation Methods: The use of LC-MSn is applied to the more complete characterization of triacylglycerols in total lipid extracts from bovine tissue and insect larvae.

Methods:

Bovine liver and insect larvae total lipid extracts were analyzed by data dependent LC/MS2 and MS3 using a Tribrid Orbitrap instrument. The MSn data were searched against the m/z of selected lipid precursor ions in the LipidSearch database and their predicted product ions and neutral losses. Each lipid adduct ion is ranked by mass tolerance, match to the predicted fragmentation and fraction of total MS-MS intensity.

Results:

The number of lipid species annotated in each experiment were assessed at the sum composition (MS) and isomer (MSn) levels. LC-dd-MS2/MS3 spectra for potential lipid species were annotated separately from positive and negative ion adducts. Each lipid annotation was correlated within a chromatographic time window by merging the positive and negative ion MSn data into a single lipid result. This approach provides lipid annotation that reflects the appropriate level of MS2/MS3 product ions and neutral losses from the entire dataset giving higher confidence in lipid annotations. The merged results were filtered by minimum number of data points, signal-to-noise ratio, adduct ion, match score, ID quality, and coefficient of variation from replicate sample injections. Compared to the results generated only from dd-MS2 HCD results, a combination of HCD and CID LC-MSn gave significantly higher quality lipid identifications. From bovine liver the number of PC and TG results with complete acyl chain information improved by 12% to 23%, respectively.

Conclusions

Lipid annotation is often over-reported because the current software/database approaches match mass spectral evidence to exact lipid structures[1]. The lipidomics community is working towards reporting the correct level of annotation based upon the available mass spectral information. Utilizing a combination of HCD MS2 and intelligent product ion or neutral loss triggered CID MS2/MS3 data improves lipid annotation available within a single LC/MSn experiment.

Novel Aspect:

LipidSearch 4.2 new software for improved lipid annotation and increased confidence using positive/negative ion, HCD/CID LC/MSn data from Orbitrap mass spectrometers

1381 - CONSTRUCTION OF NOVEL LIPIDOMICS PLATFORM COMBINED OF TARGETED AND NON-TARGETED ANALYSIS

Yasuto Yokoi (1) - Hideya Kuwabara (1) - Tadahiro Hoshino (1) - Akio Hayashi (2)

Mitsui Knowledge Industry Co., Ltd., Bioscience department, Tokyo, Japan (1) - ONO Pharmaceutical Co.,LTD., Minase Research Institute, Osaka, Japan (2)

Keywords: lipidomics; informatics; quantitative analysis; RT correction

Introduction:

Targeted lipidomics (TL) using selected ion monitoring (SRM) enable high sensitive quantitative analysis for certain lipids in biological sample. However, overlapped chromatographic peaks from isomer and fluctuations in retention time of chromatograms cause miss alignment among samples. Here we developed novel lipidomics platform named MetaboAlign which can solve these issues by combining TL with Non-targeted lipidomics on data dependent acquisition (DDA).

Methods:

MetaboAlign, which is consisted of peak detection module, alignment module, and viewer was written in Java. SRM data for rat plasma samples (n10) measured by 4000 Qtrap (Sciex) were converted to MzML by ProteoWizard. DDA data were measured by QExactive HF (Thermo Fisher Scientific), which were used for lipid identification by LipidSearch4.2TM (Mitsui Knowledge Industry). Both results were imported to MetaboAlign, quantitative profiles of lipids were calculated.

Results:

MetaboAlign performs quantitative analysis including peak detection, alignment, identification and calculation of concentration automatically. RT correction algorithm enables large number of peaks in each sample to align with high accuracy. Combination with non-targeted lipidomics (NTL) using high resolution mass (HRMS) can also assign lipid to each peak in distinction from its isomer. We applied this software to rat liver sample (n10). As a result, 861 kinds of lipid species were identified by NTL, 496 of which were acquired as lipid profiles by TL.

Conclusions

Novel lipidomics platform combined TL with NTL was developed. Rapid and accurate quantitative analysis of large sample sets was successfully achieved using the software.

Novel Aspect:

Comprehensive and effective platform for large scale quantitative analysis using combination of targeted and non-targeted lipidomics is presented.

66 - NON-SUBJECTIVE CHARACTERIZATION OF MEDULLOBLASTOMA SUBGROUP AFFILIATION WITH DESORPTION ELECTROSPRAY IONIZATION MASS SPECTROMETRY

Arash Zarrine-Afsar (1) - Michael Woolman (2) - Alessandra Tata (3) - Isabelle Ferry (4) - Claudia Kuzan-Fischer (4) - Megan Wu (4) - Sunit Das (4) - Michael Taylor (4) - James Rutka (4) - Howard Ginsberg (5)

University of Toronto, University Health Network, TECHNA Institute, Toronto (1) - University of Toronto, Medical Biophysics, Toronto (2) - University Health Network, TECHNA Institute, Toronto (3) - Hospital for Sick Children, University of Toronto, Toronto (4) - St Michael's Hospital, University of Toronto, Toronto (5)

Keywords: Desorption electrospray ionization mass spectrometry, medulloblastoma, lipid profiling, rapid pathology, tissue smears

Introduction: Medulloblastoma (MB) is a heterogeneous pediatric brain tumour comprised of 4 molecular subgroups that appear morphologically identical, under the microscope for conventional intraoperative, rapid pathologic assessment [1-3]. While each MB subgroup presents its own survival rate, unique response to chemotherapy and the necessary aggressiveness of resection, they remain indistinguishable intraoperatively.

Methods: Desorption electrospray ionization mass spectrometry is an effective technique for tumour type identification based on profiling of tissue lipid and small metabolites [4,5]. Here we subjected the rapidly prepared smears of murine models of medulloblastoma tumours to DESI-MS analysis to harness both the specificity and the sensitivity of this technique in determining MB subgroup affiliation in less than 1 min of sample preparation and analysis time.

Results: Mouse cell-line derived xenograft tumours of MB Group 3 and SHH subgroups were subjected to preparation of smear samples (30 seconds) and 100 seconds of DESI-MS data collection for the preparation of multivariate statistical model that can distinguish between the two subgroups using. The model was comprised of 400 data points (200 per subgroup) comprised of 5 independent cell lines and 10 independent tumours, and showed clear separation of data points belonging to each subgroup. The model was validated using 20% leave out test. The predictive ability of the model was then assessed using blind tests. Smear spreads from two independent tumours belonging to each MB subgroup were prepared in 30 seconds and subjected to additional 10 seconds of DESI-MS data collection and real time analysis against the multivariate model using binned spectral data. A success rate of greater than 95% was achieved using the combined platform of rapid DESI-MS analysis of smears and online multivariate recognition and model comparison platforms.

Conclusions : Rapid determination of medulloblastoma subgroups based on DESI-MS lipid profiles in less than 1 min of smear sample preparation and analysis time is shown to be possible. This observation allows prognostic information regarding surgical margin extent tailored to the specific requirement of each MB subgroup to be fully utilized within the time constraints of surgery, further highlights specificity of lipid profiling with DESI-MS.

Novel Aspect: Identification, within 1 minute, of morphologically identical subgroups of same tumour type with DESI-MS analysis of tissue smears based on lipid profiling is possible.

A.10 LIFE SCIENCES - GLYCOMICS, SACCHARIDES AND GLYCOCONJUGATES

1324 - TOP DOWN PROTEOMICS OF HUMAN ALPHA-ACID-GLYCOPROTEIN: FAST AND UNAMBIGUOUS GLYCAN ANALYSIS

Melissa Bärenfänger (1) - Bernd Meyer (1)

University of Hamburg, Department of Organic Chemistry, Hamburg, Germany (1)

Keywords: Top-Down Proteomics, Glycan Analysis, negative ion mode, Alpha-Acid-Glycoprotein, ESI-MS

Introduction:

Glycosylation is an important posttranslational modification as it modulates biological functions of proteins. An altered glycosylation is found in a variety of diseases such as cancer, neuronal diseases and inflammation. Therefore, monitoring changes in glycosylation leads to a better understanding on how glycosylation influences the development and progression of these diseases and can be applied for biomarker development.

Methods:

We present a top down approach for qualitative and quantitative analysis of highly glycosylated human alpha-acid-glycoprotein (AGP). After purification of AGP from human plasma, subsequent ESI-q/TOF-MS measurement in negative ion mode revealed the broad mass distribution caused by glycosylation. To support data interpretation, AGP was also analyzed after desialylation. In-house developed bioinformatics tools were used for data interpretation.

Results:

Analyzing AGP as native glycoprotein and after treatment with neuraminidase reduced sample preparation and led to a fast and robust method for glycan analysis. We were not only able to determine the proteins glycosylation pattern but also to identify various genetic variants for AGP-1 and AGP-2. The variants did not show significant differences in their glycosylation pattern. The fully sialylated glycoprotein showed an almost complete termination with sialic acids of all antennae, carrying on average 16 to 17 sialic acid residues. To demonstrate the possible use of this method for biomarker development, we analyzed one sample from a patient diagnosed with liver cirrhosis and one diagnosed with hepatocellular carcinoma. In both cases, a drastically increased fucosylation over all glycosylation sites was observed.

Conclusions:

Our method presents a way of detecting different genetic variants and determine the glycosylation pattern specific for each variant at the same time. Bioinformatics tools analyzed the complex heterogeneity in glycosylation unambiguously. Changes in glycosylation as e.g. increased fucosylation due to cancer diseases can be detected and quantified easily.

Novel Aspect:

Ionizing highly sialylated glycoproteins in negative ion mode enhances signal intensity and can be applied for quantification of glycans in use as clinical biomarker.

Isabelle Compagnon (1)

Institut Lumière Matière. Université Lyon 1/CNRS. Villeurbanne. France. Institut Universitaire de France. Paris. (1)

Keywords: Mass Spectrometry; Infrared Ion Spectroscopy; Carbohydrate structure; Carbohydrate sequencing

Deciphering the sequence of carbohydrates is a major challenge in glycosciences today. Whereas spectroscopic approaches (NMR, Raman, ...) and Mass Spectrometry (MS) offer valuable information on carbohydrate structure, they also suffer from severe technical limitations: on one hand, spectroscopy provides refined structural detail but requires a relatively large amount of purified sample, on the other hand MS applies to complex samples in small amounts, but does not disambiguate all carbohydrate isomerisms.

In this context, we have developed a unique hybrid Glycoanalytical approach, which adds a spectroscopic dimension to MS analysis. Based on this technology, it is possible to measure simultaneously the MS spectrum and the spectroscopic fingerprint of a carbohydrate. This enables the disambiguation of all kinds of carbohydrate isomerisms (monosaccharide content, regiochemistry and stereochemistry of the glycosidic bond, and positional isomers of functional modifications) without the need for chemical modification, labeling, or time-consuming purification.

While this new carbohydrate metric mitigates the lack of structural specificity of MS without the limitation of traditional spectroscopy, the identification of a carbohydrate however still relies on the availability of referenced standards. In order to enable true "de novo" analysis, we have established a top-down sequencing strategy based on the demonstration of a memory of the carbohydrate sequence within MS fragmentation products. [1] The performance of de novo carbohydrate sequencing will be illustrated on various classes of carbohydrates.

430 - REDUCTIVE ALKALINE RELEASE OF N-GLYCANS GENERATES A VARIETY OF UNEXPECTED, USEFUL PRODUCTS

Rudolf Figl (1) - Friedrich Altmann (1)

University of Natural Resources and Life Sciences, Chemistry / Glycobiology, Vienna (1)

Keywords: N-glycans, alkaline release, PGC-LC-ESI-MS

Introduction:

Release of O-glycans by reductive β -elimination has become routine in many glyco-analytical laboratories and concomitant release of N-glycans has repeatedly been observed. Revisiting this somewhat forgotten mode of N-glycan release revealed that all kinds of N-glycans including oligomannosidic and complex-type N-glycans from plants with 3-linked fucose and from mammals with or without 6-linked fucose and with sialic acid could be recovered.

Methods:

Typical conditions for the alkaline borohydride treatment of glycopeptides were varied in case of temperature and concentration of chemicals. Following PGC SPE cleanup, yield and chemical nature of the products were investigated using MALDI-TOF MS and PGC-LC-ESI-MS. Reducing glycans were labelled with 2-aminobenzamide, reducing glycosylamine and 1-amino-1-deoxy-glycitol with InstantPC™ dye. The fluorescent products were separated by HILIC-FLD-HPLC.

Results:

Even after 16 h incubation in 1 M sodium borohydride, a large part of the glycans occurred in reducing form. Moreover, about one third emerged in the form of the stable amino-functionalized 1-amino-1-deoxy-glycitol. Relative yields of the products reducing glycosylamine, reducing N-glycan, 1-amino-1-deoxy-glycitol or glycitol could be controlled by the release conditions.

Conclusions:

Chemical release of N-glycans constitutes a cost-saving alternative to enzymatic hydrolysis for the preparation of precursors for the production of reference compounds for various formats of N-glycan analysis. Moreover, it allows to obtain a stable amino-functionalized glycan derivative, which can be employed to construct glycan arrays or affinity matrices.

Novel Aspect:

While the principle observation of the release of N-glycans by alkali under reducing conditions was made decades ago, the very nature of the generated products has not been recognized so far.

Analysis of mouse brain N-glycans by (PGC-)LC-ESI-MS using isotopically labeled standards

Grünwald-Gruber C , Thader A ,Urteil J, Maresch D , and Altmann F

University of Natural Resources and Life Sciences, Vienna, Austria

Introduction

N-glycosylation is the most complex and heterogeneous post translational modification. It is important for protein folding, stability and biological interactions of many proteins. The large number of possible isomers yielding from one glycan composition necessitates powerful separation techniques (porous graphitic carbon LC) and the use of defined standards combined with MS/MS.

Methods

Proteins of mouse brain tissue was purified, treated with PNGase F to release the N-linked glycans and reduced with sodium borohydride. The glycans were purified and directly subjected to a PGC-LC-ESI-MS system (QTOF instrument). Prior to the measurement defined isotopically labeled N-glycan standards were added to identify and quantify the isomers occurring. The incorporation of different numbers of heavy isotopes at varying positions ($^{13}\text{C}_6$ - and $^{13}\text{C}_1$ galactose, reduction with sodium borodeuteride or deuterio acetyl groups of GlcNAc) allowed the assembly of internal multiplex standards mixtures.

Results

The major glycan was found to be a bisecting, fucosylated GnGn (GnGnF (bi) -proglycan nomenclature, www.proglycan.com). All main isoforms could be identified and relatively quantified. The ability of PGC to discriminate about 30 different isobaric mono-fucosylated N-glycans was shown (H5N4F1). Absolute quantification could be furthermore achieved by the quantitation of one ^{13}C labelled standard by amino sugar analysis. This one internal standard allowed for the calculation of the other glycoforms by the use of instrument dependent correction factors (calculated ratios known from an equimolar standard mix [1])

Conclusions

A powerful method for the analysis of N-glycans in complex tissue samples is presented. The use of different labeled standards allowed identification and quantification of glycan isoforms in a single MS-run.

363 - ASSIGNMENT OF LINKAGE, ANOMERIC CONFIGURATION, AND BRANCH LOCATION OF OLIGOSACCHARIDES VIA A LOGICALLY DERIVED MSN APPROACH

Hsu Chen Hsu (1) - Chia Yen Liew (1) - Shih-Pei Huang (2) - Shang-Ting Tsai (1) - Chi-Kung Ni (3)

Institute of Atomic and Molecular Sciences, Academia Sinica, Institute of Atomic and Molecular Sciences, Academia Sinica, Taipei (1) - Institute of Atomic and Molecular Sciences, Academia Sinica, Department of Chemistry, National Taiwan Normal University, Taipei (2) - Institute of Atomic and Molecular Sciences, Academia Sinica, Department of Chemistry, National Tsing Hua University, Taipei (3)

Keywords: carbohydrate, branched and linear oligosaccharides, structural determination

Introduction:

Carbohydrates (or glycan) play influential roles in cellular recognition processes and many other biological processes. However, the structural determination of oligosaccharides remains an obstacle and constitutes a bottleneck in carbohydrate research. An approach for de novo structural determination of linear and branched oligosaccharides based on logically derived procedure of tandem mass spectrometry was demonstrate.

Methods:

A commercial linear ion trap mass spectrometry (LTQ XL, Thermo Scientific) coupled with electrospray ionization was employed in this study. The selection of structural decisive fragment ions for the subsequent CID was guided using a procedure that we built from the understanding of the saccharide dissociation mechanism. The complete structural identification is obtained by combining the structural information from each step of CID.

Results:

A specially prepared disaccharide CID spectrum database consisted of 16 mannobioses was build. Low-energy collision-induced dissociation (CID) of sodium ion adducts was used to facilitate the cleavage of desired chemical bonds during dissociation. The linkages, anomeric configurations, and branch locations of oligosaccharides are determined by comparing the CID spectra of oligosaccharide with the fragmentation patterns based on dissociation mechanism and our specially prepared disaccharide CID spectrum database. The applications of this method to structural determination of mannose-oligosaccharides were demonstrated. The structure of a given trisaccharides from 88 isomers and tetrasaccharide from 928 isomers can be determined by only 3-5 properly selected CID mass spectra according to the logical procedure we derived. The results show that this method provides a rapid structural identification procedure for mannose oligosaccharides and can be extended to glucose and galactose oligosaccharides as well.

Conclusions:

We demonstrated a simple method that an oligosaccharide can be identified from hundreds isomers by only using 3-5 properly selected CID spectra. The required CID spectra for structural identification can be determined from the schemes we derived according to the dissociation mechanisms. The entire procedure for these four CID spectrum measurements only take few minutes, demonstrating this approach is a simple and rapid method for the structural determination of oligosaccharides.

Novel Aspect:

The approach can be built in a computer controlled mass spectrometer and ultimately developed into a automatic procedure for structural identification of oligosaccharides.

157 - FRAGMENTATION OF OLIGOSACCHARIDES AND SUPPRESSION OF METAL-SALT INDUCED ADDUCTS USING ELECTROSPRAY IONIZATION

Volker Iwan (1) - Jürgen Grotemeyer (1)

Institute of Physical Chemistry, Christian-Albrechts-University Kiel, Kiel (1)

Keywords: Mass spectrometry, FT-ICR, Oligosaccharides, CID, alkaline adduction

Introduction

It is known that alkaline adduct-ions influence CID and PD induced fragmentation mechanisms of oligosaccharides [1,2]. For proteins the use of ammoniumacetate to counteract cation induced signal suppression in electrospray ionization is published [3]. To increase the intensity of the non-adducted molecular ion the application of ammoniumacetate to oligosaccharide containing samples is of interest.

Methods

The experiments were performed on an APEX Qe FT-ICR mass spectrometer, with a 9.4 T superconducting magnet (Bruker Daltonik, Bremen, Germany). Maltopentaose (MP) was dissolved in MeOH/H₂O and ionized using an Apollo III ESI-source. To analyse the suppression of alkali-adducts NH₄Ac was added to the samples. Fragmentation of the molecular cations were achieved by SORI-CID with argon as collision gas.

Results

Several spectra of maltopentaose with different concentrations of NH₄Ac could be recorded. The S/N-ratio of the non-adducted molecular ion could be increased by nearly sixty times compared to the measurement without the use of ammoniumacetate. However, no complete suppression of the adducted molecules could be achieved. The use of NH₄Ac leads to an increased fragmentation - similar to CID experiments. Nevertheless, it allowed the comparison of SORI-CID indicated fragmentation behaviour of the different species. The spectra of the protonated species show no cross-ring cleavage, but loss of H₂O and glucose. Compared to that the CID spectra of the Na-adducts show cross-ring cleavages, also in combination with loss of glucose. In this regard the study of the effect on chromophore labelled maltopentaose and subsequent CID/PD fragmentation would be part of interest and is indeed part of ongoing research.

Conclusions

Using ammonium acetate to reduce alkaline adduct ions of oligosaccharides was successfully applied to the example of MP, whereby MS₂ experiments of the [M+H]⁺species could be performed. Doing this, no cross-ring cleavages are observable. Due to the symmetry of MP, an assignment of the fragments to the reducing or non-reducing end is not possible. Because of the precipitation of acetates and ammonium salts, this method requires a higher cleaning effort.

Novel Aspect

The use of ammonium acetate for the suppression of alkaline adduct-ions to improve the S/N-ratio of the [M+H]⁺species measuring oligosaccharides.

Chungnam National University, 99 Daehak-Ro, Yuseong-Gu, Daejeon (1)

Keywords: sucrose, charcoal, MALDI, glycosidic bond, cationization agent

Introduction:

Matrix-assisted laser desorption/ionization mass spectrometry (MALDI-MS) analysis of low molar mass compounds using a conventional matrix, such as 2,5-dihydroxybenzoic acid (DHB) or α -cyano-4-hydroxycinnamic acid (CHCA) is not commonly performed due to matrix-related peaks [1, 2]. For the effective MALDI-MS analysis of sucrose whose average molar mass is only 342.3 Da, a charcoal matrix with different cationization agents was utilized.

Methods:

Different cationization agents such as Li⁺, Na⁺, K⁺, Rb⁺, Ag⁺, and Cs⁺ were used for the MALDI-MS analysis of sucrose with a charcoal matrix. The matrix (1 μ L) was placed on a MALDI plate and dried at room temperature. Then, 1 μ L of 100 mM sucrose stock solution was deposited on top of the matrix. To compare the effectiveness of cationization agents, each additive cation (1 μ L) was loaded on top of the dried spots. Mass spectra were obtained in the positive ion reflection mode.

Results:

A higher cation-adducted sucrose peak with significantly reduced interference was observed with a charcoal matrix rather than DHB or CHCA. However, the charcoal matrix caused glycosidic bond cleavage, resulting in sucrose fragment peaks. These could not be removed, even when we reduced the laser intensity. The degree of sucrose fragmentation was inversely related to the size of the cation additive. More sucrose fragmentation occurred with small cationization agents (Li⁺, Na⁺, or Ag⁺), while little fragmentation occurred with relatively large cationization agents (K⁺, Rb⁺, or Cs⁺).

Conclusions

Charcoal has a higher energy transfer efficiency than DHB or CHCA. This may explain the increase in sucrose peaks and fragmented peaks observed when sucrose was analyzed with a charcoal matrix. The degree of sucrose fragmentation was inversely related to the size of the cation additive. The highest degree of sucrose fragmentation was observed when the cation additive was Li⁺, followed by Ag⁺, Na⁺, and K⁺. No fragmentation was observed with additives Rb⁺ and Cs⁺.

Novel Aspect:

Charcoal matrix was utilized for the analysis of sucrose in MALDI-MS with different cationization agents such as Li⁺, Na⁺, K⁺, Rb⁺, Ag⁺, and Cs⁺.

100 - COMPETITIVE UNIVERSAL PROXY RECEPTOR ASSAY (CUPRA) FOR QUANTITATIVE HIGH-THROUGHPUT GLYCAN LIBRARY SCREENING

John Klassen (1) - Elena Kitova (1) - Pavel Kitov (1) - Ling Han (1) - Zhixiong Li (1)

University of Alberta, Chemistry, Edmonton (1)

Keywords: Glycan recognition; library screening; affinity; specificity; ESI-MS

Introduction:

The absence of quantitative high-throughput (Q-HT) glycan screening assays is a significant impediment in glycomics. Glycan microarrays, wherein oligosaccharides (OS) are immobilized on glass surfaces, are the dominant HT screening technology. However, glycan microarray screening has many well-documented limitations. Here, we introduce a Q-HT electrospray ionization mass spectrometry (ESI-MS)-based method for OS library screening.

Methods:

The Competitive Universal Proxy Receptor Assay (CUPRA) assay is based on competitive protein binding and employs a universal proxy protein (UniPproxy), which binds all components of a library of modified OS (OSmod) through a high affinity tag introduced to the OS. Changes in abundances of the (UniPproxy+OSmod) complexes in solution upon introduction of a glycan-binding protein (GBP) allows for the simultaneous identification and quantification of OSmod ligands.

Results:

Implementation of CUPRA was demonstrated using a library of 70 OSmod, produced from OS with structures found in humans, and GBPs with known OS binding specificities. Application of CUPRA to cholera toxin B subunit homopentamer (CTB5) correctly identified the OSmod containing the Gal β 1-3GalNAc β 1-4(Neu5Ac β 2-3)Gal β 1-4Glc (GM1) and Fuc β 1-2Gal β 1-3GalNAc β 1-4(Neu5Ac β 2-3)Gal β 1-4Glc (Fuc-GM1) structures as the only high affinity ligands in the library. Moreover, the measured affinities agree, within a factor of 2, with the affinities measured for the corresponding oligosaccharides. Application to *Maackia amurensis* agglutinin (MAA), which is a Neu5Ac β 2-3Gal β 1-4GlcNAc/Glc specific GBP, identified Neu5Ac β 2-3Gal β 1-4Glc (3SL) and Gal β 1-4(Neu5Ac β 2-3)Gal β 1-4Glc (GM2) as ligands. A single ligand, containing the Neu5Ac β 2-6Gal β 1-4Glc structure was found for Sambucus nigra lectin (SNA). This result is consistent with the reported specificity of the GBP for Neu5Ac β 2-6Gal structures.

Conclusions:

Together, these results demonstrate that CUPRA allows for the simultaneous screening and quantification of glycan ligands with affinities $\geq 10^3$ M $^{-1}$. Future efforts will focus on expanding the size and diversity of the OSmod library, with the goal of producing a library of ~ 200 components derived from purified OS. Natural libraries of OSmod will also be produced from OS extracted from human milk and N-glycans released from isolated glycoproteins and tissue. The OSmod libraries will then be used for the discovery of biologically-relevant glycan interactions involving human, bacterial and viral GBPs.

Novel Aspect: Development of the first high-throughput and quantitative glycan screening assay

111 - MULTIPLEXED ISOTOPE LABELED STANDARDS FOR ISOMERIC ANALYSIS OF N-GLYCANS

Daniel Maresch (1) - Clemens Grünwald-Gruber (1) - Andreas Thader (1) - Friedrich Altmann (1)

University of Natural Resources and Life Sciences, Department of Chemistry, Vienna (1)

Introduction

Porous graphitic carbon (PGC) columns have proven extraordinarily useful for the LC-ESI-MS analysis of N- and O-glycans. Their shape selectivity has been demonstrated for different sialic acid and galactose linkages. The ability of PGC to discriminate about 35 different isobaric mono-fucosylated N-glycans will be shown. Application to mouse brain N-glycans revealed them to contain hybrid type glycans with fucose at the core and Le^x (but not Le^a or blood group H) determinants.

Methods

The notoriously poor reproducibility of retention times on PGC prompted us to generate internal standards with different mass increments due to thoughtful incorporation of one or two molecules of either ¹³C₆- or ¹³C₁-galactose, of BH₄ or BD₄ reduction and finally de-N-acetylation and re-N-acetylation using stable-isotope labeled acetic anhydride. The obtained multiplexed reference glycans can easily be told apart by their specific mass increment.

Results

Since expression of retention times as glucose units is not useful for LC on PGC, we propose to scale any chromatogram to a reference run and express the retention in the form of virtual minutes (vimin). Absolute quantification was furthermore achieved by the quantitation of one ¹³C₆ labelled standard by amino sugar analysis. This one internal standard allowed for the calculation of the other glycoforms by the use of instrument dependent correction factors (calculated ratios known from an equimolar standard mix [1]).

Conclusions

A strategy is proposed by which a set of multiplexed standards can serve to assign the structure of any N-glycan structure already by retention time, thus providing a new level of confidence in the analysis of structural isomers that supports and expands the conclusions drawn from MS/MS spectra.

1248 - DEVELOPMENT OF A NEW METHOD FOR THE IDENTIFICATION OF FOLLICLE STIMULATING HORMONE (FSH) GLYCOFORMS INVOLVED HUMAN FERTILITY.

Chiara Melchiorre (1) - Anna Illiano (1) - Gabriella Pinto (1) - Carpentieri Andrea (1) - Angela Amoresano (1)

Department of Chemical Science, Federico II, Napoli, Italy (1)

Keywords: FSH (Follicle Stimulating Hormone), human fertility, glycosylation, mass spectrometry

Introduction:

Follicle-stimulating hormone (FSH) plays a key role in the proliferation and development of ovarian granulosa cells in women and spermatogenesis in men [1-3]. The glycosylation of FSH is extremely important since it has a significant influence on its biological activity. The quantitative determination of FSH at the various stages of the menstrual cycle is fundamental, for this reason, it is important to develop new methodologies that can lead to the simple and sensitive determination of FSH.

Methods:

During preliminary experiments, standard FSH was digested with trypsin and the resulting peptide mixtures directly analyzed by LC-MS/MS methodologies. Specific peptides were selected on the basis of their molecular ion and their most intense fragments and used as targets to set up the Multiple Reaction Monitoring (MRM) method. The set of peptides, defined by their specific MRM transitions, can only be associated to the FSH protein leading to unambiguous identification and quantitation of FSH even within a complex biological matrix like serum with unmatched specificity and sensitivity.

Results:

Tandem mass spectrometry analysis allows us to characterize the glycosylation profile of several FSH molecules including the pituitary form in young and postmenopausal women, and some existing commercial forms. The definition of the glycoforms was carried out using cutting-edge techniques such as ETD fragmentation using a high resolution Orbitrap mass spectrometer. An immunoaffinity chromatography protocol was performed on a serum sample to isolate selectively FSH protein and to identify it. Finally, an innovative methodology for its identification and quantification was set up by MRM mass spectrometry. For the optimization of the MRM method, more unique peptides were selected and monitored in order to uniquely identify FSH in complex matrices. The building up of a calibration curve of standard peptides has allowed to quantify FSH in human serum. The research activities are performed in collaboration with the MERCK Group, leader in FSH production.

Conclusions:

This study is addressed at defining the relationship between the glycosylation pattern of FSH and its biological activity and defining similarities and differences between the various forms and the standard molecule. Because of the extreme importance in determining the exact amount of FSH during the various phase of the menstrual cycle as well as in therapy, the development of a sensitive and robust method for the identification and the quantification of specific FSH glycoforms by advanced mass spectrometry methodologies was of great importance.

Novel Aspect:

The quantitative determination of FSH is typically measured with the immunological assays [4] that suffer from numerous limitations correlated with the presence of false positives. These limitations can be overcome by innovative mass spectrometry techniques in Multiple Reaction Monitoring mode.

1135 - N-GLYCAN ANALYSIS OF VARIOUS CHLORELLA STRAINS BY MALDI-TOF AND LC-ESI-MS

Reka Tunde Mocsai (1) - Rudolf Figl (1) - Elisabeth Svehla (1) - Friedrich Altmann (1)

University of Natural Resources and Life Sciences, Department of Chemistry, Vienna (1)

N-glycan analysis of various Chlorella strains by MALDI-TOF and LC-ESI-MS
Reka Tuende MOCSAI, Rudolf FIGL, Elisabeth SVEHLA, Friedrich ALTMANN

Keywords: Chlorella, MALDI-TOF, LC-ESI-MS, N-glycosylation

Introduction:

Microalgae of the genus *Chlorella* are candidates for the production of polyunsaturated fatty acids, various dietary supplements and they are also debated as novel expression systems for recombinant proteins. Our work shows that different *Chlorella* species display widely varying N-glycan profiles with unique masses not known from embryophytes (land plants).

Materials and Methods:

Total N-glycan spectra of a panel of *Chlorella vulgaris* and *Chlorella sorokiniana* strains as well as of a broad selection of commercial *Chlorella* tablets - many of them labeled with the outdated taxonomical name *Chlorella pyrenoidosa* - were investigated by MALDI-TOF-MS and LC-ESI-MS.

Results:

Most samples typed as *C. vulgaris* contained oligomannosidic glycans with several O-methyl groups, while the *C. sorokiniana* culture strains exhibited two differing profiles with pentose containing glycans. The commercial samples -almost irrespective of their label- yet again occurred as four distinct structural groups. One resembled *C. vulgaris*, two showed rather complex patterns of methylated glycans, and one contained just one very dominant structure that turned out to contain three arabinoses, one of them methylated and a galactofuranose linked to the second N-acetylglucosamine residue.

Conclusions:

Chlorella N-glycans differ greatly from plant and vertebrate N-glycans by the lack of fucosylation, the presence of arabinose and galactose residues and the prominent O-methylation of sugars. These properties foresee a large variety of unknown glycosyltransferases and potentially immunogenic glycan structures. The occurrence of groups with clearly distinct N-glycan patterns suggests that N-glycan profiles could constitute a valuable tool for taxonomic classification as well as for determination of the origin of *Chlorella* food supplements.

580 - SEMI-TARGETED ANALYSIS OF METABOLITES IN SAPONARIA OFFICINALIS BY LC-MS

Katarzyna Pawlak (1) - Katarzyna Lech (1) - Kamil Wojciechowski (2) - Ilona Goral (3) - Piotr Bartosz (1) - Piotr Kosior (1) - Tomotheus Kiehl (1) - Anna Ornoch (1) - Kinga Kaczmarczyk (1)

Warsaw University of Technology, Faculty of Chemistry, Chair of Analytical Chemistry, Warsaw (1) - Warsaw University of Technology, Faculty of Chemistry/SapoLabs Ltd, Chair of Medical Biotechnology, Warsaw (2) - Warsaw University of Technology, Faculty of Chemistry, Chair of Medical Biotechnology, Warsaw (3)

Keywords: semi-targeted, metabolomics, saponins, plants, *S. officinalis*

Introduction:

Saponaria officinalis is a common perennial plant from the Caryophyllaceae family. It is well-known for its detergent property and has been used as a soap in ancient times, later also as an expectorant in bronchitis and in rheumatic disorders. Decoctions and infusions of this plant can be used as an emulsifier for food and cosmetic products (masks, toothpastes, shampoos). However, the fact that its properties depend on the organ and time of harvest is often overlooked.

Methods:

Saponins were tracked by LC-MS system using semi-targeted metabolomic approach. Changes in the metabolome compositions were registered by following 400 transitions in negative ion mode by 6460 ESI MS/MS system coupled to RPLC. For each parent ion (selected from the plant's analysis in the scanning mode, range 350 – 1700 m/z) at least two product ions were selected to track changes of metabolomics profiles for different organs and harvest time.

Results:

Different triterpenoid saponins, saponin osides A-M named and classified by Kazuo Koike and Zhonghua Jia [1], were detected in extracts from the whole plants of *Saponaria officinalis*. Throughout the ESI-MS profiling of RPLC eluate, it was recognized that lower molecular weight saponins of *S. officinalis* were present in the very polar fractions eluted faster. Very high diversity of the structures was observed as different sugars were found to be attached to aglycone, such as pentose, hexose, and deoxy-sugars. This was indicated as the difference between m/z values for signals such as 132, 162 and 146 for deoxyhexosyl moieties. Cluster analysis of the collected peak areas for individual saponins were visualized as a dendrogram and heat map in respect to time of harvest. We found that flowering and formation of seeds influences significantly the relative amounts of different saponin osides. The observed changes in composition show good correlation with parameters illustrating the ability of extracts to form stable and dense foam.

Conclusions

The HPLC-MS/MS analysis allowed us to detect and identify saponins, and perform their semi-quantification. Developed LC-MS/MS platform allowed to track changes in saponin's composition for different organs obtained for *S. officinalis* harvested in the period from June to October.

Novel Aspect:

For the first time, the stage of the development and organ-specificity of the crop were included in studies of *S. officinalis*.

264 - HILIC MS-HCD/FT-IT AND HYBRID SEARCH ENHANCE THE STRUCTURE ELUCIDATION OF OLIGOSACCHARIDES IN NIST HUMAN MILK REFERENCE MATERIAL

Connie Remoroza (1) - Tytus Mak (1) - Stephen Stein (1)

National Institute of Standards and Technology, Mass Spectrometry Data Center, Gaithersburg, Maryland (1)

HILIC MS-HCD/FT-IT and Hybrid Search enhance the structure elucidation of oligosaccharides in NIST human milk reference material

Connie A. Remoroza, Tytus D. Mak and Stephen E. Stein

Mass Spectrometry Data Center, Biomolecular Measurement Division, National Institute of Standards and Technology, Gaithersburg, MD, 20899-8362, USA

Keywords: Human Milk Oligosaccharides, Fourier Transform-ITMS, HILIC-MS-HCD, Isomers, MS library

Introduction:

Elucidation of complex mixture of underivatized isomeric glycans is challenging when commercial standards are not available. The NIST SRM* 1953 consists of human milk oligosaccharides (HMO) from 100 healthy breastfeeding mothers in the US was used. However, the information on these functional molecules in the reference material is limited. This study focuses on the development of MS database of annotated spectra of oligosaccharides in human milk.

Methods:

The human milk SRM 1953 underwent sample preparation [1]. The purified oligosaccharides were analyzed on Hydrophilic Liquid Interaction Chromatography-electrospray ionization in Fusion Lumos Orbitrap-based MS using HCD & Fourier transform ion trap (FT-IT) fragmentation techniques. The spectra are extracted from LC-MS raw data and processed using in-house algorithm then analyzed using different tools including NIST Tandem mass spectral library and hybrid search.

Results:

The high mass accuracy both for precursor and product ions from FT-IT and HCD data was sufficient to enable the assignment of HMOs including novel oligosaccharide structures with different adduct types in negative/positive detection mode. Core group (Gal-Glc) with different terminal sugars, Fuc-Gal-Glc eluted prior to Sia-Gal-Glc based on the HILIC chromatogram. The elution profile of oligosaccharides (>4 sugar units) with 3-4 isomers, such as fucolacto-N-octaoses and sialylated fucolacto-N-hexaoses displayed different retention times on HILIC that enhances oligosaccharide identification. A clear distinction in the HILIC elution pattern of isomeric oligosaccharides related to size and polarity also confirmed the identifications. Moreover, the hybrid search can reliably find modified oligosaccharides in comparison to non-reduced analogs, and vice versa, enabling an increase in match factors.

Conclusions

The HILIC MS/MS and NIST hybrid search facilitates the structural assignment of 70 complex oligosaccharides of 470 spectra including newly identified glycan isomeric structures. The MS library of HMOs demonstrated to aid in identifying glycans in other biological samples, which represents a new variety of mass spectral library – a concept that can be extended to other varieties of biological fluids such as detection of glycans and non-digestible artificial sugars in human & bovine milk samples.

Novel Aspect:

A comprehensive structural and tandem MS library of annotated spectra of oligosaccharides derived from the NIST human milk reference material: a robust method of detecting other compounds in milk products.

1034 - SEMI-AUTOMATIC SITE SPECIFIC QUANTITATIVE ANALYSIS OF HIGH MANNOSE AND HYBRID TYPE GLYCOSYLATION IN LIVER TISSUE ASSOCIATED WITH HCC AND CIRRHOSIS

Miloslav Sanda (1) - Julius Benicky (1) - Zuzana Brnakova (1) - Lihua Zhang (1) - Radoslav Goldman (1)

Georgetown University, Department of Oncology, Washington, DC (1)

Keywords: Glycoproteomics, Oligomannoseglycans, Hepatocellular carcinoma, Glycopeptide quantification, Liver disease

Introduction:

Glycosylation changes of serum glycoproteins associated with liver disease progression were described previously. Most of the studies were profiling detached glycans from crude human sera or isolated proteins from patient sera. Recent studies described more detailed site specific glycosylation analysis of isolated glycoproteins or site specific analysis of particular glycan modifications such as core-fucosylation after glycosidase treatment. Our study is focused on the site specific analysis of incompletely processed glycan structures as oligomannose and hybrid glycans in liver tissue associated with liver disease progression (cirrhosis, HCC). Lectin affinity enrichment combined with HR mass spectrometry analysis allowed us to identify large set of high mannose, hybrid and paucimannoseglycopeptides in complex liver tissue glycoproteome.

Methods:

Human Liver tissue biopsies divided to tumor and adjacent portions were analyzed as whole tissue lysate and lectin enriched glycopeptides. Tryptic digestion including reduction and alkylation steps was followed by ConA lectin enrichment of oligomannose and hybrid glycopeptides. Whole liver proteome and enriched glycopeptides were analyzed by HR LC-MS/MS using Orbitrap Fusion Lumos mass spectrometer working in DDA mode coupled with 3000RSLC nano-chromatography (Dionex). Peptides and glycopeptides were separated on the 50cm C18 capillary column using 90 min acetonitrile gradient. Data were processed using Proteome discoverer (Thermo), Byonic and GPS software. All glycopeptide spectra were confirmed manually.

Results:

Complex site specific glycosylation analysis as one of the most difficult analytical approach was never completely solved because of glycopeptide mass spectrometric fragmentation similarity. Using combination of selective structure enrichment, HR mass spectrometric analysis, chromatography reproducibility we were able to identify large set of high mannose and hybrid glycopeptides (2429) in human liver tissue. Byonic, GPS software and retention behavior prediction help us to identify additional high mannose and hybrid glycopeptides which were masked in crude liver tissue analysis by oligomannosylated peptides from abundant complex type glycopeptides. Large portion of identified ConA enriched fraction were trimmed paucimannoseglycostructures (734) related to increased lysosomal activity. Some of the paucimannoseglycostructures of lysosomal glyco-proteins for example prosaposin, TPP, Cathepsins or LAMP are elevated in liver HCC.

Conclusions

We have identified and quantified 2429 high mannose and hybrid glycopeptides in 6 human liver biopsies samples divided to tumor and adjacent tissue. We have detected elevation of proteins and glycoforms in tumor related to lysosomal activity.

Novel Aspect:

High mannose and hybrid type glycoproteomics related to liver disease.

476 - INTEGRATING ION SPECTROSCOPY WITH MASS SPECTROMETRY FOR THE STRUCTURAL ANALYSIS OF CARBOHYDRATES

Baptiste Schindler (1) - Gina Renois-Predelus (1) - Isabelle Compagnon (1)

Institut Lumière Matière, Université de Lyon, Lyon (1)

Keywords: structural analysis, IRMPD spectroscopy, hyphenated MS-based approach, carbohydrate sequencing

Introduction:

Sequencing techniques have been established for proteins and DNA and have revolutionized modern biology but routine techniques do not exist for glycans. In particular, top down analysis of glycans by mass spectrometry is often ambiguous due to the presence of various isomerisms. This lack of structural tools is identified as a crucial bottleneck, limiting the full development of glycosciences.

Methods:

Our instrument combines Mass Spectrometry and Vibrational Spectroscopy (InfraRed Multiple Photon Dissociation) in the 3 μm spectral range. It offers the structural resolution of spectroscopic techniques for mass-selected ions and operates at typical MS conditions, i.e. it requires significantly less sample than traditional spectroscopy.

Results:

First, we have shown that the IR signature in the 3 μm range obtained with our instrument is a powerful metric to resolve simultaneously all isomerisms: the nature of the monosaccharide content, the regiochemistry of the glycosidic bond, the anomer stereochemistry (α or β), the structure of the monomeric ring (pyranose or furanose), and the position of modifications such as sulfation or acetylation. Then the conservation of the molecular structure of a precursor ion within MS fragments has been revealed on disaccharides, opening the way to top-down, de novo MS analysis.[1] Following this demonstration, we have established a set of carbohydrate sequencing rules using a combination of Mass Spectrometry and IRMPD Spectroscopy. Finally, we have applied our approach to the determination of the sequence of various classes of saccharides.[2]

Conclusions

Without chemical derivatization of the glycan and with a minimal database of monosaccharide standards, the monosaccharide content and the stereochemistry of any oligosaccharide can be retrieved using our hybrid analytical approach based on MS-sequencing strategies and the structural resolution of carbohydrate isomerisms by IRMPD spectroscopy.

Novel Aspect:

Our approach is to combine the best of two worlds: Mass Spectrometry and Spectroscopy, for the identification of glycan isomers.

Keywords: Behcet disease, N-Glycan, Isomer, Quantitation, MRM-MS

Introduction:

Glycosylation is widely recognized as the powerful resource of biomarkers for cancers and infectious diseases. Behcet disease (BD), a typical immune disease, is a vasculitis disorder characterized by oral sores and arthritis. Until now several diagnostic criteria of BD have been proposed however, there is no reliable diagnosis/treatment method. Here, we developed glycomic-based novel approach for BD monitoring using PGC-MRM MS.

Methods:

Sera of Behcet patients (n=47) and health controls (n=47) were obtained from Samsung Medical Center in Korea. Each sample was enzymatically treated with PNGase F to release N-glycans. Native N-glycans were enriched by PGC-SPE prior to MS analysis. Targeted acidic glycans were chromatographically separated to obtain isomer-specific information and each glycan was relatively quantified by PGC-MRM MS. Total eleven N-glycan isomers were monitored.

Results:

Glycans released from human serum were initially profiled by nanoLC/MS and about 100 glycan compositions were identified. Of them, sialylated glycans which are highly present in immunoglobulin-related proteins and in human serum were further selected for quantitative analysis. Total eleven N-glycan isomers consisting of three major compositions were successfully separated on a PGC column and quantitated using MRM-MS. In particular, four glycans including mono/di-sialylated bi-antennary N-glycans (Hex5 HexNAc4 NeuAc1-2) were highly expressed in BD patients compared with control group. These glycan isomers showed high diagnostic efficacy having AUC of ROC curve over 0.98. As well as disease-specific glycans, we found the glycan expression level of female control groups was ten times higher than that of male.

Conclusions:

While global profiling of serum N-glycome has already revealed potential biomarkers for various diseases, glycan quantitation is analytically challenging due to the complexity caused by glycan isomers with a wide dynamic range of intensity. In this study we developed new technology to quantify isomer-specific glycans using PGC based MRM-MS for Behcet disease monitoring.

Novel Aspect:

The first study of isomer-specific glycan quantitation using MRM MS for Behcet Disease Monitoring

Keywords: glycosaminoglycan, HILIC-WAX chromatography, self-packed nanoHPLC column, tissue microarray, prostate cancer

Introduction

Cancer research is one of the most studied areas of science and prostate cancer (PCa) is one of the most common types of cancer among men. Tissue samples, especially biopsies are often used in mass spectrometry based biomarker research and have a great potential in understanding biochemical mechanisms underlying diseases such as cancer. Tissue microarrays (TMA) consist of several biopsies (generally 1.5 mm in diameter) of different patients fixed on a microscope slide.

Methods

Glycosaminoglycan (GAG) chains were digested into smaller fragments (GAG disaccharides) on the tissue surface with bacterial lyase enzymes prior to the nanoLC-MS analysis. The development and optimization of a chromatographic and MS method for the investigation of the GAG disaccharides was performed involving the use of novel self-packed HILIC-WAX capillary columns. For the statistical evaluation of datasets T-test and principal component analysis were used.

Results

The aim of our work was to develop and apply advanced nanoLC-MS techniques to reliably identify GAGs from the surfaces of PCa TMAs.

As for the separation method, effects of the ionic strength, the pH and the eluent strength were investigated and an isocratic separation method was found to be suitable for separating the GAG disaccharides. The limit of detection was ca. 1 fmol for each disaccharide and the limit of quantitation was between 10-50 fmol.

The nanoLC system was on-line coupled to mass spectrometer operated in negative mode and several TMA cores of different pathological grades of PCa biopsies were analyzed.

Statistically significant changes in heparan-sulphate composition were observed. The ratio of the different GAG disaccharides was found to be a potentially useful indicator of prostate cancer progression. A good correlation occurs between the cancer grade and sulphation patterns of the heparan-sulphate chains; the ratio of doubly and triply sulfated disaccharides increases with cancer progression.

Conclusions

GAGs play critical roles in cancer progression and our new isocratic HILIC-WAX-nanoHPLC-MS method provides extremely high sensitivity and reproducibility thus enabling the determination of the sulfation pattern from single TMA cores (<10 µg tissue sample). The ratio of the different GAG disaccharides correlates with PCa progression; the amount of doubly and triply sulfated disaccharides shows an increase with cancer grade.

Novel Aspect

Our novel HILIC-WAX nanoHPLC-MS method enables determination of the GAG content of single PCa TMAs and sulfation pattern of these TMA cores may be a useful indicator of PCa grade.#

¹Institute of Chemistry, Academia Sinica; ²Department of Chemical Engineering, National Taiwan University of Science and Technology; ³Department of Chemistry, Soochow University; ⁴Department of Chemistry, National Taiwan University

Keywords (5 words): Carbohydrate, Thin-layer chromatography, nanoparticle, MALDI-MS

Introduction:

Our recent study demonstrated that 2,5-dihydroxybenzoic acid conjugated Fe₃O₄ nano-matrix (DHB@MNPs) was powerful for simultaneous ionization and fragmentation of oligosaccharides by MALDI MS [1]. However, analysis of more complex mixtures of carbohydrate requires further separation. In this study, we aimed to directly couple thin layer chromatography (TLC) separation of carbohydrate with DHB@MNPs based MALDI MS detection as a novel method of analysis.

Methods:

Our new approach incorporates several stages of development. First, saccharides mixture separation was carried out on C18 modified reverse phase (RP) TLC plate. Second, we used ionic liquids as nanoparticle dispersion media. Third, dispersed DHB@MNPs was then deposited on TLC surface by spin coating technique. Fourth, the separated carbohydrate spots were directly scanned by MALDI TOF MS. Finally, the method was applied to human milk oligosaccharide analysis.

Results:

Compared to normal phase (NP) TLC, carbohydrate samples were found to be better separated on RP-TLC and yields higher fragment ion intensity which may be due to weak retention of polar carbohydrate on non-polar RP-TLC. Spot homogeneity of spin coated and ionic liquid dispersed DHB@MNPs were evaluated by acquiring spectrum from different distance from the origin. Coefficient of variation (CV) of molecular and fragment ions intensity of each separated spot fall in acceptable range (CV < 15%). Besides the molecular ions of D-Glucose and β -Lactose, several fragment ions of Lewis Y were able to be detected by direct MALDI MS scanning which enabled unambiguous structural elucidation with single MS. The isomeric pairs of Lewis B and Y were also discriminated by DHB@MNPs-induced unique fragment ions [Z1 α (372.3) and Y1 α (390.4) unique for Lewis B; 2,4A3/Y2 α (391.5), 0,3A3 α (421.1) and Z2 α (534.5) unique for Lewis Y]. Using our optimized method more than 32 neutral human milk oligosaccharides were identified from a donor at after one month lactation time.

Conclusions:(400 characters)

With our integrated platform we were able to demonstrate separation and detection of a model saccharide mixtures. DHB@MNPs matrix was dispersed well by ionic liquid and uniformly deposited on TLC surface by spin coater. Automatic scanning allowing more accurate, faster and reproducible data acquisition. Overall, our approach

provides alternative efficient carbohydrate analysis without the need of the common prior chemical derivatization and tandem MS.

Novel Aspect:

RP-TLC separation and spin coating of ionic liquid dispersed DHB@MNPs followed by MALDI MS scanning as a facile method for structural elucidation of carbohydrate mixture.

Keywords: glycopeptides, glycosylation, capturing, PTMs, LC-MS

Introduction:

Proteins post-translational modifications, eg. glycation and glycosylation are investigated as specific biomarkers for diagnosis. Limitations of standard bottom up approach are connected with peptides low relative abundance, low ionization efficiency and sample complexity. The further isolation and concentration methods are required, which can be achieved by phenylboronic acid affinity materials[i].

Methods:

The ChemMatrix® Rink Resin functionalization with 4-carboxyphenylboronic acid moiety was performed according to the solid phase peptide synthesis procedure. The glycoconjugates were captured by incubation with the functionalized resin. Capturing and liberation progress were monitored both by the mass spectrometric methods: LC-MS, FT-ICR-MS, MS/MS (all with ESI ion source) and UV spectroscopy.

Results:

Solid supports were efficiently functionalized with various spacers and 4-carboxyphenylboronic acid. The linker was characterized by LC-MS and UV and the substitution level of the resin was determined. The resin is highly stable to various reaction conditions as confirmed by LC-MS results. Synthetic glycoconjugates were synthesized using sugar-modified building blocks [ii,iii,iv]. The labeling of glycopeptides by dabcylo moiety allowed the monitoring of capturing by UV. The glycated peptides were captured efficiently by phenylboronic acid solid support (70%). The capturing progress depends on glycoconjugates concentrations as monitored by UV. The captured products were identified by LC-MS, FT-ICR-MS and MS/MS.

Conclusions:

We developed and tested the new method of glycopeptides enrichment. The affinity of glycopeptide to resin functionalized with 4-carboxyphenylboronic acid depends on the structure of saccharide moiety. LC-MS allows identification and quantification of captured of specific glycoconjugates. This method has potential applications in biomarkers identification in medical diagnosis.

Novel Aspect:

The application of ChemMatrix® resin allows convenient and fast preparation of supports with various structures, properties and specificity for glycoconjugates capturing.

Keywords: sialic acid, ethyl esterification, dimethylamidation, lactonization, isomer differentiation

Introduction:

Glycosylation is a highly complex post-translational modification that plays a key role in the organization of multicellular life. Many human proteins are glycosylated, and changes in their glycosylation occur with many disease, a phenomenon which is still poorly understood. We here present mass spectrometric methods for analyzing glycosylation at higher throughput with differentiation of biologically important sialic acid linkage isomers.

Methods:

Glycans were enzymatically released from proteins and subjected to sialic acid derivatization in a linkage-specific manner introducing a mass difference for linkage differentiation. The approach was hyphenated with MALDI-MS [1], and -imaging MS [2]. Furthermore, the method was combined with capillary electrophoresis(CE) – sheathlessnanoESI-MS after reducing-end labeling with a positively-charged tag, achieving glycan analysis at ultrahigh sensitivity.

Results:

High-throughput glycan analysis after linkage- specific sialic acid derivatization was applied to human serum and plasma samples of thousands of individuals to define disease-associated glycosylation signatures of major human diseases including inflammatory bowel disease, colorectal cancer, rheumatoid arthritis, and diabetes type 2. In addition, glycosylation signatures of age, sex, pregnancy, obesity and inflammation were determined. The derivatization method was transferred to tissue sections in order to allow glycan mass spectrometry imaging with a focus on sialic acid linkage differentiation providing valuable insights into the glycosylation heterogeneity of various types of tumors. The method was further expanded to a CE-MS variant allowed the analysis of the human plasma N-glycome with unprecedented analytical depth which proved particularly valuable for analyzing scarce biological samples that are available in very restricted amounts.

Conclusions:

Glycan isomers differing in sialic acid linkages can be readily differentiated using the tailored derivatization toolbox in combination with MS detection. The method revealed glycosylation signatures of major human diseases and provided insights into tumor heterogeneity with respect to glycosylation.

Novel Aspect:

A high-specificity derivatization step in the glycan MS workflow allows the rapid differentiation of sialic acid linkage isomers providing novel biomedical insights.

Keywords: chip nanoESI MS; ion mobility separation mass spectrometry; human adult hippocampus; gangliosides; collision-induced dissociation.

Introduction:

The central nervous system possesses the highest content of gangliosides (GGs) [1]. Considered as biomarkers of brain development, aging, and certain diseases, the gangliosides expressed in an adult hippocampus (AH) specimen, the first brain region affected in neurodegeneration [2], were here systematically investigated in a combined approach based on chip nanoelectrospray ionization (ESI) QTOF MS and ESI ion mobility separation (IMS) MS.

Methods:

GG solution of 5 pmol/ μ L concentration in methanol was investigated in negative ion mode using an orthogonal hybrid QTOF MS coupled to a fully automated chip-based nanoESI robot and in parallel by IMS using a Synapt G2s. A 2 kV ESI voltage was used for both experiments, while the sample flow rates were 50nL/min for QTOF and 2 μ L/min for IMS. For the IMS experiments, IMS wave velocity was set at 650 m/s, IMS wave height at 40 V. CID MSn were performed at energies within 10-50 eV.

Results:

The generated data clearly showed similarities of ganglioside pattern. However, significantly lower extent of in-source-induced fragmentation of GGs using chip-based ESI versus the conventional ESI-based ion source was observed. This attribute represented the major advantage considering the content in polysialylated species and complex structures modified by fucosylation or acetylation, respectively, which are prone to in-source detachment. On the other hand, ESI IMS MS separated the components based on their differential mobility through a buffer gas, isolating the GGs based on the carbohydrate chain length and the degree of sialylation. Altogether, the optimized conditions for both experiments led to the identification of over 100 distinct ganglioside structures in human adult hippocampus, some of them modified by fucosylation, acetylation and N-acetyl galactosamine attachment. Furthermore, by applying CID MSn, novel GG species, not identified before in AH, were structurally investigated in details.

Conclusions:

In this work, we report on a systematic and comparative assay based on two high-performance MS platforms for the determination of GG structural diversity in a native mixture purified from normal adult human hippocampus. The results demonstrate that the combination of chip-based nanoESI QTOF MS and ESI IMS MS and MSn data is proficient to unequivocally detect and characterize complex glycolipids with potential biomarker role and discover new structures.

Novel Aspect:

The two-step approach based on chip- nanoESI QTOF MS and ESI IMS MS provided novel insights into the pattern and structure of GGs in adult hippocampus.

3 Dipartimento di Chimica, "Sapienza" Università di Roma, Viale Regina Elena 324, 00161 Rome, Italy

Keywords: Anabolic Androgenic Steroids, Doping Control, Mass Spectrometry, Multivariate Analysis, Predictive Models

Introduction

The Androgenic Anabolic Steroids (AAS) are one of the main and most used classes of doping substances, included in the S1.1 section of the prohibited list of the World Anti-Doping Agency (WADA)[1].

An increasingly widespread phenomenon is that of designer steroids, molecules designed and synthesized by modifying the structure of known AASs, in the aim of maintaining the same biopharmacological activity but resulting undetectable at the anti-doping test.

Methods

Predictive models were constructed based on the MS characterization of 133 AAS compounds, to identify new steroids and obtain information on their molecular structure. Starting from Principal Components Analysis different chemometric methods were applied, such as classification and clustering methods, outlining a spectral and structural characterization for each subclass of AAS

Results

Mass spectrometric data obtained by GC-qTOF experiments performed on the TMS-derivatives allowed to group the AAS in 5 subclasses. PCA showed the high similarity between the class of 4-ene-3-keto steroids and the steroids substituted on the A ring.

A discriminant classification step by PLS-DA was performed to build a predictive model to separate the subclasses and to identify the most significant variables, like the unsaturation in position 17 on D ring, characteristic of the 3-hydroxy steroids category.

The use of a modeling classification method, which operates by building individual models for the different categories, allowed to define the characteristics of uniqueness of the investigated steroid subclasses. This approach resulted particularly effective to identify the salient features of the class of 5-ene steroids.

Clustering methods were also applied, with results consistent with most of the previously obtained outcomes. All the information has been summarized by identifying class specific common fragments and spectral trends.

Conclusions

The results of this study suggest that it is possible to trace, as quickly as possible and with the highest degree of certainty, any novel doping substances – and especially “designer AAS” – illicitly synthesized in such a way as to be invisible to the current tests.

The newly developed methods to reduce the time for the identification of unknown substances by fitting/unfitting them in one of the specific subclasses.

Novel Aspect

The predictive nature of the chemometric models was based on the characterization of 133 AAS, and considering the contribution of more than 30 variables.

Development and validation of multi-target analytical procedures for the identification of potential doping agents in 'over the counter' products

1 Laboratorio Antidoping Federazione Medico Sportiva Italiana, Rome, Italy

2 Dipartimento di Medicina Sperimentale, "Sapienza" Università di Roma, Viale Regina Elena 324, 00161 Rome, Italy

Keywords: Multi-target procedures, Doping analysis, Nutritional supplements, Designer drugs

Introduction

The regular use of nutritional supplements by athletes is a very common practice [1]. Contamination and/or adulteration of these products has been claimed to be the cause of numerous adverse analytical findings [2]. Different research groups confirmed the unlabeled presence of anabolics and stimulants in various products [3-4]. For the above reasons it becomes necessary to develop methods for the detection of the widest variety of substances included in the WADA list [5].

Methods

Both liquid and gas chromatography coupled to mass spectrometry were utilized. Different pre-treatment techniques including liquid-liquid extraction and solid phase extraction were evaluated. Validation was evaluated through specificity, sensitivity, repeatability, and recovery.

Results

Two different analytical protocols were developed: the former was specifically designed for the analysis of anabolic substances extracted from nutritional supplements by liquid-liquid extraction with n-pentane, and the latter for the remaining compounds included in the Prohibited List by solid phase extraction with weak cationic exchange columns. The procedures were validated and presented high specificity (no interferences at the retention time of all analytes and no carryover), sensitivity (all compounds could be detected at or below 20 ng/g), repeatability (variability of the relative retention times lower than 0.1% and of relative abundances of selected ion transitions lower than 15% for all the analytes considered in the study) and good recoveries (over 60% for all analytes). The efficacy of the multi-analyte procedures here developed was tested by analysing different products. Results revealed the presence of testosterone in a dietary supplement, while higenamine, a β 2-agonist, was found in an herbal massage cream.

Conclusions

Two different multi-target analytical methods (the former based on GC-MS and the latter on LC-MS) were redesigned, developed, validated and successfully applied. Both procedures allow to detect the presence of doping compounds in different products, confirming that both the newly proposed protocols match the requirements of routine analytical methods for the detection of trace amounts of prohibited substances in products available "over the counter".

Novel Aspect

Two complementary newly developed methods allow the detection of banned substances in both nutritional supplements and in “over the counter pharmaceutical” formulations.

Large volume injection: improving the detection capacity of endogenous anabolic steroids by GC-C-IRMS

1 Laboratorio Antidoping, Federazione Medico Sportiva Italiana, Largo Giulio Onesti 1, 00197, Rome, Italy

2 Dipartimento di Medicina Sperimentale, "Sapienza" Università di Roma, Viale Regina Elena 324, 00161 Rome, Italy

Keywords: Anabolic androgenic steroids, Doping control, Isotopic Ratio Mass Spectrometry, Programmed Temperature Vaporizer Injector

Introduction

The confirmation of the synthetic origin of endogenous anabolic androgenic steroids is performed in all doping laboratories accredited by WADA through a GC-c-IRMS analysis, due to the different carbon isotope abundance, $^{13}\text{C}/^{12}\text{C}$ ($\delta\text{‰}$), between endogenous steroids and synthetic ones. The high sensitivity requirements of current method and the limited volume of urine disposable for the analysis, led us to improve the injection conditions using the PTV technique [1].

Methods

Blank urine samples were spiked with boldenone and 19-norandrosterone standards and cleaned up by two sequential HPLC steps. The purified samples were injected in a GC-c-IRMS instrument, replacing the splitless injection mode with the use of a programmed temperature vaporizing injection (PTV). The initial sample volumes of urine was fixed at 6 mL, whereas different final injection volumes (2 to 10 μL) were evaluated.

Results

At present, the anti-doping laboratories must activate the confirmation analysis for boldenone and 19-norandrosterone by GC-c-IRMS whenever their concentration is greater than the limits defined in reference Technical Documents (TD). In details the "TD2016IRMS" [2] and the "TD2017NA" [3] impose the GC-c-IRMS confirmation for samples with a concentration in the range 5-30 ng/mL for boldenone and 2-15 ng/mL for 19-norandrosterone. In the ordinary method, 21 mL of urine are used, leading to a final injected volume, in splitless mode, of 2-3 μL [4][5]. These conditions are necessary to obtain adequate signals within the linear range of the instrument (400 to 7000 mV) considering the low LOD of boldenone and 19-norandrosterone (4 and 2 ng/mL, respectively). We investigated the possibility to increase the injection volumes, reducing progressively the initial urine volumes. We noticed that the compounds response signals improved proportionally to the larger sample volumes injected, without any significant increase of the background noise.

Conclusions

The results proved that the possibility to adjust the injection volumes, choosing injection volumes larger than those traditionally used in the splitless mode, allows to reduce and standardize the initial urine sample volumes, making faster and less laborious the preliminary sample preparation steps. The reduced urine volume also ensures a reduced risk of column overloading and a decrease the matrix effect in the instrumental analysis.

Novel Aspect

The PTV technique could be extended to detect the exogenous origin of other compounds with a very low concentration.

AP-HP-hopital Robert Debré, Laboratoire de Pharmacologie, Paris (1) - AP-HP-hopital Lariboisière, Laboratoire de Toxicologie, Paris (2) - Service Commun des Laboratoires, Laboratoire de Paris, Paris (3) - AP-HP-hopital Lariboisière/Université ParisDescartes, Laboratoire de Toxicologie, Paris (4)

Keywords:

GC-MS; clinical toxicology; illicit drug; Festive drugs

Introduction:

Poisoning by recreational use of psychoactive substances is increasingly common in Europe and is responsible for death. Intoxicology, identification needs different extractions procedures and derivatization before GC-MS analysis. Developing systematic strategies for screening drug compounds in tablets, powders, herbs or liquids remains a challenge. Through different French festive events, samples were collected with the main objective to discuss advantages and limitations of such systematic analytical procedures using conventional GC-MS.

Methods:

For solids, analytes are dissolved in EtOH. For liquids, analytes are dissolved in water and MeOH, pH was measured and acidic and basic liquid-liquid extractions were performed. After evaporation, samples were reconstituted in ethanol before injection onto a GC-MS operated in scan mode. Derivatization (acetylation, silylation, propylchloroformate) are performed and each spectra compared to different commercial (MPW, SWGDrugs, NIST) or in-house libraries.

Results:

Between July and October 2016, 81 recreational substances were collected during 10 interventions in festive gatherings. Using a systematic workflow, drugs were found in every sample, whatever the matrix (solid, liquid, resin, oil) except in blotters where LSD was expected. Drugs found were mainly "classic drugs" such as cocaine, amphetamines, or cannabis. Different derivatization is mandatory for complete identification of drugs enabling increasing sensitivity for low concentration diluents, cutting agents, adulterants and other psychoactive substances. Propylchloroformate derivatization allows covalently binding on Nitrogen heteroatom, whereas acetylation or silylation bind on oxygen heteroatom. As an example, in "Cocaine" samples, levamisole, phenacetin, caffeine, diltiazem, hydroxyzine were detected. Three new psychoactive substances (NPS) were also found: ethylphenidate, dibutylone (bk-DMBDB) and thiopropamine (tieno-amphetamine) highlighting the need for up-to-date and different mass spectra libraries.

Conclusions

The applied decision tree allowed finding all except one drugs in the samples, whatever the matrices. Drawbacks are the hard laboratory work, choosing the dilution identifying major analytes but also low concentrated cutting agents; different derivatization for exhaustive identification. Up-to-date different mass spectra libraries are also mandatory for NPS drug discovery. Without the latter, skilled technicians are required. GC-MS is not devoid of limitation. A designer drug (1p-LSD) present in blotting paper could not be identified and accurate mass analysis solved this issue. Ambient pressure ionization coupled to accurate mass is definitely the present/future for direct sample analysis. Nevertheless, conventional and systematic approaches efficacy should not be underestimated.

Novel Aspect:

Application of a systematic decisional tree for identification of illicit drugs in solid/liquid/oil/plants samples by GC-MS in clinical toxicology

1199 - EVALUATION OF THE METABOLIC PROFILE OF 2-METHIOPROPAMINE BY LC-MS/MS IN MICE AND IN HUMAN LIVER MICROSOMES

Keywords: 2-Methiopropamine, Drug Metabolism, Liquid Chromatography - Mass spectrometry, Mice

Introduction:

The aim of the present study was to investigate the phase I and phase II metabolism of 2-methiopropamine, a structural analogue of methamphetamine[1-3], after acute administration in mice, in order to select the most appropriate marker(s) of intake, also defining the excretion windows in urine. In vitro metabolism studies were carried out in order to enzymatically synthesize the metabolites of MPA and to set up the most appropriate sample pre-treatment procedures for LC-Qq analysis.

Methods:

A dose of 10 mg/kg was selected for the in vivo metabolism studies of MPA and urine samples were collected every 3 hours in the range of 0-9 hours after the injection. The in vitro studies were carried out with HLM (human liver microsomes). Samples from both studies were analysed, after extraction with tert-butyl-methyl ether at pH 9, using an Agilent 1200 HPLC equipped with a SUPELCO C18 column coupled to an API4000 triple quadrupole (Sciex) with ESI source, operating in positive-ion mode.

Results:

To reproduce the in vivo metabolism, the in vitro metabolism protocol was optimized considering different conditions: substrate concentration 20 μ M, proteins concentration 0.5 mg/mL, phosphate buffer 0.1 M at pH 7.4, and an incubation time of 4 h at 37°C. Three main metabolites were identified: Nor-MPA, Hydroxy-MPA, and Nor-hydroxy-MPA. To optimize sample pre-treatment different extraction solvents (tert-butylmethyl ether, diethyl ether and ethylacetate) and pH values (7, 9 and 12) were evaluated. The best recoveries (higher than 70%) for the principal metabolites were obtained at pH 9. In vivo metabolism studies shown the formation of three principal phase I metabolites identified as: Nor-MPA, Hydroxy-MPA, and Oxo-MPA. 2-MPA and its metabolites show a maximum of excretion in the first 3 h from administration to mice showing an increasing conversion into phase II metabolites both glucurono and sulfo-conjugates for MPA, Nor-MPA, Hydroxy-MPA; Nor-Hydroxy-MPA was detected only as a phase II metabolite.

Conclusions:

The excretion profile of 2-MPA after acute administration was evaluated identifying its principal metabolites and their excretion windows in mice. MPA and Nor-MPA are the best markers of intake in the first 0-24 hours after the administration of MPA. The present method was qualitatively validated for MPA and Nor-MPA according to WADA technical document[4-5] defining: recovery, LOD, selectivity and repeatability.

Novel Aspect:

There are few studies about MPA metabolism [3]. This is the first study identifying MPA excretion profile including phase I and phase II, also selecting the best markers of intake.

789 - QUANTITATION OF FIVE BARBITURATES IN HUMAN URINE BY LIQUID CHROMATOGRAPHY-TANDEM MASS-SPECTROMETRY

Anna Chulovskaya (1) - Dmitriy Rakov (1) - Elena Mochalova (2)

Antidoping Centre, Department of Mass Spectrometry, Moscow (1) - Antidoping Centre, Director, Moscow (2)

Keywords: barbiturates, validation, UPLC-MS/MS, forensic toxicology

Introduction:

Barbiturates are a group of medicinal substances with a wide spectrum of central nervous system inhibitory effects, from mild sedation to total anesthesia [1]. They have a similar chemical structure to each other. Here, we present rapid, accurate and sensitive UPLC-MS/MS methods for the simultaneous quantitation of five barbiturates (butobarbital, butalbital, pentobarbital, amobarbital and secobarbital) in human urine.

Methods:

Compounds were extracted from human urine samples using the LLE. The sample analysis was performed using Thermo Ultimate 3000 UPLC coupled with TSQ Vantage triple quadrupole mass spectrometer. Chromatographic separation was performed on an Acquity UPLC BEH C18 (2.1 mm × 100 mm, 1.7 μm) column coupled with Acquity UPLC BEH C18 (2.1 mm × 50 mm, 1.7 μm) guard-column. The 0.1 % formic acid in water and acetonitrile were used as A and B mobile phase, respectively.

Results:

The main difficulty behind this study is to develop a method, allowing to distinguish structural isomers pentobarbital and amobarbital. The appropriate compounds separation was achieved by linear gradient from 27 % to 95 % for 8.5 min in 0.35 ml/min at 60°C. The method was fully validated for human urine in the range of 50 – 1000 ng/ml. Correlation coefficients (r^2) for five various barbiturates were > 0.99. Recovery, repeatability, and within-laboratory reproducibility lie in the range of 89 – 97%, 3 – 5%, and 7 – 8%, respectively.

Conclusions:

A rapid and robust UPLC-MS/MS method has been developed and validated for the simultaneous determination of butobarbital, butalbital, pentobarbital, amobarbital and secobarbital in human urine. We proposed the LC conditions for the pentobarbital and amobarbital separation which allows to differ these compounds. The method are suitable for quantitation of barbiturates not only in toxicology, but in pharmacokinetic studies and clinical trials.

Novel Aspect:

High chromatographic separation power for the specificity of five various barbiturates by UPLC-MS/MS in human urine was achieved in the field of forensic toxicology.

A Systems Biology Approach for Discovering Biomarkers Indicative of Exposure to Carfentanil

Elizabeth S Dhummakupt, Bao Q Tran, Daniel O Carmany, Gabrielle Boyd, Phillip M Mach, Michael Feasel, Jennifer Sekowski, Trevor Glaros

Keywords: opioids, metabolomics, proteomics, biomarkers

Introduction: There are very few validated assays that are field-capable of rapidly detecting carfentanil, an ultra-potent, synthetic opioid related to fentanyl. Carfentanil has been responsible for numerous reports of mass localized overdoses in the United States. In order to improve the ability to detect this compound, a systems biology approach was utilized to discover host-based markers that are amplified upon carfentanil exposure.

Methods:

New Zealand white rabbits were exposed to a 0.1 ECT50 concentration of carfentanil through nose-only inhalation. Blood was drawn immediately before and after exposure, then at time points out to thirteen days post-exposure. Blood plasma was then analyzed utilizing proteomics and untargeted metabolomics pipelines. For proteomics, a multidimensional fractionation method was developed for deeper coverage, and isobaric tandem mass tags (TMT) were utilized for quantitative assessments.

Results:

For the proteomics, each animal served as its own control, due to the high inter-animal variability. By utilizing this method and stringent data processing filters, over 700 proteins were selected for statistical analysis. Of those, over 40 proteins were identified to have a two-fold ratio change in at least one time point, and 19 proteins resulted in significant p-values from ANOVA analysis. The metabolomics analysis identified over 100 features that had both a two-fold ratio change and a significant p-value from ANOVA. The PLS-DA showed significant separation when comparing pre- and post-exposure to the six-hour time point. Separation continued to become more pronounced as time progressed in both PLS-DA and PCA; however, after the first day the separation appeared to be maximized out to the latest time point. Identified proteins and metabolites suggest carfentanil exposure causes increased reactive oxygen species, possible vascular damage from coagulation and clotting, and possible myocardial infarction.

Conclusions

Proteomics and metabolomics pipelines were leveraged for a long time course study of low-dose exposure to carfentanil. A set of 19 proteins and over 100 metabolite features were identified as significant via fold-change and ANOVA. Both sets of data indicated significant changes could be seen six to 24 hours after exposure. Remarkably, a handful of metabolic perturbations were observed in samples taken immediately post exposure.

Novel Aspect:

First utilization of proteomic and metabolomic pipelines for time course analysis following carfentanil exposure.

Funding for this project is provided by the Defense Threat Reduction Agency – Joint Science and Technology Office for Chemical and Biological Defense.

820 - LC-HRMS/MS VS. LC-MRM: SCREENING OF COVALENT DRUG-PROTEIN ADDUCTS

Timon Geib (1) - Lekha Sleno (1)

Université du Québec à Montréal, Chemistry Department, Montréal (1)

Keywords: clozapine, acetaminophen, covalent protein binding, multiple reaction monitoring, high resolution tandem mass spectrometry

Introduction

Hepatotoxicity of prescription and over-the-counter medication is resulting in major drug-induced adverse effects. Acetaminophen (APAP) and clozapine (CLZ) are known to form reactive metabolites, which can covalently bind to cysteine residues in hepatic proteins. We have investigated the protein binding of these two compounds to different glutathione S-transferase (GST) isoforms.

Methods

Our developed method uses in vitro activation of APAP and CLZ to NAPQI and CLox, respectively, with either liver microsomes or CYP3A4 Supersomes, while adding purified GSTs to the incubation. Further sample preparation employed tryptic or peptic digestion, coupled to LC-MS/MS analysis. Results between SPE, immunoprecipitation and offline LC fractionation have been compared. We have developed two LC-MS/MS based strategies for screening for modified peptides.

Results

Method optimization was carefully performed on different cytosolic Homo sapiens GSTs. LC-MS/MS of information dependent acquisition (IDA) files were searched with UniProtKB/Swiss-Prot protein database. The search algorithm was altered to find NAPQI- or CLZox-cysteine adducts. Multiple reaction monitoring (MRM) was also used as a targeted screening technique. Optimal conditions for incubations were determined (3 h at 37 °C), followed by either tryptic or peptic digestion at 37 °C for 4 h or 1 h, respectively.

The first LC-MS/MS screening technique used a traditional shotgun proteomics workflow (IDA) on a QqTOF with subsequent database searching. Then, a targeted MRM method for all cysteine-containing peptides of the individual GST isoforms was tested. The GSTM2 and P1 were found to be a target of NAPQI in vitro, with more sites identified using the MRM based screening method. Cys174 in M2 and Cys48 in P1 were found using IDA and MRM; while additional sites Cys115 in M2, and Cys15 and Cys170 in P1 were confirmed by MRM only.

Conclusions

Currently, CLZox-protein binding, as well as, IP purification are being optimized to provide highly purified NAPQI- and CLZox-peptide extracts for fast LC-MS/MS analyses of complex samples, including exposed liver microsomes, S9 fractions and homogenates. Comparison of the performance of IDA and MRM analyses showed that MRM represents a complementary technique to untargeted IDA, which can be easily applied in future drug-protein binding investigations.

Novel Aspect

High sensitivity screening and identification of drug-related protein binding to glutathione S-transferases using LC-HRMS/MS and LC-MRM

1358 - DEVELOPMENT OF A LC-HRMS BASED STRATEGY FOR THE SCREENING OF CONJUGATED STEROIDS IN EQUINE URINE

Xuan Zuo (1) - Zied Kaabia (1) - Florian Bagilet (1) - Béatrice Georges (1) - Marie Collard (1) - Yves Moulard (2) - Patrice Garcia (3) - Marie-Agnès Popot (3) - Ludovic Bailly-Chouriberry (4)

Laboratoire des Courses Hippiques (LCH), Anabolic agents anti-doping department, Paris, France (1) - Laboratoire des Courses Hippiques (LCH), Medication control department, Paris, France (2) - Laboratoire des Courses Hippiques (LCH), Research and Development department, Paris, France (3) - Laboratoire des Courses Hippiques (LCH), Laboratoire des Courses Hippiques (LCH), Paris, France (4)

Keywords: LC-HRMS, Androgenic anabolic steroids, Horse racing, equine urine, Q-Exactive HF-X

Introduction:

The gold standard method for analyzing androgenic anabolic steroids (AAS) in equine urine, in the context of anti-doping control, is GC-MS/MS after deconjugation and derivatization steps. LC-HRMS can offer an alternative option for the direct analysis of AAS under their intact conjugated forms in horse urine. The aim of this study is to develop an analytical strategy allowing the extraction of conjugated AAS and their analysis by LC-HRMS using the Q-Exactive HF-X.

Methods:

AAS are mainly under their sulfo or glucurono-conjugated forms in equine urine. Therefore an adapted analytical strategy was settled for their detection. The sample preparation was optimized assessing different SPE cartridges and conditions, which have been compared in terms of extraction recovery. The chromatographic separation and the mass spectrometry parameters were also optimized for conjugated steroids detection with higher sensitivity and selectivity.

Results:

SPE cartridges with C18 or strong anion exchange (SAX) stationary solid phases were evaluated during the study. Extraction of conjugated AAS from horse urine were performed on C18 cartridges using percentages of methanol in wash steps ranging between 5 and 40%. Higher percentages of methanol resulted in cleaner extracts and lower matrix noise impact. However, increasing this percentage induced a loss of some glucuronide and di-glucuronide steroids. Unlike the C18 cartridges, the anion exchanger cartridges resulted in a higher extraction recovery of glucuronide steroids and lower extraction yields for sulfo-conjugated forms. The selected chromatographic condition using C18 column showed well-resolved chromatographic peaks and a good separation profile. Finally, the MS parameters were optimized using the ESI negative mode to reduce background noise and enhance conjugated steroids ionization. A scan mode combining FullMS and PRM was settled and AGC parameters optimized to enhance sensitivity and selectivity.

Conclusions

The developed analytical strategy was based, first, on a steroid extraction performed using a C18 SPE cartridge characterized by an efficient extraction of conjugated steroids from horse urine together with an optimized washing step reducing matrix effect during the LC-MS analysis. Then, the optimization of chromatographic and mass spectrometry parameters permitted to obtain satisfying separation and detection of sulfo and glucurono-conjugated forms.

Novel Aspect:

Unlike gold standard GC-MS/MS strategy, LC-HRMS allows conjugated AAS analysis in equine urine under their intact form insuring a gain in time and avoiding potential artifacts.

1356 - FAST GC-MS/MS FOR HIGH THROUGHPUT ANDROGENIC ANABOLIC STEROIDS ANALYSIS IN EQUINE URINE

Karen Histel (1) - Marie Collard (1) - Béatrice Georges (1) - Florian Bagilet (1) - Marie-Agnès Popot (2) - Zied Kaabia (1) - Ludovic Bailly-Chouriberry (3)

Laboratoire des Courses Hippiques (LCH), Anabolic agents anti-doping department, Paris, France (1) - Laboratoire des Courses Hippiques (LCH), Research and Development department, Paris, France (2) - Laboratoire des Courses Hippiques (LCH), Laboratoire des Courses Hippiques (LCH), Paris, France (3)

Keywords: Fast GC, Androgenic anabolic steroids, Horse racing, equine urine, mass spectrometry

Introduction:

The use of androgenic anabolic steroids (AAS) as growth promoters for equine performance enhancement is forbidden according to article 6 of the International Federation of Horseracing Authorities (IFHA) [1]. The latter bans the use of substances capable of giving horses an advantage, contrary to the horse's inherent merit. Moreover, the use of these substances is supposed to result in biological and behavioral modifications, considered dangerous for the animal.

Methods:

The gold standard method for analyzing AAS in equine urine is GC-MS/MS following hydrolysis and extraction steps. The duration of the analytical run is circa 30 minutes per sample which consists an issue for high throughput routine analysis. In order to reduce the analysis runtime and enhance performances, a Fast GC-MS/MS method has been developed using a shorter column of 20 m instead of 30 m with tighter i.d and thinner film in comparison to GC columns.

Results:

Two FastGC columns, Drug-1 (10 m x 0.18 mm x 0.18 μ m) and ZB-5MS-PLUS (20m x 0.18 mm x 0.18 μ m), were evaluated and compared to the currently used GC column DB-5MS-UI (30m x 0.25 mm x 0.25 μ m). The chromatographic profile of the 47 steroids of the study, when performing the separation on the 10 m Drug-1 column, exhibited phenomena of peak tailing and carry-over. These phenomena were caused by the matrix charge density versus the low quantity of stationary phase. The use of a FastGC column ZB-5MS-PLUS (20m x 0.18 mm x 0.18 μ m) with an optimized gradient permitted to separate the different steroids of the study and resulted in a well-resolved chromatographic profile. The FastGC-MS/MS strategy using the 20 m Fast-GC column was performant in terms of repeatability, sensitivity and selectivity following the analysis of blank and spiked urine samples and reference standards of a 47 steroids pool mixture. The developed strategy led to a considerable gain in analysis time and hence, presents a significant interest for high throughput routine analysis.

Conclusions

The developed Fast GC-MS/MS method using the 20 m ZB-5MS-PLUS column allowed to obtain well-resolved chromatographic peaks for the different steroids of the study. The performance of the Fast-GC-MS/MS strategy were satisfactory namely in terms of sensitivity and robustness. In comparison to the currently used GC-MS/MS method, a gain in analysis runtime of 8 minutes per sample and 5 hours per instrument per day was obtained.

Novel Aspect:

Fast-GC-MS/MS strategy results in a significant gain in analysis time and insures good performances which is crucial for high throughput routine analysis of AAS in equine urine.

392 - CO-EXPOSURE TO SILVER NANOPARTICLES AND CADMIUM IONS INDUCES METABOLIC ADAPTATION IN HEPG2 CELLS

Renata Miranda (1) - Vladimir Gorshkov (1) - Barbara Korzeniowska (2) - Stefan Kempf (1) - Francisco Neto (3) - Frank Kjeldsen (1)

-, University of Southern Denmark, Odense (1) - -, University of Southern Denmark, Odense (2) - -, Federal University of Parana, Curitiba (3)

Keywords: Nanotoxicology, Proteomics, Silver nanoparticles, In vitro liver cell culture

Introduction:

Although studies have reported the toxicological effects and underlying mechanisms of toxicity of silver nanoparticles (AgNP) in a variety of organisms, the interactions of AgNP with environmental contaminants are poorly understood. We used biochemical assays and mass spectrometry-based proteomics to assess the molecular effects induced by a co-exposure of HepG2 cells to AgNP and cadmium ions.

Methods:

Human HepG2 hepatocellular carcinoma cells (Sigma-Aldrich) were cultured as a monolayer in high-glucose Dulbecco's modified Eagle's medium (DMEM) and subjected to spherical AgNP (10 nm), cadmium, or a combination of the two for 4-h and 24-h's for comparison. Cell viability, ATP/ADP ratio assays were performed in parallel to quantitative proteomics (Q Exactive HF) using isotopic labeling.

Results:

Cell viability and energy homeostasis were slightly affected after 4-h exposure to AgNP, Cd²⁺, or a combination of the two; these endpoints were substantially altered after a 24-h co-exposure to AgNP and Cd²⁺, while exposure to one of the two contaminants led to minor changes. Proteomics analysis followed the same trend: while a 4-h exposure induced minor protein deregulation, a 24-h exposure to a combination of AgNP and Cd²⁺ deregulated 43% of the proteome. The toxicity induced by a combined exposure to AgNP and Cd²⁺ involved (1) inactivation of Nrf2, resulting in downregulation of antioxidant defense and proteasome-related proteins, (2) metabolic adaptation and ADP/ATP imbalance, and (3) increased protein synthesis intended to reestablish homeostasis. The adaptation strategy was not sufficient to restore ADP/ATP homeostasis and to avoid significant cell death.

Conclusions:

Co-exposure for 24 h to AgNP and Cd²⁺ induced more toxic responses than individual exposures. The toxicity induced by AgNP+Cd²⁺ was the upregulation of oxidative phosphorylation and lipid metabolism, suggesting a metabolic adaptation, as HepG2 cells usually produce ATP mainly by glycolysis, and alternative nutrients, such as lipids, may have been recruited to reestablish energy homeostasis.

Novel Aspect:

Our results provide information on the toxicological interaction of AgNP and Cd²⁺ ions in HepG2 cells, and insights into possible toxicity mechanisms.

1412 - EVOLUTION AND APPLICATION OF MASS SPECTROMETRY –BASED ANALYTICAL METHODS IN ANTI-DOPING ANALYSES

Tia Kuuranne (1)

Swiss Laboratory for Doping Analyses, University Center of Legal Medicine Geneva and Lausanne, Centre Hospitalier Universitaire Vaudois and University of Lausanne, Lausanne, Switzerland (1)

Keywords: anti-doping, WADA accredited laboratory, prohibited substances, sport, mass spectrometry

Introduction:

Accredited anti-doping laboratories operate within strict regulations of WADA, such as the International Standard for Laboratories (ISL) and technical documents, which aim at harmonizing performance and reporting of routine analyses. Due to the sensitivity and selectivity required from confirmation analyses, mass spectrometry (MS) coupled to either gas (GC) or liquid chromatography (LC) is the analytical technique of choice for identification of the analytes.

Methods:

Whereas the first routine applications were based on the GC/MS techniques, implementation of LC/MS-methodologies during the last 15-30 years dramatically extended the menu of prohibited substances amenable for MS-identification. Both platforms are, however, required for adequate coverage of analyses, which have mainly qualitative but also some quantitative targets, and benefit greatly of technical advances of sensitivity, resolution and data processing.

Results:

In the evolution of the GC/MS-techniques, the cornerstones include the implementation of enhanced trimethylsilyl (TMS) reagent for keto-group, which had a significant impact on the robust analysis of not only exogenous, but also endogenous anabolic androgenic steroids (AAS) with keto-structure. Despite of roots originating to 1980's, this technique is still actively in use in steroid profiling for athlete biological passport (ABP) purposes. Regarding the endogenous AAS, such as testosterone, another major advance has been the development of an analytical approach where GC separation, combustion to CO₂, and isotope ratio mass spectrometry (GC/C/IRMS) was combined for the determination of doping use, i.e. exogenous origin of AAS. Along the LC/MS-based methods, especially those with soft ionization methods such as electrospray, anti-doping analyses have become more sophisticated for prohibited substances with low volatility (corticosteroids), instable derivatives (diuretics), and higher molecular mass (conjugates, peptides).

Conclusions:

The spectrum of target compounds in anti-doping analyses is wide, dynamic and strongly dependent on the pharmaceutical drug development. In order to keep up with the analytical capabilities for emerging performance enhancing substances, the laboratories should maintain the flexibility of analytical pipelines but also follow the development of mass spectrometers and their performance to update the processes for improved sensitivity, selectivity and robustness.

Novel Aspect:

Samples can be stored up to ten years. With re-analyses, potential of non-restrictive data acquisition and digital matrix are proposed to increase deterrence effect of doping control.

Faculty of Pharmaceutical Sciences, University of Campinas, Campinas-SP, Brazil;

Introduction: (Limit of 400 characters without spaces)

The detection of synthetic cannabinoids (SCs) in biological fluids is challenging and requires sensitive analytical methods. The dispersive liquid-liquid microextraction (DLLME) is a sample preparation technique based on the partition of analytes using small volumes of solvent mixture (dispersive and extractor). The aim of this work is to optimize a DLLME extraction to analyze SCs in plasma by LC-MS/MS.

Methods:

Sample (400 μ L) was fortified with 40 μ L of SCs mixture, vortexed and 1200 μ L of dispersive solvent was added and centrifuged at 5500 rpm/5 min. Water (1 mL) and sodium tetraborate saturated solution (100 μ L) was added to 500 μ L of supernatant and 100 μ L of the extraction solvent was rapidly added and the mixture was centrifuged at 5500 rpm/5 min. An aliquot (180 μ L) was transferred to a vial, evaporated, reconstituted in 100 μ L of methanol and injected (2 μ L) into LC-MS/MS.

Results: (Limit 900 characters without spaces)

The dispersive and extraction solvents were rationally chosen by design of experiment (D-optimal), based on their solubility and extraction capacity, capacity to the formation of the cloudy (dispersive effect). The dispersive solvent has to be miscible with both aqueous and organic phases, in order to ensure the formation of the cloudy state that enhances the contact between two phases, thus facilitating extraction. The design of experiment pointed out that the best solvents for extraction were acetonitrile as dispersive solvent, and chloroform as extractor solvent. This combination of solvents allowed the efficient extraction of SCs as low as 0.1 ng/mL, using small plasma volume (0.4 mL). DLLME still needs to be improved and further experiments will be carried out, to evaluate the optimum condition of sample volume, pH, salting-out process and centrifugation conditions.

Conclusions

The extraction method initially optimized and applied for the extraction of SCs was adequate to recover the analytes in plasma samples at low concentrations (0.1 ng/mL), concentration expected to be found in real cases. We're improving our method, performing other studies to improve even more the extraction steps, and thus the method detectability, to finally validate and apply in real samples.

Novel Aspect:

DLLME is a microextraction technique, which requires low volume of solvents, and was successfully applied to SCs analysis, extremely toxic emergent drugs.

Keywords: UHPLC-MS/MS

Permethrin

Toxicokinetic

Gestation

Rat

Introduction:

Animal studies suggest that gestational exposure to permethrin can cause neurodevelopmental toxicity [1]. Permethrin can cross the placental barrier [2]. However, toxicokinetic data are not available to quantify this transfer. The aim of our study was to develop an UHPLC-MS/MS method to quantify permethrin isomers and their metabolites in blood, urines, feces and several tissues of interest: brain, liver, kidney, mammary gland, fat and placenta in pregnant rats.

Methods:

The extraction was performed by liquid/liquid extraction. Chromatographic conditions for cis and trans-permethrin and their metabolites (cis and trans-DCCA and 3-PBA) were optimized using different analytical columns, mobile phases and way of elution.

The final method was validated for recovery, specificity, linearity, precision and accuracy before its application to quantify samples of a toxicokinetic study in pregnant ratsexposed daily to permethrin.

Results:

Chromatographic separation was accomplished on a HSS T3 column with a gradient elution system. Two different mobile phases were used. For permethrin, the mobile phase consisted of ammonium acetate buffer and acetonitrile. For metabolites, acetonitrile and water containing 0.1% of formic acid were selected.

Relative recoveries were found to be in the range of 66 to 117% for permethrin and 43% to 140% for metabolites. No interference from other components in the matrix were observed at the retention times of the compounds.

Matrix-matched calibration curves had satisfactory linearity up to 2000 ng/mL. The LOQ ranged from 10 to 200 ng/mL for the compounds depending on the matrix. The intra-and inter-batch precision and accuracy were better than 15%.

The validated method was applied to analyze samples collected in the toxicokinetic study. Cis-permethrin, trans-DCCA and 3-PBA were detected in all matrices, including fetal matrices. Trans-permethrin and cis-DCCA were detected in all matrices except placenta and liver respectively.

Conclusions

We developed a rapid analytical method with limited sample pre-treatment sufficient to allow the simultaneous quantification of permethrin and their metabolites in biological matrices in pregnant rats and fetuses.

The method showed good performances in terms of accuracy and precision. The LOQ were better compared to a previously published method targeting the same compounds in a large panel of biological matrices in rats [3].

Novel Aspect:

This method is the first method used to successfully quantify permethrin isomers and their metabolites in a various panel of biological matrices in pregnant rats and fetuses.

938 - DETECTION OF CHEMICAL WARFARE AGENTS-RELATED PHENYLARSENIC COMPOUNDS IN MARINE BIOTA AND IDENTIFICATION OF THEIR METABOLITES IN IN VITRO STUDIES BY ORBITRAP HRMS

Hanna Niemikoski (1) - Daniel Koske (2) - Paula Vanninen (1)

Finnish Institute for Verification of the Chemical Weapons Convention, University of Helsinki, Helsinki (1) - Thünen Institute, Institute of Fisheries Ecology, Hamburg (2)

Keywords: Chemical warfare agent, arsenic, fish, metabolism, high resolution mass spectrometry

Introduction: Phenylarsenic compounds, Clark I, Clark II and Adamsite, were designed as riot control agents during World War I [1]. Nowadays, these chemicals are classified as chemical warfare agents (CWAs) by Chemical Weapons Convention. These agents were produced in a large scale during World War I and II. After World War II, their disposal began by sea-dumping. Hundreds of thousands of tons of chemical ammunitions (mainly sulfur mustard and phenylarsenic compounds) were dumped in the Baltic Sea and Skagerrak area between Norway and Denmark [2]. Several investigations have shown that sediment samples collected near these dumping areas are contaminated with CWAs as a result of leaking containers [3]. These leaking toxic chemicals are posing a threat to marine environment. In aqueous environment phenylarsenic compounds degrade forming hydrolysis and oxidation products. Previously traces of oxidation form of Clark I and/or II have been detected from lobster and flatfish samples collected from dumpsite area near Swedish coastline [4]. In order to study uptake of arsenic containing CWAs in fish in larger scale, fish samples were collected from different dumpsites and analysed. One goal of the ongoing EU-project DAIMON (Decision Aid for Marine Munitions) (2016-2019) is assessment of munitions' impact on marine biota. One aim is to develop specific and sensitive methods to assess the fate and impact of toxic CWAs on marine biota [5]. Quantitative analysis of these chemicals and their degradation products are needed to prove presence of these products in aquatic biota in order to support risk assessment for possible accumulation in food chain. There are hardly any studies about transference of arsenic based CWAs into aquatic biota. Due to the lack of information how these agents behave in living organism it's impossible to predict interactions or transformations of these chemicals. In order to study transformations of arsenic containing CWAs in fish we performed metabolism studies with fish liver homogenates. Information achieved from metabolism studies is essential when developing novel analysis methods for arsenic containing CWAs from fish samples.

Methods: Fish samples obtained from three different dumpsite areas were analysed by liquid chromatography-tandem mass spectrometry (LC-MS/MS) in the selective reaction monitoring (SRM) mode. Qualitative identification criteria based on EU guidelines were used to reliable identification of detected CWA-related compounds. In order to study transformations of phenylarsenic compounds in fish in vitro we incubated five CWA-related arsenic compounds in cod liver homogenates (S9 fraction). Protein concentration of liver homogenates was determined by using the Lowry method. Samples from metabolism studies were analysed by liquid chromatography-Orbitrap high resolution mass spectrometry.

Results: Fish samples collected from three different dumpsites contained CWA-related arsenic compounds at parts per billion (ppb, ng/g) concentration levels. These arsenic containing chemicals were analysed as their pentavalent forms by LC-MS/MS method. Metabolism studies with cod liver homogenates proved that phenylarsenic compounds as trivalent intact form as well as oxidized pentavalent form formed glutathione (GSH) conjugates. Structures of these metabolites were determined by high resolution mass spectrometry. Also reference chemicals of detected glutathione metabolites were synthesized and their structures were confirmed additionally by nuclear resonance spectroscopy. MS spectra of detected metabolites from in vitro metabolites studies were found to match spectra of synthesized reference chemicals.

Conclusions: There are hardly any studies about transference of arsenic based CWAs into aquatic biota. Previously these arsenic-containing chemicals have been detected from marine biota samples as their pentavalent oxidation state. Metabolism studies with fish liver enzymes proved that these oxidized arsenic compounds were reduced by glutathione and formed glutathione conjugates. There are no data available about toxicities of these trivalent phenylarsenic-glutathione metabolites neither how these metabolites behave in fish. It's possible that these glutathione metabolites are excreted into bile or urine. Based on this, more studies are needed to evaluate total arsenic-related CWAs concentrations in aquatic biota.

Novel Aspect: CWA-related arsenic compounds have been detected in different marine species for the first time. In order to get more specific information about transformations of these arsenic compounds in fish, metabolism studies with fish liver homogenates were applied. Phenylarsenic compounds formed glutathione conjugates which structures were confirmed by Orbitrap high resolution mass spectrometry. None of these metabolites have ever been detected from marine biota samples and this is the first time when metabolism of phenylarsenic compounds have been studied with fish liver homogenates in vitro.

305 - PROTON TRANSFER REACTION – MASS SPECTROMETRY AND ITS APPLICATIONS TO HOMELAND SECURITY: DETECTION OF ILLICIT DRUGS

DAVID OLIVENZA LEON (1) - PETER WATTS (1) - FRASER REICH (2) - CHRIS MAYHEW (3)

UNIVERSITY OF BIRMINGHAM, SCHOOL OF PHYSICS AND ASTRONOMY, BIRMINGHAM (1) - KORE TECHNOLOGY LTD, KORE TECHNOLOGY LTD, ELY (2) - UNIVERSITAT INNSBRUCK, INSTITUT FUR ATEMGASANALYTIK, INNSBRUCK (3)

Keywords:

Proton transfer reaction mass spectrometry, illicit drugs, thermal desorption, homeland security

Introduction:

Proton Transfer Reaction Mass Spectrometry (PTR-MS) is an analytical technique for the detection of trace chemical compounds in complex environments through soft chemical ionization useful in many fields including health sciences, environmental sciences and homeland security. PTR-MS is based on the volatility of the targeted chemicals and its ability to work without initial separation or preconcentration makes it suitable for on-line, real time measurements.

Methods:

PTR-MS is a suitable analytical technique to monitor volatile organic compounds (VOCs) in the air. However, compounds of interest in the field of homeland security can have low pressure, which makes their detection challenging. To amend this, a Thermal Desorption Unit (TDU) in conjunction with a PTR-MS instrument can be used. It has recently been applied to the detection of explosives [1] and here we apply it to the detection of illicit drugs.

Results:

In this study we demonstrate the application of a TDU for the on-line detection of trace quantities of the most widely used societal drugs, the reactions of which with H_3O^+ at just one reduced electric field, 120 Td, have already been reported [2].

The results shown were achieved by measuring some hundreds of nanograms deposited in a teflon swab which was subsequently inserted into the TDU for the desorption of the sample into the PTR-MS instrument. The two modes of the instrument, namely DC and RF modes, were used. In DC mode, a uniform electric field draws the ions downstream in the reactor, while in RF mode a radio frequency field is superimposed to the uniform electric field to deliver extra collisional energy to the molecules.

Conclusions:

This study shows that the TDU is a suitable tool to use in conjunction with PTR-MS for the detection of illicit drugs. The relative distribution of product ions in the DC mode agrees with the literature [2], but the results from the RF mode is controversial. For heroin, morphine and codeine both modes present similarities, showing more fragmentation of the parent ion in the RF mode, whereas for cocaine and MDMA they totally differ.

Novel Aspect:

The novelty of these results lies in the use of the TDU and the RF mode in a PTR-MS instrument for the detection of illicit drugs.

1093 - ASSESSMENT OF CHEMICAL TRACE ELEMENTS IN COSMETICS' EYESHADOWS

Aleksandra Pawlaczyk (1) - Martyna Balcerek (1) - Malgorzata Iwona Szyrkowska (1)

Lodz University of Technology, Faculty of Chemistry, Institute of General and Ecological Chemistry, Lodz (1)

Keywords: trace elemental analysis, eye shadows, cosmetics, ICP-MS, CV-AAS

Introduction:

Among color cosmetics eyeshadows deserve special attention since they are applied in the area where facial skin is thin. Many studies suggest that cosmetics belonging to the eye makeup segment contain high amount of toxic metals. The size of particles used in their production also plays a key factor in safety issues. All may contribute to the increase of allergic reactions risk or development of other side effects appearing with their prolonged application [1-2].

Methods:

ICP Mass Spectrometry with Time-of-Flight Analyzer (Ag, Ba, Bi, Cd, Pb, Sr and Tl) and Cold Vapor Atomic Absorption Spectrometry (Hg) techniques were applied for inorganic chemical elements determination in eyeshadows products. In total 94 samples (in 12 colors) obtained from the local market and originating from 8 most commonly used brands were purchased for the analysis. The samples were coded depending on their price, color, type, origin and producer.

Results:

There are no current data concerning the potential assessment of the risk connected with application of eyeshadows. The safety of their use is dependent upon e.g. the type of products (source and form of the components, size of the particles), time and frequency of the application, etc. In this study eyeshadows samples were grouped by similarity to the concentrations of the chosen chemical elements obtained by ICP-MS and CVAAS techniques. The price of products, their color, brand, origin, destiny (for kids and adults), type (matt and pearl) were used as criteria of their classification. Multivariate methods as PCA and CA were applied to observe the relationships and interactions of several analyzed elements and assess influence of chosen factors. It was shown that the average level of Cd in one sample was few times above the permissible limit (0.5 mg/kg), while the concentration of Pb and Hg in two samples should not be ignored since they slightly exceeded the Polish regulations regarding cosmetics products (10 mg/kg and 1 mg/kg, respectively).

Conclusions:

Summarizing the influence of chosen factors it can be concluded that factors having the least impact on the concentration of studied elements are color and type of eyeshadows. Factors affecting the majority of concentrations of the determined elements are the brand of the eyeshadow (Sr, Ag, Cd, Pb, Bi, Hg), country of origin (Sr, Ba, Pb, Bi, Hg) and shadow price (Sr, Ba, Pb, Bi, Hg). For the following elements: Sr, Pb, Bi, Hg the influence of the same factors was observed.

Novel Aspect:

The examination of the content of chosen trace metals in the locally sourced eyeshadows is quite relevant since there are no updated reports regarding homegrown products safety.

531 - GENERIC EXTRACTION METHOD FOR SCREENING OF 8 NARCOTIC DRUGS IN SALIVA WITH A QUICK TURNAROUND ANALYSIS BY LDTD-MS/MS

Pierre Picard (1) - Jean Lacoursiere (2) - Serge Auger (3)

Phytronix Technologies Inc, 4535 boul. Wilfrid-Hamel, suite 120, Quebec (1) - Phytronix Technologies Inc, R&D, Quebec (2) - Phytronix Technologies inc, R&D, Quebec (3)

Keywords: Narcotics, Saliva, LDTD-MS/MS, screening

Introduction:

A generic extraction method combined with LDTD-MS/MS analysis was developed for fast turnaround screening of drugs in saliva. This new method could give police officers rapid and accurate answer in less than 10 minutes allowing on-site screening on a police roadblock.

Methods:

Drugs are spiked at 50%, 100% and 150% of the decision point in saliva. 50 μ L is mixed with a solution composed of 100 μ L of internal standard and 75 μ L of buffer. The mixture is vortexed 20 seconds and centrifuged 30 seconds. 8 μ L of the upper layer are deposited in LazWell-HDE plates. The plates are dried for 3 minutes. Seven drugs are analyzed in positive APCI mode and one in negative APCI mode in a single run. LDTD's laser power was ramped from 0 to 55% of maximum power in 6 seconds.

Results:

The decision points in saliva are 15 ng/mL for THC, 50 ng/mL for Amphetamine/Methamphetamine/MDMA and 10 ng/mL for Cocaine/ Benzoylcegonine/Morphine/6-AM. Using the SWGTOX validation guidelines, a blank preparation of saliva is spiked with 8 previously enumerated drugs at concentration representing 50%, 100% and 150% of the cut-off. Validation of this new screening approach, the CV at each concentration must not exceed 20% and the average concentration \pm 2 times the standard deviation must not overlap with other concentration at the decision point. Triplicate extractions are performed for each concentration over the course of 5 days, for validation. Additional blank of saliva, one with Internal standards (IS) and the others without are extracted and analyzed. The THC is analyzed in negative mode and the others in positive. No overlapping at the decision points is observed and a %CV lower than 15% is obtained. Series of tests were timed from the saliva collection to the output result giving an average of 9.3 minutes for the complete workflow.

Conclusions:

Simple extraction method combined with LDTD-MS/MS analysis allow specific measurement of narcotic in saliva. The generic method enables accurate on-site analysis of saliva collected from an individual potentially driving under the influence of drugs with expected feedback results obtained under 10 minutes by the police officer.

Novel Aspect:

In situ High Throughput targeted screening of narcotic in saliva using LDTD-MS/MS

569 - IMPROVEMENT OF THE ATHLETE BIOLOGICAL PASSPORT BY BLOOD STEROID PROFILING: CHALLENGES OF A STEROIDOMIC APPROACH

Federico Ponzetto (1) - Julien Boccard (2) - Raul Nicoli (1) - Tiia Kuuranne (1) - Serge Rudaz (2) - Martial Saugy (3)

Swiss Laboratory for Doping Analysis, CHUV - University of Lausanne, Lausanne (1) - School of Pharmaceutical Sciences, University of Geneva, Geneva (2) - Center for Research and Expertise in anti-Doping sciences, University of Lausanne, Lausanne (3)

Keywords: steroidomics, doping, HRMS, serum

Introduction

The steroidal Athlete Biological Passport aims at revealing use of testosterone. It is implemented by GC-MS quantification of selected endogenous androgens in urine. Sensitivity of this approach suffers from confounding factors e.g. enzyme polymorphism, bacterial contamination and ethanol consumption [1]. Among the improvement strategies, quantification of steroid hormones in serum has shown promising results and a complement to the urinary module [2, 3].

Methods

A steroidomic approach was used to highlight new serum biomarkers of testosterone doping. The developed analytical workflow consisted of a SPE clean-up of steroids and their phase II metabolites, followed by UHPLC-HRMS analysis. Full Scan MS and data dependent MS/MS spectra were acquired in both positive and negative ionization modes. Samples from testosterone administration study (n=380) were analyzed in 11 analytical batches.

Results

Positive and negative ion mode data from UHPLC-HRMS analyses were treated separately: firstly, data processing including noise filtering, chromatographic alignment and peak picking was performed by means of dedicated software and resulted in datasets with approximately 40000 features for each ionization mode. Then, in order to reduce data dimensionality, ion annotation was carried out assigning confidence level 1 (confirmed with authentic standard) and 2 (consistent with predicted properties) employing a newly created in-house steroid database (350 steroids) together with retention time prediction model [4]. Intensities of annotated features (64 and 174 in positive and negative mode, respectively) were corrected with LOESS regression in order to minimize the batch effects and finally Analysis of variance Multiblock Orthogonal Partial Least Squares (AMOPLS) was performed to highlight new promising blood biomarkers of testosterone intake, similarly to what was previously done on urine matrix [5].

Conclusions

The study revealed a set of biomarkers for both oral and transdermal testosterone abuse, including hydroxylated metabolites of androgens, as well as their glucuronidated phase II metabolites. In comparison with urinary steroid profiling, these targets could increase sensitivity and extend the current detection window. In the near future, targeted quantitative UHPLC-MS/MS method will be developed for serum to validate the results of this study.

Novel Aspect

This work represents a first application of steroidomics on serum samples for anti-doping purposes, demonstrating the usefulness of holistic approaches in such a context.

1346 - IN-VITRO/VIVO STUDY OF ANDARINE METABOLISM, A SELECTIVE ANDROGEN RECEPTOR MODULATOR (SARM), IN THE CONTEXT OF HORSE DOPING CONTROL

Stéphane Trevisiol (1) - Yves Moulard (1) - Sophie Boyer (1) - Murielle Jaubert (1) - Benoit Loup (1) - Patrice Garcia (1) - Marie-Agnès Popot (1) - Ludovic Bailly-Chouriberry (1)

Laboratoire des Courses Hippiques, LCH, Verrière-le-buisson, France (1)

Keywords: Doping, horse, metabolism, SARM, in-vivo/vitro

Introduction:

Andarine is a selective androgen receptor modulator classified as non-steroid anabolic agent. Its use is forbidden by the International Federation of Horseracing Authorities at any time in horse career. This molecule has the ability to stimulate androgen receptors in muscles and bones and thus to enhance athletic performances. To control the fraudulent administration of andarine, a horse metabolism study has been performed to identify the best target metabolites.

Methods:

This metabolism study of andarine was carried out first by in-vitro approach using microsomal fractions of equine hepatocytes (S9) and then in-vivo on one horse via a subcutaneous administration route. Both in-vitro reaction products and blood/urine samples, collected up to 4 days, were analyzed by LC-HRMS2 and LC-SRM to characterize phase I and phase II andarine metabolites.

Results:

The in-vitro results obtained using S9 equine hepatocyte fractions showed an important phase I metabolism of andarine. Indeed, six phase I andarine products were identified i.e. three metabolites with a functional loss (methyl, acetyl or phenyl), one with the nitro group reduction and one which was identified as cleavage product of andarine (4-nitro-3-trifluoromethyl-phenylamine) with its hydroxylated form. The post administration study has shown the presence of the native molecule in both urine and plasma. In urine, the results were consistent with those obtained in-vitro: the metabolite of andarine 4-nitro-3-trifluoromethyl-phenylamine and its hydroxylated form were also identified. These two metabolites were much longer detected in urine than the native molecule and presented high degree of phase II conjugation with both sulfate and glucuronic acid. Limit of detections (LOD) of andarine were 1 pg/mL in plasma and 5 pg/mL in urine. Concerning the two urine metabolites their LOD was around 50 pg/mL in andarine equivalent.

Conclusions:

Andarine is prohibited at any time. Therefore, it was important to study its metabolism in horse to identify the best target metabolites to detect its misuse. The in-vitro results demonstrated that andarine was strongly metabolized. These results have been confirmed by the in-vivo experiments. This study demonstrated that the control of andarine must be performed in urine on its two major metabolites which were much longer detected than the native molecule.

Novel Aspect:

Combination of in-vitro and in-vivo approaches to study by LC-HRMS2 horse metabolism and kinetic of elimination in plasma and urine of andarine in the context of horse doping.

798 - A FIT-FOR-PURPOSE UHPLC-MS/MS METHOD FOR ROUTINE SCREENING OF SARM RESIDUES IN BOVINE AND EQUINE SERUM

Emiliano Ventura (1) - Anna Gadaj (1) - Tom Buckley (2) - Mark H. Mooney (1)

Institute for Global Food Security, Queen's University Belfast, School of Biological Sciences, Belfast (1) - Irish Equine Centre, Irish Diagnostic Laboratory Services Ltd., Johnstown, Co. Kildare (2)

Keywords: SARMS, UHPLC-MS/MS, serum, doping control, food safety

Introduction:

Selective Androgen Receptor Modulators (SARMS) are an attractive alternative to anabolic-androgenic steroids despite the fact they are not yet approved as pharmaceutical drugs [1]. Consequently, there is much evidence of their availability through black and grey market sources. In this study, a semi-quantitative UHPLC-MS/MS method was developed to monitor the abuse of 15 compounds belonging to eight different SARM families, in bovine and equine animals, respectively.

Methods:

Serum samples underwent protein crash (0.5 mM NH₄OH in MeCN), induced phase separation (NaCl) and defatting (n-hexane) before concentration under nitrogen. Extracted SARM residues were subsequently analysed by UHPLC-MS/MS operating in ESI+/ESI-. Chromatographic separation was performed using a Luna Omega Polar C18 column at 45 °C, and a binary gradient elution of 14 minutes employing H₂O and MeOH, both containing 0.1% (v/v) CH₃COOH as mobile phases at a flow rate of 0.4 mL/min.

Results:

Validation of the semi-quantitative assay was carried out according to the Community Reference Laboratories Residues (CRLs) 20/1/2010 guidelines [2]. The following performance studies were carried out during the validation process: specificity, selectivity, detection capability (CC_β), absolute recovery as well as applicability, ruggedness and matrix effects. The detection capability was calculated by assessing threshold value (T) and cut-off factor (F_m) and CC_β values were determined at the following concentrations: 0.5 ng mL⁻¹ (CDS-025139), 1 ng mL⁻¹ (AC-252636, PF-06260414), 2 ng mL⁻¹ (bicalutamide, GLPG-0492, LGD-2226, S-1, S-6, S-22, S-23) and 5 ng mL⁻¹ (BMS-564929, LGD-4033, , RAD140, S-4, S-9), respectively. Moreover, ongoing work aims to identify *in vivo* metabolites of selected SARMS compounds following animal administration studies, which could serve as additional marker residues to be included within the current test method.

Conclusions:

SARMS are widely recognised as emerging drugs of abuse in animal sport, and also as potent candidates for misuse in food producing animals. The developed method is currently being employed as a rapid, simple, environmental friendly and cost-effective tool for the screening of serum samples to evaluate the abuse of SARM drugs in stock farming and to monitor for doping practices in racing horses, ensuring customer safety and fair play in animal sport competitions.

Novel Aspect:

The developed high-throughput assay allows, through a relatively short run and a small test sample volume (400 µL) of serum, the analysis of a total of 50 samples in a single day.

Analysis of removal of pesticides and drugs in waste water by plants using Flow Injection Analysis (FIA) Magnetic Resonance Mass Spectrometry (MRMS)

Keywords: Pesticides, Flow Injection Analysis, Drug detection, Screening

Introduction:

Treatment of wastewater is important to remove pollutants, drugs and other potentially environmentally toxic molecules before release into natural compartments. Constructed wetlands in France are used to treat water from small villages. Here we present the profiling of plants to understand if pesticides and drugs can be removed from waste water through an accumulation in plants or degradation by environmental factors.

Methods:

Two poplars (*Populus nigra*) were planted - one close to the border of a pond and the other away from the pond (control). Mature leaves of these two plants were collected and extracted. Each sample was analyzed in 8 technical and 3 measurement replicates in FIA-ESI using positive and negative ion mode. A solarix 2xR (Bruker Daltonik GmbH, Bremen) MRMS system was used for these studies. Analysis of data was performed with MetaboScape 3.0 (Bruker Daltonik GmbH, Bremen).

Results:

The data of the ESI(+) and ESI(-) were combined for feature analysis. More than 3400 features have been found for the plant extract samples. Roughly 90% of the detected features could be assigned with a molecular formula using a mass tolerance of only 0.5 ppm. More than 360 compounds have been annotated in the samples using a food data base with nearly 16000 entries using same mass tolerance. Features responsible to differentiate treated and non-treated plant sample were detected by T-test and Principle Component Analysis (PCA). These compounds were analyzed in detail as possible drugs and pesticides. Based on these results 6 pesticide and 4 drug candidates were found by screening versus pesticide and drug data bases.

Conclusions:

Pesticides and their metabolites can be detected by FIA-MRMS in plant samples. Statistical analysis such as T-test and PCA can be used to find compounds responsible to distinguish treated and non-treated plants based on FIA-MRMS data. This method can be used to understand if pesticides and drugs can be removed from waste water.

Novel Aspect:

FIA-MRMS can be used to study the effect of removal of drugs and pesticides in waste water.

49 - IMPROVEMENT FOR HIGH SENSITIVITY OF THE DRUG SCREENING BY THERMAL DESORPTION AND PYROLYSIS COMBINED WITH DART-MS (TDP/DART-MS)

University of Chiba, Department of Legal Medicine, Chiba (1) - BioChromato, Application support, Fujisawa (2) - AMR Inc., Application, Meguro-ku (3) - University of Tokyo, Department of Forensic Medicine, Bunkyo-ku (4)

Keywords: drug screening, urine, TDP/DART-MS

Introduction:(396 /400 characters)

In recent years, new drugs appear one after another, including new psychoactive substance that threaten society. Comprehensive analytical method for drug screening is greatly desired, since it is difficult to examine individually the analytical conditions that are appropriate for each one. Thus, we are developing a comprehensive drug screening method for urine or blood sample without pretreatment by thermal desorption and pyrolysis-DART-MS (TDP/DART-MS).

Methods: (373 /400 characters)

Standard drug mixture solution and urine added drugs (i.e., blank urine with several kinds of drug mixture added) were used as samples. TDP/DART-MS were composed by the combination TripleTOF 5600+ (Sciex) Q-TOF mass spectrometer equipped DART ion source (IonSense) and ionRocket TDP device (BioChromato). Mass spectra were measured as samples were heated from room temperature to 300 °C at a rate of 60 °C/min, the measurement time was 5min.

Results: (764 /900 characters)

At first, analysis of standard drug mixture by TDP/DART-MS, each drug was separated and detected through adding gradient heating, and thermal desorption profiles were highly reproducible for individual drug. Additionally, the detected ions were correctly identified according to their measured accurate mass and MS/MS spectra. So, it was confirmed that TDP/DART-MS can be a suitable analytical method for our investigation. Next, we examined the minimum pretreatment such as deproteinization by ACN, since for analysis of urine added drugs without any pretreatment, it was indicated that we had to improve the detection sensitivity. Comparing non-pretreated and deproteinization pretreated, the detection intensity of each drug in urine sample pretreated deproteinization were increased considerably. Moreover, the calibration curves using urine were linear in that ranging 0.01–1 µg/ml.

Conclusions: (362 /400 characters)

In summary, TDP/DART-MS can identify drugs in urine, directly and rapidly. In addition, since the calibration curves were linear in that ranging 0.01–1 µg/ml. Although our issue is to improve the detection intensity of drugs, TDP/DART-MS will be useful for rapidly quantitative analysis of drugs in urine in the future, and this analysis method will be a useful method in the field of required rapidity such as hospital and police.

Novel Aspect: (89 /150 characters)

TDP/DART-MS is useful analysis method for rapid identification and screening of drugs in urine samples.

847 - DETECTION OF IGF-1 IN SERUM AS A BIOMARKER OF GROWTH HORMONE ABUSE BY ATHLETES

Maxim Yunin (1) - Irina Zvereva (1) - Dmitry Rakov (1) - Elena Mochalova (1)

Antidoping Centre, Laboratory of Mass Spectrometry, Moscow (1)

Keywords: IGF-1, trypsin digestion, LC-MS/MS, doping-control

Introduction

The measurement of concentrations of insulin-like growth factor-1 (IGF-1) and N-terminal pro-peptide of type III collagen in serum was suggested for detection of growth hormone abuse by athletes [1]. The method for IGF-1 concentration determination by the quantification of two "signature peptides" (T1, T2) by UHPLC-MS/MS after trypsinolysis was proposed [2]. Here, we describe our results obtained after optimization and validation of the above method.

Methods

T1 and T2 were obtained after IGF-1 binding protein complex dissociation followed by protein precipitation by acetonitrile and trypsinolysis. Calibration curves were made using rat serum fortified with human IGF-1. Also used calibrators that were stored at -80°C. T1 and T2 peptides were analyzed by Thermo Ultimate3000 UHPLC with TSQ Vantage triple quadrupole mass spectrometer. The structures of peptides were confirmed by HRMS on Q Exactive mass spectrometer.

Results

The range of bottlenecks was revealed during method implementation. Calibration solutions that allow the estimation of the inter-day precision show remarkable changes in the standard concentration over time. The critical step in sample preparation was DTT reduction. Incubation for more than 90 min at 60°C led to T1 signal disappearance. Thus, we suppose that milder DTT reduction conditions are apparently more preferable for working with long peptides. For UHPLC-MS/MS method, the use of the gentle gradient (5-45%B, 20 min, 0.22 mL/min) at 40°C and high dwell time (200 ms) were necessary for achieving a good response at low levels. The method was fully validated in the range of 50 – 600 ng/mL. The correlation coefficients (r^2) for T1 and T2 were $0.996 \pm 0.004 / 0.996 \pm 0.003$, respectively. Interestingly, the correlation coefficients (r^2) for T1 and T2 in the range of 50 – 1000 ng/mL were $0.984 \pm 0.003 / 0.984 \pm 0.003$, respectively. Therefore, the calibration point at 1000 ng/mL of IGF-1 was recognized as outlier and removed.

Conclusions

The method was fully validated and implemented for anti-doping purposes. Determination of T1 peptide was the critical point of the method, probably, due to its longer amino acid sequence as compared to T2. It was determined that high temperatures should be avoided during the reduction step. For LC conditions, the gentle gradient, low flow rate and column temperature should be used to facilitate separation T1. High dwell time is crucial for method sensitivity.

Novel Aspect

The incubation conditions in the presence of DTT, as well as UHPLC-MS/MS parameters have a significant effect on the T1 peptide sensitivity.

976 - IMPACT OF CYP2D6 GENETIC POLYMORPHISM ON THE PHARMACOKINETICS OF TRAMADOL AND ITS THREE MAIN METABOLITES IN KOREANS

Jung-Woo Bae (1) - Sooyeon Lee (1) - Kyung-Soo Chun (1) - Min Je Choi (1) - Seong-Kuk Hong (1)

Keimyung University, College of Pharmacy, Daegu (1)

Keywords: Tramadol, CYP2D6, LC-MS/MS

Introduction:

Tramadol is a centrally acting analgesic used in the treatment of moderate to severe pain. Tramadol is mainly metabolized by the CYP2D6, CYP2B6 and CYP3A4 to O-desmethyltramadol (ODMT), N-desmethyltramadol (NDMT) and N,O-didesmethyltramadol (NODMT) [1]. We investigated the effects of CYP2D6 genetic polymorphism on the pharmacokinetics of tramadol and its three main metabolites.

Methods:

A multiple oral dose of tramadol was administered to twenty-two subjects with CYP2D6EM(n=14) and CYP2D6IM(n=8). Blood samples were collected up to 72 hr after drug intake, and plasma concentrations of tramadol and its metabolites (ODMT, NDMT and NODMT) were determined by validated HPLC-MS/MS method.

Results:

AUC of tramadol ($p<0.001$), NDMT ($p<0.05$) and NODMT ($p<0.001$) in CYP2D6IM group was significantly higher than those in CYP2D6EM group. The AUC ratios of ODMT to tramadol in the CYP2D6IM group was decreased to 44.9% of that in the CYP2D6EM group ($p<0.001$). The AUC ratios of NDMT to tramadol in the CYP2D6IM group was increased to 148.8% of that in the CYP2D6EM group (N.S.).

Conclusions:

The CYP2D6 genotype was found to play a significant role in the metabolic conversion of tramadol into ODMT and, as a compensatory consequence, impacted the conversion of tramadol into NDMT.

Novel Aspect:

CYP2D6*10 allele is found to affect the pharmacokinetics of tramadol and its phase I metabolites in Koreans.

Keywords: tandem mass spectrometry, micro-extraction by packed sorbent, dried blood spots, isoprostanooids, preterm newborns

Introduction:

An innovative UHPLC-ESI-MS/MS method for the analysis of prostaglandin-E₂, 8-iso-prostaglandin-F₂α and 8-iso-prostaglandin-E₂ in dried blood spots is proposed. The non-invasive and painless monitoring of these inflammation and oxidative stress mediators in preterm newborns suffering from Patent Ductus Arteriosus could assess their potential role as predictors of response to therapy [1].

Methods:

Analytes were extracted from dried blood spots (20 μL x 3) with 70:30 v/v methanol:water mixture. The extracts were purified by a semi-automated micro-extraction by packed sorbent (MEPS) before injection in the UHPLC-MS/MS instrument. Analytes were separated by a reversed-phase Polaris-C18 column and a gradient elution with aqueous formic acid (0.1%) and 50:50 v/v methanol:acetonitrile mixture. Triple quadrupole mass spectrometer operated in ESI(-) and MRM mode.

Results:

The fast and easy sample clean-up by MEPS guaranteed a high reproducibility (RSD < 5%) and extraction yield (>70%) in less than ten minutes, and limited the required volume of both solvents (30-100 μL) and sample (100 μL), with respect to conventional solid phase extraction [2]. The MRM acquisition ensured high sensitivity and selectivity and the presence of the analytes in the samples was confirmed by a q/Q ratio within ±20% of the value measured in reference standards. Limits of detection below 20 pg/mL, linearity (R²>0.99) over three orders of magnitude and satisfactory overall intra- and inter-day precisions (RSD <10%) were obtained. The deuterated internal standard was successfully laid on the filter paper instead of the common addition to the extraction solvent [2], in order to control both storage and extraction steps [3]. Finally, particular attention was paid to stability issues.

Conclusions:

To the best of our knowledge, this is the first analytical method combining a fast and reproducible MEPS procedure and a highly sensitive and selective UHPLC-ESI-MS/MS analysis for the determination of prostaglandin-E₂, 8-iso-prostaglandin-F₂α and 8-iso-prostaglandin-E₂ in dried blood spots. The method is suitable for monitoring preterm newborns with Patent Ductus Arteriosus.

Novel Aspect:

The very reliable combination of tandem mass spectrometry and fast, semi-automated, re-usable MEPS for prostanoids and isoprostanooids analysis in dried blood spots.

CENTRO REGIONALE ANTIDOPING E DI TOSSICOLOGIA "A. BERTINARIA", UNIVERSITY OF TURIN/DEPARTMENT OF CHEMISTRY, TURIN (1)

Keywords: GC-MS, estrogens, natural rhythmic fluctuations, multivariate data analysis, female reproductive cancers

Introduction

In premenopausal women the role of estrogens is not thoroughly understood due to the large variations in estrogenic concentration throughout the menstrual cycle [1-6]. Lifestyle factors, such as smoking, physical activity and alcohol consumption may affect menstrual cycle outcomes [7]. Vice versa, the variations could influence fertility [8], the sexual behavior [9] and some diseases, such as schizophrenia [10], stress [11], insomnia [12] and anxiety [13].

Methods

A Gas Chromatography coupled to Mass Spectrometry (GC-MS) method capable of detecting 15 estrogens (17 α -estradiol, 17 β -estradiol, estrone, estriol and their principal metabolites) in urine was developed following the experimental design approach and fully-validated in accordance with the 17025:2005 principles. Multivariate data analysis was performed applying PARAFAC, Principal Component Analysis (PCA) and Linear Discriminant Analysis (LDA) to the data.

Results

The following validation parameters were successfully investigated: linearity range, selectivity, specificity, LOD, LOQ, intra-assay precision and accuracy, repeatability, matrix effect, extraction recovery and carry-over.

Urine samples derived from 9 childbearing female volunteers (age between 25-35) who collected their urine every day for 28 days, that is a complete menstrual cycle. The data were evaluated by PARAFAC and the natural fluctuation of the concentration of each estrogen throughout the 28-day menstrual cycle was extract. Then, PCA was carried out on the data and the Scores Plot showed the occurrence of three different clusters corresponding to the three phases of the menstrual cycle: follicular phase, ovulation and luteal phase. Plotting PC1 and PC2 as a function of the menstrual cycle day in two separate graphs, the transitions between the phases turned visible by identifying the starting point of both the ovulation and the luteal phase. Lastly, a preliminary LDA model was built.

Conclusions

The application of a GC-MS method coupled to multivariate statistical techniques demonstrated great potentialities in the study of the natural rhythmic fluctuations of estrogens throughout the menstrual cycle. Therefore, the next step will be the application of this innovative approach to examine in depth the relationship between the endogenous estrogens and the increased risk of female reproductive cancers in postmenopausal women.

Novel Aspect

For the first time, not only the variation of the parent estrogens was studied, but also of their principal metabolites.

1354 - ANALYSIS OF SWEETENERS IN URINE USING NOVEL STATIONARY PHASE AND SELECTIVE LC-MS/MS METHOD

Barbora Cervinkova (1) - Richard Kay (2) - Albert Koulman (3)

NIHR BRC Nutritional Biomarker Laboratory, University of Cambridge, Cambridge, United Kingdom (1) - Metabolic Research Laboratories, University of Cambridge, Cambridge, United Kingdom (2) - NIHR BRC Nutritional Biomarker Laboratory, Metabolic Research Laboratories, University of Cambridge, Cambridge, United Kingdom (3)

Keywords: sweeteners, urine, biomarkers, HILIC, UPLC-MS/MS

Introduction:

There are only a limited number of published methods for monitoring of sweeteners intake. Most of these are focused on determination of small biomarker groups [1] and investigation their role in human metabolism. Moreover, these methods were either published deep in the past[2,3] or use chemical derivatisation[4,5]. In our study we aim to develop a novel and simple LC-MS/MS method for measurement of several intake biomarkers for different groups of sweeteners.

Methods:

Analysis of the sweeteners was performed using an ACQUITY UPLC System (Waters, Elstree, United Kingdom) coupled to a Xevo TQ-XS Triple Quadrupole mass spectrometer (Waters, Elstree, United Kingdom). For optimal separation of structurally related compounds different stationary phases, including C18, Amide, HILIC and Biphenyl, were tested. Moreover, in order to achieve greater ionization efficiency for small molecules novel UniSpray ion source was tested.

Results:

Final separation was achieved using a HILIC stationary phase with gradient of buffer and acetonitrile. The mobile phase gradient separated artificial sweeteners from sugar alcohols and natural sugars over a total 7.0 minute run time. For accurate detection of analytes ionization in negative mode and specific MRM transitions were used.

Conclusions:

The novel UPLC-MS/MS method with HILIC separation of structurally related sweeteners in human urine was developed in this study. This method was sensitive enough to comprehensively detect the broad spectrum of artificial and natural sweeteners without applying complicated derivatisation steps.

Novel Aspect:

This unique method enables rapid analysis of several different groups of sweeteners in human urine in one run. It may serve to identify biomarkers in nutritional research.

Pharmacokinetic of Myriocin in rabbit's eyes

Michele Dei Cas, Federico Maria Rubino, Jessica Rizzo, Paola Signorelli, Enrica Strettoi, Chiara Platania, Claudio Bucolo, Rosario Pignatello, Riccardo Ghidoni, Rita Paroni

Keywords: myriocin, pharmacokinetic, drug delivery, eye, qTrap

Introduction:

Myriocin (Myr) is a suicide inactivator of ceramide synthesis with a complex lipid multifunctional structure. Its biological activity is exerted at very low doses, and thus highly performing quantitative methods are needed [1]. The pharmacological development of Myr to modulate ceramide levels also requires currently unavailable ADME information in healthy and pathological animal models.

Methods:

A 3200 qTRAP system was operated under manufacturer's instructions to perform extensive tandem MS studies. LC and MS were optimized for the separation, detection, identification and quantification of Myr in aqueous humor, vitreous humor and retina of rabbit after different treatments. MRM scan mode was used as protocol, to tackle the ambiguities of some samples, EPI scan, MS3 and the use of HR-MS on a 6600 qTOF was also crucial.

Results:

Tissue levels of Myr are related to the dose, pharmaceutical formulation, administration route, and administration schedule. Four types of eye drop formulations were evaluated in rabbits: Myr in buffer solution, Myr in two different types of liposomes (neutral and cationic), Myr encapsulated in a novel type of solid nanolipid particles. In particular, solid nanolipid particles were found to be extremely efficacious for the delivery of Myr in the different areas of the eye. The slow release formulation produced a T_{max} between 180-240 minutes, with a maximum concentration respectively of 10 $\mu\text{g}/\text{mL}$ in vitreous and 1.7 $\mu\text{g}/\text{g}$ in retina. Biological activity of Myr was always confirmed in rabbit's retina by a significant decrease in ceramide levels, compared to the physiological level established from untreated animals. Some untreated animals demonstrated the presence of a peak with spectroscopic and chromatographic characteristics of Myr. EPI scan, MS3, and the use of a HR-MS as protocol confirmed an upstream contamination.

Conclusions

A new pharmaceutical delivery system, such as solid lipid nanoparticles, allows Myr to accumulate into the retina by a non-invasive eye-drops administration, and to modulate sphingolipid levels. These results would be promising to study its efficacy in mouse pathological model of retinitis pigmentosa. MRM measurement needs alternative and/or complementary techniques to confirm eventual false-positive samples.

Novel Aspect:

The use of HR-MS as protocol should be quite advantageous for predicting new metabolites and for removing unwanted matrix interferences.

Pharmacokinetics and bioavailability of different acetylsalicylic acid formulations assessed by Liquid Chromatography-Tandem Mass Spectrometry in healthy subjects

Jessica Rizzo, Michele Dei Cas, Federico Maria Rubino, Rita Clara Paroni

Keywords: pharmacokinetics, LC-MS/MS, aspirin, enteric-coated formulation

Introduction

Low-dose acetylsalicylic acid (ASA, 100 mg/die) is used in thromboprophylaxis. Enteric-coated formulation (EC-ASA) is commonly used for its lower risk of side effects. Some patients on EC-ASA do not respond appropriately and recent studies showed that poor responsiveness is more frequent with EC-ASA [1]. Aim of this study was to validate a method useful to study the pharmacokinetics (PK) of ASA in healthy subjects treated with two different aspirin formulations.

Methods

Liquid chromatography tandem mass spectrometry (LC-MS/MS) technique was used for determination of ASA and salicylic acid (SA) in human plasma, using the respective deuterated isotopomers as internal standards (ASA-d₄, SA-d₄). The method was validated according to FDA guidelines and was applied to evaluate the PK of ASA and SA at different times (30 min-24 h) in healthy subjects (n=11) treated for 1 week with 100 mg of EC-ASA or plain Aspirin (plain-ASA).

Results

Analytes and internal standards were extracted from human plasma by protein. The compounds were separated on a reverse-phase column with an isocratic mobile phase. Compound parameters were optimized to have the higher signal to noise ratio in negative multiple reaction mode. Ion transitions recorded were 179→137 for ASA, 183→141 for ASA-d₄, 137→93 for SA and 137→141 for SA-d₄. The calibration curves were linear ($r^2 \geq 0.99$) over the concentration range of 20-2000 ng/mL for ASA and 20-8000 ng/mL for SA. LOQ was 20 ng/mL for both. Plasma AUC after EC-ASA administration was 702 (604-881) ng h/mL (median, 25%-75% CI). t_{max} occurred between 2-8 hours after intake. Two subjects did not show ASA absorption within the observation period confirmed by SA trend. PK of plain-ASA showed AUC of 823 (635-1013) ng h/mL and all subjects absorbed the drug with t_{max} between 0.5-1 h.

Conclusions

The developed method allowed to study the analytical fate of aspirin "in vivo" by comparing two different ASA formulations. Coated formulation showed a variable behavior and in 2 subjects absorption seemed impaired. On the contrary using plain-ASA variation is reduced and all subjects absorbed efficiently the drug. Causes of inadequate response to ASA may be related to different gastro-intestinal availability of coated formulation.

Novel Aspect:

Availability of a validated method is pivotal to study ASA absorption and metabolism in different cohorts of patients known to have poor pharmacodynamic responses to the drug.

Keywords: Comparing ionization techniques for steroids

Title:

Comparison of ESI, APCI and APPI ionization techniques for testosterone (T), dihydrotestosterone (DHT) and estradiol (E2) LCMS/MS assay.

Introduction:

High sensitivity measurement at low concentrations of non-derivatized testosterone (T), dihydrotestosterone (DHT) and estradiol (E2) requires optimizing ionization technique but few matrix-specific comparisons are available. We compared electrospray ionization (ESI), atmospheric pressure chemical ionization (APCI) and atmospheric pressure photoionization (APPI) for sensitivity and matrix interference in neat solutions and human serum.

Methods:

LC instrumentation and conditions

A Shimadzu Prominence HPLC system was used and consisted of a DGU-20A5 degasser, three LC-20 AD pumps, a SIL-20AT HC autosampler and a CTO-20A column oven (Shimadzu Scientific Instruments, Kyoto, Japan). The column was an Agilent Poroshell 120 SB-C18 (2.1 × 50 mm; 2.7 μm) with 0.3 μm in-line filter (Agilent Technologies). For the determination of LLOQs with standard solutions, column temperature was 40 °C, injection volume 20 μl, and mobile phase of 70% methanol/water, containing 0.1% (v/v) of formic acid for positive ESI and 2.5 mM ammonium hydroxide for negative ESI. APCI and APPI were used without mobile phase additions. For serum and tissue samples, a following gradient was employed (A: water, B: methanol): 0–1 min: 20% B, 1–8 min: 20 > 70% B, 8–10 min: 70% B, 10–12 min: 100% B, 12–16 min: 20% B. Flow rate was 0.3 ml/min, injection volume 40 μl and same mobile phase additions were used as for the isocratic separations. A flow-line selection valve was used to divert the eluent to waste during 0–7 min and 11–16 min. For all experiments with APPI, toluene was used as a dopant solvent, delivered with an LC-20 AD pump with a flow rate 10% of that of the mobile phase.

MS instrumentation and conditions

An API 5000 triple quadrupole MS was used with Turbo V (ESI, APCI) and PhotoSpray (APPI) ion sources (AB Sciex, Toronto, Canada). The APPI lamp was a DC-driven 10.0 eV krypton discharge lamp model PKS100 from Heraeus (Hanau, Germany). Nitrogen was employed as ion source, curtain and collision gas (Peak NM20ZL, Peak Scientific, Inchinnan, UK). For the precursor ion selection and optimiza-

tion of the MS parameters, 5 μ M solution of E2 in methanol was infused post-column into the mobile phase (70% methanol/water). The E2 infusion flow rate was kept at 5% of the mobile phase flow. Precursor and product ion selection was based on ion intensity. After establishing the MRM conditions, further optimization of the ion source parameters and the mobile phase flow rate was made with on-column injections, which enabled signal-to-noise (S/N) calculations. MS parameters not related to ionization were optimized and kept identical for each MRM transition. Both quadrupoles were set at unit resolution, cycle time was 250 ms and no signal thresholding was applied. Data acquisition and processing were performed with AB Sciex Analyst 1.5.2 software. The MRM transitions and more detailed instrument settings are described in Table 1.

We used a Shimadzu Nexera UHPLC and SCIEX API 5000 triple quad with Phenomenex Kinetex XB C18 (50mm x 2.1mm x 1.7 μ m) column at 40 C, injection volume 50 μ l, flow rate was 0.5 ml/min, mobile phase of methanol-water. For ESI we used modifiers of 0.1% formic acid for positive and 2.5 mM ammonium hydroxide for negative polarity. APCI and APPI were used without mobile phase additions but toluene as a dopant for APPI.

Results:

Direct infusions of 5 μ g/ml of T, DHT and E2 carried out to optimize the best ionization and MRM transitions in both positive and negative polarity for E2, whereas only positive mode for T and DHT with ESI, APCI and APPI. With ESI, peak responses increased with 0.1 % formic acid in positive mode and 2.5mM ammonium hydroxide in negative mode for E2 as well for DHT in positive ESI. APCI and APPI both resulted in water loss for main precursor ion for DHT and E2 with the highest intensity, although no modifiers were required for high signal intensity, toluene improved ionization with APPI. T had similar responses for all measurement. Regardless of ionization, methanol in the mobile phase enhanced ionization more than acetonitrile. After establishing the optimized MS/MS conditions serum extracts and neat samples were analyzed, to define LLOQs with a precision <20%, and accuracy of 80–120% and matrix effect. APPI had strongest S/N ratio and better LLOQs for all analytes compared to APCI and ESI.

Conclusions

Ionization technique and ion polarity both contribute to sensitivity and susceptibility to matrix interference. With serum extracts, ESI suffered from severe ion suppression compared to APPI and APCI. We conclude that irrespective of ionization, negative polarity was best for E2 whereas, for T and DHT positive polarity is best. APPI has the highest potential to produce high S/N ratio with least ion suppression.

To maximize the LC–MS assay sensitivity for E2 analysis, various approaches have been described. Sample preparation and LC separation of steroids in biofluids such as serum or plasma are reasonably well established, but the most efficient ionization technique for E2 is still to be determined. E2 can be ionized with all the common commercially available ionization APPI is much less prone to ion suppression than either APCI or ESI. Evidence indicates that ESI is especially susceptible to ion suppression effects. The high linear dynamic range and the applicability to a broad range of polarity makes APCI a good choice for steroids, especially when the APPI source is not available.

Novel Aspect:

This study comparing ESI, APCI and APPI for the analysis of T, DHT and E2 in serum provides insight on achieving high sensitivity and choice for optimal ionization to avoid matrix interference.

Accurate measurement of estradiol (E2) is important in clinical diagnostics and research. High sensitivity methods are critical for

specimens with E2 concentrations at low picomolar levels, such as serum of men, postmenopausal women and children. Achieving the required assay performance with LC–MS is challenging due to the non-polar structure and low proton affinity of E2.

Previous studies suggest that ionization has a major role for the performance of E2 measurement, but comparisons of different

ionization techniques for the analysis of clinical samples are not available. In this study, female serum and endometrium tissue

samples were used to compare electrospray ionization (ESI), atmospheric pressure chemical ionization (APCI) and atmospheric

pressure photoionization (APPI) in both polarities. APPI was found to have the most potential for E2 analysis, with a quantifica-

tion limit of 1 fmol on-column. APCI and ESI could be employed in negative polarity, although being slightly less sensitive than

APPI. In the presence of biological background, ESI was found to be highly susceptible to ion suppression, while APCI and APPI

were largely unaffected by the sample matrix. Irrespective of the ionization technique, background interferences were observed

when using the multiple reaction monitoring transitions commonly employed for E2 (m/z 271 > 159; m/z 255 > 145). These

unidentified interferences were most severe in serum samples, varied in intensity between ionization techniques and required

efficient chromatographic separation in order to achieve specificity for E2. Copyright © 2013 John Wiley & Sons, Ltd

Accurate measurement of estradiol (E2) is important in clinical diagnostics and research. High sensitivity methods are critical for

651 - HIGHLY SELECTIVE AND FAST IDENTIFICATION OF BRUCELLA BY IMMUNOAFFINITY- MALDI-TOF MASS SPECTROMETRY

Hamideh Hamidi (1) - Mahshid Zarrineh (1) - Ilnaz Soleimani (1) - Ramin Bagheri Nejad (2) - Ali Es-haghi (3) - Alireza Ghasempour (1)

Medicinal Plants and Drugs Research Institute, Shahid Beheshti University, Tehran (1) - Razi Vaccine & Serum Research Institute (RVSRI), Agricultural Research, Education and Extension Organization (AREEO), Brucellosis Department, Karaj, Alborz (2) - Razi Vaccine & Serum Research Institute (RVSRI), Agricultural Research, Education and Extension Organization (AREEO), Department of Physico Chemistry, Karaj, Alborz (3)

Keywords: MALDI-TOF; Mass spectrometry; Brucella; Immunoaffinity

Introduction: The genus *Brucella* contains highly infectious species classified as biological threat agents [1]. Brucellosis is endemic in parts of Iran, and the annual incidence of the human and animal brucellosis has been reported [2]. The timely identification of the microorganism is necessary not only to treat patients effectively but also to establish outbreak management, source tracing, and threat analyses. Matrix-assisted laser desorption ionization–time of flight mass spectrometry (MALDI-TOFMS) is a rapid method used to analyze biological differences in microorganisms [3]. In this work, we have developed a highly selective method to quickly and accurately identify bacteria in milk/ blood samples combining MALDI-TOFMS and immunoaffinity enrichment/separation.

Methods: Synthesized monodispersed magnetic particles are activated and modified with protein A for oriented immobilization of monoclonal antibodies. 5 mL of human whole blood is spiked with *B. melitensis* cells. The spiked blood is injected into a blood culture bottle and cultured at 35°C in the presence of 10% CO₂. Antibodies-modified magnetic beads are used for extraction of *B. melitensis* from artificially inoculated milk and human blood samples. After inactivation of enriched bacteria, the ethanol/formic acid extraction procedure is applied and analyzed by MALDI-TOF MS.

Results: MALDI-TOF MS results for the identification of *Brucella* strains have been investigated after enrichment by the immunoaffinity technique based on immobilization of antibody on the magnetic beads. Initial spectra from *B. melitensis* biovar 16M have been obtained for pattern matching-based bacteria identification and subsequently the experimental spectrum from a blood/milk sample has been compared with the reference one. Because of the method's high sensitivity, the blood culture time required for diagnosis can be greatly reduced. As a proof, whole blood/ milk spiked with a low initial concentration (10² or 10³ cells per mL) of bacteria is cultured, then the antibody coated beads are added to these prepared samples after different blood culturing times. Finally, the bacteria attached on the surface of beads have been eluted and analyzed by the MALDI-TOFMS. Therefore, entire diagnosis process (treatment and mass-spec analysis of *Brucellae* from blood/milk media) can be accurately accomplished less than 48 hours by using this newly developed method.

Conclusions: We have developed an immunoaffinity-MALDI-TOF MS method possessing a simple pretreatment and high sensitivity for rapid detection of *Brucella* spp. in humans and animal clinical specimens. This method indeed facilitates early accurate diagnosis of the disease which is required for further well-timed actions including effective anti-bacterial therapy or implementing control measures.

Novel Aspect: Immunoaffinity-MALDI-TOFMS method has been developed for the sensitive and rapid identification of *Brucella* strains.

1050 - ANALYSIS OF PROTEIN BIOMARKERS FROM LOW SAMPLE VOLUMES

Trine G. Halvorsen (1) - Cecilie Rosting (1) - Maren C. S. Levernæs (1) - Leon Reubsaet (1)

School of Pharmacy, University of Oslo, Oslo (1)

Keywords: protein analysis - antibodies – LC-MS/MS – affinity clean-up – biomarker analysis

Introduction:

Targeted protein determination using liquid chromatography tandem mass spectrometry (LC-MS/MS) offers a more reliable alternative to traditional immunometric assays. The interest in applying LC-MS/MS in protein biomarker analysis is hence increasing. For low volume samples (<50 µL) a highly specific sample preparation step normally is necessary to detect low abundance biomarkers (low pM-level).

Methods:

Two different approaches are discussed: 1) NanoLC-MS/MS analysis of human chorionic gonadotropin (hCG) from dried matrix samples (blood, serum, plasma and urine) by affinity sample clean-up of whole protein followed by tryptic digestion. 2) NanoLC-MS/MS analysis of progastrin releasing peptide (ProGRP) from 50 µL of serum using affinity extraction of proteolytic epitope peptide after digestion.

Results:

Ovarian and testicular cancer marker hCG was detected from four different biological matrices (whole blood, serum, plasma and urine) from 15 µL of dried matrix spots at its upper reference level (low pM-level). The detection limits (S/N=3) ranged from 14.5 pM (whole blood) to 30.5 pM (urine). The method was briefly evaluated for dried serum samples providing satisfactory results (RSD(%)=13-29% and accuracy (97-106%)) [1]. The small-cell lung cancer marker ProGRP was also determined at its upper reference level (low pM-level). Detection limits (S/N=3) of 3.9 pM from 50 µL of serum was observed when using monoclonal antibodies developed against intact proteins to capture a proteotypic epitope peptide. Compared to intact protein extraction, this concept, which we call epitope fishing, provided cleaner extracts.

Conclusions:

NanoLC and state-of-the-art triple quadrupole MS, and affinity clean-up is a powerful combination for determination of low abundance protein biomarkers available in low volumes. Both affinity clean-up of whole protein (hCG in 15 µL of dried matrix spot) and of proteotypic epitope peptide (ProGRP in 50 µL serum) have been successfully enabled at low pM-level.

Novel Aspect:

Determination of low abundance protein biomarkers is enabled from small volumes (< 50 µL) by affinity clean-up and state-of-the-art nanoLC-MS/MS.

Keywords: aspergillosis; non-invasive; diagnosis; siderophore; imaging

Introduction: *Aspergillus fumigatus* is a ubiquitous saprophytic airborne fungus responsible for more than one million deaths every year. Its siderophores represent important virulence factors contributing to microbiome-metabolome dialog in a host. From diagnostic point of view, the application of *Aspergillus* secondary metabolites is promising due to non-invasiveness and high speed, sensitivity and potential for standardization.

Methods

Using a model of experimental aspergillosis in immunocompromised Lewis rats [1], the fungal siderophores ferricrocin (FC) and triacetylfusarinine C (TAFC) were monitored in rat urine before and after lung inoculation with *A. fumigatus* conidia. Molecular biomarkers were separated in high/low dose infection models by high performance liquid chromatography (HPLC) and detected by mass spectrometry (MS). Rat results were compared with those in a set of 11 human clinical samples.

Results

In high dose rat model, the initial FC signal reflecting the aspergillosis appeared as early as four hours post-infection. Results for seven biological replicates showed increasing exponential metabolite profiles in three-day frame of the experiment. TAFC was shown to be less populated biomarker produced by *A. fumigatus* 1059 CCF strain exhibiting identical kinetic profile to that of FC. Among nine biological replicates in the low dose model, three animals did not develop any infection up to experiment termination (day 10). One animal experienced an exponential increase of metabolites and died on the day six post-infection. All remaining five animals revealed constant or random FC levels and exhibited little or no symptoms. μ PET/CT imaging, although it was not as an early tool, further determined the infection location in vivo and allowed to visually follow the infection progression in time. In a set of 11 human ICU patients with probable aspergillosis, siderophore-based approach was more sensitive than standard galactomannan (GM) testing.

Conclusions

Siderophore detection in urine (rat or human) by mass spectrometry represents an early, innovative and non-invasive tool for diagnosing aspergillosis. Further studies are needed to clarify the effect of antifungal prophylaxis to *Aspergillus* secondary metabolite production in human host. The general application of microbial siderophores in human diagnostics can soon represent the same clinical breakthrough like ribosomal protein typing 10 years ago.

Novel Aspect

Siderophore *Aspergillus* detection is non-invasive, rapid, sensitive and as such has a great potential to standardization in human diagnostics.

1377 - WHICH LC-MS/MS PLATFORM IS MOST APPROPRIATE FOR THE QUANTITATIVE ANALYSIS OF STEROIDS IN URINE, SERUM AND ORAL FLUID FOR CLINICAL RESEARCH

Sergio Indelicato (1) - Rory M Doyle (2) - Douglas McDowell (2)

Thermo Fisher, CMD, Paris, France (1) - Thermo Fisher, CMD, Somerset, New Jersey, United States (2)

Keywords: steroids, serum, triple quadrupole, liquid-liquid extraction

Introduction:

Steroid hormones control many physiological aspects in our body. A robust, sensitive, accurate and specific LC/MS/MS analytical method has been developed for the quantitation of 19 steroids in serum. A simple liquid-liquid extraction sample preparation allows achieving the required sensitivity. This research study was carried out to evaluate which LC-MS/MS instrument is best suited to characterize and quantitate the steroids in serum.

Methods:

Thermo Scientific™ TSQ Fortis™, Thermo Scientific™ TSQ Quantis™, and Thermo Scientific™ TSQ Altis™ tandem mass spectrometers and a Thermo Scientific™ Vanquish™ HPLC system were utilized. A 200 µL serum sample was used and a Thermo Scientific™ Accucore™ C18 column achieved baseline chromatographic separation. Quantitative analysis was performed using SRMscan in positive and negative mode. Accuracy of the analytical method was verified using reference samples.

Results:

Good linearity and reproducibility were obtained with the concentration range from 10pg/ml to 1000 ng/ml for the steroids with a coefficient of determination >0.995 for all mass spectrometer platforms. The lower limit of detection (LLOD) and lower limit of quantitation (LLOQ) were determined. Excellent reproducibility was observed for all platforms, being the %CV for each calibration point always < 10% for all steroids. The inter-assay precision was determined by extracting and quantifying three replicates of in-house control material resulting in %CV for the steroids of < 10% deviation from the targeted mean. The inter-assay precision was determined over three consecutive days and was found to have a %CV < 10% for each steroid within its respective linear range for the three levels of pooled serum sample control material respectively. The accuracy was determined by the analysis of in-house control material as the percentage deviation from the targeted mean. The results were < 10% for all levels in each matrix.

Conclusions:

A sensitive, simple, specific and accurate liquid chromatography QQQ mass spectrometry analytical method was developed and verified for the measurement of 19 steroids in serum and applied to any Thermo Scientific™ tandem mass spectrometer platform. The sample preparation technique is quick and easily applicable for high throughput analysis. The reported method achieves research laboratory required analytical performances for steroid analysis in serum.

Novel Aspect:

Utilization of various triple quadrupole mass spectrometers to determine the most appropriate platform for steroid analysis in serum.

1088 - BREATH ANALYSIS OF UNDERIVATIZED AMINO ACIDS AS MONITORING THERAPY FOR CHILDREN WITH TYPE 1 DIABETES

Magdalena Pyszka (1) - Lucyna Konieczna (1) - Magdalena Okońska (1) - Łukasz Szmygel (2) - Małgorzata Myśliwiec (2) - Tomasz Bączek (1)

Medical University of Gdańsk, Department of Pharmaceutical Chemistry, Gdańsk (1) - Medical University of Gdańsk, Department of Pediatrics, Diabetology and Endocrinology, Gdańsk (2)

Keywords: exhaled breath condensate (EBC) samples, amino acids, underivatization step, type 1 diabetes, LC-MS/MS,

Introduction

Insulin deficiency in type 1 diabetes leads to metabolic changes. Despite technological progress, early detection of the disease is problematic and checking sugar level is burden for 66% of patients. The use of exhaled breath condensates as a non-invasive sampling method might help patients. Liquid chromatography technique coupled with mass spectrometry may help in the detection of differences in amino acid profiles in patients with type 1 diabetes and healthy ones.

Methods

A procedure for preparing EBC samples with underivatized amino acids to chromatography analysis is based on vacuum evaporation. For the determination of low molecular weight amino acids, liquid chromatography coupled to mass spectrometry (LC-MS/MS) with a hydrophilic interaction chromatography (HILIC) column was used. All amino acid profiles were determined in exhaled breath condensate samples.

Results

A sensitive and specific method was used for the simultaneous determination of the entire L-amino acid profile in exhaled breath condensate samples, a matrix taken in a completely non-invasive way, in pediatric patients with type 1 diabetes, and the results were compared with the control group. The use of vacuum evaporation as a sample preparation step has reduced the consumption of solvents, which is consistent with the principles of green chemistry. Thanks to the use of the HILIC column, it was possible to identify 23 amino acids without the necessity to derivatize them. The condensates of exhaled breath of pediatric patients with diabetes in whom the disease has been diagnosed have been analyzed. Therefore it is a stabilized research group, so no statistically significant differences were observed in the amino acid profiles of exhaled breath condensates in children with type 1 diabetes compared to healthy control group.

Conclusions

The results indicate that it seems to be advisable to use the amino acid analysis in EBC, which is a method that does not burden the patient doing multiple blood glucose measurements and treated with insulin. Due to the chronic nature of diabetes, chronic complications are important for the patients' survival time and the quality of life. The EBC can be used as a new method allowing for their early detection and can positively affect the effects of treatment of type 1 diabetes

Novel Aspect:

A new research method based on LC-MS/MS has been developed, allowing for non-invasive diagnostics of metabolic changes occurring in type 1 diabetes.

Keywords: exhaled breath, exhaled breath condensate, metabolomics, VOCs, sputum induction

Introduction:

Exhaled breath condensate (EBC) is a promising specimen for use in diagnostics and therapy monitoring. It consists of condensed water vapor, water soluble volatile organic compounds (VOCs), as well as non-volatile hydrophilic and hydrophobic components [1]. It can be easily and non-invasively obtained, presenting an advantage over sputum, which is a more commonly used sample for respiratory disease assays, but is hard to obtain from children and weak patients.

Methods:

In this study, we explore the effects of meal and sputum induction (SI) on the EBC profile. Samples were collected from 10 healthy volunteers, divided into 2 batches. For each batch, samples were collected for 3 days at different timepoints, before and after SI and meals. Double filtration sterilization was done in consideration of plans for infectious disease biomarkers study. VOCs were analyzed using GC-MS and the non-volatile components using LC-MS.

Results:

Preliminary analysis of GC-MS and LC-MS results using principal components analysis (PCA) showed inter-batch effects for the GC-MS profiles across three days of sampling indicating possible differences in the VOC composition in the sampling environment of the two batches. It is also observed that for Batch 1, there is some separate clustering of samples before and after SI. This could be indicative of a change in the EBC VOC profile after SI. Though there were still some inter-day batch effects observed, samples before a low-fat breakfast clustered closely while the samples for each batch collected 30 minutes and 2 hours after the meal clustered together. Samples before and after a high-fat breakfast were found to cluster together. PCA of LC-MS data showed distinct clustering of samples before and after SI while samples before and after meals were mostly overlapped.

Conclusions:

Results revealed that there can be changes in the VOCs and non-volatile components of exhaled breath after sputum induction. The VOCs profile can also be affected by the meal taken before sampling while the profile of non-volatile components does not significantly vary whether sampling is done before or after meal. This indicates that EBC collection should not be performed after sputum induction of patients and at least 2 hours after a meal in breath biomarkers studies.

Novel Aspect:

This study demonstrates multi-platform profiling of EBC components using GC-MS and LC-MS to establish the effects of meals and sputum induction in EBC collection.

223 - DEVELOPMENT AND VALIDATION OF A HIGH SENSITIVITY ASSAY OF ESTROGENS IN HUMAN PLASMA BY UHPLC-MS/MS WITHOUT DERIVATIZATION.

Mikaël LEVI (1) - Hironori KOBAYASHI (2) - Jun WATANABE (1)

Shimadzu Corporation, MS BU, Kyoto (1) - Shimane University Faculty of Medicine, Department of Pediatrics, Shimane (2)

Keywords: Estrogens, plasma, high-sensitivity, UHPLC-MS/MS.

Introduction:

Estrogens play important roles in many biological functions as primary female sex hormones. In males, estrogens are present at lower concentrations but are also involved in several mechanisms. Modification of circulating estrogen levels can be associated with both positive and negative health effects.

In the last decade, LC/MS/MS has proven its capabilities in terms of sensitivity and specificity to become the gold standard methodology in steroid analysis. However, measuring estrogens at very low level remained challenging. Many published methods involve complex sample preparation, large sample volumes or derivatization. These processes are not compatible with a routine laboratory workflow. Here we present a UHPLC-MS/MS method to measure estrone (E1), estradiol (E2) and estriol (E3) together in the low pg/mL range.

Methods:

300 µL of plasma were spiked with 30 µL the ISTD solution (deuterated E1, E2 and E3) and then loaded on a SLE+400 96-well-plate (Biotage, Sweden). After 5 min incubation, target compounds were eluted with 2x 500 µL of Ethylacetate/Hexane 75/25 v/v. After evaporation and reconstitution, extracts were analyzed using a Nexera X2 coupled to a LCMS-8060 tandem mass spectrometer (Shimadzu Corp., Japan). Using a gradient of water and methanol with NH₄F, all compounds were separated on a Raptor Biphenyl column (Restek, USA) with a cycle time of 3.5 min. Data acquisition used MRM mode with the electrospray ion source operating in negative mode.

Results:

To fully optimize the detection of estrone (E1), estradiol (E2) and estriol (E3) in plasma, the method considered the impact of alternative sample preparation protocols in addition to enhancing ion sampling efficiency and MS/MS ion signals.

Several sample preparation procedures were evaluated including protein precipitation (PPT), solid phase extraction (SPE), liquid-liquid extraction (LLE) and supported liquid extraction (SLE). In this work, SLE resulted in the highest extraction recovery with a minimal matrix interference. SLE was also considered to be a simple technique to use routinely with a relatively fast sample cycle time and created further opportunities in automation. Extraction recovery was between 96 to 97% for E1, 88 to 102% for E2 and 94 to 108% for E3. Matrix effect ranged from 0.90 to 1.00 for E1, 1.19 to 1.29 for E2 and 0.91 to 1.11 for E3.

As SLE selectively extracted E1, E2 and E3 whilst minimizing possible co-extraction of isobaric matrix interferences the peak area variance for the internal standards (ISTD) in patient samples and QC was less than 16% (%RSD was 16%, 9% and 11% for D4-E1, D3-E2 and D3-E3 respectively, n=27).

As a result, we obtained limits of quantification of 0.5 pg/mL (E1), 1 pg/mL (E2) and 5 pg/mL (E3). To our knowledge, such limits of quantification have never been reported with a simple sample preparation and no derivatization. The linear calibration range was then 0.5-500 pg/mL, 1-500 pg/mL and 5-1000 pg/mL for E1, E2 and E3 respectively. Such sensitivity was successfully used to report samples that could not be quantified before with immunoassays.

The assay also generated acceptable precision and accuracy in repeated use meeting the needs of a routine steroid hormone analysis. In validating the method certified reference serums and individual patient samples with known estrogens concentrations were measured and good correlation was obtained.

Conclusions:

A method for routine high-sensitivity analysis was successfully developed for estrogen analysis in human plasma. The sample preparation is easy and very efficient to ensure low pg/mL limits of quantification as well as ruggedness and accuracy. Linearity of the assay allows to measure all kind of samples, not only the low-level ones. This method could be helpful to support clinical research.

Novel Aspect:

Development of a highly sensitive routine platform for estrogens analysis in clinical pathology laboratories.

Keywords: ICP-MS immunoassay; Nanoparticles; Determination of viruses; Multiplex detection; Clinical analysis.

Introduction: Because pathogen species can interact within the host and coinfection is quite common, it is crucial to detect viruses simultaneously in clinical analysis for accurate and fast diagnosis. So far, we have developed ICP-MS immunoassay using synthesized nanoparticles for multiplex detection and high sensitivity through particle tagging and signal amplification. And, the method has been demonstrated in a wide range of biotargets from small molecules to large cells.

Methods: In this work, we expand the ICPMS immunoassay to HIV-1 p24 and HBsAg selected among the representative viruses. For their detection, metal-doped magnetic nanoparticles and silica nanoparticles were synthesized for target extraction and tagging as probes, respectively, and sandwich-type conjugates of selected proteins representing the targets were formed through immunoreaction. Then, the quantitative determination was performed using ICPMS.

Results: For target extraction and multiplex detection, Fe₃O₄ magnetic nanoparticles were doped with Cs, and silica nanoparticles were doped with Gd/RhBITC for HIV p24 and Eu/RhBTIC for HBsAg, and then both were immobilized with the antibodies of HIV-1 p24 and HBsAg for immunoreaction, confirmed by a confocal laser fluorescence microscope and SEM. After the formation of sandwich-type conjugates, the concentration of both targets was simultaneously determined through a ratiometric detection of the doped metals using ICP-MS. The calibration curves showed a linear range of 0.78-8.0 ng/mL and 10-100 pg/mL with a detection limit of 0.61 ng/mL and 11.54 pg/mL, respectively. The multiplex detection of HIV-1 p24 and HBsAg spiked in diluted human serum produced recovery rates of 85-95%.

Conclusion: So far, we have demonstrated ICP-MS immunoassay for a multiplex detection of biomarkers, CRP (cardiovascular disease), AFP (tumor), and NSE (heart disease). In this work, we successfully expand its application to simultaneous determination of representative viruses, HIV-1 p24 and HBsAg in human serum for the first time, which implies great potential for clinical application.

Novel Aspect: In this work, we successfully demonstrated ICP-MS immunoassay using magnetic nanoparticles to determine viruses simultaneously for the first time with high sensitivity.

Keywords: Point-of-care, solid phase microextraction, therapeutic drug monitoring, microfluidic open interface, ambient mass spectrometry

Introduction:

Tranexamic acid (TXA) is an antifibrinolytic agent routinely used in clinical settings to stop or reduce blood loss during surgeries. Attainment of TXA blood plasma concentration within the therapeutic range is difficult because it presents high interpatient variability besides, persistently high TXA concentrations have been associated with seizures.¹Therefore, a quantitative point-of-care method based on SPMEcoupled to mass spectrometrywas developed and validated.

Methods:

TXA was monitored directly from plasma of 6 patients undergoing cardiac surgery using biocompatible SPME (BioSPME) fibers. The coating,4 mm-long and 25 μm thickness,used HLB[®] particles ($\leq 5\mu\text{m}$) embedded in a polyacrylonitrile polymer. A microfluidic open interface (MOI) was used to couple these fibers directly to MS.²The developed point-of-care method was cross validated against a SPME-LC-MS/MS method using Passing Bablok regression and Bland-Altman plot.

Results:

BioSPME-MOI-MS/MS revealed that the point-of-care methodherein developed was able to accurately reproduce the profiles of 6 cardiac surgical patients as the profiles did not show statistical differenceto those generated by the bioSPME-LC-MS/MS method. Statistical cross validation by means of the Bland-Altman plot and the Passing Bablok regression yielded for the former that 92% of the data pairs compared were distributed randomly within the acceptable range of the limits of agreement, demonstrating that the method had no biased tendencies for the results.The latter supported that the two methods demonstrated good statistical agreement achieving a slope of 0.984. Given that the expected concentration range of tranexamic acid is between 80 – 500 $\mu\text{g}/\text{mL}$, the method produced an acceptable linear dynamic range of 50-1000 $\mu\text{g}/\text{mL}$. One of the main advantages of this approach involves a single sample turn-around time of 15 min while in a high-throughput mode (96-well plate), the speed of analysis is below 30 seconds.

Conclusions

Bio-SPME-MOI-MS/MS proves to be a reliable and feasible tool for rapid therapeutic drug monitoring. Affording total times of analysis per sample as low as 30 seconds in its high-throughput mode configuration, the currently presented method offers comparable results to the gold standard HPLC-MS/MS method with acceptable RSDs, while only necessitating a fraction of the time needed for implementation of the HPLC-MS/MS method

Novel Aspect:

High throughput therapeutic drug monitoring achieved in a fraction of the time via point of care SPME-MOI-MS/MS.

941 - STUDY OF NON-COVALENT INTERACTION BETWEEN ALS-LINKED MUTANT PFN1 PROTEIN AND NATURAL COMPOUND BY MASS SPECTROMETRY

Mina Nekouei (1) - Parviz Ghezellou (1) - Mahmoud Kiaei (2) - Alireza Ghassempour (3)

Shahid Beheshti University, Medicinal Plants and Drugs Research Institute, Tehran (1) - University of Arkansas for Medical Sciences, Department of Pharmacology and Toxicology, Arkansas (2) - Shahid Beheshti University, Medicinal Plants and Drugs Research Institute, Tehran (3)

Keywords: Profilin1, Protein aggregation, bottom-up proteomics, protein-ligand interaction

Introduction:

Profilin 1, encoded by the PFN1 gene as one of the recently identified ALS genes, is an evolutionarily highly conserved protein[1]. Mutant PFN1 proteins form aggregates *in vivo* and *in vitro* which can be a cause of motor neuron death[2]. Mass spectrometry-based techniques can open new insights into characterization of biomarker proteins in neurodegenerative disorders. Hence, we have investigated PFN1G118V aggregation and its inhibition using mass spectrometry.

Methods:

Proteins in aggregates were identified by bottom-up proteomic analysis using LC-MS/MS and MALDI-TOF. The effect of purified natural compounds was investigated by western blotting in transiently transfected (PFN1G118V and PFN1WT) cells. Moreover, we expressed PFN1WT and ALS-linked PFN1G118V in *E. coli* and purified them using anion-exchange chromatography. Recombinant PFN1G118V was incubated with compounds at various ratios and analyzed by mass spectrometry.

Results:

The primary result of bottom-up proteomic analysis on the insoluble fraction of spinal cord lysates of hPFN1G118V transgenic mice revealed the identity of PFN1 along with other up- and down-regulated proteins in aggregates. Additionally, our data on the insoluble fractions of transfected and non-transfected cells showed that only mutant PFN1 forms aggregate compared with wild type and non-transfected cells. In order to block the aggregation of mutant PFN1, we tested natural compounds derived from a medicinal plant and observed that treatment with our ROG-102 compound decreased the aggregation of PFN1G118V *in vitro*. To test whether this compound can directly interact with PFN1G118V and inhibit its aggregation, we sought to assess it in a cell-free system. The non-covalent interaction of recombinant PFN1G118V with the selected compounds is being investigated kinetically by LC-MS/MS in non-reduced form and in digested form. Additionally, our results have been used for the binding site determination.

Conclusions:

In conclusion, our mass spectrometry results can be a significant step on the road of detailed deciphering the neurodegenerative process. The identification of proteins in the aggregates will shed light on cellular protein interactions with mutant PFN1. Moreover, anti-aggregation properties of natural compounds may be highly valuable for drug discovery and therapeutic development for ALS.

Novel Aspect:

We were able to show the anti-aggregative activity of a natural compound on mutant PFN1. This novel finding has the potential as new therapy to treat motor neuron disease.

1083 - DETECTION AND QUANTIFICATION OF CARBOHYDRATE DEFICIENT TRANSFERRIN BY MALDI-COMPATIBLE PROTEIN CHIPS PREPARED BY AMBIENT ION SOFT LANDING

Petr Novak (1) - Petra Darebna (1) - Michael Volny (2) - Viktor Ruzicka (3) - Jan Spicka (4) - Radek Kucera (5) - Petr Pompach (6)

Institute of Microbiology, Laboratory of Structural Biology, Prague (1) - AffiPro, R&D, Mratin (2) - BioVendor, R&D, Brno (3) - University Hospital Kralovske Vinohrady, Department of Laboratory Diagnostics, Prague (4) - University Hospital in Pilsen, Department of Immunochemistry, Pilsen (5) - Institute of Microbiology, Laboratory of Structural Biology, Vestec (6)

Keywords: Ambient ion landing, Protein chips, Immuno-affinity enrichment, MALDI, Carbohydrate Deficient Transferrin

Introduction:

Transferrin is the most important iron-transport carrier in the human body. Severe alcohol consumption leads to alterations in glycosylation of transferrin (CDT). Mass spectrometry can provide fast detection and quantification of transferrin isoforms since they have different molecular masses. In this study we use antibody chips prepared by ambient soft ion landing in combination with MALDI -TOF for detection and quantification of transferrin isoforms.

Methods:

Protein chips were prepared by functionalization of indium tin oxide glass using anti-transferrin antibody. Several microliters of patient serum were applied on the antibody-modified spots and after incubation, washing and matrix deposition, the transferrin molecule forms were detected by MALDI-TOF mass spectrometer. The CDT values obtained by MALDI chip method were compared with the results obtained by capillary electrophoresis (CE).

Results:

Functionalized MALDI chips were successfully used for enrichment and detection of CDT from human serum. A cohort of samples from 186 patients was analyzed using functionalized MALDI chips and the results were compared with data obtained by CE. Out of the 186 samples, 44 were positively identified as belonging to alcoholic patients, while 142 were negative by MALDI chip approach.

Conclusions:

Functionalized MALDI chips modified by anti-transferrin antibody prepared by ambient soft ion landing were successfully used for detection and quantification of CDT from human sera. The correlation of the data obtained by the CE and the chip-based MALDI was $r=0.986$, 95% confidence interval.

Novel Aspect:

MALDI chips prepared by ion soft landing are suitable for quantification of CDT.

446 - ACETYLCHOLINE AND ACETYLCHOLINESTRASE IN A NON-NEURONAL TISSUE (CORNEAL EPITHELIUM)

Inger Oulie (1) - Leon Reubsaet (1) - Trine Grønhaug Halvorsen (1) - Amund Ringvold (2)

University of Oslo, School of Pharmacy, Dept. of Pharmaceutical Chemistry, Pharmaceutical analysis, Oslo (1) - National Hospital, University of Oslo, Eye Department, Oslo (2)

Keywords: Acetylcholine, Acetylcholinesterase, Corneal Epithelium Cells, Diurnal, Twilight and Nocturnal Mammals

Introduction:

Acetylcholine (ACh) and Acetylcholinesterase (AChE) are integral parts of the central and peripheral nervous system. The substances have in addition been observed in tissues outside the nervous system such as corneal epithelial cells (CEC). ACh and AChE were analysed in CEC of diurnal, twilight and nocturnal mammals by tandem HPLC/MS-MS and fluorometric methods, respectively.

Methods:

CEC from 6 different species (cattle, sheep, pig, horse, goat and cat) were obtained from local slaughterhouses. The CEC was rubbed off the eyes with a glass slide and homogenized using a pellet mixer for 2 min in mobile phase or MilliQ-water. For analysis of ACh, a HPLC/MS-MS method was used. For analysis of AChE, Amplite™ Fluorometric Acetylcholinesterase Assay Kit from AAT Bioquest® Inc was used according to the manufacturer's recommendations.

Results:

The method for analysing ACh in CEC in this study was a modified version of the method described in [1]. Endogenous quaternary ammonium compounds (including ACh) were confirmed to be found in the CEC from all species as described in references [1,2]. The concentration of ACh and AChE in the CEC were varying between the different species. Diurnal species revealed a concentration of ACh in the range 0.18 to 2.80 µg ACh/mg CEC, in contrast to twilight and nocturnal species where ACh was close to zero, similar to previous observations [3]. Twilight and nocturnal species revealed a high concentration of AChE in the CEC, in contrast to diurnal species that revealed a low concentration. For AChE the concentration was varying from 0.5 mU AChE/mg CEC in cattle and horse to 20.4 mU AChE/mg CEC in cat.

Conclusions:

Diurnal animals (cattle, horse, goat and sheep) revealed high amounts of ACh in the CEC, in contrast to cell samples from twilight and nocturnal animals (pig and cat) that contain low amounts of ACh in CEC. For AChE, the picture is reversed: diurnal animals revealed low amounts of AChE and twilight and nocturnal revealed high amounts of AChE in CEC.

Novel Aspect:

To our knowledge, this is the first time Acetylcholine and Acetylcholinesterase has been measured in CEC from different mammals.

1273 - SET UP OF A SIMPLE, FAST AND FLEXIBLE LC-MS/MS ID METHOD FOR THE SIMULTANEOUS DETERMINATION OF STEROIDS IN DIFFERENT BIOLOGICAL SAMPLES.

Gianluca Bartolucci (1) - Marco Pallecchi (2) - Sebastiano Gozzo (2) - Giovanna Danza (2)

university of florence, Department of Neuroscience, Psycology, Drug Area and Child health, Firenze, Italy (1) - University of Florence, department of experimental biomedical and clinical science, Firenze, Italy (2)

Keywords: steroids, mass spectrometry,

Introduction

LC-MS/MS ID is nowadays recognized as the gold standard method to quantify steroids and clinical laboratories are adopting MS for steroids analysis to overcome inaccuracy of immunometric Methods:[1] Costs of LC-MS/MS are now competitive, but this technique is still less automatized, and methods are less standardized.[2] In setting up this new method we focused our attention on characteristics that facilitate routine application also with different instruments.

Methods

We set up a two dimensional chromatography. The first column (C18 Luna 5 μ m 2 cm x 2mm) was used as sampling column and flushed with a polar eluent to eliminate polar compounds and concentrate steroids; the analytical column (C18 luna 3 μ m 5 cm x 2 mm) separated androgens, progestogens, glucorticoids that were quantified with a SCIEX 6500QTRAP in positive mode. Different eluents [3] and a PFP 3 μ m 5 cm x 2 mm analytical column allowed quantification of estrogens in negative mode.

Results

This method allows the simultaneous determination of testosterone, androstendione, progesterone, 17OH progesterone, dihydrotestosterone, cortisol and cortisone, or estrone and estradiol, in a 12 min run time with high sensibility. Samples are simply diluted with the internal standard mix in methanol and water, centrifuged to eliminate proteins, and injected. It was validated calculating precision, accuracy and sensibility for each compound. To assess the method flexibility we tested it with different biological samples (urine, serum, tissue homogenates, follicular fluids), and established that the minimum sample dilution to avoid matrix effect and preserve chromatographic performance is 1:5 with an injection volume range from 10 to 100 μ L. Using the SCIEX 6500QTRAP we dilute urine and serum samples 1:10 with an injection volume of 25-50 μ L. The method is already used in our hospital (AOU-Careggi- Firenze)) for routinely analysis of urinary free cortisol and of cortisol/cortisone ratio and It will be soon adopted for serum steroids.

Conclusions

The method fit the routine characteristics being simple, fast and robust. The sensitivity reached allows an accurate determination of androgens also in women and pre-puberal subjects. The efficiency of the proposed chromatography confers flexibility necessary to the scope. In fact, the possibility to change sample dilution or injection volume, without affecting performance, are useful to adapt the method to different sample and different instruments.

Novel Aspect

The proposed LC-MS/MS system allows the analysis of steroids in many biological matrices with minimal sample preparation, maintaining high level of detection performances.

1216 - TANDEM MASS SPECTROMETRY IN THE CLINICAL LABORATORY: CAN STANDARDIZATION IMPROVE OPERATION

Marzia Pasquali (1)

University of Utah School of Medicine (1)

Keywords: Mass Spectrometry, Standardization, Operational Efficiency

Today's clinical laboratory is focused on the delivery of accurate results at the right time to the right user.

To reach this goal, all components of the laboratory, from the technologists on the bench to the analyst handling the LIS (laboratory information system) need to work in an integrated and coordinate way. The large number of methodologies used in the clinical laboratory can make the integration challenging and standardization processes are becoming the answer to the challenges brought by this diversity. Among the methodologies, mass spectrometry, whether single stage or tandem, often coupled with liquid or gas chromatography, is becoming one of the most widespread technique in the clinical laboratory, because of its sensitivity, specificity, rapid turnaround time, and low sample volume requirement. Mass spectrometry is therefore used in many areas, from newborn screening to therapeutic drug monitoring, endocrinology, infectious diseases, in addition to being used as a research tool in metabolomics applications.

We have evaluated standardization processes for the mass spectrometry area in our laboratory, in which we have two opposite settings: 1) newborn screening, high throughput/rapid turnaround time/low sample volume and 2) biochemical genetics, low throughput/high complexity/rapid turnaround time.

From our preliminary observations, we have seen that standardization of the platform used may be beneficial in the first setting, while in the second setting, standardized analytical/instrument methods could improve the workflow, independently from the platform.

In both cases, automated data transfer to the LIS is a key factor in delivering test results rapidly and accurately.

The implementation of standardization should take into account the laboratory setting in order to optimize its efficiency. Each laboratory should identify "why standardize?" and "what to standardize?" before identifying "how to standardize". This will fulfill the mission of the clinical laboratory by improving operational efficiency without compromising delivery of care.

706 - MASS-SPECTROMETRY APPROACH FOR RAPID INTRAOPERATIVE IDENTIFICATION OF BRAIN TUMOR TISSUES - A WAY FOR ONLINE ANALYSIS

Stanislav Pekov (1) - Vasily Eliferov (1) - Evgeny Zhvansky (1) - Alexander Vorobyev (1) - Vsevolod Shurkhay (2) - Anatoly Sorokin (1) - Igor Popov (1) - Alexander Potapov (2) - Eugene (Evgeny) Nikolaev (3)

Moscow Institute of Physics and Technology, Moscow Institute of Physics and Technology, Dolgoprudnyj (1) - N. N. Burdenko Scientific Research Neurosurgery Institute, N. N. Burdenko Scientific Research Neurosurgery Institute, Moscow (2) - Skolkovo institute of science and technology, Skolkovo institute of science and technology, Skolkovo (3)

Keywords: ambient mass-spectrometry, clinical application, brain tumor, neurosurgical support, microextraction.

Introduction:

It is known that the lipid metabolism reprogramming is one of the hallmarks of cancer so mass-spectrometry-based method of lipid profiling is a promising approach for precise intraoperative tumor identification. In this research we propose the online method of tissue profiling based on express and simple capsular extraction followed by ESI with an identification algorithms based on a search through a reference database containing mass spectra of different tumors.

Methods:

The online microextraction system consists of disposable capsules compatible with any standard ESI source. Tissues, dissected by the surgeon were placed into the capsules which are then connected to the ESI interface for analysis. Features were extracted from mass-spectrometry data and aligned for further analysis. Significant features were detected by shrinkage discriminant analysis and classifiers were developed with lasso-regression.

Results:

It was demonstrated that it is possible to prepare large amount (up to 5 per minute) of capsules with samples immediately during the operation because of simplicity of placing sample into the preassembled capsules so almost all the delay between receiving the tissue from surgeon and analysis depends only from transportation time between operational suite and laboratory room. The minimum amount of sample is very small (less than 1 cubic mm) so proposed method could be used during neurosurgery intervention where amount of resection could be very small. The data obtained with proposed microextraction method are in good correlation with our previous results obtained with spray-from-tissue ionization source. The rapid identification of the tumor type is allowed by the search inside the collected reference database containing mass spectra of samples that are also characterized by histopathological Methods:

Conclusions:

Application of microextraction capsules significantly simplifies the manipulations with samples by excluding any special sample preparation steps. Rapidity of method is also very important during the surgery as the minimization of surgery duration improves patient's postoperative prognosis. Developed data processing algorithms and classifiers provide the reliable differentiation of extracted brain tissue by their lipid profiles.

Novel Aspect:

The online mass-spectrometry profiling of brain tissues could be used as intraoperative technology for characterization and identification of removed tissues.

589 - DEVELOPMENT AND VALIDATION OF A SENSITIVE LC-LINEAR ION TRAP METHOD FOR THE DETERMINATION OF TRACE DI-IODOTHYRONINES IN HUMAN BLOOD SERUM

Keith Richards (1) - Josef Köhrle (1) - Daniel Rathmann (2) - Raymond Monk (1)

Charite Universitätsmedizin Berlin, Institute for Experimental Endocrinology, Berlin (1) - Chromicent GmbH, Pharmaceutical Development, Berlin (2)

Keywords:

Thyroid hormone metabolites, serum, tandem mass spectrometry, MS3, validation

Introduction:

In addition to the thyroid hormones (TH) 3,5,3'-triiodothyronine (T3) and L-thyroxine (T4), thyroid hormone metabolites (THM) to exert their own distinct biological actions [1]. By incorporating MRM/MS3 switched scanning and extract de-lipidation, we have modified and validated our tandem mass spectrometry method [2] for 3,5-diiiodothyronine (3,5-T2) and 3,3'-diiiodothyronine (3,3'-T2) in human blood serum, and applied it to measure T2 concentrations in healthy individuals.

Methods:

The method includes mixed mode cation exchange extraction (SPE) of 150 µL serum, followed by de-lipidation using Waters Ostro sorbent (both using a 96-well plate format). The liquid chromatography-mass spectrometric method uses switched mode (MRM/MS3) acquisition using a linear ion trap (LIT).

Results:

Endogenous 3,5-T2 and 3,3'-T2 were detected in commercially obtained serum, in addition to T3, 3,5,3'-triiodothyronine (rT3) and T4. Inter- and intra-day accuracy and precision for exogenously spiked TH/THM were in the range 70-100% and less than 20% RSD respectively for low, medium and high concentrations. Excellent linearity was obtained across a range from 0.01 nM to 250 nM. Sera from healthy individuals contained concentrations of T3) and T4 (65.6-181.5 nM) within expected reference ranges (1.3 - 3.1 and 65.6 - 181.5 nM respectively) [3] whilst concentrations of 3,5-T2 and 3,3'-T2 were significantly lower (0.02 - 0.05 and 0.1 - 0.25 nM respectively). Limits of quantification (LOQ) for T2 isomers were 0.01 nM. Matrix effects for all analytes were 30% or less.

Conclusions:

The use of switched MRM/MS3 scanning enables quantification of endogenous TH/THM with widely differing concentrations in a single analysis, with excellent inter- and intra-day accuracy and precision. Due to enhanced selectivity and low chemical noise, MS3 scanning delivered 4-5 times lower LOQ compared with traditional MRM for T2 isomers. In healthy individuals both 3,5-T2 and 3,3'-T2 appear to be minor metabolites (derived from T3 and T3/rT3 respectively).

Novel Aspect:

The direct SPE extraction of serum without preliminary protein precipitation, combined with solid phase de-lipidation and switched MRM/MS3 scanning.

Keywords: acute respiratory distress syndrome; albumin; isotope ratio mass spectrometry; stable isotope

Introduction:

Acute respiratory distress syndrome (ARDS) is a severe form of lung injury characterized by an increased inflammatory burden and changes in the alveolar-capillary membrane permeability with extravasation of fluid and protein into the alveoli[1]. Despite the clear association between plasmatic hypoalbuminemia and poor outcome, there are no data on albumin metabolism in ARDS patients.

Methods:

^{13}C -Leucine, as albumin precursor, was administered to 13 ARDS adults and to 8 patients without lung disease (controls). Albumin was isolated from serial plasma and tracheal aspirate (TA) samples, and its kinetic parameters were derived from the ^{13}C enrichment curve obtained by isotope ratio mass spectrometry[2]. As index of alveolar-capillary permeability the TA/plasma albumin ratio was measured.

Results:

In patients with ARDS the fractional synthetic rate was significantly higher than in control patients [15.1 (12.3-22.7) vs 11.9 (8.9-12.9) %/day; $p=0.04$].

Median albumin secretion time and half-life were 0.7 (0.3-1.9) vs 0.6 (0.3-1.0) h, and 43.3 (35.7-64.9) vs 42.7 (33.3-76.0) h in ARDS and in control patients respectively, no significant differences were observed.

In patients with ARDS the TA to plasma albumin ratio measured in the early phase after the diagnosis of acute lung injury was 7-fold times higher the level found in control patients ($p<0.001$). In the ARDS group the TA/plasma albumin ratio was significantly correlated with the $\text{PaO}_2/\text{FiO}_2$, as index of lung dysfunction ($r=-0.732$, $p=0.016$).

Conclusions:

In this study, stable isotopes have been used to better understand albumin metabolism during a disease state like ARDS. Albumin synthesis rate in ARDS patients was higher than in control adults. Furthermore, the comparison between TA/plasma albumin ratio of ARDS and control patients revealed a dramatic increase in alveolar-capillary membrane permeability during the genesis of ARDS.

Novel Aspect:

This study will give new insight into albumin turnover and compartmental distribution in patients with ARDS.

Keywords: metabolic profiling, gangliosides, Alzheimer's disease, monosialoganglioside GM1, membrane lipidomics

Introduction:

Alzheimer's disease (AD) is the most common cause of dementia (60-80% of cases) in elderly population worldwide [1]. The current body of research supports the concept that protein aggregation initiates the onset of AD [2]. However, in spite of the large number of studies, a mechanism of pathogenesis and potential treatment for AD remains elusive. We explored the distribution of membrane lipids (gangliosides) as they supposedly trigger protein aggregation [3].

Methods:

We applied ultra-high performance liquid chromatography (UHPLC) and selected reaction monitoring (SRM) as well as high resolution/accurate mass (HR/AM) orbital ion trap mass spectrometry to characterize membrane lipid composition (GM1, GM2, GM3, GD1a/b, GD2, GD3, GT1b, GQ1b) in human clinical samples (i.e. serum, cerebrospinal fluid - CSF, brain tissue) and samples from animal model of aging (Sprague Dawley, Wistar). We compared 1 month and 11 months old animals (n=26).

Results:

Our results show optimization of ganglioside extraction protocol and development of UHPLC-SRM assay. We tested several solvent systems to achieve approx. 70% extraction efficacy in biological matrix. UHPLC was optimized and suitable analytical column and mobile phase additives chosen to allow for separation of mono-, di-, tri- and tetrasialo species. Gangliosides present in biological samples were identified using HR/AM mass spectrometry. Consequently positive and negative ion mode SRM assays were utilized for determination of gangliosides. The dominant brain gangliosides were GM1, GD1a/b and GT1b and similar composition was found in CSF. In serum the most abundant species are GM3, GM2, GD1a/b, GD2 and GT1b. We have used custom synthesized isotopically labelled internal standards for absolute quantification in biological samples.

Conclusions

New analytical method established to determine 9 major gangliosides in brain tissue, CSF and serum samples with nanomolar LODs. The differences in ganglioside composition were demonstrated in specific brain structures (i.e. cerebral cortex, cerebellum, hypothalamus, hippocampus, brain stem). The composition of gangliosides in brains reflected CSF and partially also serum concentrations. The age dependent changes in composition of major gangliosides were evaluated.

Novel Aspect:

Novel analytical approach to study distribution of important membrane lipids, which are supposedly playing role in Alzheimer's disease pathogenesis.

1020 - USING DATA DEPENDENT ACQUISITION TO PRODUCE SPECIFIC AND RELIABLE MRM TRANSITIONS FOR SUSPECTS ON A QTRAP INSTRUMENT

Stine Krogh Steffensen (1) - Inge Fomsgaard (1)

Department of Agroecology, Aarhus University, Aarhus University/Department of Agroecology, Flakkebjerg (1)

Keywords: Data dependent acquisition, HPLC- QTrap MS, Benzoxazinoids, Suspects, semi-quantification

Introduction:

In complex biological samples similar small molecules often exist as different structural isomers or similar phase II conjugates such as glucosides or glucuronides. This often results in multi reaction monitoring (MRM) transitions that are too general for reliable assignment of selected unknowns or suspects in a triple quadrupole instrument. However, by letting data dependent acquisition techniques guide selection of MRMs, a reliable and sensitive method was developed.

Methods:

Benzoxazinoid-rich complex biological samples were fractionated using consecutive SPE and HPLC to concentrate benzoxazinoid metabolites. Our established HPLC-MSMS (ABSciex Qtrap 4500) benzoxazinoid quantification method was adapted for data dependent acquisition (DDA/IDA) using mainly enhanced precursor scan (EMS) and MRM in different forms as survey scans and enhanced product ion (EPI) scans as dependent scans.

Results:

24 different peaks were deduced as interesting based on their spectral properties and varying similarities to known benzoxazinoids or metabolites thereof. Figures will show selected examples of these such as the spectrum of the glucuronide of the lactam HBOA, known from rye. This spectrum contains the fingerprint of HBOA (164/136/118/108) and of the glucuronic acid (193/175/113) as well as the neutral loss of 18 u from the precursor ion (340) typical for carbohydrates. 340/164 and 340/108 were reliable MRM transitions for this ion, however general in their nature, and aided the discovery of other interesting peaks at other retention times. 340/118 and 340/136 were also reliable but much more selective. Other examples are the MRMs 354/164 and 354/108 that gave a peak at $R_t=10.9$ min. However, the spectrum varied slightly from sample to sample. Based on spectral data obtained by DDA, the MRMs 354/165 and 354/118 were introduced, revealing the presence of two distinct peaks differing by only 0.05 min in retention time.

Conclusions:

Highly selective MRM transitions were produced that enabled reliable detection and assignment of selected unknowns and suspects in complex biological matrices. Using this DDA-guided method for selection of MRM transitions, it was possible to distinguish even between compounds with similar retention times, precursor ions, and even fragment ions.

Novel Aspect:

Using DDA techniques for selection and evaluation of MRM transitions for semi-quantitative methods for selected unknowns and suspects.

281 - EVALUATION OF UDP-GLUCURONOSYLTRANSFERASE 1A1 ACTIVITY TOWARDS BILIRUBIN.

Atsuko Takeuchi (1)

Instrumental Analysis Center, Kobe Pharmaceutical University, Kobe (1)

Keywords: UDP-glucuronosyltransferase 1A1, UGT1A1, LC/MS/MS, bilirubin, enzyme activity

Introduction:

UDP-glucuronosyltransferase 1A1 (UGT1A1) catalyzes glucuronidation of bilirubin. Mutations in the UGT1A1 gene cause bilirubin glucuronidation deficiencies, leading to diseases with hyperbilirubinemia or jaundice, Crigler-Najjar syndrome type I, type II and Gilbert syndrome. Since all the patients carrying these mutations showed hyperbilirubinemia, the enzyme activities of the mutated enzymes were determined.

Methods:

We applied the liquid chromatography-mass spectrometry (LC-MS) method to evaluation of UGT1A1 activity toward bilirubin.

Chromatographic separations were performed using an Ultimate 3000 HPLC system (Dionex). Mass spectrometry was performed on an LTQ Orbitrap Discovery mass spectrometer (Thermo Scientific). The electrospray ionization source was used.

Results:

We determined the remaining UGT1A1 activity of the models of wild-type and mutant-type UGT1A1. The UGT1A1 activities of the models were considered as the normal and diseases with hyperbilirubinemia UGT1A1 activity, respectively.

We applied LC/MS to evaluation of mutation effects on the UGT1A1 activities towards bilirubin. Bilirubin has two sites capable of glucuronidation and forms bilirubin mono- and di-glucuronides. LC/MS can detect a small amount of their glucuronides with accuracy. We confirmed the reduced substrate-glucuronidation activity of mutated UGT1A1 enzymes.

Conclusions:

We aimed to establish a highly sensitive method to determine the UGT1A1 activities. The activities varied according to wild-type and mutant-type UGT1A1. We tested here all the mutations found in patients with hyperbilirubinemia. The obtained results allow us to discuss the relationship between remaining activity and clinical phenotype of the patients with hyperbilirubinemia.

Novel Aspect:

We established a highly sensitive method to determine the UGT1A1 activities and evaluated wild-type and mutant-type UGT1A1 activities.

1405 - CHEMOMETRIC OPTIMIZATION OF UPLC-MS/MS ASSAY FOR CLINICAL DIAGNOSIS AND PHARMACOTHERAPY MONITORING OF PATIENTS WITH APRT DEFICIENCY

Margrét Thorsteinsdóttir (1) - Unnur Arna Thorsteinsdóttir (1) - Finnur Freyr Eiriksson (2) - Hrafnhildur L. Runolfsson (3) - Vidar O Edvardsson (4) - Runolfur Palsson (4)

University of Iceland, Faculty of Pharmaceutical Sciences, Reykjavik, Iceland (1) - ArcticMass, Mass Facility, Reykjavik, Iceland (2) - University of Iceland, Faculty of Medicine, Reykjavik, Iceland (3) - Landspítali – The National University Hospital of Iceland, Faculty of Medicine, Reykjavik, Iceland (4)

Keywords: Clinical mass spectrometry, UPLC-MS/MS, Chemometrics, Design of experiments, APRT deficiency,

Introduction:

Patients with APRT deficiency have excessive renal excretion of 2,8-dihydroxyadenine (DHA), causing chronic kidney disease. Treatment with allopurinol or febuxostat reduces DHA excretion and kidney stones formation. A chemometric approach was used for optimization of a UPLC-MS/MS assay for simultaneous quantification of DHA, adenine biomarkers and the pharmacological agents in human urine and plasma for clinical diagnosis and pharmacotherapy monitoring.

Methods:

Design of experiments (DoE) was used for optimization of UPLC-MS/MS assay for quantification of DHA, adenine, adenosine, inosine, hypoxanthine, xanthine and the drugs allopurinol, its active metabolite, oxypurinol, as well as febuxostat in human plasma and urine. Different sample preparation methods were tested prior to analysis of samples from controls and patients with APRT deficiency, before and after treatment with allopurinol or febuxostat.

Results:

A UPLC-MS/MS assay for simultaneous quantification of DHA and the main purine metabolites in human plasma and urine was developed by chemometric approach. D-optimal design was used to reveal both quantitative and qualitative significant factors influencing retention time and peak area for the analytes. Significant factors were optimized with CCF-design and related to sensitivity utilizing PLS regression. There was a strong interaction effect between several variables, indicating that these variables cannot be independently controlled to reach optimum settings. The assay was used to measure both plasma and urine concentration of the analytes in samples from healthy controls and APRT patients, before and after treatment. The DHA concentrations in plasma from 3 APRT patients were 456, 459 and 741 ng/mL off drug treatment and 130, 61 and 27 ng/mL while on allopurinol or febuxostat therapy. DHA was not detected in plasma from healthy controls. Highly significant changes were observed in the urinary excretion of DHA and adenine with drug therapy.

Conclusions:

Optimizing UPLC-MS/MS assay by DoE, only a fraction of experiments was used compared to what would have been required by changing one separate factor at a time (COST) approach. Our data suggest that the UPLC-MS/MS assay will greatly facilitate clinical diagnosis of patients with the rare hereditary purine metabolism disorder, APRT deficiency. At the same time the clinical assay can be used for monitoring pharmacotherapy and treatment adherence among these patients.

Novel Aspect:

Implementation of UPLC-MS/MS assay to facilitate clinical diagnosis and therapeutic drug monitoring of patients with the rare kidney disorder APRT-deficiency.

271 - A BIOMPHALARIA GLABRATA PEPTIDE THAT STIMULATES EXTREME BEHAVIOUR MODIFICATIONS IN AQUATIC FREE-LIVING SCHISTOSOMA MANSONI MIRACIDIA

Tianfang Wang (1) - Russell Wyeth (2) - Di Liang (1) - Utpal Bose (1) - Guoying Ni (3) - Donald McManus (4) - Scott Cummins (1)

University of the Sunshine Coast, School of Science and Engineering, Sippy Downs (1) - St. Francis Xavier University, Department of Biology, Antigonish (2) - Griffith University, School of Medical Science, Gold Coast (3) - University of Queensland, QIMR Berghofer Medical Research Institute Berghofer, Brisbane (4)

Authors: Tianfang Wang, Russell Wyeth, Di Liang, Utpal Bose, Guoying Ni, Donald P. McManus, Scott Cummins

Keywords: Schistosoma mansoni, Biomphalaria glabrata, miracidia, kairomone, proteomics

Introduction:

The human disease schistosomiasis is caused by the parasite *Schistosoma mansoni*, which requires an intermediate host, the freshwater snail *Biomphalaria glabrata*. An excellent olfactory sense allows the parasite to locate an appropriate host. Towards identifying the kairomone biomolecule(s) that helps *S. mansoni* miracidia detect its host, we have performed an integrated analysis of the snail-conditioned water (SCW), through chromatography and bioassays of behaviour, followed by mass spectrometry.

Methods:

The lyophilised SCW crude extract was resuspended in 0.1% TFA and fractionated using HPLC, and the fractions were collected and lyophilised for bioassays, with behaviour analysed by TrackMate plugin¹ and MTrackJ² for FIJI software³. The LC-MS/MS analysis of metabolites and peptides were carried out using UHPLC-QToF and NanoHPLC-ESI-Triple TOF, respectively. Data analysis was performed using Agilent MassHunter Qualitative software and PEAKS studio. CD experiments were performed in a Chirascan CD spectrophotometer (Applied Photophysics).

Results:

Using an in vivo bioassay in conjunction with behaviour analysis, we first determined a raw mucus extract and filtered SCW could stimulate behaviour changes in *S. mansoni* miracidia, which was in alignment with previously classified miracidial responses^{4,5}. The lyophilised crude extracts from SCW were HPLC-fractionated and collected for subsequent bioassays, and a single HPLC fraction demonstrated behaviour modification bioactivity. Metabolites and proteins present within the active HPLC fraction and two adjacent fractions were identified using LC-MS/MS. We found 16 metabolites, all of which did not match to any known compound within the METLIN⁶ or HMDB⁷ metabolite databases. Also in the active HPLC fraction, a total of 24 peptides were identified that matched to precursor proteins in the genome-derived *B. glabrata* protein database⁸. The activity analysis of these 24 peptides identified a single peptide with alpha helical characteristics stimulates extreme behaviour modifications in miracidia, and it can be produced within numerous snail tissues.

Conclusions:

We have reported the identification of a peptide, which is secreted from adult *B. glabrata* and triggers extreme behaviour modifications in the *S. mansoni* miracidia. Its precursor appears to be unique to this snail, thus providing an ideal species-specific attraction cue for *S. mansoni* miracidia. This finding contributes greatly to our understanding of a key part within the parasite's life-cycle, and may help towards establishing novel control interventions for schistosomiasis.

Novel Aspect:

This information will be helpful for developing approaches to manipulate this parasite's life cycle, and opens up new avenues for exploring other parasitic diseases.

A.13 LIFE SCIENCES - SINGLE CELL

873 - ANALYSIS OF SINGLE MAMMALIAN CELLS WITH SCOPE-MS WITH MPOP

Harrison Specht (1) - Guillaume Harmange (1) - David Perlman (1) - John Neveu (2) - Christopher Adams (3) - Nikolai Slavov (1) - Bogdan Budnik (2)

Northeastern University, Bioengineering Department, Boston (1) - Harvard University, FAS, Division of Science, Cambridge (2) - Bruker, Proteomics, San Jose (3)

Keywords: single cell proteomics

Harrison Specht, Guillaume Harmange, David H Perlman, John Neveu, Christopher M Adams, Nikolai Slavov, Bogdan Budnik

Introduction:

Quantifying proteins in single cells has a long history. For decades, scientists and physicians have used antibodies and fluorescent proteins to identify or quantify a few different proteins per cell. These methods have enabled new discoveries, clinical applications, and even spawned new fields based on measuring just a few different proteins per cell. We introduced a new technique SCoPE-MS1 that allows measurements of hundreds of proteins in single mammalian cells. The biggest limitation of that technique was throughput of sample preparation procedure and losses during clean up steps. To improve throughput and minimize losses we introduce a new sample preparation protocol for single cell proteomics.

Methods:

A major limitation to applying quantitative mass-spectrometry to a small amount of sample, such as single mammalian cells, are the losses during sample cleanup. To relieve this limitation, we developed a Minimal Proteomic sample Preparation (mPOP)² method for culture-grown mammalian cells. mPOP obviates cleanup, and thus eliminates cleanup related losses while simplifying and expediting sample preparation for analysis of single cells.

Results:

SCoPE MS technique with mPOP preparation procedures were applied for several types of single cells analysis. As previously, new preparation procedures were tested for differentiation of Jurkat vs U cells to prove that new preparation protocols did not aggravate the ability to accurately quantify proteomes of the single cell. This new technique was applied to analysis of human activated Jurkat cells, mouse brain neurons and astrocytes. Obtained data shows that the new method was able to do quantitative analysis of hundreds of mammalian cells and show clustering of different types of cells according to their unique proteome properties.

Conclusions

Using mPOP with cell-sorting and liquid handling, we can lyse thousands of single cells in minutes, and quantify more than 700 proteins across 100 single cells in less than 12 hours. Likewise, mPOP enables protein measurements in 10, 100, and 1000 cell samples with unprecedented depth and throughput.

Novel Aspect: (Limit of 150 characters)

SCOPE MS with mPOP preparation procedure unlocks our ability to quantify hundreds of cells per day, with depth up to a thousand proteins. This type of analysis will allow researchers to create better models of protein-protein interaction and build a new models of biological systems as well as new biomarkers of particular cell types.

464 - FUNCTION OF PIWIL3 IN MAMMALIAN OOCYTES.

Minjie Tan (1) - Helena van Tol (1) - Mirjam Damen (2) - Tom Stout (3) - Wei Wu (2) - Bernard Roelen (1)

Utrecht University, Utrecht University/ Farm Animal Health, Utrecht (1) - Utrecht University, Utrecht University/ Biomolecular Mass Spectrometry & Proteomics, Utrecht (2) - Utrecht University, Utrecht University/Equine Sciences, Utrecht (3)

Keywords: Affinity purification crosslinking mass spectrometry (AP-XL-MS), single-cell sequencing, PIWI

Introduction:

PIWIs are argonaute proteins that interact with small non-coding RNAs (PIWI interacting RNAs; piRNAs). PIWI-piRNA complexes serve to target transposons for degradation, and are crucial guardians of genome integrity. PIWIL3 is specifically and highly expressed in unfertilized human oocytes, but a homologue is absent in mouse and rat, hence conventional animal systems cannot be used to study the critical function of PIWIL3 before fertilization[1].

Methods:

We performed an in-depth analyses of bovine oocytes by mass spectrometry. From manually dissected oocytes, proteins were extracted by repeated freeze-thaw cycles and sonication. In parallel, we (i) performed AP-XL-MS on the bovine PIWIL3 complex, and (ii) profiled the oocyte proteome by LC-MS/MS on a Q-Exactive HF mass spectrometer, with pre-fractionation at high pH. We also followed the expression of PIWIL3 by microinjection and immuno-labeling techniques.

Results:

The bovine system is the only large mammal system that expresses a PIWIL3 homologue. Herein, we investigated the expression, distribution, interaction, and argonaute function of PIWIL3 in bovine oocytes. By microinjection of PIWIL3-EGFP mRNA, we followed the localised expression of PIWIL3 in oocytes and early-stage fertilized embryos. From extremely limited oocyte material, we identified a total of 3897 proteins, which revealed the functional state of oocytes prior to fertilisation. In parallel, we identified a novel PIWIL3 interaction network involving two known regulators of argonaute function, which was independently verified by immuno-staining confirming intracellular co-localisation. Additional experiments involving single-cell sequencing and pi-RNA sequencing further support a critical role for mammalian PIWIL3 in protection of genome integrity prior to fertilization and generation of a new genome.

Conclusions

By a combination of AP-XL-MS and pi-RNA sequencing, we shed light on the role of PIWIL3 in mammalian oocytes prior to fertilization, and assign PIWIL3 to an interaction network in which its function may be further characterised.

Novel Aspect:

We showcase here the extreme sensitivity of AP-XL-MS approach in mapping protein complexes from limited starting material.

Picoliter pressure-probe-electrospray-ionization mass spectrometry for in situ monitoring single plant cell metabolite changes under stress conditions

Rosa Erra-Balsells¹, Keisuke Nakata², Hiroshi Wada³, Hiroshi Nonami¹

¹ University of Buenos Aires, Argentina.

² Ehime University, Japan.

³ NARO Kyushu Okinawa Agricultural Research Center, Japan.

Keywords: pressure probe ESI, single cell, organelle, metabolomics.

Introduction:

Cytoplasmic streaming occurs consuming the ATP energy formed during glycolysis, respiration and photosynthesis, moving organelles and metabolites all around plant cells. CPP is an instrument that can measure the water status and several properties of intact cells (i.e., volume)[1]. The CPP-mass spectrometer combination (picoPPESI-MS)[2,3] allows to measure water status, cytoplasmic streaming velocities and metabolites in cells sequentially.

Methods:

picoPressure Probe for water relations. Osmometer for cell turgor.

Internal Electrode Capillary picoPressure Probe Electrospray Ionization (picoPPESI) as ions source, with Orbitrap mass spectrometer (Exactive Plus, Thermo Fisher Scientific Inc., MA) as MS analyzer.

nanoESI- Orbitrap mass spectrometer (Exactive Plus, Thermo Fisher Scientific Inc., MA).

Results:

Plants were subjected to water stress. Water status (turgor pressure; water potential) slightly decreased and they recovered by osmotic adjustment in 12 h. The cytoplasmic streaming velocity was maintained during osmotic adjustment. PicoPPESI-MS indicated that several phosphate-metabolites (m/z 78.96 [HPO₃-], 96.97 [H₂PO₄-], and 259.02 [Glu-6-phosphate]) were transiently accumulated in the cells in response to the treatment. Furthermore, not only metabolites yielded by glycolysis occurred in cytosol (m/z 87.01 [Pyruvic ac.], 179.06 [Hex], 259.02 [Glu-6-phosphate], and 341.11 [Hex₂]) but also those from Krebs cycle in the mitochondrion (m/z 115.00 [Fumaric ac.], 117.02 [Succinic ac.], 133.01 [Malic ac.], 145.02 [α -Ketoglutaric ac.], 173.01 [Aconitic ac.] and 191.02 [Citric ac.]) accumulated in response to the stress treatment. Because these metabolic pathways are essential for ATP hydrolysis, ATP production and the osmotic adjustment, is obvious their contribution to maintain cytoplasmic streaming providing energy.

Conclusions:

Tacking into account the metabolic pathways mentioned above and the results obtained by picoPPESI-MS monitoring the cell metabolites, ATP hydrolysis, ATP production and the osmotic cell adjustment are essential for keeping cytoplasmic streaming providing the necessary energy.

Novel Aspect:

PicoPPESI mass spectrometry system has a potentiality to monitor metabolic changes in situ at cell level as well as at cell level.

1. Physical Electronics, Chanhassen, Minnesota, USA
2. University of Illinois at Urbana-Champaign, School of Chemical Sciences, Urbana, Illinois, USA
3. Colorado State University, Department of Biochemistry and Molecular Biology, Fort Collins, Colorado, USA

Keywords: TOF-SIMS tandem MS imaging, 3D imaging, HEK cell, organelle, subcellular imaging

Introduction: (Limit of 400 characters)

Goal of cellular imaging is to ascertain the composition of organelles, e.g. lipid profiling or pharmaceutical efficacy. Most subcellular imaging is accomplished by stable isotope labeling [1], but such analyses are void of molecular specificity. We employed a TOF-TOF imaging capability [2] to achieve molecular specificity and conjectured that an ER-Tracker stain would yield characteristic molecular ions with which to image the ER and ER tubules.

Methods: (Limit of 400 characters)

HEK cells, transfected to express GFP-Kv2.1 fluorescent ion channels, had a high number of endoplasmic reticulum (ER) tubules near the plasma membrane (PM). The cells were stained with ER-Tracker Blue-White DPX which selectively labels the ER. Control specimens were neither transfected nor stained. Precursor ions, defined by monoisotopic selection, were fragmented by keV-CID. A lateral resolving power of ≈ 80 nm was achieved in the TOF-SIMS tandem MS imaging.

Results: (Limit 900 characters)

We observed, by simultaneous MS imaging and tandem MS imaging, atomic and molecular moieties characteristic of the ER-Tracker stain localized to ER and ER tubule structures. The ions used for tandem MS imaging of the ER and ER tubules were shown irrefutably via the product ion spectra to arise solely from the ER-Tracker stain. 2D imaging revealed intersection of some ER tubules at the PM. 3D visualization to a depth of ≈ 40 nm revealed additional ER tubules just under the PM. Some ER-Tracker was observed in the PM indicating ER tubule contact with the PM to form ER-PM junctions. We were also able to confirm the presence and position of the PM by imaging characteristic lipids, lipid fragments and fatty acids. The observed tubule features had measured diameters in the range of approximately 500 nm to 2 μ m corresponding well with previous studies [3] and our present total internal reflection fluorescence (TIRF) observations. More than a dozen control cells were analyzed, and neither atomic nor molecular moieties characteristic of the ER-Tracker were observed.

Conclusions (Limit of 400 characters)

TOF-SIMS tandem MS imaging was employed with a molecular stain to isolate and observe ER tubules and ER-PM junctions in transfected HEK cells. Our next aim is to visualize the endoplasmic reticulum within entire cells and to assess the lipid composition at different locations within this organelle. By extension, with organelle-specific imaging, we can apply this method to aspects of pharmaceutical efficacy and metabolism.

Novel Aspect: (Limit of 150 characters)

Molecular markers together with TOF-SIMS tandem MS imaging enables the identification of endogenous and exogenous components in specific cellular organelles.

379 - LIVECELL MS METHODOLOGY IN THE CONTEXT OF DRUG DISCOVERY

carla newman (1) - Andy West (2)

The University of Nottingham, School of Pharmacy, Nottingham (1) - GSK, Bioimaging, Stevenage (2)

Keywords: LiveCell MS, intracellular drug, single cell metabolomics

Introduction:

In the last few decades, the pharmaceutical industry has transformed people's lives. However, the development of new drugs is becoming increasingly and a paradigm shift in the drug discovery workflow is required to reduce attrition and transform conventional drug screening assays into translatable analytical techniques for the analysis of drugs in complex environments, both in-vitro and ex-vivo. The ability to visualise unlabelled compounds inside the cell at physiological dosages can offer valuable insight into the compound behaviour both on and off-target.

Methods:

LiveCell MS is a semi-automated methodology that allows the collection of intracellular content using a modified CQ1 imaging system developed by Yokowaga. The instrument is equipped with a confocal microscope that allowed bright field imaging as well as fluorescence imaging with 4 lasers (405, 488, 561 and 640nm). Sampling was performed using the tips developed by Professor Masujima (reference below). The tip, holding the cellular contents, was then used for static nanospray of the contents into an Orbitrap Fusion Lumos (Thermo Scientific) and the resulting data processed using Compound Discoverer (Thermo Scientific).

Results:

In this study, we show the applicability of the LiveCell MS technology to drug discovery, as it is crucial to identify compound and its metabolites when incubated in a mammalian cell at a therapeutic dose.

We report on the validation studies performed using the LiveCell MS platform. In the first of these studies we assess the dynamic range of the assay by directly comparing the results obtained with a state of the art metabolomics assay using bulk samples with our single cell technology..

In the second validation study we explore the effects of amiodarone, an anti-arrhythmia drug, in a macrophage model (rat-derived NR8383 cell line) identifying the drug intracellularly and the detectable endogenous metabolites.

Conclusions

We demonstrate that dosed compound can be identified in a single cell after sampling using the modified CQ1. Endogenous metabolites can also be identified, that can further understanding of the drug's mechanism. This technique has direct relevance for assessing compound effects on disease relevant cells and its low sample requirement makes it applicable to studying rare cell types. The use of high content imaging system enables the effect of compounds on live cells to be studied and suitable time points selected for sampling cell contents.

Novel Aspect:

Identification of drug compounds and endogenous metabolites using an automated sampling technique and well as in combination with high-resolution mass spectrometry.

1351 - DRUG UPTAKE AND METABOLISM IN SINGLE LIVER CELLS

Liliana Pedro (1) - Patrick Rudewicz (1)

Novartis Institutes for BioMedical Research, GDC, Emeryville, United States (1)

Keywords: single cell, drug metabolism, nanospray, high-resolution mass spectrometry

Introduction: (Limit of 400 characters)

Cells, even within a genetically identical culture, possess individual differences that cannot be detected by analyzing cell populations. These individual differences can be crucial to cellular health and survival. Herein, we present a method that combines automated live single cell sampling with high resolution mass spectrometry that enables the detection and quantification of drug and drug metabolites in individual liver cells.

Methods: (Limit of 400 characters)

Amiodarone was used as a test compound. HepG2 and cryopreserved human hepatocytes were used as liver cellular models. Cells were incubated with 10 μ M amiodarone for 24h at 5% CO₂ and 37 °C. Live cells were visualized in real-time during automated single cell sampling using a confocal microscope modified with a XYZ stage robot (Yokogawa Electric Corporation). Platinum-coated glass capillaries (cellomics tip, HUMANIX) were used for cell sampling and nanospray ionization. A Bruker static nanospray source and a 7T SolariX FT-ICR-MS were used for mass spectrometry analyses.

Results: (Limit 900 characters)

CT-10 tips (10 μ m I.D.) were chosen to sample whole hepatocyte cells, which were maintained at 5% CO₂ and 37 °C inside the sample vessel of the confocal microscope until sampled. Before automatic live cell sampling, series of slice images (z-stacks) were acquired to determine the volume of each cell. The cellular metabolism was quenched immediately after cell sampling. Prior to mass spectrometry analysis, an organic solvent mixture spiked with internal standard was loaded into the tip. Direct infusion of single cell contents resulted in complex mass spectra, with varied ion abundances and many interfering background ions. The resolving power of the SolariX FT-ICR-MS enabled unambiguous amiodarone identification and, operated in CASI mode, an improvement of at least 10-fold in sensitivity. The internal standard was used for both lock-mass calibration and intensity normalization. Concentrations of amiodarone and its major metabolite (N-desethylamiodarone) were integrated over total cell spray times and multiplied by the flow rates to afford the amount of each compound within each cell. Single cell concentrations were determined by normalizing these amounts to individual cell volumes. Single cell measurements agreed well with determinations of a hypothetical average cell obtained from cell lysates. Single cell measurements were, nonetheless, more variable than technical replicate analysis of cell lysates.

Conclusions: (Limit of 400 characters)

Pioneering work conducted by Masujima and colleagues had previously demonstrated the applicability of cellomics tips for both live single cell sampling and direct infusion into the mass spectrometer by nanospray ionization without prior sample processing [1,2]. In the current work, we confirmed the feasibility of the approach and addressed many technical challenges currently associated with single cell analysis: limited sample amount, high dynamism of cellular metabolic state, low sampling throughputs, high complexity of ion mixtures and varied abundances. With this method, absolute compound quantification in the actual cells was achieved.

Novel Aspect: (Limit of 150 characters)

A new method for determining compound uptake, accumulation and metabolic stability inside individual liver cells.

267 - IN SITU MASS SPECTROMETRY UNRAVELS METABOLIC DIFFERENCES BETWEEN CELLS OF THE LIVE VERTEBRATE EMBRYO (XENOPUS LAEVIS)

Erika Portero (1) - Sally Moody (2) - Peter Nemes (1)

University of Maryland, Chemistry and Biochemistry, College Park (1) - The George Washington University, Anatomy and Regenerative Biology, Washington DC (2)

Keywords: Single-cell, capillary electrophoresis, metabolomics, *Xenopus laevis*

Introduction:

Metabolomics with single-cell resolution opens new frontiers in the study of cell heterogeneity [1] and establishment of functional differences during embryonic development [2]. Mass spectrometry (MS) is the technology of choice for metabolomics, but sensitivity limitations in detection hinder the application of traditional metabolomics to single embryonic cells. Here, we present a single-cell MS approach that enables the extraction and detection of metabolites from single cells from live *Xenopus laevis* embryos with high technical and biological reproducibility. We conduct in situ, minimally invasive sampling of identified embryonic cells to peer into metabolic pathways active during early embryogenesis. To enhance metabolite coverage, we integrate anionic and cationic analyses using a custom-built capillary electrophoresis electrospray ionization (CE-ESI) MS platform.

Methods:

Single dorsal D1 and ventral V1 cells were identified in the 8-cell *Xenopus laevis* embryo using cell fate maps, pigmentation, and morphology criteria. Our CE-MS system [3] consisted of a microprobe to aspirate ~10 nL portion of the cell's cytoplasm, which was immediately extracted in 40 % acetonitrile/40% methanol and water. Metabolites were detected in a custom-built CE-ESI system coupled to a high-resolution quadrupole-time-of-flight mass spectrometer (Impact HD, Bruker).

Results:

Our CE-ESI-MS platform provided 60 amol sensitivity and a quantitative range of 4–5 orders of magnitude. Trace-sensitive detection by this platform allowed us to detect ~250 cationic and ~150 anionic metabolite features in the positive and negative ion-mode. We identified 70 of the cationic features with high confidence as metabolites based on accurate mass, tandem MS, and migration time information against reference standards. Likewise, 50 of the anionic features were putatively assigned based on accurate mass match against data in Metlin [4]. These quantitative metadata enabled us to compare metabolic activities between cells along the dorsal-ventral developmental axis of the vertebrate embryo using multivariate and statistical analysis. Surprisingly, we observed clustering of metabolites based on their cell type of origin. Moreover, pathway analysis revealed the arginine-proline metabolism pathway (p-value 2.24×10^{-12}) and the glycine-serine-threonine metabolism pathway (p-value 5.13×10^{-10}) to be of significance, suggesting the importance of these pathways during early development.

Conclusions:

We developed a unique single-cell MS technology that enabled the metabolic characterization of identified single cells in the live vertebrate embryo of *Xenopus laevis*. Quantitative data from this study revealed previously unknown metabolic cell heterogeneity between the dorsal-ventral axis of the 8-cell embryo, raising the possibility that metabolites also contribute to cell fate specification.

Novel Aspect:

Enabling in situ sampling and detection of cationic and anionic metabolites from single-cells during early development to uncover cell heterogeneity.

Keywords: Live single cell, ambient mass spectrometry, metabolomics, microscale bioanalysis, Single-probe

Introduction: (Limit of 400 characters)

Cell is the basic unit of life. Cells are traditionally studied through population analysis, and averaged results are obtained. Understanding individual cells is critical for advances in many areas ranging from cell biology to clinical treatment. Due to its high sensitivity and broad detection range, MS is promising technique for single cell analysis.(1-4)We have developed novel techniques using microscale probe to study live single cells under ambient conditions.

Methods: (Limit of 400 characters)

We have developed a microscale sampling and ionization device (the Single-probe) that can be used for SCMS studies.(5-7)The Single-probe is fabricated by combining a laser-pulled dual-bore quartz needle (tip size smaller than a cell) with a silica capillary and a nano-ESI emitter. In SCMS experiments, cells are attached to an XYZ-translational stage for sample movement. Cell insertion is monitored using digital microscopes as the Z-stage is lifted precisely.

Results: (Limit 900 characters)

Qualitative studies. Cancer cell lines were used as model systems, and they were cultured and treated with anticancer drugs. We have successfully detected anticancer compounds, drug metabolites, and cell metabolites inside single cancer cells.(5-7)

Semi-quantitative studies. Cancer stem cells (CSCs) and non-stem cancer cells (NSCCs) were used for comparison studies. Metabolomic analyses indicated that CSCs possess higher abundances of unsaturated lipids, and the level of desaturation can be altered using inhibitors.

Quantitative studies.To quantify the amount of anticancer drugs in cells, sampling solvent containing the deuterated drug was delivered into a target cell to extract intracellular compounds. Both target and deuterated molecules were simultaneously detected, and abundances of target molecule were estimated from their relative ion intensities, the concentration of the internal standard, solvent flowrate, and data acquisition time. Standard HPLC/MS analysis of cell lysates were done for comparison.

Conclusions (Limit of 400 characters)

Using the Single-probe SCMS techniques, we conducted live single cell studies including qualitative, semi-quantitative, and quantitative analyses. Broad ranges of molecules were detected. Experimental data were comprehensively analyzed to extract metabolomic information and reveal mechanisms of anticancer drugs and cell metabolism. Drug uptake amounts by single cancer cells were estimated. Our techniques can be potentially applied in clinical studies.

Novel Aspect: (Limit of 150 characters)

Multi-functional microscale device was coupled to MS for live single cell studies. Experiments and advanced data analysis were combined to obtain metabolomic information.

A.14 LIFE SCIENCES - MS IMAGING: APPLICATIONS

962 - MICROBIAL MALDI-(2)-MS IMAGING OF STEAM-INACTIVATED CO-CULTURED BACTERIAL COLONIES AT HIGH MASS RESOLUTION

Eike Ulrich Brockmann (1) - Daniel Steil (2) - Jens Soltwisch (3) - Klaus Dreisewerd (3)

University of Muenster, Institute for Hygiene; Interdisciplinary Center for Clinical Research (IZKF), Münster (1) - University of Muenster, Institute for Hygiene, Münster (2) - University of Muenster, Institute for Hygiene; Interdisciplinary Center for Clinical Research (IZKF), Muenster (3)

Keywords: microbial MALDI-MSI, MALDI-2, high resolution, pathogenic bacteria, sample preparation

Introduction:

Standard protocols to visualize the metabolic exchange in microbial communities by MALDI-MSI are based on analyzing colonies directly from agar [1]. However, this comes with notable drawbacks such as a lacking inactivation step and a limited reproducibility [2]. Here, we introduce a robust membrane-based workflow that enables steam-inactivation and highly-resolved imaging. Examples of competing strains including probiotics (e. g. *E. coli*Nissle) are shown.

Methods:

E. coli, *S. aureus*, *P. aeruginosa* and *B. subtilis* were investigated as prominent gram-negative and gram-positive samples. Bacterial colonies were co-cultured on LB agar, using mixed ester cellulose membrane filters. Steam inactivation was performed in a home-made chamber. Synapt G2-S QTOF and QExactive plus orbitrap mass spectrometers, equipped with MALDI-2 ion sources (from Waters [3] and Spectrograph [4], respectively), were used for data acquisition.

Results:

Inactivation of pathogenic bacteria and metabolic quenching is an indispensable prerequisite for a wider use of microbial MALDI-MSI. With our protocol, this requirement was – for non-sporulating strains – achieved by steam inactivating of membrane-grown colonies for 5 s. Following heat-induced dehydration, the 3-dimensionality of the cultures was reduced to a 2D space. Following matrix application, sample flatness fostered reproducible MALDI analyses and use of laser-induced postionization (MALDI-2), boosting the signals of numerous metabolites in positive and negative ion mode. Differentiation and identification of chemical identities was supported by the high resolving power (280k @m/z 200) and tandem MS capability of the QExactive plus.

Making use of these advantages, we recorded metabolic profiles from several single and co-cultured microbial communities at high lateral and high mass resolution. Examples for the microbial interaction on a molecular level of probiotic *E. coli*Nissle and pathogenic *E. coli* will be demonstrated.

Conclusions:

With the emerging interest in microbial MALDI-MSI, a reliable protocol for handling of pathogenic samples is still challenging. Our new membrane-based culturing protocol solves this issue for non-sporulating gram-negative and gram-positive bacteria. The use of MALDI-2 in combination with a high-resolving orbitrap increased chemical coverage, a critical step for a better understanding of the complex chemical communication in bacterial communities.

Novel Aspect:

Advanced protocol for microbial MALDI- and MALDI-2 imaging, visualizing the metabolic exchange in (co-) cultured colonies with high sensitivity and mass accuracy.

Keywords: iodinated contrast agents, bioimaging, LA-ICP-MS, μ XRF, MALDI-MS

Introduction:

Iodinated contrast agents (ICAs), e.g., iopromide and iodixanol, are excreted via the kidneys. The fast and complete excretion of the unmetabolized CA is crucial with respect to toxicity issues. Rats were treated with iopromide or iodixanol with a dosage of 4 g iodine/kg bodyweight. They were sacrificed after 24 or 48 hours, kidneys were embedded and cut into 10 μ m cryosections. To investigate the accumulation and clearance of the ICAs, different bioimaging methods were used.

Methods:

Micro X-ray fluorescence (μ XRF) and laser ablation-inductively coupled plasma-mass spectrometry (LA-ICP-MS) were used to investigate the elemental distribution, especially of iodine, in rat kidneys. Matrix-assisted laser desorption/ionization-MS (MALDI-MS) generated information on the distribution of different small molecules in the range of m/z 100-1600 with MS/MS identification.

Results:

Significant differences in the accumulation and distribution of iopromide and iodixanol were detected with the three imaging methods when comparing kidney sections of rats, which have been treated with either ICA. In kidney sections treated with iodixanol and analyzed with LA-ICP-MS, the iodine was concentrated in the cortex region. The signal intensities decreased after 48 h. For iopromide, the iodine was accumulated in the medulla region. It was possible to quantify the different concentrations in kidneys spatially resolved. With μ XRF the same distribution and the decrease in intensity after 48 h were investigated.

Iodixanol was detected and identified with MS/MS via MALDI-MS. Additional information about small molecules were possible to analyze and to visualize different regions in tissue sections.

Conclusions:

It is possible to investigate the difference in clearance and accumulation in rat kidneys with the different bioimaging Methods: Due to the lower iodine concentration in medulla or pelvis, iopromide has a faster clearance. Iodixanol causes a higher urine viscosity, accordingly the iodine amount is higher and it accumulates in the cortex region. Additionally, MALDI-MS can be used to determine the phospholipid distribution in different regions of kidneys.

Novel Aspect:

Three different bioimaging techniques are used to investigate the distribution of iopromide and iodixanol in rat kidneys.

475 - REVERSING THE POLARITY – TARGETED MASS-SPECTROMETRY IMAGING ANALYSIS OF FATTY ACIDS IN POSITIVE DETECTION MODE

Andreas Dannhorn (1) - Emine Kazanc (1) - Paolo Inglese (1) - James McKenzie (1) - Nicole Strittmatter (2) - Richard J.A. Goodwin (2) - Zoltan Takats (1)

Imperial College London, Department of Surgery and Cancer, London (1) - AstraZeneca, Pathology, Drug Safety and Metabolism, IMED Biotech Unit, Cambridge (2)

Keywords: Fatty acids, Charge-remote-fragmentation, metal adducts

Introduction:

Qualitative and quantitative analysis of fatty acids can be difficult based on lack of fragmentation shown by [M-H]⁺ species. Ionization as metal adducts has proven to be a powerful tool for structure elucidation. Induction of charge-remote fragmentation results in generation of meaningful fragments, enabling identification and quantification of structural isomers.

Methods:

To study desorption and fragmentation behavior desorption electrospray ionization (DESI) analysis was performed on mixtures of fatty acids and metals spotted onto PTFE targets. Tandem MS experiments were performed to identify the underlying fragmentation mechanism. Suited metals were evaluated for direct ionization of fatty acid adducts directly from tissue sections and their fragment ions were used to create a targeted imaging approach.

Results:

Lithium adducts showed mixed fragmentation pattern along the fatty acid chain including formation of radical ions while silver adducts showed a preferred cleavage in allyl position to C=C bond through formation of cyclic intermediates.

The identified fragmentation pattern were subsequently used to identify fatty acids present in tissue sections. Washing steps to remove salts from the tissue sections prior spray-deposition of salt solutions improved the sensitivity of the method. Fatty acids present in tissue sections were identified by DESI-MS/MS experiments. Unique fragments enabling differentiation of structural isomers, e.g. arachidonic acid and eicosatetraenoic acid, were subsequently used to create multiple-reaction-monitoring (MRM) transitions for a targeted imaging approach performed on a triple-quadrupole mass spectrometer. The methodology was then used to map the spatial distribution of structural fatty acid isomers across various rodent tissues and human tumor sections.

Conclusions:

Ionization of fatty acids as metal adducts has been demonstrated to be a powerful tool for structural identification of fatty acids. Incorporated into a targeted MSI approach it enables to study distribution of fatty acids and potentially of closely related molecules, e.g. eicosanoids and prostaglandins in tissues. This is particularly interesting for the study of inflamed tissues and tumors studying the underlying disease mechanisms involving free fatty acids.

Novel Aspect:

In this study we present the use of charge-remote fragmentation for identification and targeted analysis of fatty acids in MSI experiments.

1325 - A TOF-SIMS STUDY OF LIPID CHANGES IN E. COLI MUTANTS WITH IMPAIRED PLASMID TRANSFER CAPABILITY

Kelly Dimovska Nilsson (1) - Martin Palm (1) - Anne Farewell (1) - John S. Fletcher (1)

University of Gothenburg, Department of Chemistry and Molecular Biology, Gothenburg, Sweden (1)

Keywords: SIMS, GCIB, Imaging, Depth-profiling, E. coli

Introduction:

Antibiotic resistance causes 25 000 deaths every year. The rate of the spread and the threat that antibiotic resistance pose on a global scale makes this a field of great interest for research. Transfer of plasmids (mobile DNA) between bacterial cells through conjugation is one of the major contributors to the spread of antibiotic resistance. A larger understanding of the mechanisms behind this process and how to possibly hinder it could help to quench the development observed around the world. In this study, the changes in lipid composition in the cell membrane of three mutated E. coli strains that have previously been found unable to transfer plasmids were analysed using a J105 - 3D Chemical Imager.

Methods:

The J105 (Ionoptika Ltd, UK) is an unconventional time-of-flight secondary ion mass spectrometry (ToF-SIMS) instrument specifically developed for analysis of organic materials [1]. A 40 keV CO₂ gas cluster ion beam (GCIB) is coupled to the J105 enabling imaging as well as depth profiling of native, underivatized biological samples and detection of intact lipids and other higher mass species [2]. Using the J105 coupled to a GCIB has allowed analysis of the outer membrane of mutated E. coli and how the lipid composition has changed in the membrane due to the mutations. Maximum autocorrelation factor (MAF) analysis was used as a tool to identify species of interest by mapping the largest differences within the data set.

Results:

A previous study found that the stress response in E. coli exposed to carbon starvation were changes in the lipid composition by elongation, cyclopropanation, and increased cardiolipin formation [3]. In our study, three different mutated E. coli strains unable to transfer plasmids were analysed and compared to wild type E. coli. Here we have analysed mutants that have been shown to have impaired ability to directly transfer DNA (an important process in antibiotic resistance development). The sub-set of mutants selected for SIMS analysis possess mutations that are expected to influence lipid and protein composition in the cellular envelope of the bacteria and are thus ideally targets for surface sensitive MS analysis. The preliminary results from this study show extensive lipid changes in the mutated bacterial cell membranes, some of which are closely related to those previously observed in carbon starved E. coli cultures. Changes in elongation and cyclopropanation of unsaturated fatty acids were observed along with differences in the production of cardiolipins. Such effects can influence membrane fluidity and protein incorporation and also the functional properties of pili used to initiate conjugation. Lipid structure can also influence the fusion pore formation required for plasmid transfer during conjugation.

Conclusions

The ToF-SIMS GCIB/J105 system has here proven to be a good method for analysis of the surface and the sub-surface of the cellular envelope in mutated E. coli. MAF analysis was able to identify a large number of species which showed changes in the cell membrane of mutated strains relative to wild type E. coli. Some of these species have previously been identified as related to stress response in E. coli exposed to carbon starvation.

Novel Aspect:

Linking lipid composition changes in the cell membrane in mutated E. coli to the bacteria's inability to transfer plasmids.

937 - DLEMMA-MS-IMAGING FOR IDENTIFICATION OF SPATIALLY LOCALIZED METABOLITES AND METABOLIC NETWORK MAP RECONSTRUCTION

Yonghui Dong (1) - Liron Feldberg (2) - Uwe Heinig (1) - Ilana Rogachev (1) - Asaph Aharoni (1)

Weizmann Institute of Science, Weizmann Institute of Science, Rehovot (1) - Israel Institute for Biological Research, Israel Institute for Biological Research, Ness Ziona (2)

Keywords: dual isotope labelling; MALDI imaging; metabolic pathway; structural isomers

Introduction:

Regardless of major advances in mass spectrometry imaging (MSI), there are three intrinsic limitations associated with MSI including intricate molecular identification, low molecular coverage and incapability to obtain 'true' spatial distribution due to isobaric and particularly isomeric ions interference[1].

Methods:

We have developed a novel approach that integrates in vivo dual isotope labeling of precursor metabolites with MSI for identification of spatially localized metabolite and metabolic network map reconstruction. In a proof-of-concept study, lemna plants were fed with tyrosine (unlabeled Tyr; Tyr2H4 and Tyr13C915N) and tomato fruits with phenylalanine (unlabeled Phe; Phe2H5 and Phe13C915N), they were then analyzed with LC-MS and MALDI imaging.

Results:

We have identified 60 and 28 tyrosine and phenylalanine derived metabolites in lemna and tomato fruits respectively, in which half of them were detected due to the increased concentration as a result of precursor feeding. With the identified metabolites, we were able to construct a detailed metabolic network map based on their labeling patterns and known biochemical reactions. Significantly, 20-30% of the identified metabolites were found to contain at least one structural isomer that has different distribution pattern. The noteworthy feature of this approach is that it enables distinguishing the localization of different structural isomers, hence providing the 'true' distribution of molecules of interest.

Conclusions:

This approach offers a number of advantages: (i) it improves metabolite identification; (ii) it increases metabolite coverage via precursor feeding; (iii) it allows construction of a detailed metabolic network map by tracking the specific pathway and most importantly, (iv) it enables precise localization of structural isomers, hence providing the 'true' distribution of molecules of interest.

Novel Aspect:

- (i) combined dual isotope feeding, LC-MS and MALDI imaging to address several key issues in MSI
- (ii) developed an R package for automatically and efficiently fishing out the dual isotope-labeled metabolite

Keywords: gene function; MALDI imaging; mutants;

Introduction:

Plants are highly differentiated multicellular organisms which consist of multiple specialized organs and tissues with unique anatomy features; anatomical differentiation parallels different gene expression and metabolite profiles[1]. As such, information on metabolite distribution has been regarded as important readouts of tissue-level gene function[2].

Methods:

We used various genetic tools including RNA interference (RNAi), virus induced gene silencing (VIGS) and agroinfiltration for mutating the genes in tomato and *Nicotiana benthamiana*, and characterized the gene functions using LC/GC-MS and MALDI imaging.

Results:

In this study, we proposed mass spectrometry imaging (MSI) as a potential member in functional genomics toolbox. Three examples were provided showing how MALDI imaging can benefit gene functional annotation. In particular, ultra-high mass resolution MALDI imaging ($R=1400,000$ at m/z 400) was used to visualize and compare the steroidal glycoalkaloids pathways in wild type and mutant tomato fruits. One defining feature of VIGS and agroinfiltration is that the spread of phenotype is partial in most plants, which results in two or more phenotypes heterogeneously distributed over the same sample, as demonstrated in the second and third examples. MALDI imaging allows directly compare the multi-phenotypes over the sample.

Conclusions:

MSI offers at least two unique advantages for gene functional annotation: (i) it enables detection of previous undetected gene-related metabolites due to the dilution effect in bulk metabolomics analysis; (ii) it provides tissue specific gene-to-metabolite correlation. MSI is therefore an attractive functional genomics tool; the physiological role of a gene can be inferred by comparing WT and mutant using MSI.

Novel Aspect:

(i) Applied different genetics tools to mutate genes of interest, MALDI imaging and LC/GC-MS were then used to compare the WT and mutant to infer the gene function.

903 - MASS SPECTROMETRY IMAGING IN SKIN WITH AP-MALDI AND TOFSIMS

Dana EL ASSAD (1) - Gilles FRACHE (1)

Luxembourg Institute of Science and Technology (LIST), Materials Research and Technology, Belvaux (1)

Keywords: Imaging mass spectrometry, skin

Introduction:

Latest developments in the field of MALDI imaging has led to a significant impact in the pharmaceutical and cosmetics field. MALDI imaging of biological tissue requires high selectivity which is provided by tandem MS and/or accurate mass measurements. Highly selective MALDI imaging is now enabled on high resolution Orbitrap instruments by means of an Atmospheric Pressure MALDI source.

Methods:

An AP-MALDI UHR ion source (Masstech Inc.) coupled to a LTQ/Orbitrap Elite high resolution mass spectrometer (Thermo Scientific) was used for the development of targeted and untargeted imaging Mass Spectrometry experiments. Cryosections of biological tissue were coated with matrices using a HTX-TM sprayer. Time-Of-Flight Secondary Ion Mass Spectrometry (TOFSIMS) was used as a complementary MS imaging modality.

Results:

Several applications of the AP-MALDI Orbitrap setup are presented based on samples from various types and sizes for the detection of targeted and untargeted molecules. The instrument allows for the localization of endogenous or exogenous molecules in various types of tissue.

MALDI images are correlated with other imaging techniques in a multimodal imaging workflow including e.g. optical microscopy and TOFSIMS.

Conclusions:

We show the characteristics and applications of a Masstech AP-MALDI UHR ion source as a part of a multimodal imaging workflow. With a laser spot sized down to 10 micron lateral resolution, when associated to a LTQ/Orbitrap mass spectrometer.

Novel Aspect:

Multi-modal MS imaging workflow including MALDI HR-MS or -MS_n imaging capabilities down to 10 micron lateral resolution.

Keywords: TOF-SIMS tandem MS imaging, Amazon tree wood, natural products, biosynthesis

Introduction: (Limit of 400 characters)

The secondary metabolites of rubrenolide and rubrynolide, having xylophage toxicity and antifungal properties [1], are reproduced in heartwood parenchyma cells before active or passive transfer to other cells and tissues. There are thought to be several biomolecular precursors en route to the bioactive metabolites. Our goal was to identify biosynthetic precursors and to verify their coincidence with rubr(y) nolide via TOF-SIMS tandem MS imaging [2].

Methods: (Limit of 400 characters)

Specimens culled from transition zone sections of Amazon *Sextonia rubra* were maintained at -18°C from harvest until final preparation of the analytical surface by diamond knife ultramicrotome. Biosynthetic precursor ions, defined by monoisotopic selection, were characterized by in situ analysis of the wood specimens using keV-CID; a lateral resolution of ≈ 400 nm was measured. Purified rubr(y) nolide was characterized by both TOF-SIMS tandem MS and LC-MS/MS.

Results: (Limit 900 characters)

TOF-SIMS tandem MS imaging was successfully applied to perform in situ characterization and localization of secondary metabolites and their biosynthetic precursors. MS/MS imaging significantly increased the confidence of the molecular identifications and the localization of the low abundance bioactive metabolites to anatomical structures. TOF-SIMS tandem MS images demonstrate the localization of rubr(y) nolide principally in and around ray parenchyma cells, in agreement with previous work on the biosynthesis of wood metabolites. Notably, the in situ tandem MS imaging reveals a contribution of oil cells in producing the secondary metabolites. We were able to demonstrate the presence of numerous precursors and to confirm or derive their structure using the tandem MS product ion spectra, thus contributing in the exploration of natural product biosynthesis.

Conclusions (Limit of 400 characters)

We are employing complementary structural analysis methods to obtain unambiguous identifications. Nevertheless, by TOF-SIMS tandem MS imaging alone, we have garnered unassailable evidence for previously unreported γ -lactone and obtusilactone molecules localized with rubr(y)onolide suggesting a common biosynthetic origin. These observations underpin the promise of TOF-SIMS tandem MS imaging for studies of plant metabolism and biosynthesis.

Novel Aspect: (Limit of 150 characters)

TOF-SIMS tandem MS imaging provides *in situ* identification and high resolution visualization of low abundance molecules for the study of metabolism and biosynthesis.

1323 - CHEMICAL IMAGING OF AGGRESSIVE BASAL CELL CARCINOMA USING TIME-OF-FLIGHT SECONDARY ION MASS SPECTROMETRY

kelly Dimovska Nilsson (1) - Marwa Munem (1) - Oscar Zaar (2) - Noora Neittaanmäki (2) - John Fletcher (1) - John Paoli (2)

Department of Chemistry and Molecular Biology, University of Gothenburg, Gothenburg, Sweden (1) - Department of Dermatology and Venereology, University of Gothenburg, Gothenburg, Sweden (2)

Keywords: Imaging, SIMS, skin, cancer, GCIB

Introduction:

ToF-SIMS has been successfully used for analysing lipids behaviour in biological samples like breast cancer tissue. Basal cell carcinoma (BCC) is one of the most increasing cancers worldwide and it is the most common malignancy in white people. Although the mortality is low as BCC rarely metastasises, this malignancy causes considerable morbidity and places a huge burden on healthcare services worldwide. Furthermore, people with BCC are at high risk of developing other malignancies.

Methods:

Samples were collected from patients with basal cell carcinoma, by Mohs surgery. The tissue was cryo-sectioned for ToF-SIMS analysis and H&E staining of consecutive tissue slices was performed. ToF-SIMS was performed using an Ionoptika J105 instrument using a 40 keV (CO₂)⁶⁰⁰⁰⁺ ion beam.

Results:

A set of basal cell carcinoma samples, removed by Mohs micrographic surgery and pathologically identified as having an aggressive subtype, have been analysed using time-of-flight secondary ion mass spectrometry (SIMS). The SIMS analysis employed a gas cluster ion beam (GCIB) to increase the sensitivity of the technique for the detection of intact lipid species. The GCIB also allowed these intact molecular signals to be maintained while surface contamination and delocalized chemicals were removed from the upper tissue surface. Distinct mass spectral signals were detected from different regions of the tissue (epidermis, dermis, hair follicles, sebaceous glands, scar tissue, and cancerous tissue) allowing mass spectral pathology to be performed. The cancerous regions of the tissue showed a particular increase in sphingomyelin signals that were detected in both positive and negative ion mode along with increased specific phosphatidylserine and phosphatidylinositol signals observed in negative ion mode. Samples containing mixed more and less aggressive tumor regions showed increased phosphatidylcholine lipid content in the less aggressive areas similar to a punch biopsy sample of a nonaggressive nodular lesion.

Conclusions

ToF-SIMS imaging with a GCIB distinguished cancerous and non-cancerous tissue from multiple patients along with different grades of high and low aggressive cancer.

Novel Aspect:

ToF-SIMS analysis using 40 keV GCIB was used to analyse basal cell carcinoma samples, removed by Mohs micrographic surgery.

522 - OPERATIONAL DEPLOYMENT OF MALDI MSI FOR THE ANALYSIS OF CRIME SCENE MARKS

Simona Francese (1) - Robert Bradshaw (2) - Jillian Newton (2) - Neil Denison (3)

University, Sheffield Hallam University - Biomolecular Sciences Research Centre, Sheffield (1) - University, Sheffield Hallam University, Sheffield (2) - Police, West Yorkshire Police, Wakefield (3)

Keywords: operational, casework, fingerprints, blood, MALDI

Introduction:

Nine years of intense and pioneering research into the extraction of forensic intelligence from fingerprints have resulted in the recent implementation of MALDI MSI methods in police casework in Europe. Here insights are provided into the MALDI MSI protocols in relation to the analysis of crime scene fingerprints as yet another application of MALDI MSI. This topic is discussed in the context of some casework undertaken together with highlights and limitations.

Methods:

Fingerprints were subjected to different treatments depending on the intelligence required. For profiling, they were subjected to MS and MS/MS spot analyses via either the MALDI MS Qstar Pulsar i mass spectrometer (Applied Biosystems, CA) or the Synapt G2 HDMS (Waters Corp., UK) QTOF. For imaging, they were matrix spray-coated using the automated Suncollect system (Sunchrom, Germany). All protocols were developed by using at large the same matrix (α -CHCA).

Results: Results from three example of casework undertaken will be discussed in the context of harassment, murder and sexual assault. Results highlights success and limitations various degree of success in the implementation of MALDI MSI Methods: Overall, it was possible to 1) extract intelligence on the contextual consumption of alcohol and cocaine from a 28 day old mark, in the harassment case, exceeding the information gathered by the police through conventional investigations [1]; 2) reconstruct the fingerprint ridge pattern from a two year old mark found on a tape wrapped around the victim's neck whose body was dumped in a lake; 3) assist in a case of child abuse by investigating condom lubricants presence - results reassured the mother who did not press charges against her husband. MALDI MS and Ion mobility MS/MS in profiling and imaging mode were used to provide such intelligence.

Conclusions: MALDI MSI is compatible with prior application of crime labs fingerprint enhancement techniques and can be used under full operational conditions. Detection and mapping of molecular intelligence as wells as fingerprint pattern reconstruction are possible even in harsh environmental conditions. It is not always possible to determine the reasons of the occasional limited success due to lack of knowledge on the molecular information originally available.

Novel Aspect:

Unprecedented implementation of MALDI MS based methods in police casework involving fingerprints

Title: DESI mass spectrometry imaging of the distribution of a fluorescence marker in malignant glioblastoma brain tumours

Introduction: The use of fluorescence guided surgery (FGS), using 5-aminolevulinic acid (5-ALA), is important to establish safe maximal resection and better progression-free survival for glioblastoma (GBM) patients. 5-ALA acts as an orally administered fluorescent pro-agent of protoporphyrin IX (PpIX).¹ Accumulating in glioma cells, 5-ALA is metabolized to PpIX,² affording intraoperative fluorescence visualization of the tumour, (λ_{ex} 405 nm - blue, λ_{em} 705 nm - red).

Methods: The distribution of PpIX was investigated using Desorption Electrospray Ionization MS Imaging (DESI-MSI) in preclinical and human GBM tissue samples. The fluorescence signature of PpIX was obtained using a fluorescence microscope (Olympus BX51 with QImaging Retiga 6000 camera) with excitation at 405 nm. Mass spectrometry images of the PpIX; parent ion at m/z 563.26 and CID MS/MS fragments, were obtained on a Waters Xevo G2-XS Q-ToF in positive ion mode.

Results: The distribution and detection levels of PpIX in human glioblastoma tissue is reported, with the goal of understanding where 5-ALA, and consequently PpIX, is localised relative to the tumour margins. DESI-MSI analysis of various PpIX dosed tissue homogenates, reveal detection of PpIX at the same concentrations required to observe fluorescence during surgery. Further, we describe the distribution of PpIX in samples from patients who have undergone tumour resection following the administration of 5-ALA at 20 mg/kg, 2 hours prior to time of surgery. DESI-MS images and fluorescence images of PpIX are co-registered alongside Hematoxylin and Eosin (H&E) staining sections to determine the effectiveness of fluorescence to define tumor margins, with mass spectrometry confirming the molecular source of the fluorescent signal.

Conclusions: The preclinical data confirm that PpIX, the fluorescent porphyrin that results from 5-ALA administration, is detectable by DESI-MSI. By co-registration of fluorescence and mass spectrometry images, we demonstrate that PpIX is detectable to the same concentrations required for fluorescent imaging. This work also measures the relative co-localization of molecular PpIX with the fluorescence signal in the tumours and its ability to define tumour margins.

Novel Aspect: For the first time, the distribution of a fluorescence guided surgical molecule has been mapped in malignant glioblastoma tumour samples using MSI approaches.

Keywords: MALDI-MSI, Cancer diagnosis, Method development, Organic synthesis, Metabolomics

Introduction

The diagnosis of malignant glioma, one of most aggressive brain tumor, is still a challenge in the biomedical and surgical imaging procedures. An emerging cancer hallmark is the reprogramming metabolism where the energy metabolism is adjusted to enhance the energy supply and therefore the biosynthetic pathways for the uncontrolled cell growth. The main metabolic phenotypes in a tumor cell are an overproduction of lactate, so called Warburg effect, and several mutations of mitochondrial enzymes. Due to this, an alteration of cellular metabolism occurs causing the cancer progression [1]. Imaging of cancer metabolism is an optimal diagnostic tool for an accurate glioma classification and localization of tumor in surgical biopsies.

In this regard, Matrix Assisted Laser Desorption Ionization Mass Spectrometry Imaging (MALDI-MSI), a multi-component imaging technique able to detect and localize onto the tissue many compounds at the same run, could perform a visualization of the cancer metabolism directly on the glioma tissue. Unfortunately the detection of metabolites is still challenge because of low concentrations, matrix interference and fragmentations phenomena. It is known that the chemistry of matrix serves fundamental functions in desorption and ionization. For this reason the search for new MALDI matrices is required and then improve the limit detection of metabolites without any matrix background. For the first time, the 1,8-bis(dimethylamino)naphthalene (DMAN) or Proton Sponge was used in MALDI-MS for the detection of small weak acidic compounds with any matrix interference [2]. Unfortunately it was observed that DMAN is vacuum stable and then not suitable for the long-time MALDI-MSI procedures. Indeed in order to increase the vacuum stability the DMAN was structural modified generating two derivatives 1,8-Di(piperidinyl)-naphthalene (DPN) [3] and 3-(4,5-bis(dimethylamino)naphthalen-1-yl)furan-2,5-dione (4-maleicoanhydrido proton sponge or MAPS) [4],[5].

Regarding the para-substituted derivative MAPS, it was shown that this novel MALDI-MSI matrix is able to detect and localize compounds as small as chloride directly onto glioma tissues [6].

This work wants to show the potentiality of the MAPS as MALDI-MSI matrix in the discovery of novel biomarker candidates in the glioma diagnosis and as synthetic precursor of a new proton sponge based matrices generation.

Methods

Fresh-frozen glioma sections of five patients were covered with a matrix suitable for the detection of small molecules, Maleic Anhydride Proton Sponge (MAPS), using Image Prep™ as sprayer. Afterwards the glioma sections were analyzed by MALDI-ToF (ultrafleXtrem; Bruker) using a spatial resolution of 70 μm. The ionic spatial signatures on the tissue were generated using FlexImaging (Bruker) software. The chemical identification of ions was performed using High resolution MALDI-FT-ICR (solariX; Bruker) Imaging. Furthermore, in order to investigate the tissue microheterogeneity, clustering analysis of MALDI-MSI data was performed using Cardinal® as statistical software [6]. The cluster analysis was compared with histological characterization of H&E stained glioma sections, using QuPath as software.

Two proton sponge derivatives, 4-(N-phenyl)maleimido proton sponge (PMPS) and 4-(N-methyl)maleimido proton sponge (MMPS), were synthesized and sprayed onto mouse brain sections using an airbrush. MALDI-MSI experiments were performed in reflectron negative mode using 100 μm of spatial resolution and compared with MAPS.

Results

Several metabolic pathways of glioma metabolism, e.g. aerobic glycolysis, tricarboxylic acid cycle, and aminoacids metabolism, were visualized by MALDI-MSI procedures.

In the aerobic glycolysis, ionic maps of intermediates such as glucose, glucose 6-phosphate, and lactate were observed, confirming the Warburg effect as general biomarker of cancer tissue.

MALDI-MSI of citric acid cycle metabolites, succinate and fumarate, were detected and different spatial signatures were observed in five patients thus suggesting mitochondrial enzymatic aberrations. It is very interesting to note that the spatial distribution on the tumor region of amino acids such as glutamine, which has a crucial role in the cancer progression. Moreover based on metabolite's distribution and through an unsupervised cluster analysis, specific clusters were found in the five patients showing a correlation with tumor type and grading. Furthermore the intra-tumor differentiation, shown by the clustering analysis, was confirmed by PCA.

For the first time the 4-(N-phenyl) proton sponge (PMPS) and 4-(N-methyl) proton sponge (MMPS) were synthesized, characterized and applied as matrix in the MALDI-MSI of mouse brain tissue section. Small metabolites were detected and imaged on the tissue. Indeed several tissue-specific ionic maps were obtained showing a correlation with the histological features.

Conclusions

MALDI-MSI of glioma metabolism showed the detection of patient survival correlated biomarkers by phenotypically spatial signatures e.g. IDH1 or IDH2 mutations. Moreover it was shown the heterogeneity in metabolite distribution, confirming the tissue microheterogeneity that is one of main reasons of drug resistance. Moreover a new generation of proton sponge were synthesized and applied in MALDI-MSI showing very good performance as matrices. In conclusion the para-substituted proton sponges are valid candidate as matrix for tissue profiling by using MALDI-MSI procedures.

Novel Aspect

MAPS and its derivatives could contribute to the cancer diagnosis by MALDI-MSI procedures. Moreover the generation of new proton sponge derivatives could permits to gain more insight into the MALDI of metabolites. In conclusion this study is an emerging contribution for the clinical tumor diagnosis and also an outlook for a more detailed investigation of the ion formation mechanisms in MALDI that occur in complex systems such as biological tissue.

381 - THE EFFECT OF PROTEIN BINDING OF DRUG SUBSTANCES IN DESORPTION ELECTROSPRAY IONIZATION MASS SPECTROMETRY IMAGING

Anne Mette Handler (1) - Christian Janfelt (2)

LEO Pharma, University of Copenhagen, Copenhagen (1) - University of Copenhagen, Department of Pharmacy, Copenhagen (2)

Keywords: Protein-drug interactions, Mass Spectrometry Imaging, Desorption Electrospray Ionization

Introduction:

Mass Spectrometry Imaging (MSI) is increasingly used as a tool in pharmaceutical R&D for analysing the distributions of drugs in tissue [1]. However, some drug substances are detected with greatly compromised sensitivity compared to traditional bioanalysis, due to strong binding to blood proteins such as albumin [2,3]. The study characterizes the protein binding of drugs in MSI and different approaches to improve the MSI detection of protein bound drug substances.

Methods:

Cryo-sections were made of liver homogenates spiked with different drug substances, representing different degrees of protein binding. For each cryo-section, one half was treated with different denaturants in order to break the protein binding. The sections were analyzed by Desorption Electrospray Ionization (DESI)-MSI, and the treated and non-treated tissue was compared.

Results:

DESI-MSI was applied to characterize protein binding, and significantly reduced signals were observed in tissue homogenates spiked with a strongly protein bound drug substance like Roflumilast, compared to cryo-sections of blocks of gelatin spiked to the same concentration. This effect was less pronounced for drug substances like codeine known to have a lower degree of protein binding. Different denaturants are being tested on similar cryo-section in attempts to alleviate the protein binding and improve the DESI-MSI sensitivity (work still in progress). Some of the denaturants appear to be more efficient than others in breaking drug-protein bonds.

Conclusions

The use of denaturants provide an increase in the free fraction of drug which can be detected by DESI-MSI. Although the results were obtained by DESI-MSI, it is likely that similar findings would be made with other MSI methods such as MALDI-MSI. The use of agents that denature proteins thereby breaking the drug-protein binding is worth considering as a sample preparation step in MSI in imaging of drug substances which are known to have strong protein binding.

Novel Aspect:

Investigation of protein-drug interactions in Mass Spectrometry Imaging and methods for disruption of the protein binding.

Keywords: Mass spectrometry imaging; quantitative LC-MS/MS; Lipidizer; Multiple Sclerosis; Lipids

Introduction (400/400 characters)

Multiple Sclerosis (MS) is a chronic inflammatory disease of the central nervous system (CNS) in which infiltrating immune cells form MS lesions, resulting in extensive demyelination, axonal damage and neurodegeneration. Lipids are important mediators in immune response and a main constituent of the CNS, but their phenotype and contribution to MS pathogenesis remain elusive. Here we study lipids by applying multiple mass spectrometry based approaches to human MS.

Methods (394/400 characters)

Human post-mortem brain tissue from 3 MS patients and two healthy controls were collected and sectioned for both high resolution MALDI-TOF-MSI and MALDI-FTICR-MSI, as well as for quantitative LC-DMS-MS/MS. To confirm the location of MS lesions, we performed immunohistochemical staining (IHC), using anti-myelin (PLP) and immune cell markers (LN3). The MSI data was interrogated in a histology-directed manner, and by using multivariate statistical Methods:

Results (860/900 characters)

Interrogation of the quantitative LC-MS/MS data, acquired using the SCIEX Lipidizer platform after homogenizing tissue sections, resulted in the finding that several ceramides (dLCER(16:0), LCER(18:1), LCER(18:0)) were considerably higher in concentration in the MS patient tissues, compared to the healthy control tissues. Based on mass matching, m/z features corresponding to different ceramides, both lactosyl-, and hexosylceramides (HCER), were detected specifically in the MS lesions in the MALDI-MSI analyses. The specific detection of overexpressed LCER lipids in MS confirms the findings from a previous study on an experimental autoimmune encephalomyelitis (EAE) mouse model of MS, where astrocyte-derived LCER lipids were shown to contribute to the EAE disease phenotype [1]. Besides the LCER and HCER lipids, additional lipid features were found to be specific to the MS lesions, and using spatial segmentation of the tissues the MS lesions were clearly discerned from surrounding tissues.

Conclusions (342/400 characters)

In this proof-of-principle study on the investigation of the MS lipidome by using several MS techniques, we were able to confirm, for the first time, the presence and increased abundance of lactosylceramides inside the lesion of human MS patients. This study provides a solid basis into the further investigation of the role and location as well as function of these lipids in the context of MS pathogenesis.

420 - SELECTIVE MS IMAGING OF HYDROPHOBIC/HYDROPHILIC COMPOUNDS WITH A NOVEL AU COATED BLACK SILICON SUBSTRATE

Stefania-Alexandra Iakab (1) - Pere Rafols (1) - Oscar Yanes (1) - Xavier Correig (1)

Universitat Rovira i Virgili, Department of Electrical Electronic Engineering and Automation, Tarragona (1)

Keywords: black silicon, Au, LDI-MSI, tissue imprinting

Introduction:

Silicon based substrates such as DIOS and NIMS proved their value in MS studies by successful detection of small molecules with reduced background noise and fragmentation, despite their unsafe fabrication method [1] [2]. Au nanoparticles were used in laser desorption ionization MS analyses with increased resolution and sensitivity [3] [4]. We developed Au coated black silicon substrates (BSi) with hydrophobic/hydrophilic selective regions for MSI applications.

Methods:

The BSi substrates were created by dry etching with Sf_6 and O_2 plasma mixture [5]. Au layer was deposited by sputtering and the hydrophobic or hydrophilic surfaces were created with CHF_3 or O_2 plasma, respectively. Substrates were analysed by SEM, AFM, UV-VIS spectroscopy and mean contact angle. Animal tissue samples were imprinted on the substrates by touching. The MSI acquisition was executed with a MALDI TOF/TOF UltrafleXtreme spectrometer from Bruker Daltonics.

Results:

Physicochemical characterization of the AuBSi substrates showed a needle-like array structure (<900 nm height) that absorbs ~95% of visible light, specifically 98% at 355 nm (the wavelength of the MALDI Nd:Yag laser). The hydrophobic regions of the substrates have a mean contact angle (CA) of ~165°, because of the CH_x terminal groups, while the hydrophilic regions have a mean CA of ~45°, due to the HO groups. The AuBSi substrates revealed their efficacy by promoting the ionization/desorption processes of standard compounds as well as metabolites in tissue samples. The detected Au cluster peaks allow an accurate mass calibration process throughout the full mass range. Many imprinted endogenous molecules were detected in the MS images. Therefore, the selectivity of the substrate was demonstrated by the specific adhesion of molecules: hydrophobic or hydrophilic compounds adhered to hydrophobic or hydrophilic regions, respectively. This may simplify untargeted analysis (molecule assignment process) of polar analytes from a broad mass range.

Conclusions

Selective imaging of adhered compounds from imprinted tissues is possible with our novel selective AuBSi substrates. Compounds adhered to the AuBSi substrate based on polar interactions between tissue and surface: hydrophobic analytes were found in the hydrophobic region and hydrophilic analytes were found in the hydrophilic region. Thus, knowing the polarity of the detected molecules simplifies the putative identification process.

Novel Aspect:

For the first time selective AuBSi substrates were entirely fabricated by dry etching and sputtering. No sample preparation was needed for selective imprinting of molecules.

239 - APPLICATION OF ISOTOPE-LABELING IN WHOLE-BODY DESI-MSI STUDIES FOR INTRA-ANIMAL COMPARISON OF DRUG ADMINISTRATION ROUTES

Lois Morineau (1) - Sophie Chakroun Jacobsen (2) - Karen Kleberg (3) - Harald S. Hansen (3) - Christian Janfelt (2)

Université de Nantes, UFR Sciences et Techniques, Nantes (1) - University of Copenhagen, Department of Pharmacy, Copenhagen (2) - University of Copenhagen, Department of Drug Design and Pharmacology, Copenhagen (3)

Keywords: Drug distribution analysis, DESI-MSI, whole-body imaging, stable isotope labeling, drug administration

Introduction:

The distribution of an administered drug in the organism is highly dependent on the administration route as well as the drug formulation. Therefore, assessing the distribution and metabolism of drug substances or drug candidates is of great importance in drug development, and mass spectrometry imaging has demonstrated many advantages, in particular due to its unique selectivity which enables specific imaging of several exogenous and endogenous compounds simultaneously.

Methods:

The antidepressant drug amitriptyline was intravenously (IV) dosed to a mouse and immediately after, a similar amount of a deuterium labeled version of the drug was intraperitoneally (IP) dosed to the same animal. Whole-body cryo-sections were made at t=5, 15, 30 and 60 min, according to a previously published protocol [1], and the two drug substances were simultaneously imaged with high sensitivity by DESI-MS/MS using the Displaced Dual-mode imaging approach [2].

Results:

The approach provides a unique way to compare administration routes in the very same animal, thereby eliminating uncertainties caused by animal-to-animal variation. Already after 5 minutes, the IV dosed drug was detected throughout the animal, while the IP dosed drug (deuterium labeled) was primarily found in the abdominal cavity. After 15 minutes, the IP injected drug appeared highly similar to the 5 minutes IV injection, while the IV injected had started accumulation in the stomach region. At later survival times, the differences of the two administration routes became less pronounced.

The deuterium label was partly preserved in metabolism to the primary metabolite nortriptyline, and the approach thus also enabled assessment on how the drug metabolism depends on the administration route. Interestingly, even at early survival times, the two administration routes provided highly similar metabolite distributions.

Conclusions

The presented method does not only enable IV and IP comparison, but could also be used for comparison of other administration routes such as subcutaneous or oral administration, and in the case of the latter, two different oral formulations could be tested in the same animal. While autoradiography has higher sensitivity, this study demonstrates how much more information MSI can provide with its unique selectivity, even within different isotopologues of the same drug substance.

Novel Aspect:

Highly selective MS imaging of different isotopologues of a drug and its metabolites provides unprecedented Intra-animal comparison of administration routes.

773 - SINGLE CELL LIVESCAN MASS SPECTROMETRY PROFILING AND IMAGING

Filip Kaftan (1) - Marine Vallet (2) - Tim Baumeister (2) - Georg Pohnert (2) - Aleš Svatoš (1)

Max Planck Institute for Chemical Ecology, Research Group Mass Spectrometry/Proteomics, Jena (1) - Max Planck Institute for Chemical Ecology, Research Group Plankton Community Interaction, Jena (2)

Keywords: LiveScan, single cell MS/MSI, diatoms, molecular imaging, surface associated metabolites

Introduction:

In recent years, there has been a growing interest in the investigation of single cells and unicellular organisms. Single-cell measurement science has numerous applications across the biomedical and life science fields. Especially development of ambient MS techniques along with high performance MS systems provides powerful tools [1] which push the boundaries of system sensitivity so that only a minimal amount of cell material is needed to perform an analysis.

Methods:

Unicellular marine diatoms (*Coscinodiscus* sp.), freshwater algae (*Haematococcus* sp.) and various plant cells were analyzed in LDI mode via AP-SMALDI10-Orbitrap-MS/MSI Q-ExactivePlusMS system (TransMIT/Thermo Fisher Scientific, Germany). Cells were picked up from their media and transferred on a wet membrane filter or placed in a thin hydrogel film. All substrates were moistened/rehydrated with a suitable medium in order to ensure the cell viability.

Results:

The nanostructure of the *Coscinodiscus* sp. silica frustule acts as UV laser energy absorber and provides an intense ion signal in LDI mode [2] without MALDI matrix. Especially pigments characteristic to algae such as chlorophyll a (m/z 892), fucoxanthin (m/z 658) or beta-carotene (m/z 536) were present in the spectra together with their common fragments. The identity of these signals was confirmed with standards. Furthermore amino acids, fatty acids and different groups of lipids were found in the MS spectra. In the same way an AP-SMALDI-FT MS analysis of *Haematococcus pluvialis* cells showed strong signals of its typical red pigment, the antioxidant astaxanthin (m/z 596). Moreover, PLS-D analysis of the MS spectra showed a clear separation between groups of nutrient-depleted cultures of *Haematococcus pluvialis* cells (green phase) and repleted cultures (red phase). Using the very same approach it was also possible to show distinctive patterns of old and young cells of *Coscinodiscus granii*.

Conclusions:

Our LiveScan method requires only little sample preparation. Fresh and vital algae cells isolated from their aqueous substrata were placed on a wet membrane filter/hydrogel and analyzed directly. The obtained MS spectra covered different groups of compounds including, amino acids, fatty acids, pigments and potential signaling molecules in high intensity. Characteristic patterns of the acquired spectra enable the differentiation of cell species.

Novel Aspect:

LiveScan MS-MSI represents a simple, fast and high throughput method for analyzing single cells in liquid phase under ambient conditions.

Keywords: MSI, fragile specimen, tissue embedding

Introduction:

Sectioning of fragile and small specimen can be challenge for mass spectroscopy imaging(MSI) analysis. However, embedding multiple small specimen allows simultaneous sectioning. An optimum embedding medium should meet several requirements, e.g. no altering the tissues, no negative effects for MSI and be sectionable of multiple specimen. The comparison of polymers with the freezing methods for embedding are critical factors in obtaining the best MSI result.

Methods:

5 different polymers (Gelatine, N-(2-Hydroxypropyl)-methacrylamide (HPMA), Sodium-Carboxymethylcellulose (CMC), (Hydroxypropyl-)methylcellulose (HPMC), Polyvinylpyrrolidone (PVP) were evaluated for their MSI suitability. All embedding media were evaluated for ease of sectioning, adherence to tissues and matrix interference, analyte delocalization and post-DESI histological evaluation.

Results:

Preliminary results displayed that Gelatine, HPMA, CMC, HPMC and PVP modified HPMC solution are able to provide easy sectioning whilst CMC with addition of alcohol and PVP were not suitable as they were not fully frozen under usual sectioning conditions and were not further investigated.

Adherence of the embedding medium to the tissue is important as the tissue sections must not fall out or curl up during sectioning. CMC and PVP modified HPMC are well adapted for this purpose while HPMA and HPMC are mostly suited for larger samples but not for small samples like intestines.

The last significant criteria is matrix interference. Gelatine shows chemical background from e.g. choline and arginine and tissue damage from hot gelatine solution. CMC showed adduct shift towards Na-adducts and smearing. HPMA, HPMC and PVP modified HPMC showed no matrix interference in MADLI and DESI-MSI.

Conclusion:

We found that the PVP modified HPMC is meeting all the criteria of an optimal embedding media, easy sectioning, high adherence to tissues and non-observed matrix interference.

We also found that snap freezing with isopropyl alcohol is a very promising method for preventing analyte delocalisation, block fracturing and small tissues thawing before fully frozen.

Novelty:

This study compares different polymers and freezing methods to develop a comprehensive tissue embedding protocol for MSI analysis.

939 - VISUALIZING MOLECULAR DISTRIBUTIONS ACROSS/UNDER THE HUMAN SKIN BY 2D-DESI MS IMAGING OF TAPE-STRIPPED STRATUM CORNEUM

Keishi Kihara (1) - Akira Motoyama (1)

Shiseido, Global Innovation Center, Yokohama (1)

Keywords: DESI, Mass Spectrometry Imaging (MSI), Natural Moisturizing Factor (NMF), Tape-stripping, Stratum Corneum (SC)

Introduction:

We have developed a new method combining DESI MS imaging (MSI) [1] and tape-stripping[2] techniques to visualize planer/depth profiles of natural moisturizing factor (NMF). NMF is a mixture of hygroscopic small molecules important to maintain hydration and barrier homeostasis of stratum corneum (SC) [3]. Differences of NMF content/composition are good index of skin conditions, whereas fine molecular distributions could not be obtained by conventional Methods:

Methods:

SC samples were collected by tape-stripping from the face or the inner forearm of healthy volunteers (one 30s female and one 30s male). Polymer-based adhesive sheets(25 × 70 mm, rectangular, in-house product) were used for SC collection. A high-resolution mass spectrometer equipped with a 2D-DESI source(Synapt-G2-SI, Waters) was used for DESI MSI analysis. Data processing was conducted by HDI-Imaging software® (Waters).

Results:

After the careful optimization of DESI experimental conditions, the developed visualizing method allowed to detect important 16 NMF-related molecules simultaneously. As a proof-of-principle experiments, planar distribution of NMF molecules across the half face was visualized. SC samples were collected from one side of the face on 8 adhesive sheets and measured with 500 μ m spatial resolution. It was found that the distribution/conversion of NMF molecules had large diversity. For example, serine (Ser) and pyrrolidone carboxylic acid (PCA), which are both abundant NMF [3], showed completely different distribution profiles (PCA distributed unevenly opposed to Ser). We also successfully visualized the changes of NMF depth profiles when the skin was treated with 2% sodium lauryl sulfate (SLS). SCs were collected before/after the treatment and measured by DESI-MSI. PCA was significantly eluted by the treatment, while the elution was prevented when a hand cream containing a film-forming ingredient was applied before the SLS treatment.

Conclusions:

NMF molecular distributions across the face and depth profile in the arm skin were successfully visualized for the first time. Because of the multi-target simultaneous analysis capability of the developed DESI-MSI method, molecular kinetics such as enzymatic conversion could be assessed. We believe that the new method is a promising tool for skin biological research and will provide useful insights for the development of new skincare products.

Novel Aspect:

The first application of DESI MSI to tape-stripped SC to visualize molecular distribution of NMF across the human face and depth profile.

^b Infection immunology, Research Center Borstel, Borstel, Germany

Introduction:

The rise of multi drug-resistant *Mycobacterium tuberculosis* strains creates an ever increasing need for novel anti-TB drugs. The development of anti-TB drugs however is impeded by the shortcomings of current preclinical animal models. In preparation for studies on novel anti-TB drugs, an AP-MALDI imaging method was established in this study to map the distribution of phospholipids and multiple anti-TB drugs in mouse lung tissue.

Methods:

MS imaging experiments were carried out on a Q-Exactive™ HF Hybrid-Quadrupole-Orbitrap mass spectrometer (Thermo Fisher Scientific, Bremen), coupled to the AP-SMALDI10 ion source (TransMIT GmbH, Gießen) [1]. Mass spectra with high mass accuracy (<2 ppm) and high mass resolution (R=240,000 @m/z 200) were acquired. Measurements were performed on lung tissue of BALB/c mice treated with anti-TB drugs. Different matrices were applied using a pneumatic sprayer system.

Results:

Sample preparation including matrix application and cryosectioning was optimized for several anti-TB drugs. MS imaging measurements of mice lung sections were performed with pixel sizes between 10 and 40 µm. These experiments showed high spatial details in phospholipid images, which corresponded well with histological features. Phospholipid patterns differed substantially between different tissue regions. In addition, the distribution of several anti-TB drugs could be shown in mouse lung tissue.

Conclusions

The investigated anti-TB drugs differ significantly in their physicochemical properties, for example polarity. Therefore, a sectioning protocol was adapted to avoid leaking of the drug from tissue. Different matrices and solvents had to be used for different drugs. Several drugs were detectable in treated mice, but showed different limits of detection. In conclusion, the MALDI imaging workflow must be optimized for each drug.

Novel Aspect:

We established a high resolution MALDI MSI method to analyze distributions of lipids and anti-TB drugs in mouse lungs with a spatial resolution close to the cellular level.

Keywords: nano-DESI MSI, quantification, prostaglandin, silver, uterine tissue

Introduction:

Silver ions are known to form weak charge transfer complexes with alkenes, and the addition of Ag⁺ to a double bond can therefore increase ionization efficiency and detectability of a compound. This work demonstrates nanospray desorption electrospray ionization mass spectrometry imaging (nano-DESI MSI) of endogenous prostaglandin species (PG) by utilizing the complexation between Ag⁺ and PG to enable the generation of unique PG ion images from thin tissue sections.

Methods:

Nano-DESI MSI was performed by connecting a custom built source to a Q-Exactive Orbitrap mass spectrometer. 10 ppm Ag⁺ was added to the solvent, which also contained acetonitrile and methanol (9:1), and deuterated PG species to facilitate quantification. Mouse uterine tissue sections of ~ 2 mm in diameter were imaged with higher spatial resolution using oversampling. The generated quantitative ion images of PG had an approximate pixel size of 30 μm x 10 μm.

Results:

The inclusion of silver into the solvent increased the sensitivity for [PG+Ag]⁺ ions by ~ 30 times compared to conventionally monitored [PG-H]⁻ ions. Additionally, it was found that the natural isotopic pattern from the two stable Ag⁺ isotopes was beneficial when corroborating the identity of analytes as silver ion adducts and that the exclusive binding of Ag⁺ to the alkene moiety enabled direct identification of double bond containing metabolite species.

Quantitative nano-DESI MSI revealed the localization of PG species to the luminal epithelium and glandular epithelium of mouse uterine tissue sections at day 4 of pregnancy prior to embryo attachment. Interestingly, the amount of both PGE₂ and PGF₂α were found to be three times as high in these cellular regions. The cellular regions of the glandular epithelium are only 100-300 μm in diameter, and were resolved in this study by use of oversampling. Three additional PG species were identified in the tissue with similar localizations displaying the great utility of silver-doped nano-DESI MSI.

Conclusions:

The presented results successfully demonstrate quantitative nano-DESI MSI of [PG+Ag]⁺ species directly from biological tissue without additional sample preparation. The described approach will be extremely valuable for future studies investigating the role of PG species in biological systems.

Novel Aspect:

First study detailing the specific localization and quantity of prostaglandin species in biological tissue sections.

358 - CALCIUM AND LIPID IMAGING OF REGENERATED BONY RAYS OF ZEBRAFISH CAUDAL FIN USING TIME-OF-FLIGHT SECONDARY ION MASS SPECTROMETRY

Sun Young Lee (1) - Jae Young Kim (1) - Dae Won Moon (1)

Daegu Gyeongbuk Institute of Science and Technology (DGIST), Department of New Biology, Daegu (1)

Calcium and Lipid Imaging of Regenerated Bony rays of Zebrafish Caudal Fin using Time-of-Flight Secondary Ion Mass Spectrometry

Keywords: ToF-SIMS, MS imaging, zebrafish, bone, small molecule analysis

Introduction:

We observed regenerated caudal fins of zebrafish using time-of-flight secondary ion mass spectrometry (ToF-SIMS). The spatial distribution of the small molecules including mineralized ions, lipids and fatty acids in the regenerated area of the fin was found to be different from the spatial distribution in the existing part.

Methods:

ToF-SIMS images in this study were obtained using ToF-SIMS 5 (ION-TOF GmbH) equipped with liquid metal ion gun (LMIG) and gas cluster ion beam (GCIB) sources [1,2]. The caudal fins were sputtered with Ar clusters and etched to 20-25 μm from the surface in the depth direction, then ToF-SIMS images of the bony ray and the inter-ray mesenchymal tissue were obtained using rastering of a Bi^{3+} ion.

Results:

ToF-SIMS analyzed both positive and negative ion modes and about 1000 specimen-related spectra were obtained from zebrafish caudal fins. Since the ToF-SIMS method detect mineral ions very well, it provided high spatial resolution ion images including Ca^+ , Mg^+ , K^+ , and PO_2^- ions to intuitively identify the precise location of the truncated site and the regeneration shape of the bony rays of the zebrafish caudal fin at 4 days-post-amputation (dpa) and 7 dpa [3]. Whereas the calcium and PO_2^- ions were be found to contain more in the regenerated area than in the existing area of the caudal fin at 4 dpa, there were little difference between the two areas of the caudal fin at 7 dpa. For phosphocholine ion in the caudal fins at 4 dpa and 7 dpa, the regenerated area had a higher signal intensity than the existing area.

Conclusions:

Several ion images of regenerated bony rays in the zebrafish caudal fin indicated that the regeneration of bony rays might precede the regeneration of other tissue materials. Consequently, ToF-SIMS imaging is a simple and easy approach to understanding the spatial distribution of small molecules in the regenerated caudal fin of a zebrafish.

Novel Aspect:

The zebrafish caudal fin is not only a very appropriate bio-specimen for mass spectrometry due to its thickness of less than 200 micrometers but also a very important organ for tissue regeneration studies.

Keywords: ToF-SIMS imaging, Tape-supporting sampling, Brain, Rat, Drosophila

Introduction:

Brain imaging using ToF-SIMS has been reported to produce the distorted biomolecular distributions due to the cholesterol-induced matrix effect, delocalization of the analytes, and/or inadequate tissue adherence during sample preparation. In this talk, we propose new sample preparation and drying methods that can be used to obtain accurate biomolecular images of brains at room temperature, instead of frozen-hydrate analysis using liquid-nitrogen.

Methods:

The rat or Drosophila brains prepared by using a double-sided adhesive tape on a pre-cooled ($-20\text{ }^{\circ}\text{C}$) stainless steel plate was freeze-dried in a load-lock chamber of ToF-SIMS for about an hour and moved directly to the main chamber. All measurements (depth profiles, images) were obtained using a TOF-SIMS V instrument. The 25-keV Bi^{3+} (current $\sim 0.1\text{ pA}$, cycle time: $200\text{ }\mu\text{s}$) was used as an analysis ion beam and the 5-keV Ar^{1500+} (current $\sim 3\text{ nA}$) was used as a sputtering ion beam.

Results:

We obtained the depth profiles of rat brain tissue (corpus callosum) as a function of sampling and drying Methods: In the white matter of the rat brain prepared by using the thaw-mounting method, cholesterol migrated to the sample surface regardless of room temperature-drying or freeze-drying. However, freeze-drying of the sample prepared by using the tape-supporting method did not cause the migration of cholesterol to the sample surface. In the frozen-hydrate analysis, cholesterol also did not migrate to the sample surface of the rat brain prepared with the thaw-mounting method or tape-supporting method [1]. Regarding the Drosophila brain imaging, the use of conductive double-sided adhesive carbon tape has been shown to enable the successful collection of small and fragile samples to surfaces compatible with ToF-SIMS analysis [2]. In addition, the tape-supporting method can effectively preserve the distribution of biomolecules on the rat and Drosophila brains in the same manner as that of the frozen-hydrated analysis (below $-100\text{ }^{\circ}\text{C}$) [1,2].

Conclusions:

Accurate and undistorted images of biomolecules in the rat and Drosophila brains can be obtained from brain sections prepared by the tape-supporting and freeze-drying method without performing frozen-hydrate analysis. We expect that this new sample preparation method will enable scientists using ToF-SIMS to easily and accurately detect important biomarkers for degenerative diseases.

Novel Aspect:

Our protocol circumvents cholesterol migration to the surface, delocalization of small molecules, and surface water interference.

Keywords: MALDI, MS imaging, spheroids, confocal microscopy, immunohistochemistry

Introduction

Multimodal imaging is a growing scientific field beneficial for explanation of many biological and chemical processes. Matrix-assisted laser desorption/ionization mass spectrometry imaging (MALDI MSI) together with laser scanning confocal microscopy (LSCM) conducted immunohistochemistry (IHC) allow to study drug distributions and related cellular responses. [1] In our study, 3D cell lines (spheroids) were employed as improved model for drug testing [2].

Methods

Spheroids were treated with the drug perifosine for selected time intervals, transferred to gelatine, frozen, sectioned and placed to conductive MALDI glass slides. Dried sections were covered with sublimated DHB matrix and measured using MALDI MSI. The matrix was washed away by organic solvents and samples were processed using standard IHC protocol with selected antibodies. Later, the analysis on LSCM and its correlation to MALDI MSI was carried out.

Results

The study of perifosine penetration by MALDI MSI revealed that perifosine does not penetrate the spheroid core even after 24 hour induction, it concentrates only in outer 150- μ m cell layer. A specific characteristic of this drug is also its diffusion from the tissue to gelatine medium during sample preparation. Viability assays by IHC were conducted for markers of cell proliferation and apoptosis with parallel staining of all cell nuclei. We detected elevated signals of apoptotic marker in spheroid core and proliferative cells on spheroid edges. This corresponds to general knowledge that spheroids from certain size physiologically develop necrotic core, due to by the lack of oxygen and nutrients in deeper cell layers [3]. Unfortunately, none of these spheroid physiologies were changed when the spheroids were treated by perifosine, meaning perifosine does not have any negative effect on cell viability.

Conclusions

MALDI mass spectrometry imaging and immunohistochemistry analysis of colorectal carcinoma spheroids showed no correlation between perifosine and dead cell presence. Apoptotic cells were found in spheroid core, however this was caused only by natural sample physiology. Perifosine was also not capable of penetrating the spheroid deeper than 150 μ m, suggesting a poor drug efficacy.

Novel Aspect

The analysis of the same tissue section by both MALDI MSI and immunohistochemistry, enabling correlation of both drug distribution and cell viability.

Keywords: TBI, 3D MALDI-MSI, MALDI-LTQ-XL-Orbitrap

Introduction:

Traumatic Brain Injury is mainly due to direct mechanical damage to the brain tissue leading to an axonal disruption and wide spread neural dysfunction. Monitoring lipid changes post injury could help in a possible therapeutic approach. In fact, lipid biomarkers have been studied in several brain injury models using mass spectrometry as demonstrated by Nielsen et al which identified NAPE as a biomarker of dead neurons in mice cerebral ischemia injury model.¹

Methods:

Lipid 3-Dimensional MALDI mass spectrometry imaging was applied on injured brain harvested from rat subjected to controlled cortical impact model (CCI) injury model.² Images were conducted using high resolution MALDI-LTQ-XL Orbitrap. Data visualization and processing was performed on Scis lab MVS software along with 3D image reconstruction, principal component analysis, and unsupervised spatial segmentation.

Results:

MALDI images were performed on serial sections from an injured rat brain at 3 days post injury and the 3D reconstruction was performed after performing unsupervised spatial segmentation on all sections followed by image alignment. The unsupervised spatial segmentation showed two unique clusters that co-localized within the injured cortical tissue and not expressed in any other regions of the brain. These clusters both departed from the non-injured cortical tissue on the opposite hemisphere of the brain in the PCA analysis, thus confirming the first finding of lesion specific clusters. In 3D manner, we visualized and assigned specific m/z values solely expressed in the injured tissue. At the same time, certain m/z ions showed a particular expression within the injury site and the ventricular system of the brain.

Conclusions:

Our results can help in further monitoring and identifying lesion-specific m/z in a 3D manner to obtain a better understanding and visualization of molecular and cellular events occurring post-injury. We have also showed injury-elevated m/z in common with the ventricular system of the brain thus suggesting a possible trafficking of molecules between the injured brain area and the spinal cord.

Novel Aspect:

Applying 3D MALDI-MSI on traumatic brain injury for the first time. High spectral resolution allowed to differentiate between m/z ions with a difference of up to 0.1 mDa.

787 - MULTIMODAL IMAGING OF UNDECALCIFIED TISSUE SECTIONS BY MALDI MS AND μ XRF

Anastasiya Svirkova (1) - Anna Turyanskaya (2) - Christina Strelt (2) - Martina Marchetti-Deschmann (1)

TU Wien, Institute of Chemical Technologies and Analytics, Vienna (1) - TU Wien, Atominstitut, Vienna (2)

Keywords: Multimodal Imaging, MALDI MS, μ XRF, Sample Preparation, undecalcified tissue

Introduction:

MALDI MSI visualizes distributions of a broad variety of biomolecules in tissue. μ XRF is a non-destructive elemental imaging method with high analyte specificity, and therefore a favourable choice for a multimodal imaging approach targeting elemental and molecular distributions. A methodology is presented allowing μ XRF and MALDI MSI analysis from the same undecalcified tissue section to visualize such distributions in tissue.

Methods:

Chicken feet were purchased from a local market, digits were removed and embedded in a hydrogel containing NaCMC and gelatin. Cryosectioning of the phalanx was performed with a non-disposable tungsten carbide knife according to the Ullberg's method. An in-house built μ XRF spectrometer (Atominstitut, TU Wien) was used for XRF analysis and MALDI MSI experiments were carried out on a Waters Synapt G2 after applying matrix (dithranol) by sublimation.

Results:

In this proof-of-principle study, we established and tested sample preparation strategies, allowing multimodal analysis of lipids (sphingomyelin and phosphatidylcholines) and elements relevant for bone structures as calcium, phosphorous and sulphur in the very same sample section of a chicken phalanx without tissue decalcification. The results of the investigation of such parameters as adhesive tapes supporting tissue sections, and sequence of the imaging experiments are presented. We show specific lipid distributions in skin, cartilage, muscle, nail, and intact morphology of bone by calcium and phosphorous images. Combination of molecular and elemental imaging was achieved, thus, providing now for the first time the possibility to gather MALDI MSI and μ XRF information from the very same sample without any washing steps omitting therefore analytical artifacts that inevitably occur in approaches using consecutive tissue sections.

Conclusions:

Conversely to most previous multimodal (multisensor) investigations, our imaging experiments are carried out on the very same samples without any additional steps, thus, avoiding analytical artefacts. We showed that we are able to cut difficult samples properly and visualize lipid distributions together with biologically relevant elements like Ca, P or S. We performed imaging experiments with similar lateral resolution facilitating the correlation of the images and gaining morphological information that was not possible from either analytical method independently.

Novel Aspect:

Combining MALDI MSI and μ XRF can benefit in researches where elemental and lipid interaction play an essential role.

Keywords: Mass spectrometry imaging (MSI), liver cancer (HCC), cirrhosis, LA-ICP, DESI.

Introduction: Since the pioneer work of J. J. Thomson on magnetic deflection of charged particles, mass spectrometry (MS) is the most progressing clinical tool, continuously providing new applications in medical research [1,2]. Mass spectrometry imaging (MSI) recently emerged as an option in the prospection of new biomarkers and has open many doors for clinical analysis, especially in the oncological area [2]. In hepatocellular carcinoma (HCC), MS can be used from disease surveillance in early stages into constant evaluation of effective treatments [3, 4, 5], but until now, MSI was not used on HCC molecular and elemental imaging. **Methods:** Samples were collected from patients underwent orthotopic liver transplant (OLT) within 2 distinguish groups: i) liver end-stage patients solely with hepatitis C virus (HCV) chronic inflammation (named INF); ii) liver end-stage patients with hepatitis C virus (HCV) chronic inflammation and HCC. DESI: performed in a Q-Exactive[®], a hybrid Quadrupole-Orbitrap mass spectrometer within a m/z 100–1200 with a step sized of 200 μm , a scan rate of 740 $\mu\text{m s}^{-1}$, and a pixel size of 200 $\mu\text{m} \times 200 \mu\text{m}$. Treatment was performed in BioMAP software. LA-ICP: performed in quadrupole-based ICP-MS (PerkinElmer ELAN DRC-e) coupled with a laser ablation system (New Wave UP 213), mass-to-charge ratios (42Ca^+ , 63Cu^+ , 55Mn^+ , 31P^+ and 64Zn^+). The used conditions were a spot size of 65 μm , scan speed of 50 $\mu\text{m s}^{-1}$, a frequency of 15 Hz, and a laser intensity of 55%. Treatment was performed in LA-iMageS software. COMEPE 026/98. **Results:** In the red-dashed-line the cirrhotic microenvironment (INF) and in the blue-dashed-line the hepatocellular carcinoma (HCC) (Figure 1). Co-localization generated by LA-ICP-MS and DESI approach enable the visualization of topological shifts between micronutrients abundance and metabolites relative abundance association, in intact tissues of HCC and its microenvironment (Figure 2). This study reveals spatially relative abundance association between m/z 303.23 and 42Ca in INF scenario; m/z 792.48 and 31P in HCC scenario, for example. **Conclusions:** The integration of these imaging stages provides identification of elemental microdomains and their secondary metabolism alterations, allowing direct observations on HCC heterogeneity, microenvironment diversity and tumor molecular characterization. Shedding light on the understanding of HCC metabolic regime, to improve comprehension on pathogenesis progression. **Novel Aspect:** New mass spectrometry insight for application in medical research on tracking microenvironment/cancer (HCC) shifts related to micronutrients abundance and its correlation on metabolic macromolecular regime.

1167 - COMBINING MASS SPECTROMETRY IMAGING & MICROPROTEOMICS TO INVESTIGATE INTRATUMOR HETEROGENEITY

Liam McDonnell (1)

Leiden University Medical Center
Leiden University Medical Center (1)

Keywords: MALDI, imaging, microproteomics, laser capture microdissection, intratumor het

Introduction:

MSI simultaneously records the distributions of hundreds of molecules directly from tissue. When combined with multivariate analysis it can reveal regions of tissue with distinct molecular signatures, including tumor subpopulations. The small pixel sizes and direct tissue analysis of MSI limits the achievable depth of proteome coverage. Here, we demonstrate how MSI can be combined with high sensitivity microproteomics, even of the same tissue section.

Methods:

Protein MALDI MSI data of patient tissues was combined with histopathological analysis to isolate the MSI data from tumor regions. Five independent multivariate tests were used to identify tumor subpopulations, and subpopulations associated with phenotype identified. Regions of tissue were isolated by laser capture microdissection and analyzed by LC-MS/MS using an Orbitrap Fusion.

Results:

MALDI MSI has been applied to patient tissues of gastric cancer, breast cancer, and soft tissue sarcomas. Following histopathological annotation and automated feature identification and extraction, the resulting datacube of MS images of only tumor regions, was subject to five independent multivariate methods to identify tumor subpopulations characterized by distinct molecular signatures. Associations with clinical data identified those subpopulations linked with patient phenotype (survival and metastasis).

In order to dig deeper into proteome changes in small, localized regions of tissue we have developed an SP3 based microproteomics approach utilizing 10-plex TMT labels and high-pH fractionation, to combine high relative quantitation precision with in-depth proteome profiling. We demonstrate the performance of this approach and demonstrate how it may be seamlessly combined with MALDI MSI of the same tissue section.

Conclusions

MALDI MSI combined with microproteomics can be used to identify and investigate phenotypic tumor subpopulations.

Novel Aspect:

Intratumor heterogeneity; seamless integration of MALDI MSI and LC-MS/MS, of the same tissue section.

785 - COMPLEMENTARY BIOIMAGING TO DETERMINE NANOPARTICLE AND PHOSPHOLIPID DISTRIBUTION IN LUNG TISSUE

Ann-Christin Niehoff (1) - Dörthe Dietrich (2) - Michael Sperling (2) - Uwe Karst (2)

Shimadzu Europa GmbH, Innovation Center, Duisburg (1) - University of Münster, Institute of Inorganic and Analytical Chemistry, Münster (2)

Keywords: Imaging, MALDI-MS, LA-ICP-MS, Multimodality, Nanoparticles

Introduction:

The uptake of nanoparticles (NP) such as cerium oxide or zinc oxide NP via inhalation may pose a health hazard for humans. Therefore, knowledge about their distribution in the lung and their biological effects is needed. Here, we combined elemental and molecular imaging techniques to study the distribution of NP and changes of phospholipid distribution in the lung.

Methods:

Different doses of nanoparticles were intratracheally instilled into rat lungs. The lungs were removed and cryosections were prepared. Laser ablation inductively coupled plasma mass spectrometry (LA-ICP-MS) experiments were performed to reveal the distribution of NP in the tissue. To analyze phospholipid distribution in positive and negative ion mode, matrix assisted laser desorption/ionization mass spectrometry experiments were carried out.

Results:

To analyze the impact of nanoparticles on lung tissue, MALDI-MS experiments were performed. Different phosphatidylcholines were detected in the positive ion mode and verified via MS/MS experiments by characteristic fragment of m/z 184. In case of lung inflammation increasing signal intensities of PC(32:1) and PC(36:4) were detected. In the negative ion mode phosphatidylglycerols and phosphatidylinositols were detected and were confirmed via MS/MS experiments. Nanoparticle distribution patterns as well as the distribution of naturally occurring elements such as phosphorus were depicted by means of LA-ICP-MS. Accumulations of nanoparticles could be detected in alveolar areas of the lung.

Conclusions:

The combination of elemental and molecular mass spectrometry by MALDI-MS and LA-ICP-MS shows the impact of nanoparticles on lung tissue. Depending on elemental composition, concentration, and period of incubation lung inflammation and fibrosis can occur. Alterations in phospholipid distribution were detected by MALDI-MS.

Novel Aspect:

Results show that combining MALDI-MS and elemental imaging techniques can provide new insights into local changes caused by nanoparticles in tissues.

634 - MULTISITE MULTIMODAL MASS SPECTROMETRY IMAGING OF GENETICALLY ENGINEERED MOUSE MODELS CONTAINING MUTATIONS LINKED TO BOWEL CANCER

National Physical Laboratory, NiCE-MSI, Teddington (1) - Cancer Research UK Beatson Institute, Department of Invasion and Metastasis, Glasgow (2) - AstraZeneca, iMED, Cambridge (3) - Imperial College London, Department of Surgery and Cancer, London (4) - Cancer Research UK Cambridge Institute, University of Cambridge, Cambridge (5) - Barts Cancer Institute, Queen Mary University of London, London (6) - Institute of Cancer Research, Division of Cancer Biology, London (7) - The Francis Crick Institute, Department of Tumour Biology, London (8)

Keywords: mass spectrometry imaging, bowel cancer

Introduction:

Bowel cancer is the second leading cause of cancer mortality in the United Kingdom. Mutations in the APC and KRAS genes are found in these tumours at rates of over 70% and 40%, respectively. In order to better understand the effects of these mutations on cellular metabolism, MALDI, DESI, and SIMS mass spectrometry imaging were used at multiple research sites to identify and map the localization of key metabolites in genetically engineered murine tissue.

Methods:

Murine samples were prepared and sectioned onto glass or ITO coated slides and stored at -80°C until analysis. MALDI-MSI was carried out on a RapifleX ToF-ToF (Bruker Daltonics) or Synapt G2-Si Q-IMS-ToF (Waters). DESI-MSI was carried out on a Synapt or Xevo Q-TOF (Waters). SIMS analysis was carried out on an OrbiSIMS (IONTOF, Thermo Scientific). Data were converted to imzML by imzMLconverter and analysed in MatLab (2017a, MathWorks) via SpectralAnalysis.

Results:

Colon and small intestine from sixteen animals were embedded into blocks of four containing four different genotypes each (wild type, KRAS-mutated, APC-mutated, and dual KRAS/APC-mutated). DESI and MALDI data were collected at multiple sites to discern variations in data seen between different instruments and to enhance method development to produce robust, reproducible practices. Preliminary analysis of these data indicates that the use of MSI followed by multiple computational analysis techniques including NMF, PCA, k-means clustering, and t-SNE neural networking allows for the segmentation of anatomical regions as well as grouping of phenotypic variation by genotype. Work is ongoing to utilize database matching and MS/MS studies to identify metabolites present in segmented data to correlate metabolic changes to genetic type. Lastly, further analysis of these datasets will allow guided analysis of additional samples via high resolution MSI to examine metabolite localization in a cellular context.

Conclusions:

Preliminary analysis indicates that both anatomical and phenotypic segmentation can be generated using a combination of computational analysis techniques. Current work is underway to identify metabolites within these segmented regions and determine how the APC and KRAS mutations may be effecting metabolic processes. Future work can integrate MSI results with proteomics and transcriptomics to inform additional studies.

Novel Aspect:

Multimodal, multisite analysis of bowel cancer murine models by MSI followed by multiple computational analysis methods to map metabolites using database matching.

INTERFERENCE FOR THE MALDI-MSI ANALYSIS OF IN-VIVO THYROIDBIOPSIES

Isabella Piga (1) - Giulia Capitoli (2) - Vanna Denti (1) - Silvia Tettamanti (1) - Stefania Galimberti (2) - Fulvio Magni (1) - Fabio Pagni (3)

University of Milano-Bicocca, Department of Medicine and Surgery - Clinical Proteomics and Metabolomics Unit, Veduggio al Lambro (1) - University of Milano-Bicocca, Department of Medicine and Surgery - Centre of Biostatistics for Clinical Epidemiology, Monza (2) - University of Milano-Bicocca, Department of Medicine and Surgery - Section of Pathology, Monza (3)

Keywords: Fine needle aspiration, thyroid lesion, haemoglobin interference, MALDI-MSI proteomics, thin prep.

Introduction: Fine Needle Aspiration biopsy (FNAB) is the gold standard exam to determine the malignant nature of thyroid nodules[1]. Contamination of FNAB samples with red blood cells is problematic for proteomics analysis, given that large amounts of haemoglobin (Hb) suppress other protein signals[2]. Hence, it is paramount to standardise the sample preparation of ex-vivo and in-vivo thyroid FNABs for proteomic MALDI-MSI analysis, in order to minimise Hb interference.

Methods: Human FNABs were collected and deposited onto conductive glass slides from both ex-vivo(n=9), surgically removed thyroid specimens, and in-vivo(n=12) thyroid specimens for intact proteins MALDI-MSI analysis. Three protocols were compared using ex-vivo biopsies collected from the same thyroid: a) conventional air-dried smear; b) cytological smear immediately fixed in ethanol; c) ThinPrep (TP) cytological preparation using a ThinPrep2000 system.

Results: The spectral profiles of both ex-vivo and in-vivo conventional air-dried smears were characterized by high inter-patient variability related to the abundance of the Hb peaks. In particular, the strong vascularization of some thyroid nodules is reflected in FNABs with a high content of Hb. The amount of Hb was markedly decreased in TP preparation with respect to both conventional air-dried and fixed smears. On the other hand, the absolute intensity of other protein signals, suppressed with the other two methods, were significantly increased in TP samples. Furthermore, the management of Hb interference of ex-vivo and in-vivo TP samples was comparable, indicating the opportunity to use in-vivo TP specimens for MALDI-MSI proteomic analysis and biomarker discovery. The MALDI-MSI approach combined with virtual microdissection permitted to extract specific protein signatures from different histotypes of both benign and malignant thyroid cell clusters.

Conclusions: The Thin Prep procedure for thyroid FNABs samples preparation combined with MALDI-MSI proteomic analysis allow us to obtain high-quality spectra, follicular cells specific protein profiles and to manage the haemoglobin interference. The application of this reproducible technique to in-vivo cytological samples can help cytopathologists in the diagnosis of thyroid nodules combining both morphological and proteomics information.

Novel Aspect: This study represents the first example of MALDI-MSI applied to ex-vivo and in-vivo thyroid FNABs, prepared using the ThinPrep preparation, for proteomic analysis.

216 - HIGH SPATIAL RESOLUTION IMAGING OF AGED HUMAN RETINA TISSUE

Kevin Schey (1) - David Anderson (1) - Jeffrey Messinger (2) - N. Heath Patterson (1) - Christine Curcio (2)

Vanderbilt University, Biochemistry, Nashville (1) - University of Alabama-Birmingham, Ophthalmology, Birmingham (2)

Keywords: imaging mass spectrometry, retina, retinoids, lipids

Introduction:

The human retina is made of morphologically distinct layers responsible for the absorption of photons and for sending signals necessary for vision to the brain. Imaging mass spectrometry (IMS) is a powerful tool for examining spatially disparate molecular signatures. We have applied IMS to human retina tissue to examine the spatial distribution of analytes in retina cell layers and to detect differences with age and disease.

Methods:

Fixed and frozen human retina tissue from older donors (80-89 years) was sectioned to 12-14 μm thickness and placed on ITO slides for IMS experiments. MALDI matrix was applied by sublimation and images were acquired using a modified Bruker Solarix 9.4T FTICR instrument. Data were analyzed with FlexImaging software. Registration between optical images and MALDI images was aided by autofluorescence microscopy and custom registration software.

Results:

Fixed tissue sections provided superior morphology with reduced analyte signal intensity in contrast to frozen sections that had poorer morphology but provided higher signal intensity. Ion maps unique to many retina cell layers were obtained with 15 μm spatial resolution. Autofluorescence microscopy facilitated registration of IMS and microscopy via explicit mapping of IMS pixels to their MALDI laser ablation marks, allowing confident identification of retina cell layers in the IMS data. Molecular signatures were identified for the high density of Mueller cells within the fovea, for basal laminar deposits, and for the retinal pigment epithelium (RPE). The bisretinoid metabolite, A2E, was detected in RPE cells of peripheral retina. A series of BMP lipids were detected throughout the RPE and photoreceptor outer nuclear layer. LC-MS/MS analysis is being used to identify novel compounds within the basal laminar deposits and within the fovea region. Unique signals were also observed within the inner and outer segments of photoreceptor cells.

Conclusions:

IMS provides a powerful tool to examine molecular changes in distinct retinal cell layers with age and extracellular deposits in disease. Specific lipid and retinoid metabolites have been localized to the RPE and fovea regions of older human retinas.

Novel Aspect:

Novel analytes identified in distinct retinal layers using high resolution IMS of human retina sections with characteristic aging features.

Keywords: skin, thermal desorption, ambient mass spectrometry, imaging, biomolecule

Introduction:

Skin plays a vital role in protecting human being against the attack by pathogenic microorganisms. Biomolecules such neurotransmitters, amino acids and other metabolites are also released from skin through numerous glands underneath it. Although these biomolecules on skin are possibly potential disease biomarkers, current analytical techniques are incapable to efficiently identify them on skin, except blood drawing. In this study, thermal desorption-electrospray ionization/mass spectrometry (TD-ESI/MS), a novel ambient mass spectrometric technique[1], was used to characterize the skin compounds including neurotransmitters, amino acids, lipids and metabolites without doing any sample pretreatment. Since TD-ESI/MS owns the feature of rapidness, high-throughput sample analysis, molecular imaging of skin can be presented on specific chemical compounds. Herein, ambient mass spectrometry imaging was demonstrated for visualizing the distribution of biomolecules on whole body skin.

Methods:

The TD-ESI/MS system consists of sampling probe, heated oven, electrospray device, and mass analyzer. A stainless steel probe was used to gently scrape through the skin surface for ca 1 cm for sampling. It was then inserted into a heated oven to thermally desorb the analytes on it. The analytes were carried by a nitrogen stream down to a plume consisting of acidic methanol/water and ionized by reacting with the charged species (e.g. H⁺, H₃O⁺, etc) in the ESI plume. Any residual sample on the probe was efficiently removed by burning it with a high-temperature gas torch for a few seconds. It took less than 30 seconds to complete an analysis.

Results:

In typical case, approximate 2,000 samples were collected on skin within an hour and the analysis of these samples took less than 12 hours. The imagings were obtained using commercial available imaging software. Taking caffeine or medicine as an example, the analyte ion signal was mostly detected on the upper body especially forehead, fingertips and backside of the body. This may due to different sweating rates in different skin parts as well as the distribution of veins and capillaries over the body. Not only medicines and their metabolites but regular metabolites such as neurotransmitters, amino acids, fatty acids, cholesterol, diglycerides, triglycerides and squalene were also detected and their whole body skin imagings show that the distribution of metabolites on skin also depend on the structure and chemical property of the compounds.

Conclusions:

Numberous biomolecules on the human skin was rapidly detected by insitu probe sampling and TD-ESI/MS analysis within a few seconds per sample. The ambient molecular imaging of squalene and cholesterol on whole body skin was also successfully established. In summary, we combined insitu probe sampling and TD-ESI/MS analysis, a non-invasive skin imaging technique for efficiently perform molecular imaging on the skin with high-throughput analysis was developed.

Novel Aspect:

Thermal desorption-electrospray ionization/mass spectrometry was used to perform whole body skin ambient imaging on potential biomolecules.

Aldosterone specific visualization in primary aldosteronism using imaging mass spectrometry

Keywords: Imaging mass spectrometry, derivatization, structural isomer, steroid hormone

Introduction:

Visualization of steroid hormones using MALDI-IMS is one of the active subjects for endocrine studies. Unfortunately, it is difficult to detect steroid hormones due to the low polarity. To overcome the problems, on-tissue chemical derivatization (OTCD) was developed [1], however the problem of structural isomers in steroid hormones is still remain. Herein, we introduce aldosterone specific visualization method using OTCD and tandem MS.

Methods:

Frozen tissue was sectioned and thaw-mounted on conductive glass slides. Girard's reagent T (GirT) was used and the GirT solution was sprayed on the tissue surface with an artistic air-brush. After one hour reaction at room temperature, α -CHCA was applied using two-step matrix application method. MALDI-IMS analysis was performed using LTQ XL linear ion trap mass spectrometer equipped (Thermo Scientific, Bremen, Germany).

Results:

We first demonstrated discrimination of aldosterone and cortisone which is a structural isomer of aldosterone using authentic standard sample. Aldosterone and cortisone were successfully discriminated by MS3 analysis. To confirm the utility of our method, next two experiments were performed in rat sodium diet model and human primary aldosteronism (PA), which is one of the causes of secondary hypertension. According to our experimental result, aldosterone and structural isomer of cortisone were clearly visualized separately. In PA patient tissues, we successfully visualized these hormones individually and compared with immunohistochemistry of aldosterone synthase. Our finding in this study was the expression level of aldosterone production enzyme and produced aldosterone were different in distribution.

Conclusions:

Although some literatures described MALDI-IMS approach for steroid hormone imaging, structural isomers have not been fully considered. In this study, we have developed aldosterone specific visualization method. After validation of the method in rat adrenal gland, we successfully visualized aldosterone producing region in PA. We found that combination of different imaging results (MALDI-IMS and IHC) were valuable to elucidate diseases.

Novel Aspect:

Combination of GirT and MS3 analysis allowed us aldosterone specific imaging in human adrenal gland, and it will provide more reliable information in diagnosis of PA.

660 - MALDI-MS IMAGING IN THE SEARCH FOR PROTEOMIC INDICATORS OF RESPONSE TO THERAPY IN MEMBRANOUS NEPHROPATHY

Andrew Smith (1) - Vincenzo L'Imperio (2) - Vanna Denti (1) - Mariafrancesca Mazza (1) - Silvia Tettamanti (1) - Martina Stella (1) - Isabella Piga (1) - Clizia Chinello (1) - Elena Ajello (3) - Renato Alberto Sinico (3) - Federico Pieruzzi (3) - Fabio Pagni (2) - Fulvio Magni (1)

University of Milano-Bicocca, Department of Medicine and Surgery, Clinical Proteomics and Metabolomics Unit, Vedano al Lambro (1) - University of Milano-Bicocca, Department of Medicine and Surgery, Pathology, San Gerardo Hospital, Monza (2) - University of Milano-Bicocca, Department of Medicine and Surgery, Nephrology Unit, San Gerardo Hospital, Monza (3)

Keywords: clinical proteomics, high spatial resolution, membranous Nephropathy, MS imaging, pathology

Introduction: Membranous Nephropathy (MN) is the most frequent cause of nephrotic syndrome in adults and the disease course is characterised by the “rule of third”, with one third of patients experiencing complete remission and the remaining experiencing relapses or progression [1]. Moreover, the therapeutic approach is not standardised, leading to further heterogeneity in terms of outcome [2], and a marker that can reliably predict the response of a patient a priori is lacking.

Methods: MALDI-MS imaging of renal biopsies taken from patients who differentially responded to immunosuppressive treatment (Ponticelli regimen) was performed. Initially, FFPE specimens (n=13) were analysed using an ultrafleXtreme™ MALDI-TOF-MS instrument, employing a pixel width and raster setting of 40 µm and 50 µm, respectively [3]. Analysis of additional specimens (n=7) was performed using a rapiflex MALDI TissueTyper™, employing a pixel width and raster of 10 µm.

Results: Following Receiver Operative Characteristic (ROC) analysis, three signals were determined to have a statistical significance when comparing the two patient groups (m/z 1111, 1198 and 1303). The signal at m/z 1303 displayed the greatest discriminatory power and was observed to be of higher intensity in the glomeruli of the non-responding patients. The corresponding tryptic peptide was putatively identified as macrophage migration inhibitory factor (MIF) and validated using immunohistochemistry, depositing on podocyte and parietal epithelial cells (PEC). We also generated specific profiles of the mesangial cells and podocytes of the glomeruli whilst employing a 10 µm pixel. This high spatial resolution imaging was then used to visualise the spatial localisation of those additional discriminatory signals detected (m/z 1111 and 1198) within the glomerular and tubular structures. These signals were putatively identified as tryptic peptides deriving from sonic hedgehog protein (SHH) and α-smooth muscle actin (SMA), respectively.

Conclusions: Despite much effort being made in recent years to understand the pathogenesis of MN, a biomarker able to predict the outcome of these patients following therapeutic treatment is still lacking. Here, we highlight three proteins that could differentiate between these MN patients (MIF, SHH and α-SMA) and thus represent a promising starting point in the search for protein markers to provide complimentary support in the routine prognostic assessment of MN patients.

Novel Aspect: This work represents the first study to employ high spatial resolution MALDI-MSI as a means of detecting tissue proteins with the potential to predict response to therapy in MN.

661 - PRECISION MEDICINE FOR DIABETIC NEPHROPATHY AND HYPERTENSIVE NEPHROSCLEROSIS: A MALDI-MSI PILOT STUDY

Andrew Smith (1) - Vanna Denti (1) - Mariafrancesca Mazza (1) - Vadim Iablokov (2) - Daniel Muruve (3) - Fulvio Magni (1)

University of Milano-Bicocca, Department of Medicine and Surgery, Clinical Proteomics and Metabolomics Unit, Veduggio al Lambro (1) - Snyder Institute for Chronic Diseases, Department of Physiology and Pharmacology, University of Calgary, Calgary (2) - University of Calgary, Department of Medicine, Calgary (3)

Keywords: chronic kidney disease, clinical proteomics, diabetic nephropathy, hypertension, MS imaging

Introduction: Diabetic nephropathy (DN) and hypertensive nephrosclerosis (HN) represent the most common causes of chronic kidney disease and many patients progress to end-stage renal disease [1]. Whilst both diseases are treated primarily through the management of hypertension, the latter group of patients have a more favourable outcome. Separating these two entities would allow for more appropriate resource allocation to those patients at highest risk of progression.

Methods: MALDI-MS imaging of renal biopsies taken from patients with DN and HTN was performed. These patients were also stratified into disease sub-groups on the basis of clinical parameters. FFPE specimens (n=18) were analysed using a rapifleX MALDI TissueTyper™, employing a pixel width and raster of 10 μm and 20 μm, respectively. Subsequent identification was performed using a Dionex UltiMate 3000 rapid separation (RS) LC nano system coupled with an Impact HDTM UHR-QqToF.

Results: Unsupervised Principal Component Analysis (PCA) highlighted that DN and HN could be clearly distinguished on the basis of their tryptic peptide profiles, with a cluster of signals having an altered intensity between the two disease groups. However, there was also some heterogeneity noted within each disease group. Upon further investigation, this heterogeneity was shown to be associated with the severity of each disease as defined by both clinical parameters and histological evaluation. Receiver Operative Characteristic (ROC) analysis highlighted a small panel of signals whose differential intensity was associated with the different stages of each disease. These signals were then correlated with a protein identification list obtained by complementary nLC-ESI-MS/MS analysis, resulting in a putative cluster of proteins able to discriminate between the different stages of DN and HN.

Conclusions: A sensitive and specific protein marker that can reliably differentiate between diabetic and hypertensive causes of CKD would allow for targeted monitoring guidelines for clinicians. The cluster of putative proteins presented here represents a valuable starting point for a future study employing a larger cohort of patients and, if verified, would allow for more appropriate disease intervention and potentially improve the outcome of patients with DN and HN.

Novel Aspect: This complementary proteomics strategy may provide specific markers for diabetic and hypertensive causes of CKD and highlight those patients at highest risk of progression.

High-resolution AP-SMALDI MS imaging of parasites

Bernhard Spengler, Patrik Kadesch, Tobias Hollubarsch, Anja Taubert, Carlos Hermosilla, Christoph G. Grevelding, Thomas Quack, Stefanie Gerbig, Kerstin Strupat, Mario Kompauer, Max Müller, Sven Heiles

Keywords (Limit of 5): High-resolution MS imaging, neglected tropical diseases, parasites, 3D surface imaging, atmospheric pressure MALDI

Introduction:

Biomolecular analysis by atmospheric-pressure (AP) MALDI MS imaging (MSI) at high lateral resolution¹ is a key issue for the investigation of small biological objects such as multicellular or protozoan parasites. Analysis of non-planar surfaces or tissue sections of parasites can be useful for, e.g., understanding invasion mechanisms. 3D-surface MSI² allows describing the biochemistry, chemical communication and drug response of small objects.

Methods: (Limit of 400 characters without spaces)

An AP-SMALDI⁵ AF ion source (TransMIT GmbH, Giessen, Germany) on a Q Exactive HF X orbital trapping mass spectrometer (Thermo Fisher Scientific, Bremen, Germany) was used to image two-dimensional planar sections and three-dimensional non-planar surfaces at a lateral resolution of 10 μm and below. High-speed acquisition up to 10 pixels per second was used at reduced mass resolution. Full pixel mode enhanced signal intensities for low-abundant compounds.

Results: (Limit 900 characters without spaces)

Schistosoma mansoni, a dioecious worm parasite causing schistosomiasis in humans and animals, was obtained from the Institute of Parasitology. 100 to 300 μm thick and approx. 1.5 mm long worms were investigated as couples or as individuals. Contact surfaces (the teguments) were differentially analyzed at the phospholipid and peptide levels, indicating molecular markers for males and females, and for their mating state.

Samples of apicomplexan protozoan cell pellets and monolayers of bovine umbilical vein endothelial cells (BUVEC) were studied at the lipidome level to find markers of infection. More than 20 lipid biomarkers for infection were determined for each of the parasites *Besnoitia besnoiti*, *Eimeria bovis* and *Toxoplasma gondii*.

Pixelwise autofocusing, provided by the 3D imaging ion source, was essential to reliably analyze the samples. Height adjustment in the micrometer range allowed obtaining topography-independent, concentration-related signal intensities from the surface of parasites and non-flat tissue sections.

Conclusions:

High-resolution methods were developed for pinpointing biochemical features of parasites such as schistosomes or coccidia. Molecular communication between paired male and female schistosomes was characterized by 3D surface imaging of their contact zone, the tegument.

Semi-quantitative analysis was enabled by pixelwise autofocusing, resulting in topography-independent signal intensities.

Novel Aspect: (Limit of 150 characters without spaces)

Molecular 3D surface imaging of endogenous compounds of parasites at 5 to 10 μm lateral resolution

1334 - AN UNTARGETED APPROACH TO ELUCIDATE THE METABOLISM AND TISSUE DISTRIBUTION OF PHOSPHOROTHIOATE LINKED OLIGONUCLEOTIDES BY HIGH RESOLUTION MASS SPECTROMETRY

Bernd Steinhuber (1) - Christophe Husser (1) - Andreas Brink (1)

F. Hoffmann-La Roche AG, PS, Basel, Switzerland (1)

Keywords: MALDI-FTICRMS imaging, oligonucleotides, tissue drug disposition, target site ADME, metabolite identification

Introduction:

Oligonucleotides linked with phosphorothioate bonds are a class of therapeutics under investigation in various pharmaceutical companies. Investigating the metabolism and disposition to target or non-target tissue by mass spectrometry could be a major advantage for a successful development. We developed two complementary analytical methods: To identify oligonucleotide metabolites an untargeted highly sensitive qualitative method using capillary flow liquid chromatography coupled to high resolution mass spectrometry was used, and for in situ imaging of tissue distribution a complementary method based on MALDI-FTICR MS. Both methods utilize a diagnostic fragment derived from the phosphorothioate backbone. This combined approach was successfully applied in a rat study with oligonucleotides of different sequence with and without conjugation to N-acetylgalactosamines (GalNAc).

Methods:

Metabolite identification was achieved by capillary flow liquid chromatography with column switching coupled to a Fusion Orbitrap mass spectrometer. Data-dependent scans were performed in parallel to an untargeted MS₂ experiment (AIF) and a high resolution full scan. In situ tissue imaging was performed by MALDI-MS Imaging using a 7 Tesla Solarix XR FTICRMS instrument (Bruker). Matrix (α -Cyano-4-hydroxycinnamic acid) was applied using an iMatrix Spray device. Negative polarity and 300 laser shots were applied (2000 Hz) at 50 μ m lateral resolution. The quadrupole was used in full transferring mode followed by CID (60 eV). Full scan MS was acquired in the ICR cell. Tissue distribution of oligonucleotides was also evaluated using Immunohistochemistry.

Results:

The detection and identification of oligonucleotides and their metabolites was achieved on a Fusion Orbitrap by combining full scan MS with two parallel MS₂ experiments, one data-dependent scan and an untargeted MS₂ experiment (AIF) applying high collision energy. In the AIF scan, a diagnostic fragment originating from the phosphorothioate backbone (O₂PS⁻: m/z 94.936) was formed efficiently upon collisional activation. Based on this fragment an accurate determination of oligonucleotide metabolites was achieved, independent of their sequence in an untargeted but highly selective manner. The method was effectively applied to investigate uptake and metabolism of oligonucleotides in rat liver and rat kidney homogenates down to the subnanomolar range. For MALDI-FTICR MS Imaging, oligonucleotides were detected indirectly and independently of their sequence using the quadrupole in an unselective transferring mode followed by strong collisional activation. We could identify in the ICR cell the diagnostic fragment (O₂PS⁻: m/z 94.936). Both methods were applied in a mechanistic multiple-dose rat study. Oligonucleotides with different sequence were used both as unconjugated compounds or conjugated with N-acetyl galactosamine which is a high-affinity ligand for the asialoglycoprotein receptor on the hepatocyte cell surface. Liver and kidney were investigated for metabolites and were evaluated in situ by immunohistochemistry and MALDI-FTICRMS Imaging. In the liver, unconjugated oligonucleotides were demonstrated mainly in Kupffer cells, whereas GalNAc-conjugated oligonucleotides accumulated in both Kupffer cells and hepatocytes. In the kidney, all oligonucleotides tested accumulated in the cortex primarily in proximal tubules. Interference with nucleotides of endogenous RNAs or DNAs was not observed. Phosphorothioate instead of phosphate linkage is a common modification for therapeutic oligonucleotides. Therefore, this approach might be generally applicable to investigate tissue distribution of this evolving therapeutic modality.

Conclusions:

It could be shown that the distribution and metabolism of oligonucleotides linked with phosphorothioate bonds can be analyzed in an untargeted manner by mass spectrometry. The metabolism of oligonucleotides was elucidated by LC-MS/MS whereas in situ imaging of tissue distribution was achieved on a MALDI-FTICR MS instrument. Both approaches harness the phosphorothioate backbone of these oligonucleotides as a diagnostic fragment (O2PS-: m/z 94.936) as this is not present in endogenous nucleic acids.

Both methods proved their applicability in a mechanistic multiple-dose rat study for which several oligonucleotides of different sequences were dosed.

Novel Aspect:

Untargeted approach to investigate metabolism and tissue distribution of therapeutic phosphorothioate linked oligonucleotides by high resolution LC-MS and MALDI-FTICRMS Imaging.

Clear cell Renal Cell Carcinoma, MALDI-MSI, nLC-ESI-MS/MS, glyco-proteomics

Introduction

Renal cell carcinoma (RCC) is the most frequent form of kidney cancer and approximately 80% of cases are defined as clear cell RCC (ccRCC)[1]. Understanding molecular alterations associated with the onset and progression of the disease could provide a valuable starting point for the development of new target therapies. Therefore, combined high resolution mass spectrometric approaches were used to investigate the glyco-proteome of different ccRCC grades[2-3].

Methods

FFPE tissue samples from patients with a proven diagnosis of ccRCC were analysed by MALDI-MSI. A 9.4T MALDI-FTICR-MS platform was used to investigate the spatial distribution of proteolytic peptides, whereas released N-glycans were analysed with a MALDI-TOF/TOF-MS platform from a consecutive tissue section. Finally, bottom-up proteomic using nLC-ESI-MS/MS, was performed on homogenized tissue to assign putative identifications to the molecules of interest.

Results

Considering the possibility of tumour grade-heterogeneity within a single lesion, traditional histology and molecular information obtained by MALDI-MSI were used to better define signals specific for each region of the tissue. MALDI-MSI analysis highlighted peptides signals able to discriminate between grade one and grade four lesions (e.g. m/z 944.71, m/z 1032.78, m/z 1325.99, m/z 1428.92). Nevertheless, preliminary data on the characterization of glycosylation offered an additional layer of information regarding the glyco-phenotype of different areas of the tissue. Finally, nLC-ESI-MS/MS analyses provided a list of putative identifications (protein and glycoproteins) for those signals that differed significantly among the four grades. In particular, a putative identification was assigned to the four aforementioned signals and were tryptic peptides of H2, H3, H4 and Vimentin, respectively. The identification of other signals of interest and their released glycans is currently under investigation.

Conclusions

Proteomics represents a highly specific approach in the investigation of molecular changes associated with tumour lesions. Furthermore, the study of aberrant glycosylation is bringing consistent advantages in the

understanding of ccRCC progression. All those findings represent a first attempt to highlight molecular differences among ccRCC grades and could provide further insights into the molecular mechanisms implicated in ccRCC progression.

Novel Aspect

The combination of high resolution MALDI-MSI and nLC-ESI-MS/MS is a highly effective approach for studying the proteome and the glycome of different tumour grades.

1286 - A CASE STUDY FOR DEMONSTRATING THE USEFULNESS OF IMAGING MASS SPECTROMETRY IN TOXICITY ASSESSMENT USING AN AMIODARONE-INDUCED PHOSPHOLIPIDOSIS MODEL

Koji Tanaka (1) - Akane Kashimura (2) - Hiroko Sato (2)

Mitsubishi Tanabe Pharma Corporation, DMPK Research Laboratories, Toda, Japan (1) - Mitsubishi Tanabe Pharma Corporation, Safety Research Laboratories, Toda, Japan (2)

Keywords: imaging mass spectrometry, toxicity assessment, histological examination, amiodarone

Introduction:

Investigating the local distribution of drug and biomarker in target organs provides useful information, which accelerates drug discovery and development. Imaging mass spectrometry (IMS) is a powerful technique to detect the localization of compounds of interest in biological tissue without any labeling. In the present report, we demonstrate the utility of IMS to investigate drug and biomarker distribution in an amiodarone-induced phospholipidosis model.

Methods:

Rats were orally administered amiodarone (AMD) for 7 days at 150 mg/kg/day. After the final dose, lungs, spleens and mesenteric lymph nodes were collected. Prepared cryosections (5 μ m/section) were coated with α -cyano-4-hydroxycinnamic acid using iMLayer (Shimadzu) and analyzed using the IMS system (Q-Exactive (Thermo Scientific) equipped with MALDI ion source AP-SMALDI 10 (TransMIT)). Mass images were generated using Million ver.3.2 software (TransMIT).

Results:

AMD, its metabolites (N-desethyl amiodarone and mono-oxidized amiodarone), and representative phospholipids, which are considered biomarkers of phospholipidosis, were detected in lungs, spleens and mesenteric lymph nodes in a single IMS analysis. Detection intensity of all the compounds was relatively higher in foamy macrophage infiltration areas than in non-infiltration areas. For the spleen, the distribution pattern of representative phospholipids markedly differed between AMD-administered rat and vehicle-administered rat.

Conclusions:

These results indicated that AMD and its metabolites were stored in macrophages, and this is quite consistent with the mechanism of amiodarone-induced phospholipidosis. They also indicate that IMS is a useful technique for evaluating the distribution of drugs and biological components in the elucidation of toxicity mechanisms.

Novel Aspect:

IMS analysis revealed the distribution pattern of AMD, its metabolites, and representative phospholipids in an amiodarone-induced phospholipidosis model.

Keywords: MALDI, DESI, imaging, cancer, metabolism

Introduction:

Overexpression of Myc and ErbB2 are frequent inducers of human breast cancers with distinct metabolic profiles [1]. Such metabolic deregulation is one of the hallmarks of cancer [2]. Mass spectrometry imaging (MSI) provides the potential to understand metabolic changes between genetic phenotypes, and within tumor regions; to expose therapeutic vulnerabilities. We performed a multimodal MSI study of genetically engineered mouse models of breast cancer.

Methods:

Mouse normal mammary glands, Myc- and ErbB2-induced mammary gland tumours were snap-frozen and cryosectioned at 10 μm . MALDI MSI was performed on a Waters Synapt G2-Si at 45 μm pixel size using 9-AA or DHB matrix. DESI MSI was performed on a Waters Xevo G2-XS at 75 μm pixel size with 95:5 MeOH:water as the spray solvent. Data were analyzed using PCA, NMF, k-means clustering and deep learning t-SNE. Database matching was performed to tentatively assign ions of interest.

Results:

Commonly applied analysis techniques PCA, NMF and k-means clustering proved complementary in revealing heterogeneity between subtypes and within individual tumours in an unsupervised manner. A novel deep learning t-SNE method enables visualisation of diverse chemical environments in a dataset that would be prohibitively large for traditional t-SNE Methods: Consideration of spectral factors and loadings from multivariate analysis led to the identification of peaks that delineate chemical heterogeneity. Database matching was used for tentative identifications of molecules including lipids, fatty acids and small metabolites. Information provided by multivariate segmentation was broadly consistent across techniques. MALDI and DESI were found to be highly complementary, with a number of molecules uniquely identified by each technique alone. Future work will integrate MALDI and DESI MSI into a data guided approach for high spatial and mass resolution SIMS imaging using 3D OrbiSIMS.

Conclusions:

We show the power of a multimodal MSI pipeline to delineate and define molecular heterogeneity within and between Myc- and ErbB2-induced models of breast cancer. MALDI and DESI MSI are shown to be complementary in

their coverage, demonstrating the importance of multimodal MSI. This work provides a blueprint for the design and application of further multimodal and multiscale MSI studies.

Novel Aspect:

A multimodal, multiscale MSI pipeline for the study of metabolic deregulation in genetically engineered mouse models of breast cancer is described.

Keywords: MSI, lipidomics, chemometrics, skin, bioimaging

Introduction:

Skin is large and integrated metabolic organ highly specialized in the synthesis of lipids, and skin untargeted lipidomics aim to facilitate the understanding of possible mechanisms of diseases with cutaneous pathological phenotype or pharmacokinetics of topically administered drugs [1,2].

Skin lipids present a specific distribution that might be exploited for the structural characterization of skin, thus obtaining a mapping that would guide any future detection of anomalies in the lipid profile. To this end, development of innovative high-resolution and high-sensitivity analytical approaches characterized by speed, robustness, and high metabolite coverage is essential to empower the information associated with the skin lipidome. In this context, in addition to the powerfulness demonstrated by mass spectrometry in "omics" studies, mass spectrometry imaging (MSI), a molecular analytical technology suited for simultaneously measuring multiple analytes (including lipids, drugs and their metabolites) directly from intact tissue sections, adds a new dimension and holds potential for bringing lipidomics to the spatial molecular characterization level [3].

However, such an aim represents a remarkable computational challenge due to the size and analytical complexity of a typical MALDI MSI lipidomic analysis that, especially when high spatial resolution is used to characterize the tissues, increases the problem to the scale of Big Data. Therefore, a smart combination of bioinformatics and chemometric tools for image analysis and data mining is needed to effectively support MALDI MSI skin lipidomics, but adequate and user-friendly solutions comprising all of the steps required for this aim (from peak picking, to lipid identification via multivariate statistical analysis) are still lacking.

Here we propose a novel and semi-automatic workflow to map skin lipids that, starting from multivariate statistics, leads to skin lipids mapping and biomarkers discovery in an untargeted manner under orientation of histological structures by MALDI MSI.

To prove the efficacy of the proposed workflow, both minipig, a representative preclinical species for skin studies, and human skin samples were analysed with unprecedented spatial resolution (10 μm and 25 μm) under positive as well as negative ionization mode. Data were then processed by means of multivariate statistical analysis with the aim of identifying differences among skin features.

As a result, a relatively comprehensive set of specific lipids markers for epidermis, hair follicles, and for the first time, for sebaceous glands is identified. Structure identification of identified markers is confirmed by post-MALDI MSI H&E stained optical images and validated by additional samples.

Methods:

Both minipig and human skin samples were collected and stored in -80°C before sectioning. The samples were cryosectioned at a thickness of 6 μm (minipig) or 10 μm (human) by a Leica Cryostat (Leica Biosystems Inc., Buffalo Grove, IL, USA) at -20 to -25°C . Sections for MALDI MSI were applied of matrix (DHB for positive and 9-AA for negative ionization mode) by a TM sprayer (HTX Technologies, Carrboro, NC, USA) upon optimization of spray conditions. MALDI MSI was performed using a Solarix 7T Fourier transform ion cyclotron resonance mass spectrometer (Bruker Daltonics, Billerica, MA).

Images were acquired at spatial resolutions of 10 μm and 25 μm in positive and negative ionization mode. Mass spectra were acquired in full scan mode (m/z 200-1500). Allion images were generated using FlexImaging v4.0

software (BrukerDaltonics, Billerica, MA) from the raw data. Regions of interest (ROIs) were defined under the guidance of hematoxylin and eosin (H&E) staining as: epidermis, EP, papillary dermis, PD, reticular dermis, RD, hair follicle, HF, sebaceous glands, SG, sweat glands, SWG. At least three different skin portions were chosen for each ROI. Average spectra from the different ROIs were exported from FlexImaging v4.0 software. LipoStar software [4] (Molecular Discovery, London, UK), adapted for handling MALDI MSI datasets, was used for peak detection, samples alignment as data matrix (rows: samples or ROIs, columns: m/z values), supervised (partial least squares discriminant analysis, PLS-DA) and unsupervised (principal component analysis, PCA) multivariate statistical analysis and lipid identification.

Results: (Limit 900 characters without spaces)

The skin has three main layers: the epidermis, dermis, and hypodermis. Epidermis (EP) is the surface layer in contact with the exterior, while the dermis (D) is divided into two further substructures: papillary dermis (PD), immediately adjacent to the EP, and the reticular dermis (RD). Additional skin appendages are present, namely: Hair follicles (HF), sebaceous glands (SG), and sweat glands (SWG). In order to investigate differences among substructures, tissues were analysed at high spatial resolutions (10 μm and 25 μm) under positive as well as negative ionization mode.

Data were pre-processed as described in Methods, and the obtained aligned data matrix underwent both supervised and unsupervised multivariate statistical analysis.

PCA analysis shows that groups of lipids can be identified to distinguish the different layers and structures at a spatial resolution of 25 μm for both minipig and human skin samples. For instance, a lipid was identified to be specifically localized in the epidermis and the external root sheath of hair follicles. Considering that the external root sheath consists of epithelial cells and finally merges with epidermis, this identification is consistent with histological interpretation. Another lipid was found to be specifically expressed in hair follicles that contain a shaft.

Moreover, in human skin samples, SWG and SG substructures were characterized, and by means of PLS-DA it was possible to identify lipids specifically located on those substructures. Noteworthy, a list of lipids specifically located in SG was identified for the first time.

At the higher resolution of 10 μm , it was possible to identify lipids discriminating EP from PD and substructures of SG in minipig and human skin.

Lipid specific for each substructure were tentatively annotated with LipoStar software and post-MALDI MSI H&E stained optical images were collected to confirm the structure identification. When isobars were identified, an additional inquiry to a database of lipids previously identified in skin samples allowed for a priority match assignment.

The obtained list of skin substructure-specific lipids provided a lipid mapping that will be a valuable help in future skin lipidomic investigations.

Conclusions

In this work we presented a novel high-throughput cheminformatic workflow to efficiently map skin lipids and ultimately achieve untargeted lipidomics with MALDI MSI.

With the aim of mapping skin lipids, both minipig and human skin samples were analyzed at 10 μm and 25 μm spatial resolution in positive as well as negative ionization mode. These two spatial resolutions allowed distinguishing among substructures of different size. Starting from the selection of different ROIs according to H&E staining, multivariate statistical algorithms (PCA, PLS-DA) were applied to enlightening analogies/differences among the different skin substructures (stratum corneum, epidermis, dermis, hair follicles, and for the first time, sebaceous glands). In the present work we focused our attention on finding substructure-specific lipids, that is, lipids that exclusively belong to a specific substructure. A first annotation of those lipids was also provided, resolving isobars conflicts by means of a database of lipids previously identified in skin.

Big challenges still remain, and these should guide the design of more sophisticated and fully integrated (from peak detection to pathway analysis, via lipid identification) workflow.

However, by designing a workflow to successfully bringing lipidomic studies to spatial molecular characterization, we believe that these results will pave the way to establish a data-driven histology interpretation of MALDI MSI analyses and ultimately achieve functional elucidation to support drug and biomarkers discovery.

Novel Aspect:

With the aim of performing for the first time an untargeted lipidomic analysis of skin by means of MALDI MSI, a novel cheminformatic workflow was designed to fish for lipids that are specifically localized in given skin substructures. Both minipig and human skin samples were analysed by MALDI MSI at unprecedented spatial resolution (10 μm and 25 μm) in positive and negative ionization mode. As a result, a relatively comprehensive set of specific lipids markers for epidermis, papillary dermis, hair follicles, and for the first time, for sebaceous glands is identified. To the best of our knowledge, this is the first time that histology interpretation of MALDI MSI analyses is achieved in a completely data-driven fashion. These results will guide further pathway analyses to achieve unprecedented functional interpretation, to comprehensively map skin lipids and ultimately support drug and biomarker discovery.

Keywords: *Linum usitatissimum*, Metabolites, MALDI, Orbitrap, Imaging

Introduction:

Flax (*Linum usitatissimum* L.) is used for fiber, oil, and nutraceutical production. *Fusarium oxysporum* f. sp. lini is the pathogen that causes fusarium wilt in flax. Epidemics of the disease can result up to 100% loss in yield. Some of flax genotypes are resistant to *F. oxysporum*, but the mechanisms of resistance are still unclear. Comparative analysis of metabolic changes in flax plants of resistant and susceptible cultivars in response to the pathogen infection is essential for understanding the role of metabolites in resistance and can be useful for development of antifungals.

Methods:

Seven-day-old seedlings of one susceptible (AP5) and two resistant (Dakota and #3896) flax cultivars were inoculated with spore suspension of *F. oxysporum* pathogenic isolate #39 from the phytopathogen collection of the All-Russian Research Institute for Flax. For control plants, sterile water was used instead of *F. oxysporum* spore suspension. After 48 hours from inoculation, root tips were collected. After that, roots were embedded in gelatin and gently frozen on dry ice. The frozen tissue was then sectioned into 25- μ m slices using a cryostat MK-25M (adapted for work with blades Leica DB80LS) at -20°C . The sections were thaw-mounted onto ITO slides. Matrix (40 mg/mL DHB in 50:50 water:acetonitril) was applied using an airbrush (iwata micron cm-b2). A MALDI-Orbitrap mass spectrometer (Thermo Scientific Q-Exactive orbitrap with MALDI/ESI Injector from SpectroGlyph, LLC) that was equipped with a 355nm laser (spot diameter of 20 μ m) was used in positive ion mode for imaging and MS/MS[1]. Spectra were obtained in mass range of m/z 100–1000, a mass resolution of 140,000. The tissue region to be imaged and the raster step size were controlled using the SpectroGlyph MALDI Injector Software. To generate images, the spectra were collected at 35- μ m intervals in both the x and y dimensions across the surface of the sample. Ion images were generated from raw files (obtained from orbitrap tune software) and coordinate files (obtained from MALDI Injector Software) by imageinsight software from SpectroGlyph LLC. MS/MS collision-induced-dissociation (CID) fragments were collected by isolating each m/z of interest and manually adjusting the collision energy for each compound. The “metabolites of interest” were identified by searching the accurate mass obtained with the Orbitrap instruments and the MS/MS data using MetFrag.

Results:

Metabolites in flax roots of susceptible and resistant cultivars inoculated with *F. oxysporum* or under control conditions were identified. For evaluation of metabolic responses to the fungal infection, comparative analysis was performed, and metabolites that were induced in resistant and susceptible flax genotypes after inoculation with *F. oxysporum* were identified. Resistance-related metabolites were determined. In the present study, we used susceptible and resistant flax cultivars, for which transcriptome analysis under the same conditions (inoculation with *F. oxysporum* isolate #39 and control) was performed by us previously, and diverse patterns of differentially expressed genes were revealed.

Conclusions

Complex analysis of transcriptome and metabolome data in flax plants with distinct resistance to fusarium wilt can be a promising tool for determination the mechanisms of resistance to *F. oxysporum*.

Novel Aspect:

Metabolite profiling was performed for inoculated with *Fusarium oxysporum* flax roots of susceptible and resistant to the pathogen cultivars.

482 - IDENTIFICATION OF ASBESTOS FIBRES IN A MALIGNANT MESOTHELIOMA MODEL

Oana Voloaca (1) - Laura Cole (1) - Malcolm Clench (1) - Amy Managh (2) - Sarah Haywood-Small (1)

Sheffield Hallam University, Biomolecular Science Research Centre, Sheffield (1) - Loughborough University, Chemistry, Loughborough (2)

Keywords: Mesothelioma, LA-ICP-MS, Mineral Fibres, Imaging

Introduction

Malignant Mesothelioma (MM) is an aggressive cancer of the mesothelium associated with exposure to specific Mineral Fibres (MF) [1]. There is an urgent need to develop methods to clearly identify and quantify the MF within biological samples [2].

The current project aim was to develop a biologically relevant MM model and use LA-ICP-MSI to determine the element distribution of MF within samples. Development of this technique would ultimately lead to early MM diagnosis.

Methods

MM models were developed using immortalised cells (NCIH28, MSTO211H, NCIH1975, Met5A) cultured in both 2D monolayers and 3D spheroids. Cells were exposed to various MF (concentration 0-25 µg/mL). Viability of the cultures was measured using Alamar Blue® and Hoescht/Propidium Iodide staining.

MALDI and LA-ICP-MS images were obtained at post-exposure following cell cytopsin and matrix coating. The spheroids were cryosectioned and fixed onto slides prior to the imaging.

Results

The MM models were successfully developed in both 2D monolayers spiked with MF and 3D spheroids with MF embedded within the cells. The Hoescht/Propidium Iodide staining showed an apoptotic core to the spheroids which translates to the in vivo tumour environments.

The cell viability results after MF treatment declined with exposure period, MF dose and most importantly MF type, which is in line with published literature [3]. Cell viability data of 2D models were also supported by Hoescht/Propidium Iodide images.

Some preliminary data has been acquired using LA-ICP-MS imaging, proving that this analytical method has high potential in identifying the MF within the cell cytopsin and can become a useful tool for clinical diagnosis of MM. Initial data has also shown that sections of the 3D MM model can be analysed by LA-ICP-MS and MALDI MSI to determine spatial distribution of lipids and proteins surrounding MF.

Conclusions

LA-ICP-MS has recently emerged as one of the most versatile imaging tools in biomedical research and the current study has showed great potential for its future integration in clinical settings. Method optimisation is needed before moving on to more complex 3D structures and histopathological lung tissue biopsies. MALDI MSI and flow cytometry will also be employed in future analysis of protein expression within MM samples and to support current data.

Novel Aspect

This project is the first attempt to develop a diagnosis method that uses LA-ICP-MSI to identify the full arrangement of MF at the cellular level within MM samples.

Introduction:

Non-alcoholic steatohepatitis (NASH) is an advanced form of Non-alcoholic fatty liver disease (NAFLD), and is recognized to often progress to cirrhosis and hepatocellular carcinoma[1]. A liver excised from an animal model raised to forcibly express NASH is quite useful to study the disease, because pathological findings of the organ are similar to the one from human patients. Whereas some metabolomics methods using LC- or GC-MS have been applied to the analysis of the organ, visualization of metabolites on pathological section is necessary to discuss disease states with relevance to various staining. We will present a metabolic profile of biochemical compounds in some pathological states, which is possibly related to a dynamics of the fibrosis in liver, by using MALDI imaging.

Methods:

Liver tissues were removed from 4w-, 8w-, and 16w-old male of NASH-model rat induced by high fat cholesterol diet. Dried liver sections were subject to MS imaging and some pathological staining (hematoxylin-Eosin, αSMA, sirius red, azan). Three sections with three corresponding controls were mounted onto an ITO-coated slide glass. 9-aminoacridine was sublimated onto the tissues at 0.5 μm thickness with a commercial instrument (iMLayer, Shimadzu Corp., Japan). After sublimation, a recrystallization of the coated matrix was conducted under vapor of a solvent consisted with methanol and water. MS imaging at 20 μm spatial resolution were performed with a MALDI-TOFMS (MALDI-7090, Shimadzu Corp., Japan) in negative mode at 2 kHz laser repetition, after a diameter of ablation by laser was validated. Newly developed in-house softwares were applied to visualization and analysis of all data.

Results: (Limit 900 characters)

Three liver tissues, 4w, 8w, 16w-treated, and each corresponding control tissues were subject to the high throughput MS imaging simultaneously, the advantage of which is that distributions of biochemical compounds can be recognized undoubtedly under the same matrix coating and laser irradiation. Targeted m/z of biochemical compounds obtained from LC- or GC-MS was visualized with in-house software. As typical case, since an increase of PS(18:0,18:1) and PI(16:0,18:2) in 8w- and 16w-treated liver was indicated with LC-/GCMS, m/z of both lipids were visualized to be compared with stained sections. Whereas the PS was extremely localized at fibrosis area, which was stained with azan and sirius red deeply, the PI was found at nodules in the liver tissues. Bile acids and their derivatives were also chosen as target molecules and visualized. Interestingly, whereas taurocholate and taurochenodeoxycholate distributed at nodule areas widely in 8w- and 16w-treated liver, there were significant narrow areas in the nodule, where only the taurocholate or the taurochenodeoxycholate were accumulated specifically. On the other hand, glycocholate were localized in fibrosis areas that were increasing along with the treated week. Two-dimensional operation included in the newly developed software was applied to find more precise relevance between a progress of fibrosis and a distribution of bile acids. Calculated images of NASH liver tissues obtained by dividing m/z 405 (glycocholate) by summation of m/z 498 and 514 (taurochenodeoxycholate and taurocholate respectively) indicated that a distribution of glycocholate was correlated with fibrosis areas stained with azan in detail. In general, fibrosis in liver is attributable to excessive production of collagen and extracellular matrix in hepatic stellate cell after liver injury by stress. Specific 2D profiles of bile acids and lipids shown here could

be caused with a change of global metabolism by the stress. A production of actual NASH liver in lab animals is still matter due to long necessary months. Raising the animals with high fat cholesterol diet is useful countermeasure to obtain almost the same pathology as the one in actual disease, however, pathological findings have been only the way to examine both tissues[2]. The 2D profiles obtained here is applicable to validate NASH-model at molecular level.

Conclusions:

Differently treated NASH-model livers were studied using MALDI imaging to discuss a relevance with a pathological progress. Not only a phospholipid but also both primary and secondary bile acids were mapped in fibrosis area that increases with the HFC-treated week.

2D profiles of those molecules targeted with metabolomics analysis indicate a validation of NASH-model tissue could be possible with MALDI imaging, which might contribute to investigation and development of novel medicine for NASH.

Novel Aspect:

MALDI imaging was applied to obtain metabolic profiles of bile acids and lipids in fibrosis of NASH-model liver.

968 - MATRIX-ASSISTED LASER DESORPTION/IONIZATION-MASS SPECTROMETRY IMAGING FOR DIRECT VISUALIZATION OF PLANT WOUND STRESS PHYTOHORMONES IN SITU

Chao ZHANG (1) - Karel Doležal (1) - Ondřej Novák (1)

Laboratory of Growth Regulators, Palacký University Olomouc, Olomouc (1)

Keywords: Plant wound stress, Jasmonic acid, abscisic acid, MALDI-MS Imaging

Introduction: The endogenous Jasmonic acid (JA) and abscisic acid (ABA) act as important roles in plant responding to wound stress [1]. Previous quantitative MS analysis has revealed JA and ABA levels in different damaged self-recognition stages, but changes of their spatial localizations on leaf are still unclear [2]. Aim to study JA and ABA biosynthesis and transportation in-situ, MALDI-MS Imaging was performed on leaf samples.

Methods: Leaf samples treated by mechanical damages were harvested in different healing time. Samples were cryosectioned and mounted on ITO slides, and then applied DHB matrix. MALDI-MS imaging was performed using MALDI SYNAPT G2 MS System (Water) with the mass range from m/z 50 to 1000. Further phytohormones ion intensity map creation and bioinformatics analysis were processed using in-house R scripts.

Results: 1. Intact masses of JA, ABA and other phytohormones were detected in the MALDI spectra. 2. Spatial distributions of phytohormones on leaf samples were highlighted in their ion intensity maps. 3. MALDI-MS imaging results showed unique hormonal patterns in different wound healing stages. 4. PCA analysis and hypothesis tests suggested levels of JA and ABA are correlated with other phytohormones.

Conclusions: MALDI-MS imaging demonstrates its applicability on phytohormones and their metabolites detection and imaging on plant tissues. Changes of JA, ABA and other phytohormones in the different wound healing stage are able to be visualized in-situ. Identified hormonal patterns provide a better understanding on plant wound stress and damaged self-recognition.

Novel Aspect: It is the first time that the change of JA and ABA localizations in leaf wound healing are visualized in-situ using MALDI-MS imaging.

GC-MS with Cold EI - Extending the Range of Compounds and Applications Amenable for GC-MS Analysis

Aviv Amirav, Alexander B. Fialkov, Tal Alon, and Uri Keshet

School of Chemistry, Tel Aviv University, Tel Aviv 69978, Israel.

Email: amirav@tau.ac.il Poster presentation

Introduction

The major shortcoming and Achilles Heel of GC-MS is its inability to analyze relatively non-volatile and thermally labile compounds. This problem is further exacerbated via the often weakness or absence of molecular ions in standard EI-MS.

GC-MS with Cold EI is based on GC and MS interface with a supersonic molecular beam (SMB) and electron ionization of the SMB vibrationally cold sample compounds in a fly-through ion source.

Method

We found that GC elution temperatures can be significantly lowered upon the reduction of column length and increase of carrier gas flow rate. The increase of column flow rate also lowers the elution temperatures from the injector liner into the column while ion source degradation is inherently eliminated in the fly-through ion source. Thus, GC-MS with Cold EI provides significant extension of the range of compounds and applications amenable for analysis.

Preliminary data

The transition from simple to incompatible for GC-MS analysis. As the sample compound size and polarity is increased its analysis by standard EI gradually becomes more difficult in all the performance aspects: TIC signal is reduced, molecular ion abundance is reduced, baseline noise is increased, peak tailing is increased, ion source degradation is increased, the response becomes non-linear and analysis time is increased until the analysis becomes non-practical. In contrast, with Cold EI these performance aspects decline are much weaker.

Large and labile compounds analysis. The analysis of all organic explosives including TATP, PETN, Tetryl and HMX will be demonstrated plus thermally labile carbamate pesticides, underivatized steroids and large triglycerides in oil and blood plus large synthetic organic compounds.

Isomer distribution analysis for fuels and oils characterization. The availability of molecular ions to all hydrocarbons uniquely enables isomer distribution analysis for improved fuels and oils characterization.

Novel Aspect

How GC-MS with Cold EI extend the range of compounds amenable for GC-MS analysis with new demonstrated applications

Keywords GC-MS with Cold EI

159 - DEVELOPMENT OF COMPREHENSIVE STEROID ANALYSIS METHODS USING GCXGC-TOFMS

Viatcheslav Artsev (1) - David Alonso (2) - Jonelle Shiel (3) - Georgy Tikhonov (1) - Albert Lebedev (4)

Keywords: TOFMS, HRMS, GCxGC, Steroids, Clinical

Introduction:

Identification and quantitation steroid metabolites in biological samples are essential for screening for various hormonal disorders. Many of these metabolites are closely related isomers and cannot be easily separated by LC or one dimensional GC due to their chemical and structural similarity. Comprehensive GCxGC coupled to a high resolution TOFMS provides enhanced chromatographic separation, better detection and identification of the analytes of interest.

Methods:

All data was obtained using the high resolution multiple reflecting geometry time-of-flight (TOF) mass spectrometer equipped with GCxGC with quad-jet, liquid nitrogen cooled thermal modulator and secondary column oven. We have tested various GC columns sets and oven temperature programs during GC method development. Steroids standards were obtained from Steraloids (USA) and Fisher Scientific (USA). Samples were derivatized using MSTFA method.

Results:

The steroid standards were analyzed individually and from that runs deconvoluted and curated mass spectra were obtained and included in the custom accurate mass library to assist in analytes identification in the complex mixtures. We present a workflow and analysis method that enables detection of 33 steroids from different classes in urine. Enhanced peak capacity provided by GCxGC allows separation of all analytes of interest, including structural isomers, which cannot be resolved or identified by other techniques. The high mass accuracy data along with automatic deconvolution algorithms provide reliable mass spectral information allowing accurate peak assignment. The method was transferred on to another analytical setup – the low resolution (LR) TOFMS coupled to GCxGC. Use of GCxGC-LRTOFMS represents a more practical approach of implementing the method for steroid analysis, while the HRTOFMS results can be applied for reliable analyte assignment by using HRTOFMS RI data and mass spectral match.

Conclusions:

The method is developed for comprehensive analysis of steroids in urine by GCxGC-HRTOFMS as well as GCxGC-LRTOFMS. The method allows taking full advantage of increased separation capacity of GCxGC and mass accuracy and sensitivity of the TOFMS. The reproducible sample preparation (derivatization, cleanup, etc) was the main challenge, and the future work will be focused on automation of the sample preparation process.

Novel Aspect:

33 steroids were simultaneously analyzed in complex biological matrix using GCxGC separation coupled with low and high resolution TOFMS with automatic data processing.

189 - USING ELECTROKINETIC INJECTION TO INCREASE THROUGHPUT AND IMPROVE SENSITIVITY IN THE DETECTION OF PROTEINS BY CE-MS

Walter Belloni (1)

Sciex, separations, Milano (1)

Using Electrokinetic injection to increase throughput and improve sensitivity in the detection of proteins by CE-MS

Jim Thorn¹, Stephen Lock¹, Walter Belloni² and Christopher Löbner²

B.01 Instrumentation and Methods – hyphenated techniques

Keywords: CE-MS, CESI, electrokinetic, sensitivity

Introduction:

Capillary electrophoresis (CE) is an orthogonal technique to LC separating compounds based on their charge. The properties of CE enable the reduction and often elimination of carryover and wall absorption which effects peak resolution and sensitivity of LC. In this work we will describe how a CESI-MS method has been developed to detect intact proteins between 15 -25,000 amu. CESI [the integration of capillary electrophoresis (CE) and electrospray ionization (ESI) into a single process in a single device] is now enabling the easy connection of CE to mass spectrometers.

Methods:

Protein standards were prepared in a variety of different solvents and injected by either pressure or electrokinetically onto a neutrally coated capillary under various conditions. The CE separation used MS amenable background electrolyte (BGE) consisting of a mixture of Acetic acid, Acetonitrile and Water. Proteins were detected by a MS system in MRM mode (using a capillary 30 µm ID, 91 cm long) which was fitted with a NanoSpray[®] III source which was used in either full scan or single ion monitoring mode with an ionspray voltage of 1600 - 1800 V which was optimized to the BGE being used.

Results:

The CESI-MS method was developed with the capability of detecting intact protein standards at <10 ng/mL. This study showed that electro kinetic injection was >40 fold more sensitive than an isotachopheresis (ITP) injection technique and a also more sensitive than a traditional LCMS approach and followed a similar trend as shown previously for neuropeptides. The response obtained was linear over the 2-3 orders tests with very low levels of carryover observed. Sensitivity depended on how well the protein ionized and one of the major factors shown to affect sensitivity on the electro kinetic injection was the levels of acetonitrile in the sample.

Novel Aspect: (Limit of 150 characters)

Increasing sensitivity for bioanalysis by using electrokinetik injection techniques

673 - MULTIVARIATE STUDY OF MATRIX EFFECT IN THE ANALYSIS OF PHYTOESTROGENS IN SOY-FOOD BY LC-ESI-MS/MS

Barbara Benedetti (1) - Marina Di Carro (1) - Emanuele Magi (1)

University of Genova, Department of chemistry and industrial chemistry, Genova (1)

Keywords: liquid chromatography-tandem mass spectrometry, matrix effect, experimental design, QuEChERS, phytoestrogens

Introduction

Matrix effect is an important aspect to consider when analyzing extracts from complex food matrices by LC-ESI-MS [1]. In fact, if no labeled standards are available, accurate quantitation is a difficult task. The work deals with the evaluation of matrix effect involved in the analysis of phytoestrogens in soy-based food. QuEChERS [2] were used as extraction/purification technique and the multivariate approach of experimental design was used to optimize the procedure.

Methods

The phytoestrogens daidzein (DAID), genistein (GEN), coumestrol (COUM), formononetin (FORM) and biochanin A (BIOCH) were extracted from soy-based burgers using the QuEChERS methodology: the steps involved are extraction by acetonitrile-water, phase separation by salts addition and clean-up. Two subsequent experimental designs were employed to study the factors influencing the procedure. LC-MS/MS in multiple reaction monitoring mode was used for the analysis.

Results

Matrix effect (ME) was assessed by comparing the analytes' signals in neat standards and in soy-burger extracts. A screening design (Plackett-Burman) [3] was employed to select the important variables involved in the QuEChERS procedure and affecting ME (response). No factors were significant for DAID and GEN; in fact, they were determined in diluted extracts, where negligible ME was observed. As for COUM, FORM and BIOCH, the factors considered statistically significant ($p < 0.05$) were: sample amount, PSA (Primary Secondary Ammine) sorbent and FLORISIL sorbent (used in the clean-up stage). A subsequent Box-Behnken design [4] allowed to obtain the response surfaces (models of the response as a function of the variables). The models for COUM and FORM were subjected to ANOVA and showed good R^2 coefficients (0.85 and 0.78 respectively). Conversely, the model for BIOCH was not significant. The optimal conditions to minimize ME (ion suppression $< 20\%$) were: 200 mg of sample (for 10 mL of solvent) and clean-up of 2 mL of extract with 40-50 mg of PSA and 80-90 mg of FLORISIL.

Conclusions

Thanks to the approach of experimental design and response surface methodology, it was possible to study the problem of matrix effect in LC-ESI-MS analysis of complex matrices (soy-based burgers). The QuEChERS procedure, including a clean-up step, was optimized with a limited number of experiments, despite the several factors involved. The method is cheap, rapid, does not require specific equipment and provides a valid alternative to the use of labeled internal standards.

Novel Aspect

Application of the multivariate approach to optimize matrix effect in the analysis of a complex and novel matrix (soy-based burger) without the use of internal standards.

70 - APPLICATION OF SPME GC-MS TO EXPLORE POSSIBLE DIFFERENCES IN FREE-LACTOSE MILKS FROM THE MARKET

Riccardo Bottiroli (1) - Eugenio Aprea (1) - Emanuela Betta (1) - Flavia Gasperi (1)

Edmund Mach Foundation, Food Quality and Nutrition Department, San Michele all'Adige (1)

Application of SPME GC-MS to explore possible differences in free-lactose milks from the market

Keywords: lactose-hydrolyzed milk, SPME GC-MS, volatile organic compounds

Introduction

Positive effects of milk on the human health are well-known. However, 70% of the global population is lactose intolerant [1]. For this reason lactose-free products, obtained adding lactase, have been released on the market [2]. According to the step in which lactase is added, downside effects can arise over time, due to its proteolytic side activity [3]. The present study aim to explore the potential of SPME GC-MS to catch VOCs profiling of commercial lactose-free milk.

Methods

UHT lactose-free milks from the local market, three freshly produced (FM1, FM2, FM3) and two after 180 days of storage (SM1 and SM2) were analyzed by SPME GC-MS according to Bergamaschi et al. (2015) [4]. Compounds were identified using the NIST-98/Wiley library and calculated retention indices (RI). Samples were compared by one-way ANOVA and Tukey post hoc test, when necessary, using the STATISTICA software (Dell Software Inc., Palo Alto, CA).

Results

Fifty-nine volatiles were identified and 64% of them were present in all the samples, suggesting differences in the VOCs profile. Many of those were already reported in other studies focused on lactose-free milk [3, 5, 6]. Fresh samples (FM1, FM2 and FM3) differed significantly for 7 compounds and 6 of them were higher in FM3. At the moment, we cannot speculate on the observed differences but the results suggested that the SPME GC-MS can catch the differences among milk batches. Fresh and stored milk differed significantly for 6 compounds, 5 of them having higher intensity after 180 days of storage (SM1 and SM2). Several of the VOCs that differed among the samples were methyl-ketones, well-known for their contribution to the off-flavor in UHT milk [7]. Some, such as 2-undecanone and 2-tridecanone, have long carbon chain and can be responsible for the heated flavor of milk [7]. The formation of methyl-ketones can also be addressed to the Maillard reaction, whose proceeding can be referred to the higher levels of these compounds found in SM1 and SM2.

Conclusions

The study indicated that the SPME GC-MS approach was able to catch differences in volatiles profiling of the milk tested. Conservation had a relevant impact and most of the changes were related to compound intensity. As the proteolytic side activities of lactase may play a role, it will be verified further. A shelf-life study is envisaged to verify the evolution of the VOCs profile in the samples and its contribution to the products sensory profile.

Novel Aspect

This study is an attempt to verify the suitability of the SPME GC-MS for tracking the evolution of the off-flavours formation in lactose-hydrolysed milk during storage.

123 - POST-COLUMN IN-SOURCE DERIVATIZATION IN LCMS: A TOOL FOR NATURAL PRODUCTS CHARACTERIZATION AND METABOLOMICS

Adriana Cirigliano (1) - Gabriela M Cabrera (2)

DQO, FCEN, Universidad de Buenos Aires, DQO, FCEN, Universidad de Buenos Aires, Buenos Aires (1) - DQO, FCEN, Universidad de Buenos Aires, UMYMFOR-DQO,UBA-CONICET, Buenos Aires (2)

Keywords: Post-column derivatization, LC-MS, in-source derivatization

Introduction:

Metabolite characterization is crucial for many aspects of basic research, such as de-replication of crude extracts in natural products chemistry or tentative identification in untargeted metabolomics. This information makes the subsequent decision-making process easier and more efficient. Derivatization with hydrazines is a known method in this respect, which allows the characterization of carbonyl functional groups [1-2].

Methods:

Liquid Chromatography-Mass Spectrometry was performed using Electrospray or Atmospheric Pressure Chemical Ionization as ionization techniques. The post-column addition of the reactants (hydrazines) was done by means of a syringe pump via a T-junction before entrance into the ion source. Experimental conditions were optimized. LCMS runs without addition were also performed for comparison.

Results:

Different compounds with at least one carbonyl group in its structure were analysed by this method. Triterpenoids like cycloartanes, steroids, cardenolides and other terpenoids were included in this study. All the analysed samples showed a similar behavior. The spectra of compounds with aldehyde groups exhibited as main signals those corresponding to the hydrazones, which are the expected products for the reaction between aldehydes and hydrazines. On the contrary, compounds with conjugated ketones did not react with hydrazines and did not show additional signals, and compounds having non-conjugated ketones presented in their spectra mainly those signals corresponding to the product of the nucleophilic addition adduct of hydrazine to the carbonyl group.

Conclusions

The in situ derivatization of carbonyl compounds in the ionization source was achieved, and applied in high-performance liquid chromatographic analysis. The typical derivatives of carbonyl compounds with hydrazines were obtained. Other reactions are being evaluated to further extend this method to other classes of derivatives.

Novel Aspect:

The use of post-column in-source derivatization in LCMS allows the characterization of compounds with carbonyl groups in their structures in a quick and easy way.

1180 - CONJUGATION AMONG NUCLEOTIDES AND CYANOCOBALAMIN FUNCTIONALIZED WITH CISPLATIN: A STUDY BY LIQUID CHROMATOGRAPHY COUPLED WITH ESI AND MULTISTAGE MS

Giovanni Ventura (1) - Cosima Damiana Calvano (1) - Andrea Viola (1) - Valeria Cinquepalmi (1) - Francesco Palmisano (1) - Tommaso Cataldi (1)

university of bari, chemistry department, bari, Italy (1)

Keywords: LC-MS, cisplatin, cyanocobalamin, RNA, prodrugs

Introduction:

Cisplatin has been largely used in antineoplastic therapy [1]; diverse drug delivery systems have been studied in order to reduce its serious side effects [2]. DNA is general accepted as the critical target for platinum-based compounds, nonetheless adducts between cisplatin and proteins [3], lipids [4] and RNA [5] might contribute to their effectiveness. In this study, interaction between cyanocobalamin-cisplatin (CNCbl-CP) prodrug and RNA bases has been studied via LC-MS.

Methods:

After the reaction between CNCbl and CP, a complex with empirical formula $[C_63H_{94}ClCoN_{16}O_{14}Pt]^+$ is generated [6]; its reactivity with in vitro incubation of individual adenosine monophosphate (AMP), guanosine monophosphate (GMP), cytosine monophosphate (CMP) and uridine monophosphate (UMP) in aqueous solution at 37 °C was studied by comparing results obtained using two different HPLC columns coupled to electrospray ionization and a linear ion trap (ESI-LIT) mass spectrometer.

Results:

The use of innovative drug delivery systems able to increase selectivity against cancer cells is a common strategy to reduce cisplatin toxicity; CNCbl functionalized with cisplatin is an example of prodrug. The formation of adducts between CNCbl-CP and RNA purine and/or pyrimidine bases was studied following two approaches: reaction was performed first on individual NMPs and later with competitive reactions in simultaneous presence of four NMPs. An appropriate gradient elution program based on methanol was developed to attain a separation both on a conventional and an amide-embedded ODS stationary phase; those two columns may provide complementary selectivity towards platinum adducts. All the NMPs react with CNCbl-CP by substitution of the last chlorine ligand on the cisplatin. The comparison between obtained and simulated isotopic patterns together with MS/MS analyses confirmed the presence of platinum in the reaction products.

Conclusions

From the obtained data it was clear that AMP and GMP are the most reactive nucleotides due to the presence of purine rings; three isobaric chemical species have been identified at m/z 965.8 for AMP, while a single protonated adduct at m/z 973.8 was generated for GMP. Also, adducts with CMP and UMP have been identified at m/z 953.8 and m/z 954.3, respectively. Plausible structures have been proposed by using tandem (MS/MS) and MS3 spectra.

Novel Aspect:

The interaction between CNCbl-CP and RNA bases has been proved by using HPLC-MS; the examination of fragmentation patterns was found very useful to gain insight into detailed molecular information.

1035 - ANALYTICAL METHOD FOR QUANTIFICATION OF BIXIN IN EXTRACT OF ANNATTO USING V-EASI(-)-LC-MS A METHOD SOFTER THAN ESI-LC-MS

Luan Felipe Campos Oliveira (1) - David Ulisses Tega (1) - Mirela B Coelho (1) - Damila Rodrigues de Morais (1) - Mariana Baptistão (2) - Marcos Nogueira Eberlin (1)

UNICAMP, Chemistry Institute, Campinas (1) - Unicamp, Chemistry Institute, Campinas (2)

Analytical Method for Quantification of Bixin in Extract of Annatto Using V-EASI(-)-LC-MS a Method Softer than ESI-LC-MS

Keywords:

Analytical Methods, mass spectrometry, V-EASI, LC-MS, Bixin

Introduction

Ventury Easy Ambient Sonic-Spray ionization (V-EASI) is a ionization source softer than electrospray (ESI) derived from Sonic Spray (SSI)[1]. Until now it has been little explored, used only for qualitative analyses[2-4]. This study is a proof of concept of an LC-MS system using the V-EASI source applied to develop a quantitative method of of bixin, a natural dye from annatto sensitive to high voltage[5].

Methods

The quantification was performed in LC-MS system using a Waters 510 chromatographic pump coupled with V-EASI source, and the quadrupole-mass spectrometer (LCMS shimadzu 2010), where was used the column C18 in the measurements. Methanol, bixin standard, lauric acid (internal standard), acetic acid (modifier) were used. For the validation, the guidance of validation from FDA was employed[6].

Results

The method was developed and optimized using the SIM mode for the ion of m/z 199 (lauric acid) and ion of m/z 393 (bixin) by V-EASI(-). We have found with the optimization the best analysis condition, as follow: 6 Bar of source, MS analyzer and block at the temperature of 250 °C, detector voltage of 1.50 kV, chromatographic run with 100% of methanol (0.05% acetic acid, v/v) where internal standard eluting at 3.8 min and bixin in 4.4 min. The validation data showed a linear range of 0.5 to 10 ppm, limit of detection and quantification of 0.02 and 0.07 ppm, respectively. The imprecision interday and intraday were 4.6% and 8.4%, respectively. The method also was considered accurate in an agreement with the official method by HPLC-DAD[7], it provides statistically equal results and has been shown to be a selective method with no matrix effect.

Conclusions

We were able to do the validation of a new V-EASI(-)-LC-MS method for bixin quantification, which presented similar results in comparison with the official method[6]. The method opens the perspective of a new system aiming the quantification of sensitive compounds and may be a new possibility for omics sciences.

Novel Aspect:

A powerful coupling among mass spectrometer, liquid chromatography and V-EASI source for the bixin quantification.

76 - SIMULTANEOUS QUANTIFICATION OF SIXTEEN POLYPHENOLS IN 31 LEGUMES BY USING HPLC-MS/MS DYNAMIC-MRM TRIPLE QUADRUPOLE

Giovanni Caprioli (1) - Massimo Ricciutelli (1) - Sauro Vittori (1) - Franks Kamgang Nzekoue (1) - Gianni Sagratini (1)

School of Pharmacy, University of Camerino, Camerino (1)

Keywords: polyphenols, triple quadrupole, HPLC-MS/MS, legumes

Introduction:

Pulses represent one of the most important traditionally dietary component worldwide, supplying proteins, dietary fibers, minerals and vitamins. The Food and Agriculture Organization declared 2016 the International Year of Pulses [1]. The potential health benefits of legumes are attributed to the presence of a wide range of phytochemicals including polyphenols that, according to the literature, are directly associated with antioxidant activity [2].

Methods:

Different extraction procedures such as acidic, basic and neutral extraction have been tested at different pH, by combining different temperatures and extraction times and the first one was the best. The separation of the different analytes was performed by using a Kinetex PFP column and the mobile phase was composed by water and methanol both containing 0.1% of formic acid. The analysis has been carried out by using HPLC-MS/MS Dynamic MRM triple quadrupole.

Results:

The polyphenols of interest are: shikimic acid, gallic acid, delphinidin, catechin, chlorogenic acid, epicatechin, vanillic acid, caffeic acid, siringic acid, cumaric acid, ferulic acid, 3,5 di-CQA, rutin, kaempferol, cyanidin, quercetin. Chromatographic run is very fast as 16 polyphenols elute within about 10 minutes. The approach used implied Dynamic MRM acquisition mode in which analytes are only monitored while they are eluting from the LC and valuable MS duty cycle is not wasted by monitoring them when they are not expected. The sensitivity of the Dynamic MRM method was higher with respect to the MRM one. The LODs achieved with Dynamic MRM method range from 0.0015 mg/l to 0.015 mg/l and LOQs ranged from 0.001 mg/l to 0.05 mg/l. Considering linearity, the obtained coefficients of correlation were in the range 0.9907-0.9998 for the MRM method and 0.9934-1 for the Dynamic MRM method.

Conclusions:

The application to real samples indicated that black beans (458.64 mg/kg) and ruviotto beans (189.02 mg/kg) displayed the highest amount of total polyphenols. This study highlights that the content of polyphenols is related with the dark color of coat pulses and that certain polyphenols are characteristic in specific pulses variety. These aspects may be useful for increasing the health knowledge of legumes and for proposing new functional foods.

Novel Aspect:

A new analytical method that uses HPLC-MS/MS and triple quadrupole in Dynamic MRM mode was developed for the analysis of sixteen polyphenols in pulses.

585 - THIN LAYER CHROMATOGRAPHY COMBINED WITH FLAME-INDUCED ATMOSPHERIC PRESSURE CHEMICAL IONIZATION MASS SPECTROMETRY (FAPCI/MS) FOR VOLATILE AND SEMI-VOLATILE COMPOUND ANALYSIS

Sychyi Cheng (1) - Jentaie Shiea (1)

National Sun Yat-sen University, Department of Chemistry, Kaohsiung (1)

Keywords: thin layer chromatography, desorption flame-induced atmospheric pressure chemical ionization

Introduction:

The combustion of hydrocarbons in a flame produces reactive ionspecies. In addition, the high temperature generated in a flame allows thermal desorption of small compounds on surfaces. A flame is therefore directed toward the sample to characterize analytes on surfaces, so called desorption flame-induced atmospheric pressure chemical ionization (DFAPCI). In this study, thin layer chromatography (TLC)was combined withDFAPCI/MS to analyze a mixture.

Methods:

The developed TLC plates were set on a XY stage and moved by a robotic platform for DFAPCI/MS analysis. A combustion head fabricated by arranging two concentric stainless steel tubes was utilized to generate a micro-flame. The combustion head was set at an angle of 45° with respect to the TLC plate surface. Volatile and semi-volatile compounds such as caffeine, drug molecules, and plant extracts were analyzed by TLC-DFAPCI/MS.

Results:

A light-brown line with 1-1.5 mm width was producedon the gel bed after analysis. This line clearly revealed the surface bearing a steam of heated jet from an oxyacetylene flame.The surface temperature of a TLC plate was measured to be 300 ± 10 °Cas the plate passing through the desorption/ionization (DI) region. A mixture containing nicotinamide, 2-phenylacetamide,and dibenzylamine was separated by a silica gel TLC plate for the subsequent DFAPCI/MS detection.Positive ions ofnicotinamide (m/z 123, $[M+H]^+$),2-phenylacetamide (m/z 136, $[M+H]^+$), and dibenzylamine (m/z 196, $[M-H]^+$) were detected.The limit of detections (LODs) of TLC-DFAPCI/MS for the analysis of three standards were tested and concluded to be 50 ng/spot for nicotinamide, 25 ng/spot for 2-phenylacetamide, and 5ng/spot for dibenzylamine. Samples such as amine and amide standards, drug molecules, and aromatherapy oil were successfully characterized by TLC-DFAPCI/MS.

Conclusions:

Compared with other TLC-AMS approaches, TLC-DFAPCI/MS shows advantages including cheap, simple instrumental setup, and easy to be fabricated. Since the analytes were vaporized by a heat, TLC-DFAPCI/MS was suitable to characterize volatile, semi-volatile, and thermally stable compounds. We are combing laser desorption (LD) with FAPCI/MS, which will be capable of detecting non-volatile substances.

Novel Aspect:

Thin layer chromatography (TLC)has combined with desorption flame-induced atmospheric pressure chemical ionization(DFAPCI) to analyzea mixture.

978 - EVALUATION OF GAS CHROMATOGRAPHY COUPLED TO ELECTROSPRAY-ATMOSPHERIC PRESSURE PHOTON IONIZATION ORBITRAP MASS SPECTROMETRY AS AN ADVANCED STRATEGY FOR POLYAROMATIC HYDROCARBON ANALYSIS

Yunju Cho (1) - Eunji Cho (2) - Sunghwan Kim (1)

Green-Nano Material Research Center, Kyungpook National University/Chemistry, Daegu (1) - -, Kyungpook National University/Chemistry, Daegu (2)

Keywords: Orbitrap, Gas chromatography, Mass spectrometry, High resolution, polyaromatic hydrocarbons

Introduction: Heteroatom containing PAHs (HPAHs) play an important role in petroleomics due to their toxicity, stability in links of the catalyst development during oil refining process. However, general GC-EI/MS is not suitable for polar PAHs due to ionization process. [1] Also, no single ionization technique has capability to ionize different variety of compounds. [2] In this study, GCESI-APPI MS provides a technique with high sensitivity and accurate m/z values of the HPAHs.

Methods: About thirty PAHs including nitrogen, sulfur and oxygen containing compounds were used for the establishment of GC ESI-APPI orbitrap MS conditions. GC was performed using an Agilent 7890A equipped with in-house heated column transfer line that was heated by a programmable temperature controller with a temperature sensor. [3, 4] Mass spectrometer was orbitrap Q-Exactive (ThermoFisher Scientific Inc.) equipped with an ESI source and APPI lamp.

Results: Depending on the analytes, GC has been coupled to various detectors, e.g. MS, FID and NPD. GC-MS is the most commonly employed in EI. But EI may be lost the parent ion of the analytes because of extensive fragmentation. FID is the presence of heteroatoms in molecular decreases the detector's response. To solve this problem, element-selective detectors, like NPD, have been used. But NPD has limited signal stability due to mechanism of detection that is based on the bead. [1] To overcome such concerns, orbitrap MS with high sensitivity and resolution were applied to the HPAHs combining ESI which is soft ionization causing minimal fragmentations and APPI that it has been used to study PAHs in oils [5] hyphenated GC. The several ESI solvents were compared [6] and acetone showed the best ionization efficiency among the tested solvents. Also it is observed that the results using GC ESI-APPI MS for HPAHs is higher sensitivity than using GC-MS with single ESI source. Therefore, the GCESI-APPI MS is suited for simultaneous analysis of HPAHs as an advanced ionization.

Conclusions: The aim of this research was to evaluate an instrument to couple GC with high-resolution orbitrap MS using an ESI source and APPI lamp. The studies demonstrated that the GC ESI-APPI MS has more element-selectivity, sensitivity and accuracy even better than obtained with traditional GC EI/MS for HPAHs. Therefore, we expect that this method should be useful in the selective analysis of complex mixtures as nitrogen-rich oil, spilled oil, metabolite and humic substances.

Novel Aspect: GC coupled to high-resolution orbitrap MS with ESI-APPI was used to evaluate heteroatom containing PAHs analysis at the molecular level compared with GC ESI MS and GC EI MS.

791 - ONLINE COUPLING OF NON-DENATURING CHROMATOGRAPHY TO NATIVE MASS SPECTROMETRY IS NO MORE AN IMPOSSIBLE MARRIAGE

Anthony Ekhkirch (1) - Oscar Hernandez-Alba (1) - Thomas Botzanowski (1) - Sarah Cianféroni (1)

LSMBO/IPHC, University of Strasbourg/CNRS UMR7178, Strasbourg (1)

Keywords: native mass spectrometry, ion mobility, LC-MS, therapeutic protein

Introduction:

Mass spectrometry performed in non-denaturing conditions (native MS or IM-MS with ion mobility) has gained interest for the qualitative and quantitative characterization of intact proteins. However, online hyphenation of non-denaturing chromatographic (ndLC) techniques to native MS/IM-MS is still not straightforward, which hampers its routine use in high throughput automated environments.

Methods:

The 1DLC-MS system consists of an Acquity H-Class coupled to a Synapt G2 HDMS (Waters). Several Acquity BEH SEC (Waters) columns were used for 1D SEC-native MS. For 2D LC-MS, an Acquity I-Class was added to the 1D setup. For the 1st dimension, the column was a MAbPac HIC-10 (Thermo Scientific) or a Yarra SEC-X300 (Phenomenex); the 2nd SEC dimension was an AdvanceBio SEC (Agilent Technologies).

Results:

We present here 1D and 2D LC-MS setups for online coupling of ndLC to native MS for the intact protein analysis. Native MS is mostly performed in ammonium acetate (AcONH₄) [1] while ndLC techniques (e.g. size exclusion SEC or hydrophobic interaction HIC chromatography) require large amounts of non-volatile salts [2]. We present here the benefits of 1D SEC-native MS in AcONH₄ for automated online buffer exchange and protein aggregation studies [3]. As AcONH₄ is not optimal for HIC/SEC, a multidimensional approach combining HIC/SEC in the 1st dimension and SEC in the 2nd one (HICxSEC or SECxSEC) was developed. The 1st ndLC dimension (HIC/SEC) aims at achieving optimal protein separation, while the 2nd ndLC (SEC) serves for fast desalting. Benefits of HIC/SECxSEC-native MS/IM-MS are shown for different types of proteins, including monoclonal antibody-based (mAb) products and amyloid proteins.

Conclusions

Our results demonstrate the possibility to online couple ndLC to native MS/IM-MS. Benefits of ndLCxLC-native MS/IM-MS setups provided comprehensive and streamlined characterization of different types of proteins [4]. The synergic online coupling HIC/SEC to native MS/IM-MS is envisioned to definitely push native MS approaches at the forefront of intact protein characterization.

Novel Aspect:

Online hyphenation of non-denaturing LC to native IM-MS

1D SEC-native MS/IM-MS

2D HIC/SECxSEC-native MS/IM-MS

1101 - IDENTIFICATION AND TIME VARIATION ANALYSIS OF PERFUME BY USING GCXGC/HRTOFMS WITH EI/FI/PI

Robert Cody Robert (1) - Michael C. Long (2) - A. John Dane (1) - Koji Okuda (1)

JEOL USA, Inc., Mass Spectrometry, Peabody, MA (1) - Biopalette, Inc., Independent, Troy, NY (2)

Keywords: Perfume analysis, ComprehensiveGC, High resolution, High mass accuracy, Soft ionization

Introduction: (Limit of 400 characters)

GCxGC-TOFMS is a powerful tool for measuring complex samples. Using EI with this method allows for NIST searches, but these searches may result in mis-assignments without additional exact mass information for the molecular ion as generated through soft ionization techniques like FI or PI. In this study, we measured perfume oil by using GCxGC-HRTOFMS with EI, FI and PI.

Methods: (384, Limit of 400 characters)

All samples were measured by using a high resolution TOFMS and GCxGC system. A pure perfume oil was qualitatively measured using EI, FI and PI. For the time studies, 0.1 μ L of pure oil for the same perfume was placed in a 22 mL vial and heated at 35°C for 0 hour, 0.5 hour, 1 hour and 3 hours. Afterwards, the headspace was sampled by using a SPME fiber and then measured with GCxGC FI.

Results: (788, Limit 900 characters)

The 2D chromatograms for EI, FI and PI showed the same retention time (R.T.) patterns. Additionally, the FI and PI data showed stronger molecular ion signals than the EI data. As an example, the peak detected at R.T. 25.70 minutes (1st column) and 1.55 seconds (2nd column) showed relatively high fragment ion intensities for the EI measurements. The NIST search for this mass spectrum showed several compounds with a match factor over 900 but with different chemical compositions. In order to narrow down the possibilities, it was necessary to measure the molecular ion using FI and PI. The results for these techniques showed an accurate m/z value within 1 mDa of the calculated mass for C₁₂H₂₀O₂. This estimated composition narrowed the EI library search candidate to linalyl acetate.

Conclusions (337, Limit of 400 characters)

The combination of EI fragmentation information with the accurate mass molecular ion information from FI and PI provided a means for narrowing down the NIST library search to help identify the compounds measured. We will present the qualitative results for the other compounds in the sample along with the perfume time variation studies.

Novel Aspect: (104, Limit of 150 characters)

Qualitative and quantitative analysis of perfume by GCxGC-HRTOFMS with EI, FI and PI ionization Methods:

1116 - SECONDS-PER-SAMPLE: NOVEL ACOUSTIC HYPHENATED APPROACHES TO ENABLE TRULY LABEL-FREE ULTRA HIGH-THROUGHPUT AMBIENT MASS SPECTROMETRY ADVANCING DRUG DISCOVERY

Sammy Datwani (1) - Lucien Ghislain (2)

Labcyte, Inc - Chemistry, San Jose (1) - Labcyte, Inc. - Chemistry, San Jose (2)

Keywords: Acoustic droplet ejection (ADE), Acoustic mist ionization (AMI), Open port probe (OPP)

Introduction:

A truly label-free ultra-high throughput screening technology is the “holy grail” platform for drug discovery. We have integrated acoustic droplet ejection (ADE) technology that couples ambient mass spectrometry with two novel approaches enabling low sample consumption (nanoliters), low cost and ultra-high-throughput.

Methods:

We first highlight the principles of ADE and key technologies that enable robust acoustic liquid handling operations. The first modality utilizes direct electro spray ionization (ESI) whereby ADE delivers up to 1,500 spray events per second from an assay well in a microplate into the MS via a heated transfer optic [1]. The second modality explores an exciting method of sample injection to the MS by integrating ADE with 2.5 nL droplets into an open-port probe (OPP) sampling interface [2].

Results:

The first modality, acoustic mist ionization (AMI), integrates ADE with a Waters Xevo G2-XS QToF mass spectrometer. The utility of this integrated system as an ultra-high throughput platform in this format was demonstrated on a biochemical screen of more than 250,000 compounds identifying new and novel inhibitors of a relevant drug target. The sample assay was able to tolerate the changes to buffer conditions without impacting enzyme activity or kinetics. A data processing algorithm was designed to deal with large sample batches. In the second modality the ADE-OPP-ESI-MS system operates with a continuous-flow of carrier solvent (MeOH) for direct sample dilution that also actively cleans the entire flow system, mitigating carry over. “Classic” ESI ion source used in this setup enables detection of a broad range of analytes including small drug molecules, antibody standards, peptides (MW>1500) and proteins. High sensitivity (attomol loading for small molecules, or sub-femtomol for intact antibody) and reproducibility (<8% CV) was demonstrated without internal standard normalization.

Conclusions

We highlight ultra-high throughput ambient mass spectrometry hyphenated approaches with an acoustic sample introduction interface — a MS based plate reader that enables broad applications in drug discovery. Next steps on the commercialization perspectives are addressed with these two modalities and the need to integrate the MS spectra “big data” collection to support label-free ultra-high throughput ambient MS and advance the state of the art for drug discovery.

Novel Aspect:

Novel acoustic hyphenated sampling approach with mass spectrometry for ultra-high throughput label free screening and other applications in drug discovery.

Chuanfan Ding (1) - Fuxing Xu (1)

Fudan University, Chemistry Department, Shanghai (1)

Keywords: Linear ion trap, Electric field radius, Hyperbolic electrode, non-hyperbolic electrodes.

Introduction:

The electric field radius is a fundamental character of an ion trap, it measures the basic properties of ion trap. For a quadrupole ion trap with idea hyperbolic electrode, its electric field radius can be simply obtained by its geometrical structure, but it is very difficult to calculate the electric field radius if it was built with non-hyperbolic electrodes. In this work, the electric field radii of different size rectilinear ion traps were measured by experiments.

Methods:

The rectilinear ion traps with 5.0mmx5.0mm, 5.50mmx5.00mm, 6.00mmx5.00mm, 6.50mmx5.00mm, and 7.00mmx5.00mm respectively were used for radius testing. All experiments were performed using an electrospray ionization (ESI) rectilinear ion trap mass spectrometry. The digital power supply was used for both ion trapping and dipolar excitation of mass selected ion during CID experiments. And the electric field radius of each ion trap was deduced by the results.

Results:

For a quadrupole linear ion trap (LIT) with hyperbolic electrodes, the ion motion inside ion trap can be described by Mathieu equation.

$$q = \frac{4eV}{mr^2\Omega^2} \quad (1)$$

And we can get following (2) from (1):

$$\frac{m}{e} = \frac{V}{qr^2\pi^2} T^2 \quad (2)$$

Whether an ion of m/e can be trapped depends on the radial size r , or it is so called the electric field radius, the RF angular frequency $\Omega=2\pi f$, the voltage (V), and q . The property of an ion trap, such as the ion trapping capability, ion mass range and so on are mainly dependent on the ion trap parameters, and particularly, the electric field radius. For a LIT with non-hyperbolic electrode such as rectilinear ion trap, its r cannot be directly deduced from equation (1). But it can be measured by CID experiment when a ion of m/e was performed at the optimal RF period of T according to (2) when V is fixed.

For the rectilinear ion traps with 5.0mmx5.0mm, 5.50mmx5.00mm, 6.00mmx5.00mm, 6.50mmx5.00mm, and 7.00mmx5.00mm, their measured electric field radii were measured, and they are 4.89mm, 5.15mm, 5.30mm, 5.79mm and 6.10mm respectively.

Conclusions

The electric field radii of rectilinear ion traps can be measured by experiments. For proving the reliability of this method, a hyperbolic electrode ion trap with $r_0=4.00$ mm was built and its measured electrode field radius was 4.07mm.

Novel Aspect:

The electric field radii of different size rectilinear ion traps were measured by experiments.

224 - UNIVERSAL ELECTRODE FOR QUADRUPOLE ELECTRODE SYSTEMS

Mikhail Dubkov (1) - Mikhail Burobin (1) - Vladimir Ivanov (1) - Alexandr Malutin (1) - Victor Gurov (1)

Ryazan State Radio Engineering University, Department of General and Experimental Physics, Ryazan (1)

Keywords: quadrupole mass filter, universal hyperbolic electrode

Introduction

It is offered to create quadrupole mass-analyzers as short identical units-monoblocks with the relevant electrodes concatenated mechanically and electrically to form the unified system of electrodes [1, 2]. Each unit-monoblock consists of all-purpose hyperbolic electrodes which are concatenated with the help of ceramic isolators.

Methods

To create an all-purpose hyperbolic electrode the electrolytic molding technology [3] which allows making thin-walled copper electrodes (1–2 mm) with high accuracy was applied.

Results

The design principle described is worked in practice. The all-purpose hyperbolic electrode is made of copper by the electrolytic molding method, its length is 75 mm, its wall thickness is 1–1,5 mm. The electrode is clothed in coating of 5–10 micron thickness by means of electrical deposit. The peripheral zone houses manufacturing holes which allow fastening electrodes together with a screw through ceramic isolators. The webbing along the electrodes' ends in addition to its intended purpose is for the fastening of separate electrodes' units together during the assembling of extended systems as well as for the setting of the whole electrodes' system in vacuum chamber. The quadrupole mass filter was created with the using of the all-purpose hyperbolic electrodes.

Conclusions

The all-purpose hyperbolic electrodes allow creating quadrupole electrodes' system as separate blocks which can be connected with each other to get transit-time mass-analyzers of practically any length. The longitudinal distortion of electrical field doesn't occur as the accuracy depends on the performance quality of a separate monoblock.

Novel Aspect

The application of the all-purpose hyperbolic electrode created by the electrolytic molding method with one precision form usage for quadrupole mass-analyzers creation.

165 - DEGRADATION STUDIES OF THE ANTIBIOTIC SULFAMETHOXAZOLE UTILIZING HPLC/MS.

Kevin Eckey (1) - Uwe Karst (1)

University of Münster, Institute of Inorganic and Analytical Chemistry, Münster (1)

Keywords: Sulfamethoxazole, HPLC, ICP-MS, Hyphenation, Environmental

Introduction:

The removal of micropollutants from surface waters is a topic of growing awareness. Not all xenobiotics are sufficiently removed by wastewater treatment plants, so additional disinfection steps such as ozonation or direct photolysis utilizing UV light are investigated. Many of these procedures are already well elucidated regarding degradation efficiency or energy costs but only few studies deal with the identification of formed products and their toxicity.

Methods:

Sulfamethoxazole (SMX) solutions adjusted to pH 3 and pH 8 respectively were degraded using direct photolysis (220-500 nm). The resulting transformation product mixture was characterized using HPLC/ESI-HRMS and fragmentation experiments. Sulfur-containing compounds were quantified using HPLC/ICP-TQ-MS.

Results:

In the present study, the degradation of the frequently used antibiotic sulfamethoxazole (SMX) was investigated using photolysis as degradation process focusing on the identification and characterization of formed transformation products by means of high performance liquid chromatography coupled to electrospray-mass spectrometry (HPLC/ESI-MS). The SMX solutions were pH-adjusted using a phosphate buffer to study the pH dependency of the product generation. In a further step, formed transformation products containing sulfur were quantified using HPLC/ICP-TQ-MS. From the quantitative data, rate constants of the photolytic degradation could be determined.

Conclusions:

More than 30 degradation products were found, with some being already described in literature. It was shown that the pH value has a great impact on the SMX degradation behavior and on the selection of formed transformation products.

Novel Aspect:

An HPLC/ICP-TQ-MS hyphenation was developed for the quantification of sulfur-containing organic compounds and the method was optimized to an LOD of about 100 ng/mL.

87 - SPEEDING UP GC-MS ANALYSIS – FROM FEW MINUTES DOWN TO REAL-TIME ANALYSIS

Alexander Fialkov (1) - Uri Keshet (1) - Tal Alon (1) - Aviv Amirav (1)

School of Chemistry, Tel Aviv University, Tel Aviv (1)

Speeding up GC-MS analysis – From Few Minutes Down to Real-Time Analysis

Alexander B. Fialkov, Uri Keshet, Tal Alon and Aviv Amirav
School of Chemistry, Tel Aviv University, Tel Aviv 69978, Israel,

Introduction

Fast analysis requires speed optimization of the whole analysis including sample collection, introduction, separation, detection, identification and quantitation. We developed instruments and methods that each facilitates faster GC-MS analysis:

Fast GC, Open Probe Fast GC and GC-MS with Cold EI.

Method

The fast GC is based on a short capillary column inside thin walled metal tube that is resistively heated to provide sub one minute separation. Open Probe is based on a heated oven that is mounted on a low thermal mass fast GC which is open to room air with helium purge flow protection to prevent air penetration. Open Probe fast GC-MS operation is simple: touch the sample with a holder, insert it into the Open Probe and start running with 30 s separation and 50 s ready for next sample.

Preliminary data

We evaluated our low thermal mass Fast GC with Agilent 5975 GC-MS with standard EI and with GC-MS with Cold EI and demonstrated sub-one-minute full analysis cycle time. With the concept of low pressure chromatography we found that a mere factor of four loss of GC separation could bring a factor of 64 faster GC separations.

Open Probe Fast GC-MS provides sub-one-minute full analysis times, including sample preparation. Thus, Open Probe Fast GC-MS acts like the range of ambient desorption ionization techniques yet with separation, library identification at the isomer level, superior sensitivity and the use of low cost single quad MS of GC-MS.

Novel Aspect

New instruments and methods for low thermal mass fast GC and Open Probe Fast GC-MS for sub one minute fast GC-MS and real time analysis with separation

Keywords Real time analysis with separation

86 - THE IMPORTANCE OF ENHANCED MOLECULAR IONS IN GC-MS

Alexander B. Fialkov (1) - Uri Keshet (1) - Tal Alon (1) - Aviv Amirav (1)

School of Chemistry, Tel Aviv University, Tel Aviv (1)

The Importance of Enhanced Molecular Ions in GC-MS

Alexander B. Fialkov¹, Uri Keshet¹, Tal Alon¹ and Aviv Amirav^{1,2}

1. School of Chemistry, Tel Aviv University, Tel Aviv 69978, Israel,
2. Aviv Analytical Ltd, 3 Haarad Street, Tel Aviv 69710, Israel.

Introduction

A major limitation of GC-MS is the weakness or absence of molecular ions in its standard EI mass spectra. Enhanced molecular ions by the use of EI of cold molecules (named "Cold EI") has many benefits.

Method

We used GC-MS with Cold EI based on the combination of an Agilent 5977 MSD with the Aviv Analytical supersonic molecular beam (SMB) interface and fly-through ion source with electron ionization of internally cold molecules in the SMB (hence the name Cold EI) and the following are its benefits:

Preliminary data

Cold EI provides both enhanced molecular and fragment ions thus it is the only "soft" ionization method that is compatible with library identification.

Unexpectedly, enhanced molecular ion actually improves NIST library identification probabilities.

Molecular ions strongly decline with mass in standard EI (20% for added carbon in hydrocarbons) while in Cold EI it is about size independent.

Cold EI eliminates vacuum background and reduces column bleed thus make it easier to visually identify the molecular ions than standard EI and/or ESI-LC-MS.

Enhanced molecular ions and high mass fragments provide extended structural and isomer information.

Molecular ions enables the use of TAMI software with unit resolution quadrupole MS for the conversion of isotopomeric abundances into elemental formula.

Matrix interference is reduced with mass thus it is reduced on molecular ions no less than with MS-MS on fragment ions.

The molecular ions in large compounds provide superior sensitivity in SIM or RSIM.

Novel Aspect

How enhanced molecular ions in GC-MS with Cold EI improve GC-MS based sample identification and several other GC-MS performance aspects

Keywords Benefits of enhance molecular Ions

208 - STUDY OF ENDOCRINE DISRUPTING COMPOUND RELEASE FROM MEDICAL DEVICES IN PLASMA SAMPLES OF PREMATURE NEWBORNS THROUGH AN ON-LINE SPE UHPLC-MS/MS METHOD

Fabio Gosetti (1) - Bianca Bolfi (1) - Marcello Manfredi (1) - Elisa Robotti (1) - Federica Ferrero (2) - Gianni Bona (3) - Emilio Marengo (4)

University of Piemonte Orientale, Department of Science and Technological Innovation, Alessandria (1) - Ospedale Maggiore della Carità, Terapia Intensiva Neonatale, Alessandria (2) - University of Piemonte Orientale, Department of Health Sciences, Novara (3) - Alessandria, Department of Science and Technological Innovation, Alessandria (4)

Keywords: endocrine disrupting compound release; migration; medical devices; mass spectrometry; perfluorochemicals

Introduction: Endocrine disrupting compounds (EDCs) are exogenous substances that mimic/antagonize the endogenous hormone effect. Everyday people are exposed to many products containing EDCs such as plastic containers, cladding films in aluminum food cans, medical devices (MDs), and personal care products. The underdeveloped reproductive apparatus and immune system of newborns can be exposed to unusually high concentrations of EDCs difficult to metabolize or excrete [1].

Methods: The study deals with the development of an online UHPLC-MS/MS method for the determination of 25 EDCs belonging to different chemical classes (perfluorochemicals PFCs, bisphenols, alkylphenols, phthalates, and parabens). To evaluate the possible EDC migration from different MDs of diverse materials used for blood sampling or for parenteral nutrition therapies, the devices were put in contact with physiological and parenteral solutions at prefixed time.

Results: The first step of the study was to identify a possible release of EDCs from the MDs and successively the EDC accumulation in plasma of the hospitalized newborns during the therapies to which infants have been subjected. The results demonstrated the released of some EDCs (such as parabens at concentration of few $\mu\text{g mL}^{-1}$, diethylphthalate and dibutylphthalate at ng mL^{-1} level), when using physiological solution as the leaching agent. In addition, the presence of a PFOS structural isomer was found at 25.0 ng mL^{-1} : this compound was released in part from the infusion tubes and mostly from the venous catheters. The releases from the infusion tubes of the same materials (PE) from different manufacturers are very comparable, whereas the catheter of silicone releases greater amount of EDCs than that of polyurethane. As concerns plasma samples, butylparaben has greater concentrations in healthy newborns than in premature ones, while PFOA and PFHpA show greater concentrations in newborns hospitalized in neonatal intensive care unit.

Conclusions: The developed and validated method is attractive for routine analysis as it is characterized by high sensitivity, selectivity, robustness and reduced runtime analysis. The release from MDs of different plastic materials were investigated and diverse amount of EDCs ranging from a few $\mu\text{g mL}^{-1}$ to about twenty $\mu\text{g mL}^{-1}$ were found. EDCs were present also in the plasma of newborns and their monitoring have to be taken into consideration to avoid pathologies.

Novel Aspect: A new method has been developed and validated to quantify the migration of 25 EDCs belonging to different chemical classes (including PFCs) from MDs in plasma.

540 - TRIODE-TYPE MCP-BASED ION DETECTOR ENABLING MINIATURE MASS SPECTROMETERS TO OPERATE AT LOW VACUUM UP TO 1PA

Masahiro Hayashi (1) - Yuya Washiyama (1) - Kentaro Ishii (1) - Joji Sakakiyama (1)

Hamamatsu Photonics K.K., Electron Tube Division, Hamamatsu (1)

Keywords: microchannel plates, triode structure, low vacuum operation, miniature mass spectrometer

Introduction:

Recent interest in portable mass spectrometry applications has spurred a great deal of research into the development of miniature mass spectrometers (MS) such as desktop type explosives trace detectors (ETDs). In the near future, there is a possibility that ETDs used at checkpoint screening will change from the current ones based on ion mobility spectrometers to ones based on next-generation MS.

In order to retain the major advantage of portability, miniature MS systems typically use small vacuum pumps with relatively low pumping speeds, meaning the miniature MS has to be operated at relatively low vacuum levels ($>1e-2$ Pa). Also in terms of sensitivity and vacuum condition, almost all miniature MS systems under development have adopted the ion trap analyzer. In these system configurations, ion detectors are required to have both low vacuum operation ($>1e-2$ Pa) and high gain ($>1e+6$). Currently, channel electron multipliers (CEM) are mainly used in miniature MS, but it is difficult for CEM to satisfy the required specifications.

Conventional electron multiplier based detectors including CEM and microchannel plates (MCP) cannot be adapted to operate at low vacuum ($>1e-2$ Pa) because of ion feedback (IFB), which causes discharges and decreases in S/N. However, the reduced dimensions of a typical MCP detector, which can be less than the mean free path in conventional electron multiplier based detectors, make it suitable for operation at low vacuum. The major source of IFB, which is a peculiar phenomenon of secondary electron amplification, was found to be the creation of ions from residual gas molecules.

We concluded that controlling the residual gas ions is more important than suppressing the ion generation. In order to realize this idea, we introduced a triode structure into the conventional MCP detector to enable it to operate at low vacuum condition.

Methods:

The mechanism of IFB in an MCP detector was investigated, and it was found that 1) IFB is caused by EI-generated residual gas ions, which are generated between the MCP-out and an anode by the reaction of residual gas and electrons from the MCP, 2) after traveling in reverse through the MCP channel, the residual gas ion generates secondary electrons by impinging on the MCP channel surface, and 3) IFB occurs repeatedly like an avalanche phenomenon and it becomes a huge noise signal. We concluded that controlling residual gas ions is more important than suppressing ion generation.

Almost all MCP-based ion detectors have a bi-planar structure which consists of a chevron stack MCPs and an anode. The potential is $MCP-in < MCP-out < anode$, so the residual gas ions (+) return to the MCP and cause an IFB. The triode structure has a mesh electrode placed between MCP-out and a dynode as the third electrode. The aim of adopting the triode structure is to prevent positive ions returning to the MCP. Therefore, the novel potential is $MCP-in, dynode < MCP-out < mesh$, so that the dynode can function as an ion capture electrode and the mesh as an electron capture electrode.

It is confirmed that the triode structure prevents ion feedback at low vacuum condition by evaluating various characteristics. Since the usual electron gun could not be operated at low vacuum condition, ultraviolet rays were used as input signals instead of electrons. The vacuum pressure of the chamber which contained the triode MCP detector was controlled by opening and closing the manual gate valve and monitored with a vacuum gauge. It was

difficult to keep the vacuum pressure constant in the high pressure region, and it slowly deteriorated during the measurement.

Results:

The prototype triode MCP detector was examined using standard MCP detector characterization equipment in high vacuum levels ($1e-4$ Pa or less), which is the recommended environment for the standard MCP detector. The gain characteristic of the triode MCP detector was $5e+6$.

The triode detector operated in two potential modes: a) bi-planar mode [MCP-in < MCP-out < mesh = dynode (connected)], b) triode mode [MCP-in = dynode < MCP-out < mesh]. When the gain of MCPs was lower ($1e+3$ or less), IFB did not occur in both modes. When the gain was higher ($1e+5$ or more), IFB occurred at $1e-3$ Pa in bi-planar mode without input signals, but did not occur in triode mode up to 1 Pa. It was found that the MCP detector was capable of high pressure operation by adapting the triode structure with a novel potential mode.

Since the charge of the input signal could not be measured by using ultraviolet rays, the peak channel from PHD characteristics analysis using a multichannel analyzer system, which measured the amount of charge from the MCP output signal, indicates the gain at each degree of vacuum level. Despite more than $1e-2$ Pa, the dark noise which derived from the IFB could not be confirmed in the PHD characteristics. When the vacuum pressure was 1 Pa, the calculated gain of $5e+6$ was maintained.

In order to confirm the stability of the detector operation, the outputs of the detector were monitored for about 90 minutes while input signal was turned on and off at 15-minute intervals. The output of the triode detector was stable from the long-term examination results irrespective of the degree of vacuum.

Conclusions

The MCP detector for low vacuum operation was developed by combining the triode structure with a novel potential mode. A compact detector for miniature MS could be realized by simplifying the structure in terms of supply voltage conditions and achieve the target gain of $1e+6$ at 0.1 Pa. We will confirm the MCP detector operation in a lower vacuum region by improving the current evaluation system, and optimize the MCP detector for a commercialized MS.

Novel Aspect:

The MCP detector for low vacuum operation was developed by combining the triode structure with a novel potential mode. A compact detector for miniature MS could be achieved with the target gain of $1e+6$ at 1 Pa.

419 - THE DYNAMIC BEHAVIOR OF NANO LIQUID BRIDGE DURING AMBIENT SAMPLING IONIZATION IN SCANNING PROBE ELECTROSPRAY IONIZATION MASS SPECTROMETRY

Bui Kamihoriuchi (1) - Yoichi Otsuka (1) - Aya Takeuchi (1) - Futoshi Iwata (2) - Takuya Matsumoto (1)

Osaka univ., Department of chemistry, Toyonaka (1) - Shizuoka Univ., Department of engineering, Hamamatsu (2)

Keywords: Tapping-mode scanning probe electrospray ionization (t-SPESI), Nano liquid bridge, Mass spectrometry imaging, Atmospheric pressure ionization, Ambient sampling ionization (ASI)

Introduction:

Tapping-mode scanning probe electrospray ionization (t-SPESI) have been used for mass spectrometry imaging. In t-SPESI, the formation of a liquid bridge and the generation of an electrospray by a vibrating capillary probe realizes the ambient sampling ionization (ASI) [1-4]. However, the dynamic behavior of the charged liquid bridge at the probe apex is unclear. In the present study, we studied a probe motion during ASI with the optical detection method.

Methods:

We developed the measurement system of the probe displacement. The optical lever method and the sample stage controller was incorporated in the experimental setup of t-SPESI. Mass spectrometry was conducted at the same time to capture the time changes of ion intensity. The commercial available silica emitter and the Rhodamine B thin film on glass was used as a probe and the specimen. The physical properties of the probe were simulated with finite element method.

Results:

The spring constant of the probe was estimated to be about 37 N/m (18 mm long probe) and 5.0 N/m (35 mm long probe). We found that the probe with lower spring constant is suitable for the measurement of the probe displacement during ASI with high sensitivity. The probe apex was drawn toward the sample just before the contact, indicates the timing of liquid bridge formation. During the retraction of probe from the sample, the probe was released from a liquid bridge. Considering the retraction distance and the simulated spring constant, the force applied to the apex of the probe was about 25 μ N just before the breakage of liquid bridge. At that time, the ion intensity became stronger and it gently became weak within 1 to 2 second. From these result, it was found that the sampled molecules were ionized over time just after the breakage of liquid bridge. In addition, the result of experiment with a nanopipette (a nanoscale diameter opening glass pipette) will also be presented.

Conclusions

New optical lever method was developed for SPESI. The formation and the breakage of the liquid bridge was captured by the displacement of probe during ASI. The sampled molecules are ionized over several seconds after the breakage of liquid bridge. The pulling force by the probe to break the liquid bridge was estimated to be larger than the expected surface tension of liquid bridge.

Novel Aspect:

This report is the first result to capture the dynamic probe motion during the sampling and ionization process using liquid bridge and electrospray in SPESI.

484 - INTEGRATION OF A DROPLET MICROFLUIDIC CHIP WITH MASS SPECTROMETRY – A STEP TOWARDS HIGH THROUGHPUT CELLULAR ANALYSIS

Emily E. Kempa (1) - Xin Li (2) - Clive A. Smith (2) - Perdita E. Barran (1)

University of Manchester, Manchester Institute of Biotechnology, Manchester (1) - Sphere Fluidics Limited, Chemistry, Cambridge (2)

Keywords: Droplets, Microfluidics, lab-on-a-chip, Cells

Introduction:

A major bottleneck to directed evolution workflows is the throughput required to screen a large number of genomic variants for the most efficient biocatalysts [1]. Current screening methods often rely upon well-plate fluorescent readouts which become problematic when the product of interest is not inherently fluorescent; hence, 'label-free' detection is highly desirable.

Methods:

Mass Spectrometry coupled with a droplet microfluidic chip system offers a 'label-free' screening platform in which each genomic variant of the combinatorial library is encapsulated in a ~500 picolitre droplet suspended within an immiscible fluoruous oil phase. MS analysis of the cell filled droplets allows for the identification and capture of the highest product producing genomic variants.

Results:

Droplet generation occurs at a rate of 5 Hz within a custom designed microfluidic chip followed by immediate flow of the droplets into a mass spectrometry source for ionization and then subsequent analysis. Loss of droplet order and droplet merging is avoided through 'plugs' of the oil phase and hence, each droplet arises in the TIC as a distinct peak at the same rate as generation. This allows for a mass spectrum for each peak to be obtained such that information regarding products or metabolome fingerprint in 1 discrete droplet can be extracted. This has been performed for a range of standards (including droplet mixtures [2]) and for bacterial cells cultured within droplets as proof of concept. Other on-chip processes such as droplet splitting have also been successfully trialed independently, with the aim to incorporate droplet capture of those identified by the MS as 'hits'.

Conclusions:

We demonstrate direct coupling between chip and two different Ion-Mobility enabled Mass Spectrometers to analyse discrete droplets without the prior removal of the contents (both protein and small molecule standards and cells) from the oil phase. This has been achieved with a throughput of ~5 Hz, which already surpasses the rate of many current sample introduction systems.

Novel Aspect:

Novel aspects include ultra-high throughput capabilities (~5 Hz) and miniaturization of sample introduction platforms for life science applications.

Keywords: portable GCMS, cold electron, nanovalve, carbon nanotube, VOC

Introduction

Recently, a miniaturized ion trap mass spectrometer with cold electron ionization was developed by our group as an ultra-portable mass spectrometer [1]. To extend the applicable field of the portable MS to a complex gas mixture analysis, we integrated a gas chromatography (GC) system to the miniaturized ion trap mass spectrometer using a nano-litervalve interface and evaluated the analytical performances of the system using typical volatile organic compounds.

Methods

A new portable GC was developed using a new carbon nanotube (CNT) heating paste. The GC column was heated by a bobbin type heater made of anodized aluminum and CNT heating paste applied on the inner surface of the heater. The miniature cylindrical ion trap MS was developed using a cold electron source to ionize analyte gas. An accurate nanovalve was developed and used as an interface between GC and the MS to avoid the failure of ion pump by abrupt increase of chamber pressure.

Results

The analytical characteristics of the portable GCMS were evaluated as individual components and as complete GCMS system. The performances of gas chromatography were evaluated with an adsorption concentrator using standard VOC samples while changing the column temperature gradient up to 100 degree/sec for rapid analysis. The performances of cylindrical ion trap were tested with nanoliter injection valve using the standard gas. With built in 2 L/sec ion pump and nanoliter injection valve, maximum 10 times/min sample injection was the limiting factor of analysis frequency while maintaining the operatable pressure of the ion trap. The electron ionization was using electrons from electron multiplier induced by UV photons from a diode. The optimal transmission condition of the electrons to the ion generation region was derived from SIMION simulation and used for the analytical performance test of ion trap. The developed GC/MS system was less than 10 kg and showed better than unit MS resolution and sub-ppm detection limits for typical VOCs.

Conclusions

Using a portable gas chromatography and a miniaturized cylindrical ion trap mass spectrometer, a new portable GCMS was introduced with CNT heating paste showed a high temperature-gradient for rapid analysis, and with a cold electron ionization source optimized for higher electron transmission to the ion generation region showed improved detection efficiencies. The integrated system showed detection limit of down to sub-ppm levels for the standard VOCs.

Novel Aspect

A novel hand-carriable GCMS was developed using a carbon nanotube heating paste for GC and cold electron ionization for portable ion trap MS to detect VOCs real-time in the field.

1129 - ANALYTICAL PROCEDURE FOR DETERMINATION OF PERFLUOROALKYL ACIDS, PARABENS AND COTININE FROM A LOW VOLUME HUMAN SERUM SAMPLE BY LC-MS/MS

Jani Koponen (1) - Hannu Kiviranta (1)

National Institute for Health and Welfare (THL), Health Security, Kuopio (1)

Keywords: biomonitoring, cotinine, epidemiological study, paraben, perfluorinated substances

Introduction:

In studies on the health effects of environmental chemicals it is desirable that multiple compound groups can be analyzed from the same low volume serum aliquot. Thus, we have developed and validated a single analytical procedure for determination of three different compound groups, perfluorinated substances (PFAS), parabens and cotinine (as a metabolite of nicotine), which are associated with a variety of adverse health outcomes [1-7].

Methods:

Serum sample of 0.1 mL was pre-treated with two step extractions, and all the analytes were separated and detected with LC-MS/MS. The limit of quantitation (LOQs) for PFAS, parabens and cotinine were 0.1 - 0.3 ng/mL, 0.20 - 1.0 ng/mL and 0.10 ng/mL, respectively. These limits are highly sufficient for studies where the exposure effects of PFASs, parabens and tobacco smoke is evaluated.

Results:

Validation data shows that the method has excellent accuracies and repeatabilities. For PFAS the accuracies ranged from 94 to 106% and the repeatabilities (as RSD%) from 2.2 to 5.6 %. The accuracies and RSDs for parabens were 73 - 120 % and 2.2 - 9.7 %, respectively, and for cotinine 102 - 106 % and 2.9 - 3.5 %. The main PFAS found in population based serum were perfluorooctanesulfonate (PFOS, range 1.3 - 23 ng/mL), perfluorooctanoate (PFOA, range 0.54 - 6.6 ng/mL), perfluorononanoate (PFNA, range 0.19 - 4.1 ng/mL) and perfluorohexanesulfonate (PFHxS < 0.15 - 5.5 ng/mL). For parabens the methyl (range < 1.0 - 49 ng/mL) and propyl (range < 0.2 - 1100 ng/mL) conjugates were the abundant compounds found in this study. Cotinine level in serum of tobacco smokers was over 50 ng/mL, whereas in serum of non-smokers the level was usually below 0.1 ng/mL.

Conclusions:

A simple, sensitive and high throughput method for analysis of 21 PFAS, 8 parabens and cotinine from 0.1 mL of serum was developed and validated. Analysis throughput time for 150 serum samples is one week. Besides the high throughput performance, the method is suitable for studies where the sample volume is limited since only a low sample volume is needed.

Novel Aspect:

This is the first method to gather these 3 classes of environmental pollutants (perfluorinated substances, parabens, and cotinine) in a single procedure.

783 - COLD VAPORIZATION OF TISSUES BY PICOSECOND INFRARED LASER ABLATION (PIRL) - UNIQUE ACCESS TO THE PROTEOFORM COMPOSITION.

Marcel Kwiatkowski (1) - Hartmut Schlüter (2)

University of Groningen, Department of Pharmacokinetics, Toxicology and Targeting, Groningen (1) - University Medical Center Hamburg-Eppendorf, Institute of Clinical Chemistry, Mass Spectrometric Proteomics, Hamburg (2)

Keywords:

Picosecond infrared laser ablation (PIRL)

Protein extraction

Tissue proteomics

Proteoform

Clinical proteomics

Introduction:

The proteoform composition of tissues has a high diagnostic value. Proteoforms regulate biological processes and an aberrant composition may cause diseases. Intact proteoforms are exposed to enzymatic degradation reactions during sample preparation and methods are needed that provide access to the original proteoform composition of tissues. PIRL ablation minimizes degradation reactions and provides access to the original proteoform composition of tissues.

Methods:

PIRL-ablated proteins were analyzed by LC-ESI-MS/M and MALDI-MS to investigate if their chemical composition and enzymatic activity remained unaltered. Tissues were homogenized either by conventional mechanical methods or by PIRL ablation. The homogenates were separated by 2-DE and SDS-PAGE, followed by quantitative LC-MS/MS analysis. Enzymatic degradation reactions were analyzed by proteoform SDS-PAGE migration profiles.

Results:

Comprehensive MS analysis showed that the exact chemical composition of proteins was not altered during the PIRL ablation process and even posttranslational modifications and enzymatic activities were reserved (1). 2-DE analysis indicated that PIRL yielded a higher number of intact proteoforms compared to mechanical homogenization. These results were confirmed by SDS-PAGE migration profiles. Relative degrees of proteolysis were significantly lower in case of PIRL (2%) compared to mechanical homogenization (23%) (2).

These results were further confirmed by spiking experiments. Total yield of intact alpha-casein proteoforms and number of identified phosphopeptides were significantly higher using PIRL, whereas mechanical homogenization showed significantly higher amounts of enzymatically degraded proteoforms.

PIRL-derived extracts are almost free of particles minimizing sample, thus providing a higher reproducibility and significantly higher protein identification rates compared to conventional tissue homogenization.

Conclusions

PIRL releases intact proteoforms from tissues without changing their exact chemical composition including posttranslational modifications. The ultrafast release and transfer of intact proteoforms into frozen condensates minimizes exposure to enzymatic degradation reactions and provides a unique access to the original proteoform composition of tissues.

Novel Aspect:

PIRL provides a unique access to the original proteoform composition of tissues and facilitates molecular diagnostics of tissues at the proteoform level.

From niche application to essential research tool; why SFC-MS is the must have technique

Keywords

Supercritical fluid chromatography - mass spectrometry

Introduction:

SFC now delivers the chromatographic promises with robust and reliable instrument. The solvation power, selectivity and peak capacity of modern Ultrahigh Performance Supercritical Fluid Chromatography (UHPSFC) coupled with mass spectrometry affords the ideal analytical platform to address classes of compounds that were previously a challenge for GC-MS and RP-UHPLC-MS approaches.

UHPSFC-MS sits between LC-MS and GC-MS affording extended capability and complementarity and delivers unique solutions across a broad range of application areas, e.g. synthetic organics, pharmaceuticals, petrochemistry, lipids, nucleotides and many other areas.

Methods

Ultra-high performance supercritical fluid chromatography (UHPSFC) methods have been developed using a simple column screening protocol. A Waters Acquity UPC2 is coupled to a TQD mass spectrometer and a range of cosolvents and additives are utilised to deliver generic and bespoke Methods: Further tuning of the organic make-up solvent has been used to deliver specific assays.

Results

UHPSFC, in the form of Ultra Performance Convergence Chromatography (UPC2) has been incorporated into the open access (walk-up and use) chromatography mass spectrometry facility within Chemistry at the University of Southampton in 2013. This technology complements existing liquid chromatography and gas chromatography options (HPLC-MS (ESI/APCI), GC-MS (EI/CI) and affords high throughput reaction monitoring for new chemistries and highly specific research solutions, e.g. lipids, isocyanate polymers, petrochemistry, molecular wires and supramolecular chemistry.

Novel Aspect

New chromatography solutions, extension of open access mass spectrometry.

953 - CONVENTIONAL-FLOW LIQUID CHROMATOGRAPHY–MASS SPECTROMETRY FOR EXPLORATORY PROTEOMIC ANALYSES

Juraj Lenčo (1)

Department of Analytical Chemistry, Faculty of Pharmacy in Hradec Kralove, Charles University, Hradec Králové (1)

Keywords: Conventional-flow LC-MS, exploratory proteomics.

Introduction:

Although conventional-flow LC-MS platforms have penetrated targeted proteomics successfully, their possibilities in discovery-oriented proteomics have not yet been thoroughly explored. Our objective was to determine what optimization and adjustments to a conventional-flow LC-MS system must be undertaken to identify a comparable number of proteins as can be identified on a nanoLC-MS system.

Methods:

A trypsin digest of HeLa cells lysate was used to compare proteomic identifications between nanoLC and conventional-flow LC-MS setup. Following parameters of the conventional-flow LC-MS configuration were optimized in order to improve identifications: DDA settings, column diameter, extra-column peak dispersion, temperature, flow rate, column length, mobile phase acidifiers and additives.

Results:

We demonstrate that the amount of a complex tryptic digest needed for comparable proteome coverage can be roughly 5-fold greater, providing the column dimensions are properly chosen, extra-column peak dispersion is minimized, column temperature and flow rate are set to levels appropriate for peptide separation, and the composition of mobile phases is fine-tuned. Indeed, we identified 2 835 proteins from 2 µg of HeLa cells tryptic digest separated during a 60 min gradient at 68 µL/min on a 1 mm × 250 mm column held at 55 °C and using an aqua–acetonitrile mobile phases containing 0.1% formic acid, 0.4% acetic acid, and 3% dimethyl sulfoxide.

Conclusions:

Although we have not exploited all options for improving LC–MS performance, we conclusively show that conventional-flow exploratory proteomic analyses are feasible. Providing the instrumentation and method are adjusted appropriately, the extra sample amount need not correspond to the theoretical 178-fold greater burden [1].

Novel Aspect:

Our results document that nanospray-free, conventional-flow LC–MS is an attractive alternative for bottom-up exploratory proteomics.

Huwei Liu (1) - Yiding Zhang (1) - Xianjiang Li (1) - Honggang Nie (1) - Yu Bai (1)

Peking University, College of Chemistry and Molecular Engineering, Beijing (1)

Keywords: Ambient mass spectrometry, surface plasmon resonance, hyphenation method, molecular interaction

Introduction:

Surface plasmon resonance (SPR) is a powerful technique widely utilized in the studies based on interaction processes such as cellular analysis [1] and clinical researches [2]. Despite its versatility, there still exist some intrinsic deficiencies due to the principle of SPR, among which the insufficiency in qualitative analysis remains a significant one. Generally, the information acquired by conventional SPR instruments is inadequate for the identification of the samples, constraining the application of SPR in the researches dealing with unknown species such as ligand fishing [3] or active ingredient identification [4]. Consequently, the combination of SPR with other analytical approaches that can provide molecular information has been highly desired [5-9].

In this work, a newly developed interface to couple SPR with MS using spray tip and DART was reported. The SPR flow solution was led into a sprayer, whose tip was put in middle of the DART outlet and the MS inlet, thus the solution could be sprayed and ionized. Proof-of-concept experiments using 4 chemicals dissolved in 3 types of salt-containing solvents were conducted, showing the practicability of this interface by observing the consistent change of the signals of MS and SPR. The performance of this interface and its salt tolerance suggested its high potential in the screening of the unknown interaction under physiological conditions using SPR-MS.

Methods:

SPR sensor chip modification. The sensor chip was modified with HSA using common EDC/NHS coupling method. The sensor chip was first cleaned by immersing it in a solution blended by ammonia solution, hydrogen peroxide and water with the volume ratio of 1:1:5 and being kept at 90 °C for 10 min. After installing the cleaned chip into the SPR analyzer, the following modification process was carried out by successively injecting and flowing: a. 3-MPA with TCEP, for 60 min; b. EDC and NHS for 20 min; c. HSA for 12 h; d. ethanolamine for 10 min. The change of SPR angle before and after the HSA modification proved that the protein had been successfully immobilized onto the sensor chip.

SPR-AMS experiments. Acetaminophen, metronidazole, quinine and hippuric acid were selected to be the model analytes, with PBS, TBS and EBSS chosen as the representative solvents to simulate the physiological conditions that might be used in usual SPR experiments. There were all together 12 kinds of sample solutions. A single run was started by commencing SPR and MS data acquisition simultaneously. For the first 2 minutes, pure solvent was delivered. At the beginning of the 3rd minute, the sample solution started to flow, and lasted for 4 minutes. During these 4 minutes, the analyte might bind to the HSA immobilized on the sensor surface, leading to a change in the SPR signal. From the 6th minute, again the pure solvent was delivered, and the analyte would be washed away. After the SPR signal fell back to its baseline and the MS signal became stable, the data acquisition was stopped. The raw SPR data was denoised by fast Fourier transformation smoothing before further analysis.

The solution flow rate of all of the runs was 0.20 mL/min. The nebulizing gas was nitrogen at a pressure of 15 psi. The SPR analyzer was set at constant angle mode recording the reflected light intensity at the SPR angle. For the DART-MS ion source, the temperature was set at 450 °C with helium as working gas. The MS parameters were: capillary voltage, off; dry gas temperature, 325 °C; dry gas flowrate, 5 L/min. The range of m/z between 100 and 400 was scanned with a maximum ion accumulation time of 200 ms. MS was operated at positive mode when analyzing solutions containing acetaminophen, metronidazole or quinine, and negative mode for solutions of hippuric acid.

Results:

Optimization of the DART conditions. As preliminary experiments, the following parameters that might affect the DART ionization and the MS analysis were optimized: DART source temperature, the vertical distance between the spray tip and the DART-outlet-MS-inlet plane (d3), the total horizontal distance between the DART outlet and the MS inlet (d1), the flow rate of the solution and the nebulizing gas pressure for the spray. As these parameters were

independent, a series of experiments based on the orthogonal experimental design were conducted, using 25 mmol/L acetaminophen dissolved in PBS as the sample.

For d_3 , the temperature and the flow rate, higher values would lead to better signals, and for the nebulizing gas pressure, a lower value would be better. The values of d_1 showed no clear tendency. These effects could be explained by the principle of the interface. As the interface was spray-based, a better spray condition was of great concern. The droplets in the spray would get smaller and better distributed as they flew away from the spray tip, so a larger d_3 would be beneficial. Also, as the analytes were dissolved in the solutions and the sprayed droplets, the ionization would consist of the evaporation and desolvation process, thus a higher source temperature would be more productive. For the nebulizing gas pressure, if it was too high, the droplets would be blown away too fast from the DART ionizing stream, so a lower pressure would be better. The flow rate meant the amount of sample, and a higher value led to a stronger signal. The value of d_1 showed least importance, thus it was selected considering other parameters.

The horizontal distance between the spray tip and the MS inlet (d_2) could also affect the results. However, as there was a restrictive requirement that d_2 must be less than d_1 , the value of d_2 could not be included in the orthogonal experiments and it was optimized separately. Generally, a smaller d_2 could allow more ions to go into the MS inlet, but it might also lead to the sample residue at the MS inlet. Also, a larger d_3 would result in more residues. With consideration to the signal intensity and the sample residue contamination, the following parameters were selected: DART source temperature, 450 °C; d_1 , 2.0 cm; d_2 , 10 mm, d_3 , 6 mm; flow rate, 0.20 mL/min; nebulizing gas pressure, 15 psi. Additionally, helium was used as working gas for all of the sample solutions.

Performance of the SPR-DART-MS experiments.

As mentioned in the experimental section, there were 12 sample solutions. It was undoubtedly proven that the as-designed spray and DART based interface could be used successfully and practically for on-line coupling of SPR with MS, as the MS signal changed consistently with the SPR signal. For the first 2 minutes during which the pure solvent flowed through the SPR analyzer, SPR signal stayed at its baseline, so did the MS signal. As the solution containing analytes started to flow at the 3rd minute, the SPR signal started to increase as the analyte bound with the HSA immobilized on the sensor chip. The MS signal also increased, as the excess analyte in the solution got sprayed and ionized. From the 6th minute, pure solvent flowed again, and the SPR signal changed to its original values because of the dissociation of the bound analytes, and the MS signal also decreased.

There is an observable lag of approximately 1 min between the increase of the MS signal and the injection of the sample solution. This was mainly because of the volume of the SPR flow cell and the connecting tubes. All of these volumes between the pump and the MS would act like the dead volume similar in a chromatography process, delaying the change of the MS signal. Besides the dead volume, there were another two reasons explaining the delay of this decrease. First, there remained analytes bound on the sensor chip, the elution of these analytes would last for some time, thus the MS signal would remain high during all this elution process. Second, as the aqueous solutions containing non-volatile salts were used, the evaporation of the sprayed droplets would often be incomplete, resulting in the residue of the analytes in the vicinity of the spray tip and the MS inlet, keeping the MS signal from decreasing. Notwithstanding this residue, it demonstrated the necessity and advantage of the DART-based interface, that it could prevent the residue from contaminating conventional ESI source.

Salt tolerance of the DART interface.

For most analytes and solvents, the interface showed a high tolerance of the non-volatile salts. For the 3 analytes in positive mode, both of PBS and EBSS showed even higher signal intensity than water, indicating that the low-molecular-weight salts might help the proton transfer to form positive species. TBS showed lower signal intensity, which could be explained by the competitive ionization between the analyte and tris contained in TBS, which was supported by the strong tris peak ($m/z = 122$, $[M+H]^+$) observed in most of the MS spectra using TBS. For the analyte in negative mode, all of the salt containing solvents showed a depression in signal intensity, suggesting the salts' negative effects in negative mode. These results proved the as-designed interface had an adequate tolerance of the non-volatile salts, and should suffice the applications for direct on-line coupling of SPR with MS using salt-containing solutions.

Conclusions

A novel interface relying on DART ionization and spray tip for direct and on-line coupling of SPR with MS was designed and developed. Experimental results using different model compounds and buffers exhibited the feasibility of the online combination of SPR and MS. This system showed a high tolerance of the non-volatile salts during the test, suggesting its potential utilizations in SPR-MS experiments, especially when physiological conditions should be

needed. This interface provided a new approach for online coupling of SPR-MS, and would contribute to the fast detection of the interaction between substrate and the ligand and simultaneous identification of the ligand [10].

Novel Aspect:

A novel interface for direct and on-line coupling of SPR to AMS was developed. A spray tip connected with the outlet of the SPR flow solution was conducted as the sampling part of the DART-MS, with which the online coupling interface of SPR-MS was realized. Four model samples, acetaminophen, metronidazole, quinine and hippuric acid dissolved in three kinds of common buffers were used in the SPR-DART-MS experiments for performance evaluation of the interface and the optimization of DART conditions. The results showed consistent signal changes and high tolerance of non-volatile salts of this SPR-MS system, demonstrating the feasibility of the interface for on-line coupling of SPR with MS and the potential application in the characterization of interaction under physiological conditions.

Keywords: Mobile, GCMS, performance, VOCs, profiling

Introduction:

The fast development and exhaustive search for effective VOCs analysis with mobile MS has become an important research field, due to the advantages of miniaturized systems for on-site applications over laboratory-scale instrumentation. Nevertheless, it is important to rely on valid analytical platforms capable of achieving high sensitivity, reducing process times, and, specifically for on-site analysis [1], enabling multi-component determinations.

Methods:

An extensive evaluation of three commercially available mobile GCMS, the Hapsite ER (Inficon, Germany) and the E2M (Bruker, Germany) with quadrupole mass analyzers, and the Torion T-9 (PerkinElmer, Germany) with a toroidal ion trap mass analyzer, was performed using a complex mixture of 24 compounds introduced by different devices, and compared to a state-of-the-art bench-top GC-2010 Plus coupled to a TQ-8040 triple quadrupole mass spectrometer (Shimadzu, Japan).

Results:

First, the performance was assessed in terms of sensitivity, approximately only 50% of the analytes were detected in the mobile mass spectrometers independent of the introduction devices (thermal desorption TD, direct probe and SPME) and compared to the TD stationary system. In contrast, after average normalization, the reproducibility of consecutive measurements ($n=3$) seemed to be strongly influenced by the pre-concentration system. While ~30% RSD was determined for adsorption-desorption methods (SPME and TD), even higher variance and unstable results were obtained using the direct probe system; all of them were considerably higher than the 15% RSD found on laboratory scale. In addition, spectra reproducibility was probed for its impact on spectral similarities with common reference spectra libraries, but still some of the corresponding softwares showed several limitations for data transformation, data transfer, and even selection of quantitation and confirming ions for proper determinations and statistical analysis.

Conclusions

Mobile devices for on-site application of unknown samples still need to overcome several analytical limitations during qualitative and quantitative analysis, specifically for volatile profiling with multi-component determinations.

Novel Aspect:

Mobile GCMS was assessed for appropriate method development and validation for analysis of complex standard mixtures and compared to state-of-the-art bench-top GCMS.

Keywords:

UHPLC-MS/MS, antibiotics, solid-phase extraction, surface water

Introduction

Antibiotics are used as human and veterinary medicines to treat diseases. Studies have found various antibiotics in surface water, which has raised concern on the human health effects. To investigate the occurrence and fate of these low level contaminants and measure them in a variety of water matrices; sensitive, selective and reliable methods are needed. In this study, a selective solid phase extraction (SPE) method was evaluated for sample clean-up and analyte concentration for analysis on an UHPLC-MS/MS system.

Methods

Water samples were subjected to solid-phase extractions. Analytes were determined by coupling the UHPLC system to a highly sensitive PerkinElmer QSiight 220 triple quadrupole mass spectrometer with dual ESI/APCI sources. Under the optimized conditions, the method was validated in terms of its specificity, sensitivity, linearity, accuracy, and precision. Recoveries from sample matrix were evaluated by fortifications of analytes at 3 different concentrations.

Results and Conclusion

In this study, to effectively remove interfering components and enriched analyte of interest from complex environmental water sample matrices, several SPE extraction phases with different functionalities were evaluated, such as reversed phase, ion exchange and mixed mode cartridges. The extraction and elution conditions were also optimized for SPE procedures. Calibration curves were built with matrix-matched standards to compensate for any matrix effects. The regression coefficients (R^2) for the calibration curves obtained for all antibiotics studied were all greater than 0.990, and the limits of quantification (LOQs) ranged from 0.1 to 5 µg/L for the targeted compounds. The mean recoveries from the samples spiked at three different concentrations, respectively, were between 70% and 120%. The intra-day and inter-day variations, expressed as RSD, were less than 5%, respectively. The results demonstrated that the accuracy and precision of the present method were acceptable for routine monitoring purposes. The analyte confirmation in sample was achieved by comparing their respective retention times and peak area ratios of two MRM transitions with those obtained from the corresponding reference standards. The method developed in this study provides an effective tool for determination of multi-antibiotics in surface water and a large number of actual water samples were analyzed using this method to evaluate the occurrence of the analytes in local water systems in Chengdu, China.

Novel Aspect

Highly selective SPE extraction method coupled to highly sensitive UHPLC-MS/MS for low level antibiotics analysis in surface water.

Keywords: Ion mobility - Capillary-electrophoresis – Lipopeptides – High resolution Mass Spectrometry – Reverse phase liquid chromatography

Introduction:

Cyclic lipopeptides (CLPs) are produced by bacteria in a ribosome independent manner and consists in a hydrophilic peptide chain linked to a β -hydroxy fatty acid chain. CLPs are a very large and diverse group of molecules, that has recently gained lots of attention for their potential applications in agricultural or pharmaceutical industries [1, 2]. In that aim, the development of reliable analytical methods for new CLPs isolation and characterization is essential.

Methods:

Capillary Electrophoresis-Mass Spectrometry was performed on a CESI 8000 instrument coupled to a tandem linear ion trap and high resolution mass spectrometry FT-ICR. A bare fused silica capillary of 90cm x 375 μ m (OD) x 50 μ m (ID) was used for the separation. In addition, CLPs were analyzed by ion mobility mass spectrometry on a timsTOF instrument.

Results:

The obtained separation of up to four isobaric CLPs by capillary electrophoresis mass spectrometry will be presented. The fragmentation spectra enabled the identification of each compound detected. The mobility of the CLPs in solution will then be compared to the measured collision cross section in the gas phase by ion mobility mass spectrometry.

Conclusions:

Capillary electrophoresis appears to be a reliable technique for cyclic lipopeptides separation and shows promising applications for new CLPs identification. Capillary electrophoresis and ion mobility mass spectrometry are complementary techniques for CLPs structural analysis.

Novel Aspect:

To our knowledge, this is the first report on cyclic lipopeptides separation by capillary zone electrophoresis method.

1141 - TANDEM IONISATION FOR GC(xGC)-MS: COMPLEMENTARY SOFT ELECTRON IONISATION FOR INCREASED CONFIDENCE IN COMPOUND IDENTIFICATION

Nick Bukowski (1) - Laura McGregor (1) - Joe Blanch (2) - Pete Grosshans (2)

SepSolve Analytical, SepSolve Analytical, Peterborough (1) - Markes International, Markes International, Llantrisant (2)

Keywords: soft ionisation; TOF MS, tandem ionisation

Introduction:

Electron ionisation (EI) at 70 eV is standard practice for GC-MS, due to the high degree of ionisation (and thus good sensitivity) and consistent mass spectra generated.

Nevertheless, the identification of individual compounds in complex samples remains challenging when multiple compounds in a chemical class have similar spectra, or weak molecular ions at 70 eV EI. This problem can be addressed by the use of soft ionisation to reduce the degree of ion fragmentation, but this approach has been cumbersome to implement until now.

Methods:

The mass spectrometer used in this study incorporates a unique ion source design enabling both hard and soft electron ionisation spectra to be acquired simultaneously – in a technique deemed Tandem Ionisation. Multiplexing between ionisation energies allows conventional 70 eV spectra to be obtained - for routine identification against commercial libraries - as well as simplified soft EI spectra for enhanced confidence in identification of compounds which may exhibit weak molecular ions and/or similar spectra at 70 eV.

Results:

The soft EI spectra consist of only structurally-significant fragments for reduced demand on dynamic range and an increase in peak capacity. In addition, greater orthogonality between the mass spectra of isomeric compounds is evident, thus simplifying compound identification and reducing reliance on retention indices.

Conclusions

Fast multiplexing during acquisition greatly improves the performance of a TOFMS, enabling two complementary MS datasets to be acquired simultaneously.

Novel Aspect:

The use of a novel, patented ion source design to provide both hard and complementary soft electron ionisation in a single run.

825 - EVALUATING THE CAPABILITY OF DIFFERENT NON-TARGETED MS-BASED APPROACHES FOR THE COMPREHENSIVE CHARACTERIZATION OF OLIVE TREE-DERIVED MATRICES

Lucía Olmo-García (1) - Nikolas Kessler (2) - Aadil Bajoub (3) - Carmen María Sánchez-Arévalo (1) - Arsenio Muñoz de la Peña (4) - Heiko Neuweiger (2) - Carsten Baessmann (2) - Alegría Carrasco-Pancorbo (1) - Alberto Fernández-Gutiérrez (1)

Keywords: non-targeted approaches; food metabolomics; LC-MS; GC-MS; complementarity platforms

Introduction:

Virgin olive oil consumption has been associated to a lower incidence of some chronic diseases, largely due to its non-glyceridic minor compounds, which are also found in other vegetal tissues derived from the olive tree. Thus, the deep characterization of the main parts of the olive fruit and tree might be a key step when trying to find natural sources of bioactive compounds. To do it so, different MS-platforms were used (LC-ESI/APCI-MS and GC-APCI-MS).

Methods:

Picudocv. samples were prepared using an unselective liquid/solid-liquid extraction protocol. The extracts were analyzed by LC and GC coupled to a QTOF detector by means of ESI and APCI interfaces in the case of LC and an APCI source in GC. In LC, the analytes were eluted in a C18 column (2.1x 100 mm, 1.8 µm), with acidified water and acetonitrile at 40 °C. The silylated extracts were also analyzed in GC (BR-5 column) with a T gradient from 150 to 320 °C (ramped at 4 °C/min).

Results:

The extracts (from lyophilized olive pulp, olive seed, fruit skin, leaves and wood from the branches, as well as virgin olive oil, olive oil obtained from pitted and dehydrated fruits and oil obtained from the seed contained inside the pit) were prepared and analyzed. Data acquired were processed with MetaboScape® 3.0 (Bruker), which automatically extracts and combines isotopes, adducts and fragments belonging to the same compound into one feature. Information obtained from Metaboscape was studied to point out the adequacy of each methodology for the determination of each family of compounds, as well as to describe the distribution of the identified plant metabolites within the selected olive oils and tissues (their presence, absence, relative area in each matrix and relative response in each platform were checked). The identification of more than 130 compounds from the extracts (phenolic compounds, triterpenic acids and dialcohols, tocopherols, sterols and free fatty acids) was achieved.

Conclusions:

- The potential of different non-targeted MS-based approaches to cover the metabolome of 80 European derived matrices was assessed.
- The coupling to a high resolution MS through different ionization sources (ESI and APCI in LC and APCI in GC) allowed the detection of compounds from different chemical classes.
- The use of a great number of standards and the annotation strategies (MetaboScape) lead to the identification of more than 130 compounds in the extracts.

Novel Aspects:

Study of biosynthesis and distribution of minor bioactive compounds in olive oils and tissues applying innovative non-targeted LC-ESI/APCI-MS and GC-APCI-MS approaches.

615 - AN ENERGY-RESOLVED TANDEM MASS SPECTROMETRY APPROACH TOWARDS IDENTIFICATION OF SMALL ISOMERIC METABOLITES

Takemichi Nakamura (1) - Takenori Hama (1) - Masayo Sekimoto (1) - Futoshi Sato (2)

RIKEN CSRS, Molecular Structure Characterization, Wako, Saitama (1) - Nihon Waters K.K., Market Development Technology Center, Shinagawa, Tokyo (2)

Keywords: Isomer Differentiation, Energy-resolved (ER) MS/MS, CID, Ion Mobility, Collision Cross Section

Introduction:

Identification of isomeric organic molecules would become a big challenge for mass spectrometry with ambient in situ setup where no chromatography is available. We explore a viable generic strategy for differentiation of small isomeric metabolites in such situations; the potentials and limitations of widely available low-energy CID MS/MS and ion mobility analysis have been evaluated by using a set of isomeric C4 amino acids as a model.

Methods:

Analyte ions were generated by electrospray ionization on directly injected standard solutions. Quadrupole/time-of-flight (Q-TOF) hybrid and triple quadrupole tandem mass spectrometers were used for energy-resolved (ER) CID MS/MS experiments. A traveling wave ion mobility analyzer built in one of the Q-TOF systems was used for ion mobility analysis in N₂. For the CID experiment, He, Ne, Ar, or N₂ was used as the collision gas.

Results:

Six C4 amino acids, i.e. 2-aminobutyric acid (2-ABA), 3-aminobutyric acid, 4-aminobutyric acid, 2-aminoisobutyric acid (2-AIBA), 3-aminoisobutyric acid, and N,N-dimethylglycine (DMG) are one of the simplest examples of small isomers. Among them, 2-ABA, 2-AIBA, and DMG gave similar CID spectra that were attributable to common major fragmentation pathway, loss of 46 Da (CO and H₂O) from protonated molecules (m/z 104) to form m/z 58. Obviously the spectral patterns were condition dependent; however, the difference in energy requirement to give m/z 58 from each isomer could be clearly visualized in breakdown diagrams obtained by ER MS/MS experiments. On the other hand, ion mobility analysis was shown to have limited discrimination power on these isomers. The predicted collision cross section (CCS, calculated by IMoS software [1]) of 2-AIBA protonated molecule was roughly 2% larger than those of the other isomers whereas the predicted CCS of m/z 58 from 2-ABA was 3% larger than the CCS of m/z 58 from others.

Conclusions:

An ER MS/MS approach by using commonly available instruments was shown to be useful for differentiation of small isomeric organic molecules. As the lab-frame collision energy values depend on geometry of the CID device, collision gas species, and gas pressure, method for standardize collision energy axis should be established to facilitate platform independent differentiation and identification of isomers.

Novel Aspect:

Potentials and limitations of an ER-MS/MS-based integrated approach for differentiation and identification of small isomeric organic molecules have been evaluated.

1110 - HIGHLY EFFICIENT ON-LINE PROTEIN DIGESTION AND PEPTIDE ANALYSIS: EXPLOITING NEW SHORT-BED TRYPsin-REACTORS

Marina Naldi (1) - Urh Černigojc (2) - Ales Štrancar (2) - Manuela Bartolini (1)

Alma Mater Studiorum University of Bologna, Department of Pharmacy and Biotechnology, Bologna (1) - Bia Separations d.o.o, Bia Separations d.o.o, Ajdovščina (2)

Keywords: Trypsin; Immobilized enzyme reactor; Monoliths; Liquid chromatography-mass spectrometry; Proteomics

Introduction:

Trypsin is the gold standard enzyme used in shotgun proteomics for the conversion of proteins into MS-friendly peptides[1]. However, long incubation times and possible covalent modifications induced by digestion conditions are common drawbacks of classic in solution protocols. To achieve high digestion efficiency, automation and a significant decrease in analysis time were considered the development of trypsin-based immobilized enzyme reactors (tryp-IMERs).

Methods:

Trypsin-based monolithic tryp-IMERs were obtained by covalent immobilization on short-bed CIMac™ columns (5 mm x 5.2 mm I.D.) exploiting different chemistries and immobilization protocols. IMERs were inserted in an integrated platform featuring analytical columns for peptide analysis and an ESI-Q-TOF mass spectrometer. Optimized procedure was validated in terms of intra- and interday and IMER to IMER reproducibility, ruggedness, stability and sensitivity.

Results:

The IMER-based analytical platform allowed the on-line digestion and identification of protein substrates, the separation of peptides and acquisition of MS/MS spectra in an automated manner. In the optimized working conditions no memory effects, nor significant nonspecific interactions were detected. Very short digestion time (90 s), good intra-day and inter-day analysis reproducibility (%RSD in terms of %SQ ≤ 1.2) and good sensitivity down to picomol level were achieved. The high digestion efficiency was confirmed by the analysis of high-molecular weight (HMW) proteins such as a pool of human immunoglobulins G and the HMW fraction of plasma proteins, as challenging real sample. Indeed, efficient protein digestion could be achieved albeit sample complexity, allowing the identification of 281 plasma proteins. Furthermore, the excellent sequence coverages achieved with best performing tryp-IMERs were generally higher than those obtained by in solution digestion (overnight) or with the commercially available tryp-IMER Poroszyme™.

Conclusions:

CIMac columns were suitable supports for the development of highly efficient IMERs. Tryp-IMER performance in terms of digestion of single proteins, protein mixtures and real plasma samples were comparable with that of some capillary and nano-IMERs, without requiring hyphenation to micro- or nano-analytical instrumentation. Automation and high digestion efficiency make the short-bed tryp-IMER appealing new tools for shotgun proteomics and protein analysis.

Novel Aspect

Short-bed CIMac columns were for the first time exploited for the preparation of tryp-IMERs which can be inserted in classic LC-MS systems enhancing automation and throughput.

290 - A COMPARISON OF THE RESULTS OBTAINED FOR THE ANALYSIS OF SOUTH AFRICAN PINOTAGE WINES USING GCxGC-TOFMS WITH HYDROGEN AND HELIUM AS CARRIER GASES

Yvette Naudé (1) - Peter Charles Gorst-Allman (2)

University of Pretoria, Chemistry, Pretoria (1) - Separation Science Consultant, Separation Science, Pretoria (2)

Keywords: Pinotage wine, carrier gas comparison, GCxGC-TOFMS, principal component analysis, taste profile

Introduction

The relatively low price and availability of helium have made it the default carrier gas for the majority of GC and GC-MS users over the last 40 years. Since the helium shortage of 2012 a number of GC methods have been revalidated for use with hydrogen. This has been driven not only by availability, but also by price, as the cost of helium has doubled in the last 24 months. We compare the analysis of pinotage, a uniquely South African wine, using hydrogen and helium as carrier gas.

Methods

We have analysed seven samples of South African pinotage wines using comprehensive gas chromatography – time of flight mass spectrometry (GCxGC-TOFMS) and both hydrogen and helium as carrier gases. The results were then subjected to principal component analysis (PCA) to investigate the comparability of the components identified using the different carrier gases.

Results

Within the carrier gas groups (i.e. helium or hydrogen) results were comparable, but some differences were observed between carrier gas groups. These differences relate primarily to detectability and signal to noise variations for many components, and an attempt has been made to clarify and explain the discrepancies. There are no obvious differences in the mass spectra obtained for the same compounds detected with different carriers, and the mass spectra using both carriers give good quality library matches with spectra contained in commercial mass spectral libraries. By and large the same compounds were found in the same samples analysed with different carriers. In addition the wines were compared by a tasting panel, and an attempt has been made to correlate the wines scoring most highly with their chemical composition and price.

Conclusions

It is likely that helium will be required for GC applications for a long time to come, but as its price continues to rise and it becomes harder to source, laboratories will face continued pressure to pursue alternatives. Hydrogen is the most suitable alternative to helium for many analyses and it is likely to be adopted by GC labs because of its cost effectiveness, availability, and the existence of programmes permitting easy adaption of existing helium based Methods:

Novel Aspect

This is the first time that the compounds providing the organoleptic properties of pinotage wine have been compared using different carrier gases, and GCxGC-TOFMS. The study provides information on analysis of wine using hydrogen as carrier gas, and also highlights several caveats when using this approach.

564 - ANALYSIS OF AN ANTIPARASITIC FRACTION AGAINST GASTROINTESTINAL NEMATODES OF SHEEP FROM LEAVES OF MAYTENUS ILICIFOLIA BY LC-ESI-IT-MSn.

Micaela Escobal (1) - Guillermo de Souza (1) - América Mederos (2) - Cristina Olivaro (3)

Universidad de la República, Espacio de Ciencia y Tecnología Química, Tacuarembó (1) - Instituto Nacional de Investigación Agropecuaria, Programa Nacional de Carne y Lana, Tacuarembó (2) - Universidad de la República, Espacio de Ciencia y Tecnología Química, Tacuarembó (3)

Keywords: Maytenus ilicifolia Leaves extract, antiparasitic fraction, gastrointestinal nematodes of sheep, LC-ESI-IT-MSn.

Introduction:

Maytenus ilicifolia is an important folk medicinal plant, largely found in Paraguay, Uruguay, Argentina, and Brazil. Contributions to human health have been reported [1-3]. A purified fraction from the ethanol extract of Maytenus ilicifolia leaves exhibits antiparasitic activity against gastrointestinal nematodes of sheep. The aim of the present study was to perform a preliminary structural characterization of this bioactive fraction by LC-ESI-IT-MSn.

Methods:

The ethanolic extract of *M. ilicifolia* was subject to a bioguided fractionation on a VLC column and subsequent separation on C18 SPE. The antiparasitic activity was determined against parasites in naturally infected sheep in Uruguay, through egg hatching and inhibition of larval migration in vitro assays. The bioactive fraction was investigated by liquid chromatography/electrospray ionization ion trap multiple-stage mass spectrometry in negative ion mode.

Results:

The bioactive fraction was adequately separated by chromatography on a C18 reverse phase UHPLC column using a mobile phase gradient of acetonitrile in water at acidic conditions. The mass spectrometer was set to monitor, select and fragment the most abundant ions [M-H]⁻ in the range m/z 200–1500.

According to their [M-H]⁻ ions, characteristic product ions and retention times, several constituents were identified. Catechin and epicatechin were found. Flavonoid glycosides ranging from 1 to 4 monosaccharide units, having mainly quercetin and kaempferol as aglycones moieties were identified. Tannins were also found, the main ones being composed of catechin/epicatechin and afzelechin/epiafzelechin.

The results of the egg hatching and the larval development assays will be presented at the Conference.

Conclusions

The LC-ESI-IT-MSn is a method quick and easy that can be extended or transferred to other purified bioactive fractions from other plant extracts, allowing a preliminary characterization of its main compounds. In this way the structure of the compounds could be related to the biological activity.

Novel Aspect:

This work shows that a purified fraction of ethanolic extract of Maytenus ilicifolia rich in flavonoids and condensed tannins present a good antiparasitic activity against gastrointestinal nematode of sheep.

563 - FIRST REPORT ABOUT THE STRUCTURE OF AN IMMUNOADJUVANT SAPONIN FRACTION FROM QUILLAJA BRASILIENSIS LEAVES BY LC-ESI-IT-MSN

Federico Wallace (1) - Zhora Bennadji (2) - Fernando Ferreira (3) - Cristina Olivaro (4)

Universidad de la República, Universidad de la República/Espacio de Ciencia y Tecnología Química, TACUAREMBÓ (1) - Instituto Nacional de Investigación Agropecuaria, Programa Nacional de Investigación en Producción Forestal, TACUAREMBÓ (2) - Universidad de la República, Universidad de la República/Laboratorio de Carbohidratos y Glicoconjugados, Montevideo (3) - Universidad de la República, Universidad de la República / Espacio de Ciencia y Tecnología Química, TACUAREMBÓ (4)

Keywords: Triterpenic saponins, Quillaja Leaves extract, Immunoadjuvant saponin fraction, ESI-MSn, UHPLC.

Introduction:

Quillaja brasiliensis is an endemic tree species in Brazil and Uruguay. It has been shown that the aqueous extract and some of the purified saponin fractions obtained from its leaves have immunoadjuvant activity comparable with Quil-A[®], the main commercial adjuvant product based on Q. saponaria saponins [1, 2]. The aim of this study was to perform a preliminary structural characterization of the immunoadjuvant fraction of saponins designated as Fraction B (FB).

Methods:

The aqueous extract of Q. brasiliensis was subjected to a separation on an SPE column to remove non-saponin components and the fractions containing saponins were reunited. This fraction (FB) was investigated by direct infusion and liquid chromatography/electrospray ionization ion trap multiple-stage mass spectrometry in negative ion mode (DI-ESI-IT-MSn and LC-ESI-IT-MSn). The characterization was performed based on MS2 and MS3 experiments of the [M-H]⁻ ions.

Results:

The saponins contained in FB were adequately separated by chromatography on a C18 reverse phase UHPLC column using a mobile phase gradient of acetonitrile in water at acidic conditions. The mass spectrometer was set to monitor, select and fragment the most abundant ions [M-H]⁻ in the range m/z 1300–2000, using different collision energies. One of them allowed the production of the precursor ion [M-H]⁻ in good yield, while the second energy was set to a higher value in order to produce more product ions that provided more structural information. According to their [M-H]⁻ ions, characteristic product ions and retention times, twenty seven saponins, were tentatively identified [3]. These saponins feature four different triterpenic aglycones, namely quillaic acid, gypsogenin, phytolaccinic acid and its O-23 acetate. All the saponins are bidemosidic, bearing oligosaccharides chains linked to the aglycone at C-3 and C-28, the last one containing or not a branched dicarboxylic acid linked or not to a terminal Ara residue.

Conclusions

This is the first detailed report about the structure of Q. brasiliensis saponins. Further work will be necessary to fully characterize all the immune stimulating saponins present in the Q. brasiliensis species.

Novel Aspect:

Q. brasiliensis is an alternative source of immunoadjuvant saponins. The production of Fraction B could scale and become a commercial product comparable with Quil-A[®].

1209 - A VERSATILE SEMI-PREPARATIVE HPLC PLATFORM, INCLUDING HR MS AND NMR, TO SUPPORT PROCESS DEVELOPMENT IN INDUSTRIAL BIOTECHNOLOGY

Burhan Ozalp (1)

DSM, R&D, Delft, Netherlands (1)

Keywords: Chromatographic fractionation, high resolution mass spectrometry, high field NMR, structure elucidation

Introduction:

Identification of the chemical structure of impurities and characterization of their biological activities in the early stage of product development as well as in final product is very important in industrial biotechnology. This is a crucial aspect of “process understanding” and “product specification”. Furthermore, regulatory authorities (ICH, FDA, EMA) have established clear guidelines demanding close monitoring, in-depth investigation and unambiguous confirmation of the chemical structure of impurities in drug products.

Methods:

Various approaches can be considered to identify compounds but most of them require relatively pure compounds. While MS has a very high sensitivity, NMR identification in the past required more material. Nowadays NMR instruments have higher sensitivity and approximately 50 µg of pure compound is sufficient for the identification of unknowns, meaning that the composition (identity and relative quantities of elements) and constitution (nature and sequence of bonds), can be determined. Such small amounts can be obtained easily from a semi preparative HPLC platform using 10 to 20 mm i.d. columns.

Results:

This study presents a workflow to effectively isolate impurities by using semi preparative HPLC followed by high resolution mass spectrometry and high field NMR analyses for structure elucidation. Furthermore, the workflow can be applied as untargeted approach to characterize complex matrices where the whole chromatogram is fractionated and each fraction separately tested on e.g. biological activity and further characterized by HR-MS and NMR. The workflow includes checks on purity and stability of collected fractions and concentration and desalting steps before HR-MS and NMR analysis.

Conclusions

A practical workflow has been developed for the identification of the chemical structure of impurities. The workflow is based on isolation of impurities using a semi preparative HPLC and followed by high resolution mass spectrometry and high field NMR analyses for structure elucidation. The workflow has been applied successfully for structure elucidation of a number of unknown impurities in various biotech products. Furthermore, it has been also demonstrated that this workflow can be used to characterize samples consisting of complex mixtures.

Novel Aspect:

Fast and robust protocol for semi-prep chromatography, HR-MS and NMR workflow for targeted and untargeted fractionation in combination with intermediate checks on purity of collected fractions

University of Waterloo, Chemistry, Waterloo (1)

Keywords: Sample Preparation; Ambient MS; SPME; On-site; In-vivo Determinations

Introduction: Since first introduction in 1990, Solid phase microextraction techniques have continually evolved in terms of architecture in order to further push down detection limits while maintaining a clean extraction, portable and easy to handle design. With this portability in mind, the SPME fiber has been appropriately coupled with emerging miniaturized MS technologies for on-site analytical applications. In this way various complex, including living systems can be monitored. The most challenging are biomedical applications. Patient monitoring, metabolomics and biomarkers discovery are an integral part of medical diagnosis and biomedical research. However, tissue analysis remains the bottleneck of such studies due to the invasiveness of presently used sample collection based on biopsy, as well as the laborious and time-consuming sample preparation protocols. In the proposed technology, we have integrated in vivo sampling, sample preparation including global extraction of metabolites together with convenient coupling to analytical instrument resulting in medical biopsy tool.

Methods: This approach based on a small sorbent coated flexible metal fiber format of solid phase microextraction was developed and evaluated during organ treatment and transplantation in rodent or pig model as well as applied to human organs. Other formats will be discussed as well. In this approach, only molecules of interests are extracted onto biocompatible sorbent from the investigated system, however no tissue is not removed from the organ. By using extraction phase with appropriate chemical property and morphology, the analytes are enriched onto the sorbent with minimum of interferences collected. Therefore, the direct coupling of the chemical biopsy probe to mass spectrometry is feasible. Such hyphenation facilitates rapid quantification of the compounds of interests resulting in possibility of close to real time monitoring. This approach has potential in biological and clinical on-site investigations including bedside medical diagnosis.

Results: In the presentation we will discuss diverse SPME-based devices recently developed in our laboratory for the extraction/enrichment of analytes of interest from tissue and small volumes of complex sample matrices, which can be directly coupled with mass spectrometry instruments for rapid analysis. In these applications we use SPME devices containing coatings with matrix compatible morphologies. The approaches tested include Coated Blade Spray (CBS), SPME-transmission mode-direct-analysis-in-real-time (SPME-TM-DART-MS), SPME- microfluidic open interface (SPME-MOI). Total analysis time wastypically 5 minutes, but did not exceed 15minutes and sample volumes ranging between 1-100 μ L to the whole organs were used. Sampling/sample-preparation is performed either by spotting the sample onto the SPME-device, or by immersing the SPME-device in a vessel containing the sample or placed directly into tissue. Despite short extraction times, limits of detection in the sub-ng/mL range were obtained, while good accuracy, and linearity were attained for all the studied probes (e.g. therapeutic-drugs, drugs of abuse, and immunosuppressants) in the diverse matrices scrutinized (e.g. urine, plasma, blood, saliva, brain, muscle and other tissue). In the presentation we will describe exemplary cases in which the mere coupling of SPME to MS is not sufficient to answer relevant analytical questions and the use of strategies that allow for removal of co-extracted interferences or source artifacts, such Ion Mobility and Multiple Reaction Monitoring with Multistage Fragmentation (MRM3), will also be discussed.

Conclusions: Matrix compatible coatings provide clean extraction suitable for direct coupling to mass spectrometers.

Novel Aspect: SPME biopsy probe hyphenated to MS facilitates on site monitoring even of complex and living systems

Keywords: ultra-high performance liquid chromatography, hydrophilic interaction chromatography, supercritical fluid chromatography, mass spectrometry, quercetin, phenolic compounds

Introduction:

Quercetin is one of the most discussed flavonoid compounds with beneficial effects to human health due to its antioxidant properties. In human body, it is metabolized to two groups of health affecting metabolites with different physico-chemical properties including acidity, molecular weight, and log P. Therefore, it is difficult to determine these compounds in a single analytical run [1][2].

Methods:

Three chromatography methods with different selectivity using mass spectrometry (MS) detection in both electrospray positive and negative ion modes were chosen and optimized. These methods included reversed phase ultra-high performance liquid chromatography (RP-UHPLC), hydrophilic interaction chromatography (HILIC), and complementary supercritical fluid chromatography (UHPSFC).

Results:

We carried out columns screening with emphasis on separation of isomeric pair of tamarixetin and isorhamnetin. Shield RP18 column using methanol and 0.1% formic acid as the mobile phase enabled the baseline separation of all analytes in RP-UHPLC. Pentahydroxyl, amide, silica, and zwitterion columns with acetonitrile and different aqueous solutions in wide pH range were used for separation in HILIC mode. However, the separation of flavonoids was less successful due to the peak broadening. Ten different columns were screened for SFC. The most promising results were obtained using the diol column and methanol with the addition of organic acids, buffers, ammonium hydroxide, and water. Finally, the MS parameters were tuned to get sensitive detection.

Conclusions:

The optimized methods will be compared in the terms of selectivity, retention and sensitivity. The targeted analysis of quercetin and related compounds including small phenolic acids and large metabolites with preserved flavonoid structure in combination with high throughput sample preparation step will be used to explain their metabolism and the health effects.

Novel Aspect:

The simultaneous analysis of quercetin and its metabolites with different physico-chemical properties using various separation mechanisms with MS.

129 - MULTIDIMENSIONAL GAS CHROMATOGRAPHY COUPLED TO ISOTOPE RATIO MASS SPECTROMETRY IN SPORTS DRUG TESTING

Thomas Piper (1) - Marlen Putz (1) - Mario Thevis (1)

German Sport University Cologne, Institute of Biochemistry - Center for Preventive Doping Research, Cologne (1)

Keywords: testosterone misuse, carbon isotope ratios, Deans switch, long term detectability

Introduction:

Testosterone (T) is frequently misused in sports and its administration is forbidden under the rules of the World Anti-Doping Agency [1]. Its detection remains challenging as T is an endogenous substance. Only by carbon isotope ratio determinations it is possible to distinguish endo- from exogenous T. Sample preparation is commonly based on twofold high performance liquid chromatography clean-up, which is laborious and requires up to 2 working days [2].

Methods:

Multidimensional gas chromatography (MDGC) is suitable for the separation of complex matrices. Therefore, one GC equipped with a column of lower polarity is used for sample clean-up and hyphenated to a second GC that employs a more polar column for analyte separation by a pressure-controlled Deans switch device. The effluent from the second GC is partitioned between an isotope ratio and a single quadrupole mass spectrometer to enable simultaneous determinations of isotope ratios and peak purity.

Results:

The developed method was fully validated following the guidelines of the World Anti-Doping Agency [3] and employing linear mixing models and reference population derived thresholds [2]. The method demonstrated comparable results to the current screening procedure and sample preparation was shortened to 1 day. Additionally, it was possible to implement measurements of a recently detected new long-term metabolite of testosterone administrations. This epiandrosterone prolongs the detection time by a factor of 2 to 3 [4]. Only for testosterone itself a bias between the screening and the new method was found, which can be partly compensated by population-derived threshold levels.

Conclusions:

The developed method employing multi-dimensional gas chromatography instead of high performance liquid chromatography was found to be fit-for-purpose and has been applied to sports drug testing complementing the current routine procedure. Epiandrosterone was found to be a suitable marker for steroid administration and was successfully implemented into doping controls.

Novel Aspect:

Multi-dimensional gas chromatography hyphenated to isotope ratio mass spectrometry was successfully employed for doping control analysis substantially reducing the workload for sample preparation.

Keywords: Miniaturization, μ -TOF, in situ detection, focusing, instrument development

Introduction: Mass Spectrometry detection on-site

Fast and precise insitu gas sensing and identification is of utmost importance in the case of an industrial chemical accident, of atmospheric pollution mapping, for homeland security... The systems used for such kind of purpose need to be of small overall dimensions and weight in addition of their top level performance. Towards this goal, a few research groups [1,2] have developed miniaturized mass spectrometer systems based either on standard or on microfabricatedtechnics.

Methods: Micro Mass spectrometer on chip

This microsystem is fabricated using Micro Electro Mechanical Systems (MEMS) technology. This technic is more promising for size reduction, but also more challenging than standard manufacturing techniques.TheMEMS developed in this work have a size of only 1 cm \times 2 cm for a micro-mass spectrometerbased on Time-of-Flight (TOF) separation. The micro-TOF ion source is studied and optimized subsystem by subsystem [3,4].

Results: Mass analysis by a linear Micro-TOF

Using electron impact ionization (EI 70 eV), ions are generated in an ionization chamber, then extracted and focalized by electrostatic lenses constituted by 6 electrodes. Ion beam is collected in linear mode in a Micro Channel Plate (MCP) detector and mass spectra are recorded. Using ultrafast pulsing of these ions, the micro ion source is used as a linear TOF spectrometer that is able to separate simple gas mixtures efficiently.Ionization of neutrals atoms is shown to be efficient by electron impact. Using comparison with ion trajectories simulations, the extraction and focalization are optimized to be able to extract the highest ionic current from the ionization chamber. Pure electrostatic simulation can be used as guideline and limits of the simulation values are discussed. Theelectrode voltage setting of ionization and focusing areas were studied and influences on signal intensity and on mass resolution are followed. Mixes of noble gas, alkane or BTEX were tested in linear micro-TOF.

Conclusions

Miniaturization on chip of mass spectrometer Time-of-Flight is operational and provides repetableand reproducing results. These devices allow studies of extraction and ion focusing on chip. Electrostatic simulation could be used as global guideline and is a tool for the understanding of ion beam behaviour. Resolution will be improved using orthogonal injection.

Novel Aspect

Gas analyses by linear micro-TOF are available and this work shows encouraging results and pulls the μ -TOF one step closer towards a fully integrated portable analytical system.

⁴Techn. University Darmstadt, Department of Organic Chemistry and Biochemistry, 64287 Darmstadt, Germany

Keywords

Online-Biosensor-MS combination; T-SPR biosensor; continuous flow microfluidics; antibody epitope identification; epitope peptide affinity determination.

Introduction

Analysis of biomolecular interaction epitopes is a key step in the development of therapeutic antibodies, biomedical peptide and protein biomarkers and molecular vaccines. Bioaffinity analysis using biosensors has become an established technique for detection and quantification of biomolecular interactions. However, a principal limitation of biosensors is their lack of providing chemical structure information of affinity-bound ligands. Proteolytic excision/extraction (PROTEX-MS) is a major techniques for mass spectrometry based elucidation of protein- ligand interactions, but affinity-MS analysis does not provide quantitative affinity data. A new online proteolytic excision SPRMS combination (PROTEX-MS) enables simultaneous structure identification and affinity quantification of antibody epitopes from a protein- ligand complex immobilized on a gold chip.

Methods

Key tools of the online proteolytic excision SPRMS Epitope Analyzer are (i), a new SPR biosensor that enables the application of microfluidic systems suitable for direct ESI-MS that is not sensitive to buffer change normally required for SPR (T-SPR); (ii), an integrated, automated interface that provides elution and sample concentration for direct MS analysis of the eluted epitope peptides [1]; and (iii), a new high pressure proteolytic system, high pressure barocycler digestion. The high pressure digestion enables substantially enhanced speed, efficiency and automation of protease digestion and proteolytic affinity-extraction, compared to conventional digestion.

Results

Initial validation of the new PROTEX-To validate SPR-MS system, analysis on a well-defined affinity pair has been studied. Results from the tests on anti-Beta Amyloid antibody interacting with Abeta 1-40 and 1-16 protein provided us with a KD values of 0.628 μ M and 0.796 μ M and with the protein/peptide structural information. The broad application potential of the PROTEX-SPR-MS Epitope Analyzer has been ascertained by identification of protein epitope structures from therapeutic and pathophysiological antibodies, such as an unusual mixed-disulfide antibody epitope of the rheumatoid target protein, HLA-B27; and the interaction site identification of chaperone complexes of lysosomal enzymes [2, 3]. Interaction epitopes as diverse as antigen-antibody and lectin- carbohydrate complexes [4, 5], with affinity binding constants (KD) from milli- to nanomolar ranges can be directly analyzed. Applications amenable with the PROTEX- SPR-MS Epitope Analyzer include affinity-based biomarker identification; identification of protein and peptide epitopes; precise antibody affinity determinations; direct label-free antigen quantification; and clinical epitope analyses of pathophysiological antibodies, suitable for clinical apheresis and hyposensitization of patients after immunogenic protein therapy [4-6].

Epitopes from antisera of Fabry disease (FD; α -Galactosidase deficiency) patients were identified using the PROTEX-SPR-MS combination. Tryptic peptide mixtures were loaded onto the SPR-MS; after washing out nonbinding peptides, epitope peptides were eluted with 0.01% TFA into the affinity interface, ESIMS was performed with a Waters QuattroUltima MS. The epitope peptide, α -Gal(309-332) was identified from 2 FD patients and revealed high affinity (KD, 39 nM) comparable to the full length enzyme (KD, 16 nM). Linear, stabilized epitope peptides were prepared by SPPS.

Conclusions

A number of applications are amenable with the new online PROTEX-SPR-MS epitope analyzer, including affinity-based biomarker identification, identification of protein and peptide epitopes, precise antibody affinity determinations, and direct label-free antigen quantification. In addition, the clinical application potential was shown in epitope elucidation from therapeutic and pathophysiological antibodies of lysosomal enzymes, with affinity constants (KD) amenable from milli- to nanomolar ranges.

Novel Aspect

A new powerful tool for epitope and affinity analysis of biomolecular interactions was developed. The PROTEX-SPRMS Epitope Analyzer provides a breakthrough (i) for proteolytic digestion of proteins; and (ii), direct affinity determination in combination with MS.

710 - ATMOSPHERIC PRESSURE CHEMICAL IONIZATION – CONSTRUCTING IONIZATION EFFICIENCY SCALE AND DERIVATIZATION REAGENT SUITABILITY.

Riin Rebane (1) - Piia Liigand (1) - Jaanus Liigand (1) - Maarja-Liisa Oldekop (1) - Koit Herodes (1) - Ivo Leito (1)

University of Tartu, Institute of Chemistry, Tartu (1)

Riin Rebane,* Anneli Kruve, Piia Liigand, Jaanus Liigand, Koit Herodes, Maarja-Liisa Oldekop and Ivo Leito

Keywords: ionization efficiency; atmospheric pressure chemical ionization (APCI); derivatization reagents.

Introduction:

Recent evidence has shown that the atmospheric pressure chemical ionization (APCI) mechanism can be more complex than generally assumed. In order to better understand the factors affecting the APCI, an ionization efficiency scale for an APCI source has been created for the first time. Moreover, based on the scale, five different derivatization reagents for amino acid analysis were tested for APCI suitability (eluent, sensitivity, matrix effects etc).

Methods:

The MS responses were recorded in a flow injection mode as previously done by Kruve et al. [1] For every compound, the response versus concentration slope was measured and the ionization efficiencies were expressed in relative terms, using pyrene as the reference compound. Comparison of derivatization reagents was carried out with optimized LC-APCI-MS methods on a reversed phase column.[2]

Results:

For the first time an ionization efficiency scale for 40 compounds has been created for APCI source. All logIE values are presented relative to pyrene, chosen as the reference compound with the assigned logIE value 3.41, and range from -0.62 up to 4.32, i.e., spanning almost 5 orders of magnitude. [3]

Suitability of five derivatization reagents for amino acids analysis (diethyl ethoxymethylenemalonate (DEEMM), benzyl ethoxymethylene malonate (DBEMM), dansyl chloride (DNS), 9-fluorenylmethyl chloroformate (FMOC-Cl) and 2,5-dioxopyrrolidin-1-yl N-tri(pyrrolidino)phosphoranylideneamino carbamate (FOSF)) were tested for APCI. Acetonitrile proved to be more suitable for the analysis and sample dilution approach in green tea showed that APCI is, in general, less prone to matrix effect than electrospray ionization. FMOC-Cl had poor sensitivity and also high matrix effects (ME). DEEMM and DNS-derivatives were less influenced by the ME than DBEMM and FMOC-derivatives. [2]

Conclusions:

The results show that the best ionized compounds in the APCI are not small volatile molecules. Overall the ionization efficiency vs molecular structure trends in APCI are very similar to ESI. Results imply that in APCI several ionization mechanisms operate in parallel and mechanism(s) not relying on evaporation of neutral molecules from droplets has significantly higher influence than commonly assumed. Moreover, derivatization reagents for APCI were DEEMM and DNS.

Novel Aspect:

For the first time an ionization efficiency scale spanning over 5 logIE units and including 40 diverse compounds has been created for APCI source.

984 - MICROFLUIDIC CE-MS FOR NEWBORN SCREENING: A SINGLE SYSTEM FOR MONITORING SMALL MOLECULE AND PROTEIN BIOMARKERS

Erin Redman (1) - J. Scott Mellors (1)

908 Devices Inc., Life Sciences, Boston (1)

Keywords:

Introduction:

After birth several assays are typically performed to determine if an infant suffers from conditions that could have long-term health effects. The compounds measured range from small molecules to larger proteins. Few techniques are capable of effectively analyzing both small and large molecules rapidly and simply. In this work we present a microfluidic CE-MS system for analyzing both small molecules and intact proteins related to newborn screening assays.

Methods:

Microfluidic chips with a 10 cm separation channel were used for small molecule assays and chips with a 22 cm separation channel were used to analyze protein biomarkers (908 Devices Inc.). Samples for small molecule assays a liquid extraction was performed to elute the compounds from dried blood spots. Protein biomarkers were measured from whole blood or isolated erythrocytes. MS analysis was performed using a Thermo Orbitrap MS.

Results:

Results will be presented demonstrating microfluidic CE-MS analysis of several common biomarkers regularly monitored during new born screening. Using the same method, amino acids and acyl carnitines can be monitored to assess whether samples are indicative of Phenylketonuria (PKU) or fatty acid metabolic disorders, such as Carnitine acylcarnitine translocase deficiency (CACT). The small molecule biomarkers are able to be quantified over the appropriate physiological ranges indicative of disease states. Hemoglobin subunits from whole blood or purified erythrocyte lysates were analyzed to detect hemoglobin variants indicative of hemoglobinopathies, such as Sickle Cell Anemia. The alpha, beta, gamma, and abnormal subunits were resolved in the microfluidic CE separation within 4 minutes and the identity of the subunits was confirmed by mass. In the samples analyzed, beta chain variants indicative of sickle-cell disease were characterized.

Conclusions

The microfluidic CE-MS platform can be used to perform rapid small molecule and protein assays related to new born screening. Additionally, multiple small molecules can be assessed with a single method providing the ability to screen for different disease states in a single run. By analyzing hemoglobin at the subunit level, minor modifications can be identified and detected by both their mass and anticipated change in migration times due to modification.

Novel Aspect:

In this work a single system is used to demonstrate new born screening assays for small molecule and protein biomarkers.

413 - CHEMICAL PROFILING OF THE HUMAN SKIN SURFACE FOR MALARIA VECTOR CONTROL USING A NON-INVASIVE SOLVENT MODIFIED SORPTIVE SAMPLER WITH GC×GC-TOFMS AND UPLC-IMS-HRMS

Madeliën Wooding (1) - Tyren Dodgen (2) - Marc Bouwer (3) - Yvette Naudé (1) - Egmont Rohwer (1)

University of Pretoria, Department of Chemistry, Pretoria (1) - Microsep, Application Specialist, Johannesburg (2) - University of Pretoria, Forestry and Agricultural Biotechnology Institute, Pretoria (3)

Keywords: GC×GC-MS, UPLC-IMS-HRMS, human skin compounds, sorptive sampling, malaria vector control

Introduction:

Odour mosquito lures are currently being used as part of integrated vector control strategies in the fight against malaria. Variation in inter-human attractiveness to mosquitoes, as well as the preference of mosquitoes to bite certain regions on the human host are possible avenues for identifying lead compounds as potential attractants[1-4]. These may prove more effective in lure and kill strategies.

Methods:

Two different areas of the human skin, namely wrist and ankles, were compared following a 1 hour sampling period. Skin surface compounds were concentrated using a solvent modified polydimethylsiloxane (PDMS) sampler. Sampling was followed by analyses with GC×GC-TOFMS and UPLC-IMS-HRMS. The sampler was thermally desorbed directly in the inlet liner of a GC system, while for LC analyses the PDMS sampler was solvent back-extracted prior to analyses.

Results:

The skin profiles for the ankle and wrist groups were compared using principal component analyses. Compounds responsible for the differences in the chemical profiles were tentatively identified based on a comparison of sample mass spectra to that of the NIST14 library for the GC analyses. Accurate mass, isotope fit values and fragmentation patterns were compared to online ChemSpider databases for the LC analyses. Binary compare using an OPLS-DA Model highlighted the differences between the ankle and wrists groups for the LC-MS data sets. Viburtinaland Menaquinol, as well as Allodeoxycholic acid and N,N-Diethylbenzeneacetamide, were tentatively identified, using the Human Metabolome Database. These form plausible lead markers for the wrist and ankle groups, respectively. A comprehensive list of collision cross section data of human skin chemicals was compiled for LC amenable markers.

Conclusions:

In this study, methods were developed to chemically profile the human skin surface with the aim of determining the compounds responsible for attracting the mosquito vector to its human host. A PDMS sorptive sampler was modified with solvent to give improved extraction of polar analytes from the skin surface. This multi-approach gave a comprehensive human skin chemical profile consisting of volatile, semi-volatile, and non-volatile compounds.

Novel Aspect:

Skin surface compounds were concentrated using a solvent modified, non-invasive, in-house developed PDMS sampler for GC-MS and LC-MS. CCS library for skin surface compounds.

B.01.1 INSTRUMENTATION AND METHODS - HYPHENATED TECHNIQUES

1311 - DEVELOPMENT OF RAPID SCREENING APPARATUS WITH DIP AND PI/MS FOR ADDITIVES IN POLYMER MATERIALS.

Yuji Mishima (1) - Takahisa Tsugoshi (2)

KMTL, KMTL, Tokyo, Japan (1) - AIST, NMIJ, Tsukuba, Japan (2)

Keywords: direct inlet probe, fragmentless ionization, screening, silent change, additive,

Introduction:

The globalization of the economy has made risks of quality control due to the "Silent Change" apparent in manufacturers, particularly in the electrical and electronic industries. The Silent Change refers to material specifications being modified without approval in the supply chain, and leads sometimes to serious accidents, that causes to product recall and the loss of the brand image.

For its quality control, rapid screening technique is required with all detection of additive species because of many specimens of lots, and with simple operation of apparatus.

Methods:

For all detection of additives, it is better to use DIP, direct inlet probe that extract additives thermally in vacuum. However low boiling point chemicals are vaporized and disappeared at measurement, so that technique to cover the specimen is used, named SET, Suppressing Evaporation Technique. Separation technique as GC and LC takes time, so that it is required a fragmentless ionization that realizes informational separation in a mass spectrum because one peak indicates one species.

Results:

JMS-Q1500GC by JEOL was accepted as a base instrument for the developed new apparatus. This instrument has both options of DIP and photoionization that is one of the fragmentless ionization techniques. However these options are exclusive. To be consistent with both, an alteration had been required. Further new design of DIP had been required. We manufactured a new design vacuum chamber and DIP by way of trial. At this stage of development, performance of the trial apparatus had been checked with some specimens. For example, good calibration curve has been obtained from VitaminE within 10 min., but not from Decabromodiphenyl because of the design of instrument.

In this design, DIP was inserted to an underside of the chamber, so that the operability was not good. The performance of coupling of DIP and Photoionization had already ascertained, consequently we moved to the next step to solve the operability problem. Newer designs of DIP and vacuum chamber were required for that DIP is possible to insert to a front of the chamber. And the new design has resolved the detection problem of Decabromodiphenyl.

Conclusions

The new apparatus with both of DIP and photoionization consistently has been successfully developed. The measurement is without property dependence from chemicals, e.g., a difference of boiling point, as all detection.

Novel Aspect:

The developed apparatus offers high level quality control to avoid the silent change with rapidity and easy operation. It can be a deterrent to the silent change.

B.01.2 INSTRUMENTATION AND METHODS - HYPHENATED TECHNIQUES

1100 - COMPARISON OF THE DISPLACEMENT MODE VERSUS GRADIENT MODE FOR PROTEOMICS USING AN ONLINE 2D-LC-MSMS SYSTEM

Hartmut Schlueter (1)

University Medical Center Hamburg-Eppendorf, Mass Spectrometric Proteomics, Hamburg (1)

Keywords: on-line-two-dimensional-liquid-chromatography-tandem-mass-spectrometry (2D-LC-MSMS); displacement chromatography; proteomics;

Introduction:

The extreme complexity of proteomes is a major challenge for LC-MSMS-based proteomics. Two-dimensional-(2D)-LC applying cation-exchange chromatography (CEX) in the first dimension has been successfully used for increasing the number of identified proteins. In this study it was investigated if CEX performed in the displacement mode (DM) within an online-2D-LC-MSMS system offers advantages in comparison to the gradient mode (GM) for the analysis of proteomes.

Methods:

Tryptic peptides of HeLa cells (5 µg total) were applied to an online-2D-LC-MSMS system (1st dimension: CEX column; 2nd dimension reversed-phase column). Tryptic peptides were eluted from the CEX either by pulsed injections of increasing amounts of ammonium acetate (GM) or by pulsed injections of spermine (DM). Resulting MS data were subjected to OpenMS, MaxQuant and mathematica scripts.

Results:

The total number of identified peptides and proteins as well as the sequence coverage was significantly higher by using DM compared to GM. A major reason for this phenomenon is, that DM was giving a significantly better separation via CEX of doubly charged tryptic peptides (charge state in the mobile phase of the LC), which represent the majority of tryptic peptides in mammalian proteomes. The results are in good agreement with former studies about the application of the displacement mode for the separation of complex mixtures in combination with mass spectrometry [1, 2]. However, in comparison to the former study [2] in the current study a big step forward was achieved regarding the operating time (reduction from 6 days to approximately 12 hours) of the 2D-LC-MSMS analysis. In addition the total sample amount was reduced down to 5 µg.

Conclusions

In comparison to gradient mode the displacement mode for cation-exchange chromatography within an online system comprising two-dimensional liquid-chromatography coupled to tandem mass spectrometry for identifying proteomes via tryptic peptides is significantly more efficient.

Novel Aspect:

First study comparing the efficacy of displacement mode versus gradient mode for proteomics using online-2D-LC-MSMS

193 - LOW-FLOW ATMOSPHERIC PRESSURE CHEMICAL IONIZATION BASED ON A GAS DYNAMIC VIRTUAL NOZZLE NEBULIZER

Timotej Strmeň (1) - Vladimír Vrkoslav (2) - Ondřej Pačes (2) - Josef Cvačka (1)

Institute of Organic Chemistry and Biochemistry of the Czech Academy of Sciences, Department of Analytical Chemistry, Faculty of Science, Charles University in Prague, Prague (1) - Institute of Organic Chemistry and Biochemistry of the Czech Academy of Sciences, Institute of Organic Chemistry and Biochemistry of the Czech Academy of Sciences, Prague (2)

Low-flow atmospheric pressure chemical ionization based on a gas dynamic virtual nozzle nebulizer

Keywords: low-flow APCI, GDVN,

Introduction:

Atmospheric pressure chemical ionization (APCI) is a useful tool for analyzing small and relatively stable molecules, e.g., lipids [1], at milliliter-per-minute sample flow rates. Despite the previous effort to develop low-flow APCI [2,3], no such an ion source has been commercialized yet. We are currently developing a nebulizer for an APCI source operable at sub-microliters per minute flow rates.

Methods:

The sprayer was manufactured from a borosilicate glass tube (I.D. 1.15 mm) and two fused-silica capillaries, which were fixed inside the tube: (i) tapered-tip capillary for the sample and (ii) capillary for gas delivery. The device generated liquid jet thanks to gas-dynamic forces exerted by a co-flowing nitrogen (gas dynamic virtual nozzle, GDVN [3]). It served as a nebulizer for low-flow APCI.

Results:

The spray created by the GDVN nebulizer operated at 120 ml/min nebulizing gas flow rate and 200 nl/min liquid sample flow rate had a conical shape with the diameter of 1.5 mm at the distance of 2.4 cm. To facilitate fast solvent evaporation, a short, resistively heated glass tube was placed between the sprayer orifice and corona discharge region. Test compounds including acridine in methanol and acetonitrile, cholesterol in toluene, cis-11-hexadecenol in acetonitrile (all in positive mode), and 5-nitrosalicylic acid in methanol (in negative mode) were successfully detected. Their spectra were similar to those recorded from the conventional APCI. The signal stability was rather moderate (RSDs of acridine signal recorded for ten minutes were about 30 – 40 %). High signal intensities of the analytes suggested the enhanced sensitivity of the GDVN APCI source.

Conclusions:

An APCI source with a GDVN nebulizer was found appropriate for nanoliter-per-minute sample flow rates. Various compounds were detected using a liquid flow rates down to 200 nl/min. No clogging of the sprayer was observed throughout the measurements, which, together with its high sensitivity, makes it a good candidate for a nano-HPLC and mass spectrometry hyphenation.

Novel Aspect:

For the first time, GDVN sprayer was successfully used as a nebulizer for liquid samples in an ion source.

Keywords: Enzyme, laundry detergent, SDS-PAGE, MALDI-TOF

Introduction:

There is a major challenge for the development of method in order to identify the enzymes in raw and manufactured materials in cosmetic industries [1, 2]. In this study we used SDS-PAGE and MALDI-TOF-MS instrument for identification of main types of enzymes used in laundry detergents: protease, lipase, cellulose, amylase, and mannanase.

Methods:

A certain weight of granular solid concentrates, was dissolved in Tris-base, and the suspension was stirred for 30 min. After centrifugation, equal volume of TCA and supernatant were mixed, and enzyme precipitation was accomplished with TCA protocol. These mixtures were separated according to their molecular weights on 12% Bis-Tris gels and visualisation was performed using Coomassie brilliant blue. After cutting of gel and remove of Coomassie reagent, the mass values has obtained by using MALDI-TOF-MS.

Results:

Smamples were load on the gel, and the separation was done based on the peptides' molecular weight. The main protein bonds were detected at approximately 26, 72 & 40, 32, 55, 55, and 35 kDa for Everlase, Carezyme, Mannaway, Termamyl, Duramyle, and Lipolase respectively. In order to obtain precise mass values, the same solutions were analyzed by MALDI-TOF-MS. Finally, the precise mass values were obtained, 26.6, 72.5 & 35.6, 33.7, 55.6, 55.6, and 31.7 kDa for Everlase, Carezyme, Mannaway, Termamyl, Duramyle, and Lipolase respectively and results have compared with reported MS results of these enzymes. Also, the protein bonds were detected successfully in ternary, quaternary and quinary mixtures of crude enzymes. As a final point the granular enzymes were analyzed with SDS-PAGE and MALDI-TOF. According to the obtained results, we can identify every kind of granular enzymes.

Conclusions:

In this study, determination of protease, lipase, cellulose, amylase, and mannanase was accomplished by SDS-PAGE and MALDI-TOF-MS. The MALDI-TOF-MS as a high-throughput screening method can be proposed for monitoring of enzymes used in laundry detergents, owing to its advantages such as speed, sensitivity, reproducibility and label-free readout.

Novel Aspect:

SDS-PAGE and MALDI-TOF-MS can be proposed as a versatile quality control approaches for detergent industry to identify used enzymes.

977 - MECHANISTIC REACTION INSIGHTS BY IN-SITU MONITORING OF AN AACVD REACTION USING GC-MS: STUDYING THE ZNFE2O4 THIN FILM GROWTH PROCESS

Ime C Usen (1) - Upul Wijayantha-Kahagala-Gamage (2) - James C Reynolds (2)

Loughborough University, Chemistry, Loughborough (1) - Loughborough University, Chemistry, Loughborough (2)

Keywords: AACVD, Gas Chromatography Mass Spectrometry, Reaction Monitoring, Volatile profile, Exhaust gas.

Introduction

A variant of the conventional chemical vapour deposition (CVD) process, the aerosol-assisted (AA) CVD method, uses aerosol droplets to transport the precursors, with the aid of inert or reactive carrier gases to the substrate for thin film coating. It is important to monitor the reaction that takes place in the AACVD system. A novel adaptation of GC-MS is developed which enables direct monitoring of AACVD exhaust gases for the first time providing valuable information.

Methods

The AACVD setup described by Tahir et al. (1) was directly interfaced via a heated transfer line and semi-automated port valve to GC-MS with DB-1 column. AACVD was conducted by systematically increasing the temperature from 300 to 550 °C in 50 °C intervals. Measurements were performed under programmed temperature conditions and the resulting films were characterised by X-ray diffraction and Raman spectroscopy to understand material properties and chemical nature.

Results

The exhaust gases were monitored for the solvent (ethanol) and the individual precursor components; zinc acetate and iron (III) chloride and $[\text{Fe}_2(\text{acac})_4(\text{dmaeh})_2][\text{ZnCl}_4]$ the precursor. The GC-MS peaks were successfully observed for the entire experiment at the various temperatures. Key observations noted were: the exhaust gas profile changes depending on temperature; the ethanol changes into acetaldehyde if no precursor is present; when the precursor dissolves in ethanol, other species are observed which are from either the direct breakdown of the precursor, or reaction in the AACVD system, acetone, ethyl ether, ethyl acetate, butenal, 2-butanone and 3-penten-2-one.

The optimal temperature required to produce ZnFe_2O_4 was 450 °C from precursor in ethanol. The exhaust gas profile obtained from the GC-MS was confirmed through (XRD) and Raman spectroscopy studies. This study shows that this method can be used to give a mechanistic insight into the processes that take place in the AACVD system for the first time, with potential for further research.

Conclusions

The volatile profile obtained from the exhaust of an AACVD system provides clear insight to the progression of the overall reaction. Observation of specific reaction products acetone, ethyl acetate, ethyl ether and butenal in exhaust gas phase can be used as an indication for the formation of ZnFe_2O_4 film from precursor $[\text{Fe}_2(\text{acac})_4(\text{dmaeh})_2][\text{ZnCl}_4]$ in ethanol at 450 °C. The technique has the potential of being incorporated into simple sensor technology for a wider use.

Novel Aspect

A new application of GC-MS has been developed for in-situ monitoring of AACVD process, with mechanistic information from the volatile profile of the exhaust gas being so vital.

Keywords: Sensitivity, Time of flight, Ion Extraction, Pulse

Introduction:

Better sensitivity is the long-lasting pursuit of an instrument designer. In most cases of the time of flight (TOF) mass spectrometer (MS), ions were extracted from the ion source continuously and path through the push area of the TOF-MS. Hereafter, most of the ions in the push area was repeatedly accelerated to the free field area, and will finally reach the detector in sequence, which is decided by their mass to charge ratio.

Methods:

A pulsed extracting field and an accelerating field was introduced into a TOF-MS between the ion source and the push area. Thus the ions could be extracted and spread along its path to the push area. Where an ion's position among them depends on its mass to charge ratio. If the push pulse is synchronized to a certain time, it could seize the interested ions by their mass to charge ratio, leave other ions passing by.

Results:

Experiments were done on an off-axis TOF with thermal ionization ion source and Cs sample with contamination of Na and K. Working in continuously extracting mode, the acquired mass spectrum will show that the mass peak of Na is much higher than that of Cs. While in pulsed ion extraction mode and synchronized push, the mass peak of Cs is enhanced to several times higher if Cs was focused. The mass peak of Na could be suppressed to below 20% at the same time. If it is synchronized to Na, the mass peak of Na would be enhanced and Cs be suppressed. In this experiment, the difference of the synchronize time, or push pulse delay, between focused to Na and Cs is about 5 micro-seconds, which can be easily handled.

Conclusions

Pulsed ion extracting mode could enhance the interested mass peak by several times and greatly suppress other mass peaks at the same time. Comparing to the continuously extracting mode, it could greatly improve the sensitivity of the instrument without significant change for an off-axis TOF-MS.

Novel Aspect:

Pulsed ion extracting mode could enhance the interested mass peak by several times, which shows its great talent on improving the sensitivity of an off-axis TOF-MS, and other instruments.

287 - PROBING THE LIMITS OF ON-LINE REACTION MONITORING BY SMALL FOOTPRINT ESI-MS AND NMR

Christopher Whitmore (1) - Alan Kenwright (1) - Andrew Ray (2) - Steven Coombes (2) - Jackie Mosely (1)

Durham University, Department of Chemistry, Durham (1) - AstraZeneca, Global Chemical Development, Pharmaceutical Development, Macclesfield (2)

Keywords: on-line, reaction monitoring, ESI-MS, compact

Introduction:

The proliferation of relatively cheap small-footprint MS instruments presents an opportunity for their application to on-line reaction monitoring, particularly when used in combination with other small footprint analytical instruments [1]. The opportunities and limitations of small footprint ESI-MS in reaction monitoring are explored here.

Methods:

A combined system consisting of a Waters QDa single quadrupole ESI-MS instrument and a Magritek Spinsolve 43 MHz NMR instrument were used to monitor a variety of reactions, with on-line dilution provided by a system of Teledyne-SSI LS class HPLC pumps and a Rheodyne Mass Rate Attenuator.

Results:

The versatility of the combined ESI-MS/NMR system are demonstrated, as well as the value of a combinatorial approach to reaction monitoring, with examples presented in which data from a single technique would be misleading, and in which the combined data can be used to overcome inherent issues with the techniques in question. The capabilities of the system with regard to extremes of temperature, pH and other reaction conditions are reported.

Conclusions:

System is shown to be robust to a variety of conditions, though the performance of rare-earth magnet based NMR to reactions with off-gassing or extremes of temperature is found to be poor. Challenges are found with the use of the single quadrupole MS instrument for the monitoring of reactions with particularly complex mixtures, with methods developed to correct for suppression in ESI-MS.

Novel Aspect:

Combined portable small footprint NMR/MS system utilized on a variety of reactions, capabilities of system explored and discussed.

1158 - IMPROVEMENT OF ELECTROSTATIC QUADRUPOLE ZOOM LENS FOR FIXED MULTI-COLLECTOR SYSTEM IN LRI-MS

Xianglong Yuan (1) - Zhiming Li (1) - Lihua Zhai (1) - Jiang Xu (1) - Xiaopan Shen (1) - Hu Deng (1) - Wei Wang (2)

Northwest Institute of Nuclear Technology, Northwest Institute of Nuclear Technology, Xi'an (1) - Northwest Institute of Nuclear Technology, Northwest Institute of Nuclear Technology, Xi'an' (2)

Keywords: LRIMS; Multi-collector; Zoom lens; Electrostatic quadrupole

Introduction:

The Laser-Resonance-Ionization Mass Spectrometer (LRI-MS) is a type of mass spectrometer with high elemental selectivity and high sensitivity, which is able to overcome the possible isobaric interferences [1]. Although frequently utilized in the reported LRI-MS facilities or instruments [2-5], time-of-flight (TOF) analyzer is not very appropriate for precise isotope ratio measurements due to its inherited shortcomings of the detection system, such as variation of signal detection efficiency [6]. In our laboratory, a LRI-MS system equipped with a magnetic analyzer (MA) has been used to measure the isotope ratios of plutonium [7] and tin [8] with peak-jumping method. Recently, a LRI-MS system equipped with an electrostatic analyzer (ESA), a magnetic analyzer (MA) and a fixed multi-collector system has been developed for precise isotope ratio measurement. In this instrument, the distance between the ion beams of different mass numbers at the focal plane is proportional to the relative mass dispersion. In order to achieve simultaneous detection of ions with different central mass by using the fixed multi-collector system, a zoom lens based on electrostatic quadrupoles has been developed to adjust the distances of the ion beams at the focal plane [9]. However, the zoom effect, that is, the horizontal magnification simulated by SIMION is quite different from that predicted by theoretical model.

In this work, the reason why the zoom effect in the simulation is so different from that in theoretical model is carefully analyzed. Based on the analysis, the zoom lens was improved to obtain a more accurate zoom effect. By using a home-made diagnostic tool capable of visualizing the shape of ion beam, the zoom effect of the improved zoom lens was evaluated experimentally.

Theory and Methods:

Quadrupole lenses are focusing in one plane and defocusing in another perpendicular one [10]. Thus, several quadrupole lenses could be combined for a useful lens system. A perfect quadrupole consists of four hyperbolic rods. Since hyperbolic rods are difficult to be manufactured and fabricated, round rods with a diameter of 1.148 times the desired diameter of the quadrupole field were used instead [11]. The shortcoming of such quadrupole lenses is that it occupies more space. In electrostatic field, the solution, which satisfies Laplace equation and given boundary conditions, is unique. Thus, a rectangular boundary field which saves more space could be used. Several segmented electrodes can be used to fit the rectangular boundary of the quadrupole field. However, high-order field components will be introduced. In order to reduce the high-order field components, the structural parameters of the electrodes must be carefully designed. In ideal quadrupole lenses, the electrostatic field strengths are assumed to start and end abruptly, which is impossible in real lenses. To eliminate the influence of the fringing field, an effective length should be evaluated accurately. One method to evaluate the effective length of the quadrupole with round rods is to use the empirical formula $l_e = l_0 + 1.1 a_0$, where, l_e , l_0 and a_0 mean the effective length, real length and aperture of the quadrupole, respectively[12]. But it is not verified in the segmented quadrupole with a rectangular boundary. Another method to evaluate the effective length is fringing field integration. It needs the accurate fringing field distribution, which can be determined by the finite element method (FEM) or finite difference method (FDM). To achieve point-to-point focusing in horizontal direction and make the lens system not too complicated, a better choice is to use two quadrupoles, the parameters of which can be calculated based on the design requirement and ion optics theory.

Experiment and Results:

In previous work[9], 24 electrodes were used to fit the rectangular(30 mm×30 mm) field boundary in which 11×2 electrodes were installed in vertical position while 1×2 electrode in horizontal position. It was found that high-order field components and a large constant field existed, the potential of which was 18.5% of the quadrupole field amplitude voltage. To eliminate the constant field and reduce the high-order field components, the rectangular was changed into 60 mm×30 mm, and the left and right electrodes were replaced with three electrodes each side, the potentials of which were equal and the positions of which were hyperbolic. This improvement was verified by the simulation results. After simulated the fringing field distribution by the finite element method, it was observed that the effective length of the field was roughly equal to the actual length of the electrode plus 25 mm.

The improved zoom lens was manufactured and fabricated into the LRIMS. By visualizing the ion beams of europium and barium isotopes at the focal plane, respectively, using a home-made diagnostic instrument, the zoom effect was evaluated experimentally. The results showed that the horizontal magnification ratio is between 0.6 and 1.2 when the longitudinal magnification ratio varies from 0.7 to 1.1. The relative difference between the measured value of the magnification ratio and the predicted value is better than 1%. By fine adjustment of the real voltage of the electrodes, relative to the theoretical voltage, simultaneous detection of the isotopes of different elements has been realized by the fixed multi-collector system.

Conclusions and Novel Aspect:

Based on the simultaneous detection requirement of the LRI-MS equipped with an ESA, a MA and a fixed multi-collector system, an ion zoom lens based on the quadrupoles was developed and improved. The influence of the fringing field of the quadrupole is evaluated. The experimental results showed that the lens system achieved accurate zoom effect of the ion beams in the range of 0.6 to 1.2.

B.02 INSTRUMENTATION AND METHODS - FTMS AND INNOVATIVE METHODS FOR (BIO)ANALYSES

707 - TOP-DOWN ANALYSIS OF ENDOGENOUS TAU FRAGMENTS IN HUMAN CEREBROSPINAL FLUID USING IMMUNOPRECIPITATION AND FOURIER TRANSFORM MASS SPECTROMETRY

Gunnar Brinkmalm (1) - Claudia Cicognola (1) - Johan Gobom (1) - Erik Portelius (1) - Henrik Zetterberg (1) - Kaj Blennow (1)

University of Gothenburg, Sahlgrenska Academy, Mölndal (1)

Keywords: top-down MS, immunoprecipitation, tau protein, cerebrospinal fluid, endogenous peptides

Introduction:

Many proteins in cerebrospinal fluid (CSF) exist in processed forms, many of which reflect corresponding species present in the brain. Previously an abundance of endogenous fragments from amyloid precursor protein, including variants of amyloid β has been identified both in CSF and brain. Until recently, the other core biomarker for Alzheimer's disease, tau, has been more difficult to assess with mass spectrometry (MS) due to its lower abundance in CSF.

Methods:

Tau was enriched from human CSF by immunoprecipitation (IP) using six different antibodies directed towards different tau regions. Top-down was the main approach, but bottom-up was also utilised for these samples. Analysis was performed by nanoflow liquid chromatography–Fourier transform MS. Quantitative data were obtained by addition of an isotope labeled protein standard before IP. Data processing was performed using Mascot Distiller and PEAKS Studio.

Results:

Starting with three commercially available antibodies endogenous tau fragments were identified using top-down MS of IP'd CSF samples. Based on these data two new neospecific antibodies (Tau123_C and Tau224_C) were developed. In total more than 100 endogenous tau proteoforms were identified by IP-MS using all six antibodies. These mainly covered the N-terminal half, but there were also species originating from the C-terminal quarter. The protein N-terminal was found to be acetylated and phosphorylation at Thr181 was observed. The bottom-up approach tryptic peptides covering slightly more than the N-terminal half were identified. From the quantitative measurements it could be observed that proteoforms covering the mid-region are most abundant, followed by the N-terminal region and a small contribution from the C-terminal part. Three major cleavage sites were identified; in the N-terminal quarter, in the mid-region, and in the C-terminal quarter. These results are in concordance with published data indicating that CSF tau appears in various processed forms, dominated by species originating from the N-terminal half of the protein [1].

Conclusions:

IP-MS is a powerful tool for proteoform mapping in biological samples. It is vital to understand tau processing and its relation to neurodegenerative diseases. These data can be used to guide development of new immunoassays targeting specific tau proteoforms.

Novel Aspect:

Characterisation of endogenous tau fragments in CSF using IP-MS methodology reveals the complexity of biomarker development and evaluation.

Keywords: FT-ICR-MS, Protein Glycation, ECD, Absorption mode

Introduction:

Methylglyoxal, a non-enzymatic by-product of glycolysis, is the most relevant glycation agent in vivo. Protein modification by methylglyoxal is found in association to several human pathologies, most notably amyloid neurodegenerative diseases [1]. Characterization of glycated proteins is extremely challenging [2] calling for extreme resolving power and multiple ion-fragmentation Methods:

Methods:

Methylglyoxal modified proteins were analysed by direct infusion in a 7 Tesla Bruker Solarix XR mass spectrometer equipped with the dynamically harmonized FT-ICR ParaCell, in magnitude and absorption modes, at 4 to 8 MB acquisition sizes. Proteins were fragmented by using different ion-activation methods, including ECD.

Results:

Top down analysis of glycated proteins allows the identification of most modified species at MS, while MSMS analysis pinpoints location and chemical nature of modifications. While in vitro glycated proteins are highly heterogeneous, in vivo glycated ones show a higher degree of homogeneity. Most of the methylglyoxal derived glycation products can be identified and their location defined.

Conclusions:

Glycated proteins have often been analysed by bottom-up methods that do not allow any insight on the diversity and heterogeneity. Top-down analysis reveals the extreme complexity of glycated proteoforms, paving the way for interpreting the glycation effects on protein structure and function, essential for understanding its effects in living cells.

Novel Aspect:

Extreme resolution is a key requirement for analysing heterogeneously modified proteins, combined with a diversity of MSMS methods and in cell isolation of modified proteoforms.

411 - IDENTIFICATION OF NEW LIGAND-PROTEIN COMPLEX FOR MYCOBACTERIUM TUBERCULOSIS USING FOURIER TRANSFORM MASS SPECTROMETRY

Angela Di Capua (1) - Peter Myler (2) - Ronald Quinn (1)

Griffith Institute for Drug Discovery, Don Young Road, Brisbane (1) - Center for Infectious Disease Research, University of Washington, Seattle (2)

Keywords: natural products, native mass spectrometry, target identification

Introduction:

Natural products are an infinite resource for drug discovery and development. Native mass spectrometry (MS) is an approach used to study proteins in the native folded state and useful to investigate non-covalent ligand protein complexes. We applied this method to screen our natural-product-based fragment library against Malaria proteins [1] and natural product fraction library against Tuberculosis (TB) proteins.

Methods:

37 frozen, shipped proteins are buffer-exchanged with ammonium acetate solution and then diluted to run the mass spectrometry assay. The concentration range used for protein is between 1-10 μ M. Screening compounds or fractions are pooled together, dried and treated with 1 μ L methanol. The molar ratio of protein to single compound is 1:5. Screening is performed using Triversa Nanomate (Advion) coupled with a FT-ICR-MS Solarix (Bruker).

Results:

37 proteins were tested for visibility in native state using FT-ICR-MS. 31 proteins have been screened against 362 pooled active fractions. 26 proteins are able to bind a component with high (ligand-protein complex > 50%), medium (ligand-protein complex > 15%), or weak (ligand-protein complex < 15%) affinity. We identified components able to bind only one protein, components able to bind different proteins and proteins that show different ligand-protein complexes from the same pool fraction. Two proteins showed high ligandability (more than 7 binding complexes), 16 proteins showed medium ligandability (more than 3 binding complexes) and 7 proteins showed low ligandability (less than 3 binding complex). Fraction were confirmed and compound isolation is in progress.

Conclusions:

We used the native mass spectrometry approach for a high throughput screening with natural fractions active against TB. We investigate 37 potential targets and we have identified 26 proteins that bind to a total of 90 components from active tuberculosis fractions.

Novel Aspect:

Native mass spectrometry can be considered an alternative approach for High Throughput Screening of pure compounds as well as fractions libraries and target validation.

1069 - COUPLING GAS-PHASE FRACTIONATION AND PROTON-TRANSFER REACTION FOR IMPROVED TOP-DOWN PROTEOMICS

Luca Fornelli (1) - Romain Huguet (2) - Christopher Mullen (3) - Ryan Fellers (1) - Rafael Melani (1) - John Syka (3) - Neil Kelleher (1)

Northwestern University, Molecular biosciences/Chemistry, Evanston (1) - Thermo Scientific, LSMS Product Management, San Jose (2) - Thermo Scientific, LSMS R&D, San Jose (3)

Keywords: proton-transfer reaction; top-down; proteomics; Orbitrap; gas-phase fractionation.

Introduction:

The major limitation in top-down proteomics is its reduced throughput. Here, we implement a series of gas-phase fractionation strategies on a Thermo Scientific Orbitrap Fusion Lumos Tribrid mass spectrometer to improve the number of detectable proteoforms. Specifically, we applied proton-transfer reaction (PTR) to both deepen the proteome coverage in the 0-30 kDa mass range and to facilitate the analysis of large proteoforms up to ~60 kDa.

Methods:

Classic data-dependent acquisition (DDA) methods (i.e., "top-N" strategies) based on either full MS1 or selected ion monitoring (SIM) scans for precursor identification were compared with gas-phase fractionation based on PTR. Quadrupole-isolated (width: 10-50 m/z units) multiply charged protein ions were subjected to PTR MS2 in the ion trap; precursors identified by PTR MS2 were isolated for HCD MS3 fragmentation using a MultiNotch method in the linear trap.

Results:

Orbitrap MS allows for the characterization of proteoforms from 0 to ~60 kDa.[1] However, even when applying extensive fractionation only the most abundant proteoforms are typically characterized. We performed gas-phase fractionation as previously described by the McLuckey and Hunt groups, by applying PTR on a selected portion (10-50 m/z units) of the spectrum at a time, to reduce spectral complexity. By reducing the charge state of protein cations, PTR also limits the problems in the narrow isolation of single proteoform precursors ahead of dissociation. We analyzed both bacterial (*Pseudomonas aeruginosa*) and human (HeLa cells) proteomes, in order to determine the different effects of PTR-based gas-phase fractionation on samples with different complexity. We also modified the synchronous precursor selection (SPS) method to adapt it to intact protein cations of different masses and charge states, making the selection of multiple precursors combined with HCD fragmentation efficient even for large proteoforms (>30 kDa).

Conclusions:

We implemented a novel data acquisition strategy based on PTR MS2 followed by isolation of multiple precursors for MS3 fragmentation that is aimed at improving the proteome coverage in top-down proteomics. The flexibility offered by the Tribrid Orbitrap platform offers the possibility of adjusting the degree of gas-phase fractionation in consideration of the complexity of the targeted proteome.

Novel Aspect:

Proton-transfer reaction is performed on a Tribrid Orbitrap mass spectrometer to detect and characterize more proteoforms in top-down proteomics.

282 - DETAILED ANALYSIS OF TEMPORAL ION CLOUD DISTRIBUTIONS UNDERGOING COULOMB INTERACTIONS IN FT-ICR MASS SPECTROMETRY: A MANY-PARTICLE SIMULATION

Makoto Fujiwara (1) - Hisashi Takahashi (1) - Naohisa Happo (1) - Koichi Tanaka (1)

Hiroshima City University, Grad School of Information Sciences, Hiroshima (1)

Keywords: FT-ICR, Coulomb Interaction, Many-Particle Simulation

Introduction:

In FT-ICR MS, many different m/z ions are simultaneously trapped and excited in the cell and the temporal variation of each m/z ion cloud distribution is complicated. In particular, at high ion density the Coulomb interactions are important. To analyze the Coulomb-interaction-induced effects by many-particle simulation, we have combined a special-purpose computer for many-body problems with a PC and the computer configuration has been accelerated[1].

Methods:

On the above accelerated configuration, the influence of Coulomb-interaction-induced degradation of excited coherent ion cyclotron motion on FT-ICR mass spectral peak shape was investigated by many-particle simulation. The simulation particles were equally assigned to each of m/z 130.0 and 130.1 ions. Ion excitation was performed by frequency sweep at 7 T and the mass spectra were simulated as a function of total ion population initially trapped in the cell.

Results:

From analysis for temporal variations of the ion cloud distributions during detection period it has been found that the coherent ion cyclotron motion of m/z 130.0 ion (lighter weight ion) cloud is out of phase earlier than that of m/z 130.1 ion cloud with increasing initial ion population. However, under certain conditions it has also been found that the spectral peak shape obtained from m/z 130.1 ion cloud appears to be distorted earlier than that from m/z 130.0 ion cloud. We have extracted respective ICR signal components resulting from m/z 130.0 and 130.1 ion clouds. In comparison between the two components, it has been found that the component from m/z 130.1 ion cloud is more significantly modulated than that from m/z 130.0 ion cloud. Further we have analyzed in more precise detail temporal variations of the ion cloud distributions and have presumed that the phase locking may occur for a part of remained (non-ejected) m/z 130.1 ion cloud with m/z 130.0 ion cloud.

Conclusions:

The simulation results suggest that the relationship between the Coulomb-interaction-induced degradation and the spectral peak shape is quite complicated.

Novel Aspect:

Temporal variations of the ion cloud distributions undergoing Coulomb interactions in the FT-ICR cell have been analyzed in more detail by many-particle simulation

1036 - FT-ICR MS WITH ABSORPTION-MODE DATA ACQUISITION: METHOD DEVELOPMENT AND HIGH-RESOLUTION APPLICATIONS

Anton N. Kozhinov (1) - Konstantin O. Nagornov (1) - Yury O. Tsybin (1)

Spectroswiss Sàrl, EPFL Innovation Park, Lausanne (1)

Keywords: FT-ICR MS, transient, absorption mode FT, data acquisition, ion phase

Introduction:

Unlike the modern Orbitraps, many FT-ICR instruments worldwide offer magnitude-mode FT as a default, and sometimes the only, method to generate mass spectra. Previously, we introduced a data acquisition technology that enables recording FT-ICR mass spectra directly in absorption mode, and tested this with a 7T LTQFT Ultra. Here, we extend this technology to more FT-ICRs, and evaluate it in wide-range applications including petroleomics, imaging, and proteomics.

Methods:

Peptides, calibration mixtures, proteins, oils, and tissues were analyzed on commercial FT-ICR MS (9.4T solariX XR with ParaCell or custom NADEL cell, and two 7T LTQFT Ultra). Measurements were conducted in the $w+$ regime on the 7T and 9.4T instruments (original ICR cells), and in the w and $w+$ regimes on the 9.4T instrument (NADEL cell). Transients were acquired in parallel with the instrument manufacturer's data, using a custom data acquisition system (FTMS Booster).

Results:

A wide use of absorption-mode FT in FT-ICR MS applications is limited by high numerical costs of phase correction procedures, substantial phase distortions from standard data acquisition systems, and other complications. To avoid these, we developed a high-performance data acquisition system for recording FT-ICR data as transients with in-phase ions signals (or as mass spectra generated in absorption mode), compatible with both types of FT-ICRs from this work. The system operation was defined based on the textbook principles, namely: (i) the convolution property of FT and (ii) sampling of both detect and excite signals. The system was designed to sample and in-line process the two signals in order to produce a single transient for each measurement cycle. Our preliminary results demonstrate that with this technology FT-ICR mass spectra can be generated in absorption mode with no or a little tuning of the phase function. As a result, improved analyses of petroleum and proteomics samples, and increased throughput in tissue imaging are achieved.

Conclusions:

This work's high-performance electronics and methods for acquiring FT-ICR mass spectra in absorption mode significantly simplify the use of absorption-mode FT processing in real-life high-resolution FT-ICR MS applications, reduce phasing artifacts in mass spectra, increase numbers of identified and quantified peptides, lipids and compound classes; and make for bringing the absorption mode processing to FT-ICR MS as a standard method to generate mass spectra.

Novel Aspect:

Method development, implementation in hardware, and evaluation in applications of absorption-mode data acquisition for FT-ICR MS, including both, Bruker and Thermo, makes.

437 - FACTOR XA ANTICOAGULANT BIOACTIVE PROTEINS DERIVED FROM SCORPION VENOM

Meng Li (1) - Yuko P. Y. Lam (1) - Peng Chen (2) - Remy Gavard (3) - Cookson K. C. Chiu (1) - Christopher A. Wootton (1) - Qiong Wu (2) - Mark P. Barrow (1) - Hongzheng Fu (2) - Peter B. O'Connor (1)

University of Warwick, Department of Chemistry, Coventry (1) - Peking University, School of Pharmaceutical Science, Beijing (2) - University of Warwick, MAS CDT, Coventry (3)

Keywords: Fourier Transform Ion Cyclotron Resonance (FTICR) MS; Scorpion Venom; Anticoagulant drug; Proteomics; Chemometrics

Introduction:

Of the 1400 species of scorpions worldwide[1], the Chinese scorpion is used in Chinese medicines for cardiovascular problems[2], antimicrobial[3], and tumors[4]. The venom is a complex mixture of proteins containing bioactive components[5], some showing inhibition of enzyme factor Xa, which prevents blood coagulation[6]. These proteins are often modified and crosslinked with multiple disulphide bonds, with only partial genome sequences, therefore requiring de novo sequencing.

Methods:

Crude scorpion venom was fractionated using step elution on C18 cartridge, and in-vitro inhibition of factor Xa was tested. Nano-LC-FTICR MS/MS analysis of each fraction was acquired with collisionally activated dissociation (CAD) and electron capture dissociation (ECD) as fragmentation Methods: Chemometrics was used to obtain possible pharmaceutical targets. Spectra were collected on a 12 Tesla Bruker Solarix FTICR MS, using both top-down and bottom-up proteomics.

Results:

Using direct infusion FT-ICR MS, more than hundred unique molecular species (approximately 2-12 kDa) were observed in the crude venom, but with bottom-up proteomics, only a small number of proteins can be identified, even though many of these unidentified peptides have good fragmentation spectra. To accurately identify potential bioactive compounds, methodologies were developed to correlate the spectra with the bioactivity results. Quantification of compounds present in each fraction made it possible to use linear regression approaches such as partial least square (PLS) to establish a correlation, which allowed for the identification of the compounds that have stronger correlations with the bioactivity. Therefore, a list of compounds that strongly correlate to the bioactivity could be potential pharmaceutical targets. In addition, from the current results, most of these target compounds are proteins that range from 2k to 5k Da, with 30% of the proteins have sequences that are not in the genome database from Uniport.

Conclusions

The potential factor Xa inhibitors were de novo sequenced using both top-down and bottom-up approaches. The high mass accuracy and resolving power of the FTICR-MS allowed for the highest possible confidence during analysis, which aids the sequencing study of these novel scorpion venom proteins. The method is applicable to identifying potential pharmaceutical leads from other natural products.

Novel Aspect:

Ultra-high resolution FTICR MS for the analysis of scorpion venom reveals bioactive anticoagulant proteins.

1190 - NATIVE TOP-DOWN FOURIER TRANSFORM MASS SPECTROMETRY OF PROTEINS AND PROTEIN COMPLEXES AS A TOOL FOR STRUCTURAL BIOLOGY AND DRUG DEVELOPMENT

Joseph A Loo . (1) - Huilin Li (1) - Wonhyeuk Jung (1) - Carter Lantz (1) - Michael Nshanian (1)

University of California, Los Angeles (UCLA), Los Angeles, CA USA (1)

Keywords: native mass spectrometry, FT-ICR, protein complexes, ligand binding, membrane proteins

Introduction:

Native mass spectrometry (MS) of protein assemblies reveals size and stoichiometry. But elucidating their structures to understand their function is more challenging. Membrane proteins are involved in many biological functions, but their characterization by a variety of techniques is challenging. We use top-down Fourier transform ion cyclotron resonance (FT-ICR) MS to derive ligand-binding sites and topological information for large proteins and complexes.

Methods:

Proteins were analyzed by nanoESI-MS under native buffer conditions (pH 6.8, 200 mM ammonium acetate) using a high resolution 15-Tesla Bruker Solarix FT-ICR system. The FT-ICR MS instrument is equipped with electron capture dissociation (ECD; 1-3 eV) and a CO₂-laser operating at 10.6 μ m for activated ion-ECD and infrared multiphoton dissociation (IRMPD). Electron ionization dissociation (EID) was effected by using higher energy electrons (30-50 eV).

Results:

Native top-down MS generates information on the surface topology, ligand binding sites, and post-translational modifications of protein complexes [1]. We are using native MS/MS to investigate the molecular action of compounds that prevent amyloid fibril formation in neurodegenerative diseases such as Alzheimer's and Parkinson's disease [2]. To date, membrane proteins have not been addressed by native top-down MS. Optimal activation of membrane proteins in detergent micelles is required. For the homotetrameric 97 kDa water channel, Aquaporin-Z (AqpZ), increasing the collision energy yielded varying degrees of 4M liberation from the detergent micelles as well as fragmentation into the asymmetric dissociation 3M and M substituents. Activated ion ECD to release weakly-bound products generated a top-down spectrum rich in c-/z-products. Product ions originate from regions in the C-terminal portion of the structure, with most localized to the periplasmic domains.

Conclusions:

Electrospray ionization's gift for transforming solution-phase macromolecules into gas-phase ionized counterparts without disrupting weak noncovalent interactions is key for applying MS to study protein complexes. For the first time, native top-down MS yields structural and sequence specificity for characterization of membrane proteins. The various activation methods available with FT-ICR MS allow protein complexes to be measured with high accuracy.

Novel Aspect:

Native top-down mass spectrometry yields higher order structural parameters and ligand binding sites for protein-ligand complexes and membrane proteins.

Keywords: Orbitrap analyzer, high resolution, native mass spectrometry, protein complex, top-down

Introduction:

Analysis of high-mass protein and protein complexes poses unique challenges to mass spectrometry (MS), driving deep re-thinking of principles earlier validated on small molecules and peptides. In this work we examine limitations of standard MS for high-mass analysis and explore new ways for extending high-mass performance in various directions.

Methods:

Experiments were performed using a modified Thermo Scientific™ Q Exactive™ Plus Orbitrap™ MS with a series of enhancements, including pulsed trapping of ions in the front end of the MS, reduction of RF frequencies on all ion guides and changes in Orbitrap injection. Separately, a new geometry of the Orbitrap analyzer with better vacuum within the trap was explored.

Results:
