Advances towards analysis of ions in the megadalton mass range and m/z detection in excess of 20,000 became possible only after tackling several major technical challenges, especially insufficient or poorly controllable desolvation and low transmission of high-mass ions. These challenges were addressed by instrument modifications listed above and guided by ion-optical modeling.

Performance was evaluated in MS/MS and pseudo-MS3 experiments for several homomeric and heteromeric megadalton non-covalent protein complexes, including ribonucleoprotein ones.

Separately, a new research-only Orbitrap design facilitated better mechanical balance and vacuum within the trap, enabling for the first time baseline isotopic resolution on intact 150 kDa antibodies both under denaturing and native conditions in infusion mode while employing conventional nitrogen supply for C-trap and HCD cell.

Conclusions

Significant improvements in sensitivity and resolving power were demonstrated for intact proteins, MS/MS and pseudo-MS3 for native top-down analysis of membrane proteins and megadalton non-covalent protein and ribonucleoprotein complexes. This progress yields new insights into the composition, dynamics and interactions of some of nature's most elaborate and enigmatic molecular machines.

Novel Aspect:

Theoretical and practical aspects of improving Orbitrap performance for high mass analysis.

990 - MICROCHIP CAPILLARY ELECTROPHORESIS-ESI-MS FOR RAPID, MULTI-LEVEL ANALYSIS OF COMPLEX PROTEINS

J. Scott Mellors (1) - Erin Redman (2)

908 Devices Inc., Life Sciences, Boston (1) - 908 Devices Inc., Life Sciences, BOSTON (2)

Keywords: Protein characterization, capillary electrophoresis, microfluidics

Introduction:

Mass spec characterization of proteins often requires multiple “levels” of analysis for complete characterization. For LC-MS methods these analyses typically require completely different columns and mobile phases. With Microchip CE-ESI-MS a single set of experimental conditions can be used for all levels. This enables rapid multilevel characterization of proteins, with no down-time between samples.

Methods:

All work was performed using a commercially available microfluidic CE-ESI system (ZipChip, 908 Devices Inc.), attached to an orbitrap mass spectrometer (Thermo). Proteins were analyzed intact by diluting to an appropriate concentration before analysis. Middle-down and bottom-up analyses utilized standard reduction and enzymatic digestion. Methods: All samples were analyzed using the same microfluidic device and the same background electrolyte.

Results:

To achieve successful analysis at all three structural levels, a BGE with a relatively low pH was chosen. In this denaturing BGE we observe just a single mAb peak, but the electrophoretic separation still functions to electrokinetically “desalt” the sample. This yields a clean mass spectrum with a simple dilute and shoot method. Middle-down analysis of mAbs yields separation of three main segments of the molecule: the free light chain (LC), and the Fc and Fd domains of the heavy chain. We also observe separation of variant forms of each of these segments. Top-down analysis of smaller proteins using this method yields similar separation of variants. The separation of sialic acid variants of alpha-1-acid glycoprotein will be presented as an example. Additionally, a high degree of sequence coverage in <20 minutes will be demonstrated for bottom-up analysis. Results will focus on the ability to rapidly characterize protein structure and determine biologically relevant information.

Conclusions

The microfluidic CE-MS system is a simple and rapid way to perform multiple levels of protein characterization. By choosing a BGE compatible with all types of analysis, there is no need to change the system or analysis conditions between types of characterization assays. Therefore, users can obtain intact, middle-up, and peptide mapping data without any downtime due to system turnover.

Novel Aspect:

Demonstration of a unique mass spec front end separation capability for rapid characterization of proteins

635 - ION TRAPS WITH QUADRATIC POTENTIALS IN FOURIER TRANSFORM BASED MASS SPECTROMETRY. HARMONIZED MULTI-ELECTRODE KINGDON TRAPS AND FT ICR CELL.

Keywords:

FT MS, ion traps, Harmonized Kingdon traps, dynamically harmonized FT ICR cell

Introduction:

The review of current stage of development of the ion trap devices, which are using electric fields with quadratic dependence on coordinate and FT MS approach to signal detection and processing, will be given with emphasize on multiple electrode harmonized Kingdon traps [1] and dynamically harmonized FT ICR cells [2]. The general approach both analytical and digital to electric field calculation for such devices will be presented as well.

Methods:

Trap electrode geometries were obtained as the result of solving Laplace and Hamilton-Jacobi equations. Regular high precision machine work and three different 3D printing methods: Selective Laser Sintering, Lost-wax Micromolding (Microcasting) and Inkjet Metal Printing as a methods of traps electrode making are discussed. Simulation of electric field distribution and ion motion dynamics was done by using combined SIMION and SIMAX software.

Results:

Ion motion in the electric field with quadratic potential is oscillation, which frequency depends only on m/z and the field curvature. By measuring this frequency and applying FT MS processing method, we can determine m/z of oscillating ions. For static electric field it is possible to create quadraticity in only one direction what follows from basic laws of electrodynamics. One dimensional quadratic electric fields have been offered for the first time by Knight [3]. Golikov [4] and Koester [5] have offered the options for harmonized traps with multiple internal electrodes. The general approach both analytical and digital to electric field calculation for such devices will be presented. Many variants of the four electrode harmonized Kingdon trap were designed and manufactured. Initial evaluations of different traps performances will be given. The idea of electric field quadraticity emerged in FT ICR mass spectrometry through dynamically harmonized FT ICR cells as a method of significant improvement of resolving power will be discussed as well.

Conclusions

Harmonized multi-electrode ion traps of Kingdon type with quadratic dependence of electric potential along one of the coordinates could be manufactured by different modern technologies both conventional and additive with electrode surface precision high enough to deliver resolving power comparable to Orbitrap [6] analyzer. Dynamically harmonized FT ICR cell and harmonized Kingdon traps could be described analytically using common mathematical approach.

Novel Aspect:

The new approaches to characterization of FT MS ion traps based on harmonized multi-electrode Kingdontraps and dynamically harmonized FT ICR traps was developed.

University of Warwick, Department of Chemistry, Coventry (1)

Title: The Next Dimension in Proteomics

Authors: PuiYiu (Yuko) Lam, Chris Wootton, Federico Floris, Cookson K. C. Chiu, Tomos Morgan, Remy Gavard, Maria van Agthoven, Meng Li, Peter B. O'Connor*

Abstract:

2-dimensional mass spectrometry (2DMS) offers intriguing new advantages in proteomics analysis. In particular, 2DMS provides the ability to fragment all proteins/peptides simultaneously in a complex mixture and to accurately correlate which fragment derives from which precursor. The resulting mass spectra are somewhat unusual in appearance, resembling the 2D-NMR results from which the experiment is derived, but the spectra are relatively easy to understand in the context of modern MS/MS experiments. In this presentation, we will discuss the current results on how to best optimise 2DMS experiments for proteomics (in both Bottom-up and Top-down modes). In particular, we will explore the comparison between 2DMS-based proteomics and more traditional nLC-MS/MS results.

For this comparison, a series of standards including BSA and mixtures of standard proteins were used so that the proteomics comparison would focus on known proteins and peptides. In addition, yeast is compared between the two methods where the proteins are also largely known.

The current results clearly show that, in bottom-up proteomics mode, 2DMS can provide very similar levels of sequence and cleavage coverage on these standards, albeit at lower sensitivity at the moment. Additionally, 2DMS doesn't suffer from the co-eluting peak problem in LC-MS/MS, or rather 2DMS is a method that is uniquely capable of handling many precursor and fragment species simultaneously by expanding the spectra into a second 'modulation' dimension which allows correlation of precursors with fragments.

For top-down proteomics, we can use MS/MS in the hexapole collision cell, followed by 2DMS in the ICR cell to effectively achieve MS3 data for all primary fragments for each and every precursor protein. Our current results show that this methodology can improve cleavage coverage for proteins in top-down proteomics experiments, but further research is ongoing. Latest results will be presented.

1107 - TWO-DIMENSIONAL (2D) FT-ICR MS AT HIGH RESOLUTION ON PRECURSOR IONS.

Christian ROLANDO (1) - Fabrice BRAY (1) - Julien BOUCLON (2) - Philippe PELUPESY (2) - Marc-André DELSUC (3)

CNRS, University of Lille, Villeneuve d'Ascq (1) - PSL, Ecole Normale Supérieure, Paris (2) - IGBMC, University of Strasbourg, Strasbourg (3)

Keywords: FT-ICR, 2 dimensional, high resolution on precursor ions

Introduction:

Most of modern mass spectrometers use quadrupole analyzer isolation with a selection window in the range of one m/z to the best as the transmission is decreasing fast beyond. We developed also non-uniform sampling (NUS) acquisition for 2D FT-ICR MS which consists in skipping points randomly on the first dimension which give access to a higher resolution in the same amount of time.

Methods:

Nevertheless, the maximum delay between the two encoding pulse increases as the resolution and reaches 1 second using for a 2Megapoints acquisition with a 0.5 microsecond dwell corresponding on a 9.4 Tesla instrument to a resolution of 380,000 at m/z 200. Obtaining sounded 2D FT-ICR implies that ions stays in place without drifting during this time with a precision better than the ECD or IRMPD beam.

Results:

We will describe here the optimization of the acquisition and of the treatment which allow us to obtain square 2D spectra. First of all we continue our analytical calculations of the ion movement to better understand the fundamental of 2D FT-ICR during the complete sequence. With this tool in hands the acquisition was optimized in two ways: (i) by modifying the Bruker IRMPD device to obtain a wider bean and a more precise control of the alignment; (ii) by a fine tune of the ICR cell for 2D acquisition (iii) and by using an optimized 2D pulse sequence. The data treatment was based on the iterative use of an improved version of the urQRd algorithm, which we developed previously for denoising, considering the missing points as noise.

Conclusions:

Currently we are recording 2D of size F1 (precursor) 256k and size F2 (fragments) 256k points which allows us to reach a resolution of 50,000 at m/z 200 for precursors and fragments which is five times higher than our previous best results. The acquisition is performed with a NUS ratio 1/16 which means a physical size of 16k which can be recorded overnight.

Novel Aspect:

We describe here for the first time the analysis of a complex mixture by MS/MS analysis without chromatography with high resolution on precursors.

Keywords: Flavonoid annotation; MSⁿ;Tribrid Orbitrap; Mass Frontier 8.0; Compound Discoverer 3.0

Introduction: (346/400 characters without spaces)

Flavonoid annotation from natural products remains challenging because of their structural diversity and lack of authentic standards. Simple MS² based analyses are often not sufficient for complete structural annotation of flavonoids. We present a new flavonoid annotation workflow that uses comprehensive fragment ion information from HCD MS-MS and higher order FTMSⁿ for rapid flavonoid annotation.

Methods: (329/400 characters without spaces)

Flavonoid extracts from different types of natural products were analyzed using LC-MS. A modified Orbitrap Fusion™ Tribrid™ mass spectrometer was used for collecting HRAM MS and MSⁿ data. The data were processed using Compound Discoverer™ 3.0 software. A novel structure ranking algorithm was applied to the MS and MSⁿ data for confident structure elucidation of the unknown flavonoids.

Results: (672/900 characters without spaces)

The flavonoid extracts from multiple tea and fruit/vegetable juice samples were analyzed using the developed flavonoid annotation workflow. The MSⁿ (up to 5) scans were only triggered when one of the sugar neutral loss product ions (162.0523, 180.0628, 146.0574, 164.0685, 176.0315, and 194.0421) was detected in the MS/MS scan. The collected data were processed using Mass Frontier 8.0 and Compound Discoverer 3.0 software. A novel structure ranking algorithm included in the Compound Discoverer 3.0 software was applied to the MS-MS and MSⁿ data for confident structure characterization of the unknown flavonoids based on ChemSpider database and custom flavonoids database. The MSⁿ data were critical, especially for the annotation of flavonoid glycoconjugates and flavonoid isomers.

Conclusions (323/400 characters without spaces)

The new LC-MSⁿ workflow allows intelligent MS/MS fragment ion dependent MSⁿ data collection. In combination with dedicated software for data processing, the new workflow enables improved throughput, identification coverage and confidence for flavonoids annotation from natural products by using comprehensive fragment ion information from HCD MS-MS and higher order FTMSⁿ.

Novel Aspect: (150/150 characters without spaces)

The innovative LC-MSⁿ workflow on a modified Tribrid instrument enables improved throughput, identification coverage and confidence for flavonoids profiling experiments.

734 - FUNDAMENTALS OF FT-ICR MS AT THE CYCLOTRON FREQUENCY

Oleg Tsybin (1) - Konstantin Nagornov (2) - Anton Kozhinov (2) - Yury Tsybin (2)

Peter the Great Saint-Petersburg State Polytechnic University, Ion Physics Laboratory, Saint-Petersburg (1) - Spectroswiss, Biomolecular Mass Spectrometry Laboratory, Lausanne (2)

Keywords: FTMS, ion cyclotron resonance, ion motion, cyclotron frequency, transient

Oleg Y. Tsybin, Konstantin O. Nagornov, Anton N. Kozhinov, Yury O. Tsybin

Introduction:

Recently, we introduced and initially described FT-ICR MS at the cyclotron frequency instead of the reduced cyclotron frequency using the narrow aperture detection (NADEL) ICR cells and applicable for biomolecular applications [1-3]. Here, we will present an analytical model for signal generation at the cyclotron frequency based on our understanding of the underlying principles of this new concept of ion motion, excitation and detection in the NADEL ICR cells.

Methods: (Limit of 400 characters without spaces)

Transient waveforms at single and multiple cyclotron periods were measured experimentally and calculated theoretically by taking into account: (i) the trajectories of ion-oscillators with time-dependent instantaneous frequency (TDIF) [4], and (ii) different angular size of detection electrodes, including traditional wide (e.g., 90-120 degrees) and narrow (e.g., as in NADEL ICR cells) configurations. Ion motion simulations performed using SIMION [2].

Results:

Constant in time frequencies of ion motion, including cyclotron and magnetron components, have been widely described in the FTMS literature using solution of a well-known algebraic ICR frequency equation. However, the latter is applicable only when ions are trapped in a quadratic potential with axially-symmetric trajectories and their Coulombic interaction is negligible. However, in a real-life FTMS the instantaneous frequency of ion motion is normally time-dependent. Contrary to the quadratic trapping potential of the modern ICR cells, the non-quadratic trapping potential of the NADEL ICR cells appears to be responsible for the signal generation at the cyclotron frequency. By using the TDIF theory, in a combination with the experimental and computational results, we establish a relationship between the asymmetric trajectories of ion oscillations, transient modulation, detection electrode dimensions, and composition of resulting Fourier spectra. That allows us to formulate the analytical model for cyclotron frequency approach.

Conclusions

FTMS performance is limited by the space charge. It is responsible for peak interferences in mass spectra which result in peak shifts and, ultimately, coalescence. Experimental and simulation data with FT-ICR MS at the cyclotron frequency indicates it as a possible candidate for the space charge-tolerant FTMS. Presented here considerations and analytical models provide further insights into the fundamentals of this novel approach to FTMS.

Novel Aspect: (Limit of 150 characters without spaces)

An analytical model is developed for signal generation at the reduced and true cyclotron frequency in FT-ICR MS, including for the narrow aperture detection electrode ICR cells

Introduction:

Previously, we implemented a high-performance data acquisition technology enabling users to access unprocessed data (transients) from any FTMS instrument (ICR or Orbitrap). Now, we extend this capability to enable acquisition of much longer, than typical, transients on their FTMS instruments. This instrumentation development, together with advanced data processing software, unlocks previously unseen ultra-high resolution (UHR) FTMS performance.

Methods: (Limit of 400 characters without spaces)

Drugs, metabolites, complex mixtures, proteins, and tissues were analyzed using commercial ICR and Orbitrap FTMS instruments; including Q Exactive and Fusion Orbitrap FTMS series. Mass spectral and transient data were acquired in parallel using original manufacturer and in-house developed data acquisition hardware (FTMS Booster). Custom software was developed for acquisition and processing of very large datasets of transients and mass spectra.

Results:

Orbitrap FTMS applications are normally performed with transients (much) shorter than 1 s. Our preliminary results demonstrate that modern Orbitrap mass analyzers can sustain the high coherence level of periodic ion motion - enabling routine acquisition of 3-10 s transients, even from benchtop Orbitraps. As a result, resolution levels exceeding 500,000 at m/z 800 can be achieved. This ultra-high resolution (UHR) enables isotopic fine structure analysis, up to at least 1000 Da, providing increased molecular identification confidence for, e.g., drugs and metabolites (lipids). This UHR performance may also support quantitative analyses of lipids and peptides subjected to neutron-encoded isotopic labeling that yields nearly isobaric species. Interestingly, top-down protein analysis and imaging at these UHR levels is an uncharted territory, which is now ready for exploration. Among other examples, we will demonstrate increased sequence coverage and confidence in product ion assignment for top-down UHR FTMS using HCD MS/MS on a Q Exactive HF.

Conclusions

High manufacturing quality of Orbitrap mass analyzers together with high performance of modern data acquisition and processing technologies enable routine UHR FTMS for applications beyond proteomics. We will show how the UHR FTMS may leverage life sciences applications, including metabolomics, top-down, and imaging. Interestingly, even the benchtop Orbitrap technology (for selected mass spectrometers) is capable of delivering the UHR FTMS performance.

Novel Aspect:

Implementation, performance evaluation, and application of ultra-high resolution capability on Orbitrap FTMS instruments, including on a benchtop series

434 - USE OF SIFT-MS IN THE ANALYSIS OF VOLATILE COMPOUNDS ARISING FROM THE ADDITION OF SODIUM HYPOCHLORITE AS AN IRRIGANT IN INFECTED ROOT CANAL TREATMENT

Kostas Ioannidis (1) - Sadia Niazi (1) - Sanjukta Deb (1) - Francesco Mannocci (1) - David Smith (2) - Claire Turner (3)

King's College London, Dental Institute, London (1) - Transspectra Ltd, Newcastle-under-Lyme (2) - The Open University, School of Life, Health & Chemical Sciences, Milton Keynes (3)

Keywords: SIFT-MS, volatile organic compounds; dentistry

Introduction

Sodium hypochlorite (NaOCl) is a widely used disinfectant^{1,2} and in dentistry, is routinely used as an irrigant in disinfecting infected root canals. In this study, we used selected ion flow tube mass spectrometry (SIFT-MS) to investigate the formation of toxic volatile organic compounds resulting from the reactions of NaOCl with a model system for infected root canals.

Methods

Samples representing a model tooth model system consisting of combinations of dentine powder (from ground freshly extracted molars), microbial suspensions and serum in a buffered suspension were incubated at 37°C under both aerobic and anaerobic conditions and then NaOCl was added. After incubation for 30 minutes, they were centrifuged. Volatile compounds in the headspace of the supernatants were analysed by selected ion flow tube mass spectrometry (SIFT-MS).

Results

During root canal chemomechanical preparation, NaOCl interacts with dentine, leading to denaturation of the organic matrix and changes in mineralised dentine^{3,4}. However, the production of potentially toxic organic compounds has not been widely investigated. SIFT-MS analysis of samples using the precursor ions H_3O^+ , NO^+ and O_2^+ showed that various volatile compounds were produced in abundance when NaOCl was added to different model tooth system components. NH_3 was produced when serum, dentine and bacteria were present, but there was much less in samples without serum. NaOCl also led to CH_3CN formation, possibly due to NaOCl's reaction with aldehydes and monochloramines, themselves formed through protein degradation by NaOCl. Furthermore, ions were detected at m/z 83, 85 and 87 using O_2^+ precursor. These ions are present with peak intensities in the ratio of 9:6:1, implying a 2 chlorine compound of which the only candidate is $CHCl_2^+$. This closed shell ion is known to be the product of the O_2^+ reaction with chloroform ($CHCl_3$)⁵.

Conclusions

SIFT-MS was an effective technique at identifying the volatile compounds produced in a model infected root canal system with the addition of the irrigant, NaOCl. Toxic compounds were formed by the interaction of NaOCl with the components of the model system, including chloroform and acetonitrile. These have the potential to contaminate the environment and lead to dental health worker exposure or may enter the patient's bloodstream.

Novel Aspect

The identification of toxic compounds produced during dental treatment is a novel application of SIFT-MS.

1030 - OPTIMAL SIGNAL-TO-NOISE AND PEAK ASSIGNMENT FOR TWO-DIMENSIONAL MASS SPECTROMETRY

Maria van Agthoven (1) - Rémy Gavard (1) - Alice Lynch (1) - Tomos Morgan (1) - Christopher Wootton (1) - Lionel Chiron (2) - Marc-André Delsuc (3) - Mark Barrow (1) - Peter O'Connor (1)

University of Warwick, Department of Chemistry, Coventry (1) - CASC4DE, Research, Strasbourg (2) - IGBMC, Université de Strasbourg, Illkirch-Graffenstaden (3)

Keywords: Two-dimensional mass spectrometry, FT-ICR MS, ECD, ubiquitin, denoising

Introduction:

Two-dimensional Fourier transform ion cyclotron mass spectrometry (2D MS) is a tandem mass spectrometry technique that requires no isolation and that maps the fragmentation patterns of all ion species in complex samples in a single 2D mass spectrum [1]. Scintillation noise in 2D mass spectra is minimized using the uncoiled random QR denoising algorithm (urQRd) [2]. The effect of denoising on the structural information available in 2D mass spectra is studied.

Methods:

Seven 2D ECD mass spectra of ubiquitin were acquired on a 12 T solarix FT-ICR mass spectrometer. All spectra were processed using the SPIKE processing software with the urQRd denoising algorithm using different ranks and without the urQRd denoising [3]. All horizontal fragment ion scans were peak-picked and the resulting peaklists were analyzed using the Themis software to assess the reproducibility of the 2D mass spectra [4].

Results:

A 2D mass spectrum shows the fragmentation patterns of all the compounds in a sample. Each peak corresponds to a particular dissociation, where fragment ion scans, precursor ion scans and dissociation lines can be extracted from the 2D mass spectrum. The main source of noise is scintillation noise in the precursor ion dimension. The urQRd algorithm is routinely applied in the precursor ion dimension to lower the signal-to-noise ratio, but also removes peaks in the precursor ion dimension that are below the signal-to-noise ratio. In the fragment ion dimension, the signal-to-noise ratio is also drastically reduced, but many peaks are revealed by the orthogonal application of urQRd. We have extracted the peaklists from the fragment ion scans of seven 2D ECD mass spectra of ubiquitin processed with decreasing urQRd ranks, which corresponds to increasing levels of denoising. The peaklists have been compared using the Themis software to separate peaks corresponding to actual fragments from noise peaks.

Conclusions

This study enables a more confident assessment of signal-to-noise levels fragment ion scans in 2D mass spectra. With decreasing ranks of urQRd denoising, fragment ions are revealed in fragment ion scans. Below the optimal denoising level, fragment ions are removed alongside the noise and structural information is lost. This study improves the accuracy of the structural information that can be extracted from a 2D mass spectrum in terms of ubiquitin cleavage coverage.

Novel Aspect:

Use of Themis software on protein top-down 2D MS. Study of the effect of urQRd denoising algorithm in 2D MS in the dimension orthogonal to the one it is applied to.

Keywords: desorption electrospray ionization (DESI), mass tag, signal amplification, Wilms tumor gene

Introduction:

The use of mass spectrometry (MS) as a readout system provides several advantages of high sensitivity, high resolution, rich structural information, and absolute quantification capability. Fast qualitative and quantitative analysis of biological samples, such as whole blood drops[1], tissue sections[2], and single cells[3], has been realized by MS, especially after ambient mass spectrometry (AMS) emerged[4,5]. However, it has limitations for ultrasensitive direct detecting of large biomolecules by AMS[6]. Herein, a simple desorption electrospray ionization mass spectrometry (DESI-MS)-based bioassay utilizing signal amplification strategy was developed for ultrasensitive detection of large biomolecules, such as proteins and DNA.

Methods:

A glass chip was functionalized with thiol-modified capture oligonucleotides, while gold nanoparticles were functionalized with both DNA capture oligonucleotides and mass tags. Here, a new ionic small molecule was synthesized as mass tag. The target, WT1 DNA (67 base long ssDNA oligonucleotide, an important biomarker for minimal residual disease (MRD) in leukemia)[7], was captured by a sandwich assay between biochips and nanoparticles. After being dried, the active biochips were detected by DESI-MS. The dissociated mass tags, together with internal standards, were detected by MS for quantitative analysis of target oligonucleotides.

Results:

Interesting dissociation results were found that a large number of mass tags were dissociated from gold surface and produced abundant mass tag derivatives by DESI just in the open air without high-energy laser or high temperature. As hundreds of mass tags are carried by one gold nanoparticle, good amplification can be achieved for target molecule. Benefiting from the signal amplification, the detection of WT1 DNA could achieve ultrahigh sensitivity with a limit of detection of 0.5 amol (1 μ L, 0.5 pmol/L) and a wide linearity range from 1 amol to 500 amol.

Conclusions:

A novel platform for large biomolecule detection was developed, which combined the signal amplification strategy and DESI-MS to achieve ultrahigh sensitivity and high efficiency detection of a disease biomarker (WT1 DNA). As a general method, this bioassay could be utilized for other DNA or protein biomarkers, which would be valuable for the early diagnosis in clinical diagnosis.

Novel Aspect:

Multistep signal amplification with mass tags was realized by DESI-MS in the open air without high-energy laser or high temperature, and high sensitive detection (lower than attomole) of WT1 DNA was achieved by the simple DESI-MS bioassay.

514 - TOWARDS ROUTINE INTACT LEVEL QUANTIFICATION OF MONOCLONAL ANTIBODY IN PLASMA BY HRMS

Yun ALELYUNAS (1) - Mark Wrona (1) - Henry Shion (2) - Caitlin Dunning (1) - Jayne Kirk (1)

Waters Corp, Scientific Operations, Milford (1) - Waters Corp, Scientific Operations, Milford (2)

Keywords: HRMS, Monoclonal Antibody, Quantification, Intact, Bioanalysis

Introduction:

Monoclonal antibodies (mAbs) are an important class of innovative medicine for the treatment of cancer and other immune mediated diseases. Five of the top ten best-selling medicines in 2017 worldwide were mAbs. Traditionally, bioanalysis of mAbs has been done almost exclusively using ligand binding assays with some structural characterization provided by high resolution mass spectrometry (HRMS). More recently, direct intact level quantification based on HRMS has gained attraction, as it offers direct analysis, simpler sample preparation compared to surrogate peptide approach, and also provides some structural and isoform information associated with the mAb in study. In this presentation, the quantification of several mAbs in biological matrix is performed. Best practices for sample preparation, LC separation, MS detection, and data processing for achieving the high sensitivity are described. Challenges and the needs for next generation sample preparation and analysis of intact mAb analysis are discussed.

Methods:

Adalimumab, infliximab, or trastuzumab samples were prepared by spiking mAb solution into mouse plasma. Each mAb was immuno purified from plasma using goat anti-human Fc prepared either in streptavidin coated plate¹ or magnetic beads. A Tecan Genesis liquid handling platform was employed in sample preparation. After elution under acidic conditions, extracted mAb was quantified by UPLC-HRMS. The LC-MS system consists of a binary pump, sample manager, column manager, and a Vion QToF HRMS. The mass range used for data acquisition was 500-4000 m/z, and the system was operated in ESI+ full scan sensitivity mode. A generic gradient was used with a flow rate of 0.2 mL/min and a total run time of 13 minutes. Data was acquired, analyzed and quantified using the UNIFI informatics system.

Results:

A standard calibration curve was prepared by spiking a serial dilution of monoclonal antibody into mouse plasma using BSA as a carrier protein. After immunoaffinity purification, the solutions were analyzed by LC-MS under generic reversed phase conditions using LC/MS friendly mobile phase consisted of acetonitrile, H₂O, and formic acid. LC-MS conditions were optimized including chromatographic separation of the mAb from the carrier protein, glycan isoform spectral profile, and charge state summation and XIC tolerances for processing, yielding best bioanalytical performance. Excellent sensitivity (<50 ng/mL) using the optimized conditions was achieved. Comparing immunoaffinity purification from streptavidin plate vs magnetic bead, it was found that the plate offered lower background signal compared to magnetic bead. Preliminary results showed that LLOQ determined from streptavidin coated plate is <50 ng/mL compared to 250 ng/mL using streptavidin coated magnetic bead. Data processing parameters were also extensively evaluated and optimized. It was found that both XIC mass tolerance window and the number of charge states included in the peak area summation can have a large effect on data quality, especially at the LLOQ level. A flexible informatics workflow evaluating multiple parameters was used for a quickly viewing the data and determining the best analysis method.

Conclusions

HRMS quantification of intact mAbs offers analytical scientists many advantages over traditional approaches. In addition to simpler sample preparation (versus surrogate approaches), structural information at the whole molecule level can provide additional information in understanding the state of mAb in question in biological systems and interpreting quantitative outcomes. In this study, high sensitivity quantification of monoclonal antibody is presented. Results show that the combination of a sensitive mass spectrometer with the best practice in sample preparation and data processing parameters are critical in obtaining the highest sensitivity. Combination of these best practices brings us a step closer to routine intact level quantification of mAbs in plasma.

Novel Aspect:

The present study provides a complete workflow for intact level mAb quantification in plasma from automated sample preparation through automated data processing and data review. The LLOQ of <50 ng/mL represented the best sensitivity so far and further closing the gap between intact level and surrogate peptide approaches in the quantification of monoclonal antibody in plasma.

390 - PROGRESS TOWARDS IMPLEMENTING ACCURATE MASS MS FOR ROUTINE BIOTHERAPEUTIC ANALYSIS

Henry Shion (1) - William Alley (1) - Jonathon Pugh (2) - Robert Lewis (2) - Ying Qing Yu (1) - Weibin Chen (1)

Waters Corp, Scientific Operations, Milford (1) - Waters Corp, Waters, Wilmslow (2)

Keywords: fit-for-purpose time-of-flight MS, biotherapeutics, intact mass analysis, peptide mapping, glycan analysis

Introduction: The adoption of accurate mass MS for routine analysis has been hindered by instrument size, operation complexity, hardware robustness, and reproducibility. Yet, there is a need for this approach; for example, efficient data collection and analysis of quality-relevant information within the pharmaceutical industry. Here, we describe the performance evaluation of a prototype small-footprint time-of-flight MS that could overcome many of the above challenges.

Methods: To assess the performance and reproducibility across a range of biotherapeutics, trastuzumab, NIST mAb, infliximab, trastuzumab emtansine, brentuximab vedotin, and EPOs were analyzed using the prototype MS coupled with various chromatography separation modes for intact, subunit, peptide mapping and released glycan experiments. Data acquisition, processing, and reporting were all achieved within a single workflow-centric informatics platform.

Results: For intact mass analysis, a dilution series for both trastuzumab and NIST mAb established a limit of detection (LOD) and intra-system LOD reproducibility. Results were comparable to other high resolution MS systems. More structurally complex proteins (infliximab, trastuzumab emtansine, and EPOs), were analyzed and data demonstrated the greater heterogeneity of these molecules. The average drug-to-antibody ratio (DAR) for a cysteine-conjugated ADC agreed with values from commercial MS systems and hydrophobic interaction chromatography (HIC).

NIST mAb subunits showed good mass accuracy. Low oxidation levels were observed for both subunits after forced degradation experiments.

Peptide mapping of the NIST mAb was used to evaluate system robustness. A high sequence coverage was determined through precursor accurate masses and identification of fragment ions.

Glycan analysis was performed on the NIST mAb. All major glycans were correctly identified as well as many lower abundance glycans, including some potentially immunogenic glycans.

Conclusions: Several key biopharmaceutical experiments were performed on a small-footprint prototype TOF MS instrument. The data generated for all experiments (intact mAb mass, peptide mapping, glycan analysis) were very comparable to currently available commercial high resolution MS instrumentation. Thus, these data show great promise that this instrument could be an appropriate choice for routine MS-based biopharmaceutical analyses.

Novel Aspect: A prototype small-footprint oa-TOF MS provides fit-for-purpose data for multiple experiment types relevant to routine biotherapeutic analysis.

158 - MULTIPLEXED ANALYSIS OF ENVIRONMENTAL SAMPLES BY GCXGC-HRMS WITH MULTI-IONIZATION CAPABILITIES

Viatcheslav Artaev (1) - Georgy Tikhonov (1) - Albert Lebedev (2)

LECO Corporation, R&D, St. Joseph (1) - Moscow State University, Chemistry Dept., Moscow (2)

Keywords: GCxGC, TOFMS, HRMS, Non-targeted, Environmental

Introduction:

The Gas Chromatography coupled to Mass Spectrometry provides powerful analytical tools, combining selectivity, sensitivity, reliability, and information capacity for targeted or non-targeted methods of environmental analysis. Yet, the complexity of the environmental samples and variety of the analytes of interest in them demands the novel methods of analysis, taking advantage of modern advances in gas chromatography, mass spectrometry and data processing.

Methods:

The GCxGC equipped with thermal modulator and coupled to High Resolution TOFMS was used for untargeted screening of snow samples. The mass spectrometer was equipped with a novel ion source, capable of three modes of ionization - EI, PCI and ENCI. The snow samples were analyzed in different ionization modes using same instrument and at the same chromatographic conditions. The chromatograms were realigned for assisting in identification of the analytes.

Results:

The high resolution TOFMS is an ideal GC-MS detector for screening and quantifying unknowns as it collects high mass accuracy full mass range mass spectra at very high acquisition rates without any data loss. The technique provides highly reliable data suitable for automatic accurate spectral deconvolution of the coeluting analytes present in the samples in the wide concentration range. The GCxGC technique increases separation power, allows chromatographic separation of closely eluting constituents, making analyte identification more reliable and makes comprehensive analysis of environmental samples more realistic. Comparison of analytes detected in the same sample using EI, PCI and ENCI ionization shows that individual ionization method may miss certain types of the analytes, and combining data from three modes of ionization improves the quality of the results. The presentation will demonstrate the practical implementation of the technique and will report examples of false negative results if only one ionization method is used.

Conclusions:

Application of the highly efficient multiplexed technique of GCxGC-HRTOFMS with multi-ionization capabilities has proved to be very powerful for increasing coverage and reliability of the untargeted screening results of environmental samples. Combining data from all three ionization modes increased the number of detected analytes by at least 30% and improved reliability of the analyte assignments.

Novel Aspect:

GCxGC-HRMS analysis with EI, PCI and ENCI ionization of analytes was used for comprehensive analysis of snow samples collected at the same day in various parts of large city.

University of Barcelona, Department of Chemical Engineering and Analytical Chemistry, Barcelona (1)

Keywords: gas chromatography, atmospheric pressure photoionization, high resolution mass spectrometry, semi-volatile fluorinated compounds, water

Introduction:

Semi-volatile fluorinated compounds are currently determined by GC-MS using electron and chemical ionizations [1], but problems related to their low ionization efficiency have been reported. Considering the proved advantages of atmospheric pressure photoionization (APPI) for the analysis of non-polar compounds [2], in this work we explored the applicability of this technique for the determination of several families of fluorinated compounds by GC-MS.

Methods:

GC-APPI-HMRS (Orbitrap) method combined with HS-SPME was developed for the determination of fluorotelomer olefins (FTOs) fluorotelomer alcohols (FTOHs) and fluorinated sulfonamides (FOSAs) and sulfonamide-ethanols (FOSEs) in river water samples at trace levels. The HS-SPME method was performed using a PDMS/DVB/CARB fiber and the GC-APPI-HRMS determination was carried out in the negative ion mode using fullscan acquisition at a resolution of 35,000 (FWHM).

Results:

Semi-volatile fluorinated compounds were ionized via dopant-assisted in negative ion mode, generating the $[M+O_2]^-$ as base peak of mass spectra for most of FTOHs and FOSEs, while the $[M-H]^-$ and several in-source CID fragment ions were mainly observed for FOSAs and FTOs, respectively. Acetone was found to be the best dopant for achieving the highest responses for all the compounds. The GC-APPI-HRMS method provided low limits of detection, ranging from 0.05 to 10 pg injected, and non-significant matrix effects for the analysis of water samples with different pollutant loads. HS-SPME was used to extract analytes from water river samples and the method limits of detection achieved ranged from 24 pg L⁻¹ to 15 ng L⁻¹. The HS-SPME GC-APPI-HRMS method provided good linearity ($R^2 > 0.993$) in the calibration working range. The precision and trueness of the developed method were determined using spiked blank river water samples, obtaining for all the compounds RSD% values lower than 11% and relative errors down to 12%, respectively.

Conclusions

GC-APPI-HRMS has shown to be an excellent alternative to the existing GC-MS methods using classical ionizations for the determination of semi-volatile fluorinated compounds, providing LODs up to 80 times lower than EI and CI techniques. Moreover, the response of the GC-APPI-HRMS is not significantly affected by the matrix. On that way, the developed GC-APPI-HRMS method in combination with HS-SPME allowed the detection of the target compounds down to pg L⁻¹ levels.

Novel Aspect:

This is the first time that a GC-APPI-HRMS method is proposed for the determination of semi-volatile fluorinated compounds in river water samples at very low concentrations.

899 - DETERMINATION OF QUANTITATIVE AMOUNTS AND RATIO BETWEEN ENZYME VARIANTS IN A SAMPLE, BY SPIKING WITH STABLE ISOTOPE LABELLED PEPTIDES

Janne Bech Thøgersen (1)

DuPont Nutrition Biosciences ApS, Advanced Analysis, 8220 Brabrand (1)

Keywords: Protein mutation variants, quantification, isotopic labelled peptide standards

Introduction:

A sample was found to contain two similar protein variants ("F" and "Y"), only differing by amino acid substitutions at a few positions. An attempt to estimate the ratio between the two variants had previously been carried out, using proteolytic digestion of the sample. Two peptides separating the variants were used for calculation of a chromatographic peak-area-ratio. However, this method suffered from poor precision mainly caused by variations in the nanoLC-MS system. Accordingly, the aim of the present work was to improve the precision of the ratio determination and to know the exact quantitative amount of the variants in the sample.

Methods:

Initially, protein concentration was estimated using a BCA assay, to control protein to enzyme ratio, and for the final quantitative calculations of the content of variants relative to the total protein amount.

One of the positions at which the variants were differing, was captured by digestion using endo-proteinase Asp-N, giving two good responding peptides. The Asp-N digested sample was spiked with corresponding AQUA peptides, purchased as synthesized variants with the C-terminal amino acid being heavy isotopically labelled (+4 Da). Accordingly, it was possible to distinguish the spiked peptides from the peptides originating from the sample. As preparation for nanoLC-MSMS analysis the peptides were purified by solid-phase extraction.

Results:

Adjusting the "simple area based ratio estimation" using heavy isotopically labelled peptide standards, eliminated most of the previous observed deviation. By spiking the heavy isotopic labelled peptides in known concentrations, it should be possible to quantify the amounts of variants in the sample, corrected for differing MS response and possible sample matrix effect. However, recovery of the spiked internal standard is not the only challenge of an absolute quantification, which also depend on recovery of the many steps in the sample preparation procedure (solubilization/extraction, BCA protein quantification, digestion and SPE purification).

Conclusions:

The precision, of a "simple chromatographic peak-area-ratio" describing the ratio between two protein variants in a sample, was remarkably improved by adjusting to internal standards in the form of heavy isotopic labelled peptides. Absolute quantification depends on many steps of the sample preparation procedure and each step require validation.

cosima damiana calvano (1) - maria capozzi (2) - angela punzi (2) - gianluca farinola (2) - francesco palmisano (2) - tommaso cataldi (2)

university of bari, Chemistry, bari (1) - university of bari, chemistry, bari (2)

Keywords: croconaine, electron transfer, proton transfer, MALDI

Introduction:

Croconaine dyes are appealing molecules based on the condensation of croconic acid and a reactive electron-donating aromatic or heterocyclic structures [1,2]. Fast investigation of these dyes was accomplished by matrix assisted laser desorption/ionization (MALDI) MS in positive ion mode after a systematic matrix selection. Since few or no information on the gas-phase ion energetics of croconaines are available, an empirical approach was followed.

Methods:

All experiments were performed using a 5800 MALDI ToF/ToF analyzer in reflectron positive mode. Different matrices such as protonating 2,5-dihydroxybenzoic acid (DHB), and α -cyano-4-hydroxycinnamic acid (CHCA), electron-transfer (ET) secondary reaction matrices as trans-2-[3-(4-t-butyl-phenyl)-2-methyl-2-propenylidene]malononitrile (DCTB) and 1,5-diaminonaphthalene (DAN) and basic as 9-aminoacridine (9AA) were examined.

Results:

The investigated croconaines bring symmetrical substituents on the indolenine core including heteroatoms as fluorine and bromine or different aromatic structures. Typically, when dyes were analyzed by using proton transfer (PT) matrices as DHB and CHCA the base peak assigned to the protonated adduct $[M+H]^+$ and the concomitant presence of an odd electron molecular ion, $M+\bullet$, was observed. This outcome suggests that gas-phase PT and electron transfer ET secondary reactions are competing processes when acidic matrices are employed. The presence of many signal contributions represents a drawback in terms of sensitivity and trouble when running tandem MS. Among the ET matrices, DAN provided the highest ionization yield leading to the specific formation of odd-electron molecular ion $M+\bullet$ without other contributions. This allowed to select the precursor ion in a unique form for MS/MS analyses. Singular behavior was observed for bromine substituted croconaine when fragmented with DAN since bromine ion was detected as unusual Br^+ cation.

Conclusions:

Protonating matrices generate a mix of odd molecular ions and protonated adducts alongside sodiated species. Among the ET matrices, DAN provided the highest ionization yield leading to the specific formation of odd-electron molecular ions $M+\bullet$ with a negligible fragmentation. Finally, MALDI MS/MS of the radical charged molecular species provide useful structural information, thus making identification very straightforward for all croconaines investigated.

Novel Aspect:

The analysis of croconaines by MALDI MS is presented for the first time. Tandem MS and DAN reveal common fragmentation patterns and the occurrence of uncommon positive ions.

Keywords: Efficient Preparation; Organoimido functionalization; Lindqvist hexamolybdate; Leidenfrost droplets; Electrospray mass spectrometry

Introduction:

Polyoxometalates (POMs) are discrete anionic metal-oxygen clusters which exhibit a great diversity of applications ranging from catalysis, medicine, etc.[1] POM-based inorganic/organic hybrids have drawn enormous attention in the past decades as exciting applications of these materials have been discovered in such diverse areas as light-emitting diodes, field-effect transistors, and solid-state lasers. Such hybrid materials may provide additional and/or enhanced functions and properties as a result of synergistic interactions between their inorganic and organic components.

Peng et al. reported a facile and efficient method to synthesize organoimido derivatives of POMs by using dicyclohexylcarbodiimide (DCC) as a catalyst, which was implemented by refluxing the reaction mixture of aromatic amines and TBA2[Mo6O19] in acetonitrile for 12 hours.[2] Leidenfrost droplets have been used as microreactors for the preparation of metal nanoparticles and for accelerated organic synthesis.[3] However, there is no report on the preparation of inorganic-organic hybrids which show promise in material science and homogeneous catalysis. Herein, we report preliminary result for the functionalization of POM clusters with aromatic amines, a model example of this type of reaction and its first implementation using the Leidenfrost effect to perform accelerated chemical synthesis in droplets. We show that interfacial effects are involved in acceleration and prepared macroscopic amounts of synthetic products within minutes. Compared to Peng's method, which was reported to be faster, more efficient, and the reaction conditions are much milder than earlier methods, Leidenfrost experiment is more competitive in which interfacial effects may play a pivotal role in the reaction acceleration.

Methods:

Efficient Preparation of Organoimido Derivatives of Lindqvist hexamolybdate in Leidenfrost Droplets.

Results:

Four reactions of Lindqvist hexamolybdate [Mo6O19]2- with aromatic amines to generate organoimido derivatives were used as model reactions to explore the use of the Leidenfrost effect for accelerated chemical synthesis of organo-modified POMs in droplets. It is clear to see that observable amounts of products were formed over the time course of the experiment (240 s) for the Leidenfrost droplet experiment while in the parallel bulk-phase reactions no detectable product formation is evident.

Conclusions:

We show that interfacial effects are involved in acceleration and prepared macroscopic amounts of synthetic products within minutes. Compared to Peng's method, which was reported to be faster, more efficient, and the

reaction conditions are much milder than earlier methods, Leidenfrost experiment is more competitive in which interfacial effects may play a pivotal role in the reaction acceleration.

Novel Aspect:

We report the first implementation using the Leidenfrost effect to perform accelerated synthesis of organo-functionalized POMs in droplets.

656 - A NOVEL PTR-TOF REACTION CELL SUPERPOSING DC AND RF FIELDS LEADS TO TEN-FOLD IMPROVEMENTS IN SENSITIVITIES AND LODS

Luca Cappellin (1) - Felipe Lopez (1) - Manuel Hutterli (1) - Jordan E. Krechmer (2) - Sonja Klee (1) - Benoit Plet (1)

TOFWERK AG, R&D, Thun (1) - Aerodyne Research Inc., R&D, Billerica (2)

Keywords: PTR-MS, time-of-flight, sensitivity, reaction cell, VOCUS

Introduction:

The working principle of Proton Transfer Reaction - Mass Spectrometry (PTR-MS) is chemical ionization upon reactions between H_3O^+ ions and the analyte VOCs within a reaction cell. A DC field within the cell moves the primary and product ions towards the detector. In conventional reaction cell ion losses occur at the reaction chamber cell walls because of diffusion and scattering. This problem affects the instrumental sensitivities and limits of detection (LOD).

Methods:

The solution involves adding oscillating RF fields on top of the linear field in the reaction cell. The ions are not only moved along the cell by the conventional DC field but are also simultaneously focused by the oscillating RF fields, so that more ions can reach the detector. The chemistry of ion-molecule reactions within the cell is similar to that of the old design, while the spatial distribution of primary and product ions is changed to achieve the extra focusing.

Results:

The additional ion focusing which is reached in this way greatly improves the transmission of ions towards the detector region. The net gain in sensitivity exceeds one order of magnitude and previous boundaries in LODs are overcome thus providing unprecedented performances for a PTR-MS. The new reaction chamber has been coupled to state-of-the-art mass analyzers such as time of flight mass spectrometers (ToF-MS) reaching 15,000 ($m/\Delta m$ FWHM) in mass resolution. This new instrument has been denominated VOCUS PTR-TOF. In the case of xylene, the achieved sensitivity is 20000 cps/ppbv and the LODs are <1 pptv and <10 pptv in 1 s and 1 min integration time, respectively. Another problem which is overcome by the new reaction cell is the dependence of calibration factors on the sample humidity. Calibration factors for VOCUS PTR-ToF are independent of sample humidity.

Conclusions

A new PTR-MS reaction cell design is introduced adding oscillating fields to the linear field. Ion losses due to scattering and diffusion are avoided, strongly improving the instrument performance. Limits of detection and sensitivity are improved by more than a factor of ten. The dependence of concentration calibration factors on sample humidity, which is a problem in conventional PTR-MS, is overcome.

Novel Aspect:

The addition of an oscillating field to the PTR-MS reaction cell leads to a sensitivity gain of more than ten-fold.

195 - DETERMINING ACETYLCHOLINESTERASE ACTIVITY USING PAPER SPRAY MASS SPECTROMETRY

Daniel Carmany (1) - Gabrielle Boyd (2) - Phillip Mach (2) - Elizabeth Dhummakupt (3) - Paul Demond (2) - Michael Busch (2) - Trevor Glaros (4)

Excet Inc, ECBC, Gunpowder, MD (1) - Excet Inc, ECBC, APG, MD (2) - Nation Research Council, ECBC, APG, MD (3) - US Army, ECBC, APG, MD (4)

Determining Acetylcholinesterase Activity Using Paper Spray Mass Spectrometry

Daniel Carmany, Gabrielle Boyd, Phillip M Mach, Elizabeth S Dhummakupt, Paul S Demond, Michael Busch, Trevor Glaros

Keywords: Paper spray, acetylcholinesterase, chemical warfare agents, VX, enzyme

Introduction:

Paper spray (PS) is an ambient ionization technique that has been used to detect and quantitate a wide range of small molecules from complex matrices. Recently, PS mass spectrometry was shown to be a rapid alternative for measuring the results of enzymatic reactions which took place in microcentrifuge tubes. Herein, we present an assay where the enzymatic reaction occurs on the PS substrate to monitor the activity of acetylcholinesterase (AChE) in blood to determine inhibition due to chemical warfare agent exposure. This substrate assay is simple, rapid, and requires minimal sample volume.

Methods:

The paper substrate required vapor application of silanes to generate a hydrophobic surface. The reaction was generated in a vial and spotted onto the surface of the PS cartridge. Due to the hydrophobicity of the substrate surface, the reaction solution formed a 'reaction sphere'. The loaded PS cartridges were then incubated at 37°C for 30 minutes. The cartridges were then analyzed on a Thermo Scientific Orbitrap Elite mass spectrometer for AChE activity.

Results:

Enzymatic reactions were successfully performed on-substrate using PS-MS to determine AChE activity. AChE activity was determined using the synthetic substrate 1,1-dimethyl-4-acetylthiomethylpiperidinium (MATP), m/z of 202.0836, which is cleaved by AChE generating a resultant fragment at m/z of 160.0837. The change in ratio of these 2 ions demonstrates AChE activity, with corresponding increases in signal as additional substrate was reacted. It was determined that a 30 min incubation at 37°C resulted in a log difference in the ratio. The nerve agent VX was used as a control for the reaction to identify AChE as the functioning enzyme, via direct inhibition. A method was then designed that allowed for not only the determination of AChE activity but to also identify the toxic inhibitor, VX, with tandem mass analysis. This method was used to analyze blood from animals exposed to VX. The results were compared with analysis of the same samples utilizing the standard Ellman's Assay. There was consensus between the Methods:

Conclusions:

PS-MS is suitable for determination of AChE activity in blood. The assay requires only MTAP as a reagent, and no secondary reaction is required. Using a hydrophobic PS cartridge, the reaction may be performed on-substrate with both high and low resolution instruments being utilized for analysis. The assay performed similarly to standard laboratory procedures when analyzing samples from exposed animals, even at a dose a log less than is required to observe symptoms.

Novel Aspect:

An assay has been developed to measure AChE inhibition using PS-MS. The assay requires a single reagent and also allows for mass based identification of the toxicant.

1012 - LC-HRMS BY MEANS OF UNTARGETED DATA-DEPENDENT ACQUISITION FOR THE CHARACTERIZATION OF 'SUPERFOODS'

Francesca Di Ottavio (1) - Julia Gauglitz (2) - Louis Felix Nothias (2) - Morgan Panitchpakdi (2) - Pieter Dorrestein (2) - Dario Compagnone (1) - Manuel Sergi (1)

University, University of Teramo/ Faculty of Bioscience, Teramo (1) - UCSD, University of California San Diego/ Skaggs School of Pharmacy, San Diego (2)

Keywords: Mass-Spectrometry, Food Analysis, super-food, GNPS, in-silico annotation

Introduction:

We provide a workflow to identify characteristic signatures of superfoods, a poorly defined marketing term referring to food with high levels of nutrients that may benefit health.

A set of 500 plant-based and superfood samples were analyzed by using untargeted UPLC-QTOF-MS/MS and new computational tool. We identified distinct molecular signatures including the diversity of polyphenols, flavonoids and microbial peptides that can be used to categorize superfoods.

Methods:

Samples were extracted and chromatographically separated by UPLC-QTOF system and C18 column separation. Spectra were acquired in positive data dependent acquisition and the five most abundant ions were selected for fragmentation spectra acquisition. Greater than 500 plant-based samples were analyzed by UPLC-MS/MS in DDA and processed on the GNPS webplatform [1].

Results:

Untargeted MS analysis was used to obtain an overview of all features, focusing on compounds with anti-inflammatory, antioxidant or antimicrobial properties across a broad range of plant-based foods.

Spectral library search was performed against public and commercial libraries (GNPS, MassBank, Metlin, NIST), and molecular networks were generated to expand spectral annotations. In addition, computational mass spectrometry strategies were employed to annotate bioactive compounds such as polyphenols, flavonoids and phenolic acids. Those include: (1) the automatic network annotation propagation of in silico annotations, (2) the dereplication of bioactive peptides using the Dereplicator workflow [2], (3) the annotation of sub-structures using MS2LDA [3], (4) the computation of the molecular formula using Sirius and CSI:Finger [4] and (5) the prediction of the chemical class using Canopus fingerprint.

Conclusions

Unique microbial peptides with antimicrobial, anti-inflammatory or antioxidant properties and putative unknown cyclolinopeptide variants were found in some superfoods (score > 15, p values < 1E-11, FDR < 1%).

The presence of unique compounds, as well as the proportions of polyphenols, flavonoids and bioactive peptides between superfoods and common fruit and vegetables is proposed to define criteria underlying the chemical characteristics of superfoods.

Novel Aspect:

We are presenting criteria to classify superfoods based on the number and the diversity of bioactive Compounds.

1151 - HIGH-RESOLUTION MASS SPECTROMETRY IN COMBINATION WITH IN SILICO PREDICTION MODELS TO IMPROVE ACCURACY FOR COMPOUND IDENTIFICATION

Eric Dossin (1) - Pierrick Diana (1) - Anneke Glabasnia (1) - Mark Bentley (1) - Philippe Alexandre Guy (2)

Philip Morris Product S.A., Product research, Neuchâtel (1) - Philip Morris Product S.A., Product research, Neuchâtel (2)

Keywords: compound identification, high-resolution mass spectrometry, complex mixture analysis, linear retention index prediction

Authors:

Dossin E., Diana P., Glabasnia A., Bentley M., Guy P. A.

Introduction:

Chemical characterization remains a major hurdle for analytical chemists when dealing with non-targeted screening analyses. This work focuses upon the identification of unknown volatile and semi-volatile compounds using gas chromatography coupled to high-resolution mass spectrometry (GC-HRMS) operating in electron ionization (EI) acquisition mode.

Methods:

552 reference compounds, including n-alkanes used as chemical markers, were analyzed by GC-HRMS. Accurate mass spectra (MS) were registered in a Personal Compound Database Library, which enabled targeted screening for these compounds. These compounds were randomly split into training (n=401) and test (n=151) sets, and linear retention index (LRI) values were used to build LRI prediction models [1].

Results:

These models were used to predict LRI values for several thousand of chemicals reported to be present in tobacco and tobacco aerosol, plus a range of specific flavor compounds [2]. These predicted LRI values were used in conjunction with EI nominal MS available from commercial libraries to enhance the confidence in structural elucidation.

These models were also used to predict LRI values for hits proposed from the comparison of deconvoluted spectra with commercial MS libraries. The similarity between calculated and predicted LRI values added an additional layer of confidence for compound identification. A final score was calculated as a combination of MS similarity score and the accuracy for experimental versus predicted LRI values.

Recently, a set of 350 reference compounds were analyzed and used to validate the accuracy of the models and highlight any limitations.

Conclusions:

The combination of accurate LRI prediction and MS similarity improved the ranking of compound proposals, thus demonstrating that computational LRI prediction facilitates the evaluation of non-targeted data. This workflow has been used to improve the confidence in structural elucidation for the analysis of complex matrices.

Novel Aspect:

Combination of two LRI prediction models with EI acquisition mode for identification of unknown chemicals.

952 - HIGH-THROUGHPUT QUAN/QUAL LC-MS ANALYSIS: WHERE IS THE SWEET SPOT?

Anne-Charlotte Dubbelman (1) - Filip Cuyckens (2) - Lieve Dillen (2) - Rob J. Vreeken (2) - Thomas Hankemeier (1)

Leiden University, Leiden Academic Centre for Drug Research/Systems Biomedicine and Pharmacology, Leiden (1) - Janssen R&D, Pharmacokinetics, Dynamics and Metabolism, Beerse (2)

Keywords: Quan/Qual; UHPLC-QTOF-MS; high-throughput; metabolomics; drug metabolism

Introduction:

High-throughput simultaneous quantitative and qualitative (Quan/Qual) analysis is attractive to combine targeted with non-targeted analysis, e.g. in pharmacometabolomics and drug metabolism studies. But, when using a Q-ToF, where is the 'sweet spot', viz. an optimal balance between quantitative and qualitative data and optimal use of instrumental capabilities? That is what we investigated in this study.

Methods:

An ultra-high performance liquid chromatography (UHPLC) method with high chromatographic resolution (peak capacity of 266 with a gradient time of 2.25 min) and a Synapt G2S were used to investigate and optimize mass spectrometric parameters for Quan/Qual analysis. The optimized method was applied to a rat metabolomics study investigating the effect of the fasting state and the administration of a dosing vehicle on the rat plasma metabolic profile.

Results:

The scan mode and scan rate proved to be highly important parameters for high-throughput Quan/Qual analysis. The amount of qualitative information that a method can provide correlated negatively with its quantitative performance (accuracy, precision, sensitivity, linear dynamic range). The MSE scan mode with a short scan time of 30 ms provided the optimal balance. The resulting 4.25-min Quan/Qual analysis method enabled quantification with accuracy and precision values $\leq 20\%$ at the lowest quality control (QC) level and $\leq 15\%$ at higher QC levels for 16 out of 19 tested analytes. It provided both parent m/z values and fragmentation spectra for compound identification with limited loss of chromatographic resolution. It revealed biologically relevant metabolites in its application to the rat metabolomics study.

Conclusions:

High-throughput Quan/Qual method development requires balancing between the amount of qualitative data, the quality of the quantitative data and the analysis time. We will share recommendations for MS resolution, scan mode, scan rate and smoothing in Quan/Qual method development and analysis.

Novel Aspect:

This work highlights the importance of optimizing high-resolution mass spectrometric parameters for Quan/Qual analysis, opposing the general idea of their insignificance.

Susanne Ekroth (1)

National Food Agency, Chemistry Department, Uppsala, Sweden (1)

Keywords: SweEt multiresidue method, Screening, Orbitrap mass analyzer, Compound Discoverer

Introduction

As more and more new food compounds are being developed and deployed around the world, contaminants not in target lists can appear in products through environmental or manufacturing contamination or misuse. This makes it essential that food safety laboratories stay vigilant for an ever-increasing number of analytes to screen for, and for new, unexpected and unwanted compounds[1] [2].

At the moment, the LC triple quad MS and GC triple quad MS systems are the workhorses of the pesticide laboratory. Most labs in Europe still use these technologies more than any other. But there's a trend toward implementing high-resolution accurate mass (HRAM) technology, because analysts are no longer satisfied with just finding the expected compounds in the samples; now, the aim is to identify everything (or at least as much as possible). In other words, there is a steady move away from targeted analysis. Screening allows us to discover what is in the samples with less bias – at odds with simply looking for what we already suspect is present.

This poster will show an efficient workflow for a non-targeted acquisition MS-mode for different compound groups and demonstrate a next-generation workflow for more efficient control of unexpected and unwanted compounds in food. The Swedish Ethyl acetate multiresidue method (SweEt), coupled with a high-resolution mass spectrometer offers:

The ability to screen for several compound groups at the same time, in the same sample

Advanced software tools for screening evaluation and identification

A validated and accredited method to screen for around 500 pesticides in fruits and vegetables

Methods

The main extraction techniques used today are making high-moisture food sample preparation faster and more straightforward. SweEt [3](Swedish Ethyl acetate), is amenable to a wide range of matrices and offer a number of advantages over the traditional sample preparation techniques. With a range of polar and non-polar contaminants potentially present in food samples, it is essential that the sample preparation approaches are able to extract a very broad range of analytes. However, it can be challenging to develop methods that are both comprehensive as well as convenient to use. This presentation will describe the workflow for SweEt with around 550 pesticide analytes in targeted mode and the screening workflow for semi/non-targeted mode.

Results

With a generic method it is possible to screen and identify several compound groups in the same sample. The poster will present examples of findings of aflatoxin, benzophenone and pesticides.

Conclusions

Pesticides alone account for around 1000 analytes and can be found in different food commodities. Meanwhile other types of unwanted analytes can also be found such as mycotoxins, alkaloids, food additives, veterinary drugs and food contact materials. The broad variety of compound groups has limitations regarding extractability with different solvents. Therefore it is important to have a generic method and if possible to extract suspect samples in various ways. [4]

Novel Aspect

This poster presents an efficient screening workflow which can make laboratories better equipped to manage what the future may hold. There is a need to stay alert and anticipate what's beyond the conventional and expected findings, for example food frauds, contaminations or simply misuse of substances.

555 - BRIDGING THE GAP BETWEEN IMAGES AND MOLECULES: PARALLEL ACQUISITION OF FTMS MASS SPECTROMETRY IMAGING AND MS/MS DATA COUPLED WITH AUTOMATED AND HIGH CONFIDENCE LIPID IDENTIFICATIONS

Shane Ellis (1) - Martin Paine (1) - Gert Eijkel (1) - Josch Pauling (2) - Peter Husen (3) - Mark Jervelund (2) - Martin Hermansson (2) - Christer Ejsing (2) - Ron Heeren (4)

Maastricht University, The Maastricht Multimodal Molecular Imaging Institute (M4I), Maastricht (1) - University of Southern Denmark, Department of Biochemistry and Molecular Biology, Villum Center for Bioanalytical Sciences, Odense (2) - University of Southern Denmark, Department of Physics, Chemistry and Pharmacy, Odense (3) - Maastricht University, The Maastricht Multimodal Molecular Imaging Institute (M4I), Maastricht (4)

Keywords: mass spectrometry imaging; lipids; tandem mass spectrometry; Fourier transform mass spectrometry; automated identification

Introduction:

Mass spectrometry imaging (MSI) enables visualizations of lipid distributions throughout tissues. Yet, it has struggled to translate images to underlying lipid biochemistry. A significant contributor is the lack of automated and broad MS/MS acquisition and structural identifications tool. We address this limitation via an innovative MSI approach enabling parallel acquisition of MS/MS and FTMS-MSI of every ion without prolonging MSI acquisition time.

Methods:

Data were acquired using an Orbitrap Elite and a dual MALDI/ESI source (Spectrograph, LLC). Norharmane matrix and a 20x40 μm step size were used for MSI [1]. For DDA-Imaging IT-MS/MS were acquired in parallel with each Orbitrap transient. Acquisition of MS/MS for every m/z was achieved without prolonging the FTMS-MSI acquisition. ALEX123 software was used to assign both sum-composition and molecular-lipid identifications utilising both FTMS and IT-MS/MS data [2].

Results:

Exploiting the parallel operation of the Orbitrap Elite our DDA-Imaging-method yielded both high mass resolution FTMS (encoding both the MSI data and sum-composition level lipid assignments) and high quality IT-MS/MS of nearly every ion observed in the MSI experiment. Both a 240,000 resolution FTMS scan and an IT-MS/MS spectrum could be obtained in parallel from each 40 μm region of tissue. Even for low abundance lipids having relative intensities less than 1% high contrast images and high quality MS/MS data were acquired.

We used ALEX123 to perform automated identification of detected lipids using both the high mass accuracy (± 2 ppm tolerance) and IT-MS/MS data. We automatically identified 165 unique sum-composition-level lipid species and 113 unique molecular lipid species that were present in all replicates of rat cerebellum tissue. All IDs are supported by both FTMS and MS/MS and in relevant cases, cross-correlation of positive- and negative-ion mode data. For all lipid species their spatial distribution is also acquired via the FTMS data.

Conclusions

Our method overcomes the current limitations of broadband molecular identifications in MSI. By exploiting a hybrid ion trap/Orbitrap instrument, MS/MS data are acquired without expanding additional experiment. To fully exploit the information-rich datasets, ALEX123 software provides automated and high confidence lipid identifications in parallel to MSI experiments, allowing broad assignment of MS-images to identified lipids.

Novel Aspect:

Parallel FTMS-MSI and MS/MS combined with ALEX123 software provides both MSI and broad structural identification data in a single acquisition.

1105 - UHPLC-HRMS METHOD FOR TARGETED ANALYSIS OF CYANOTOXINS IN FRESHWATER

Daria Filatova (1) - Massimo Picardo (1) - Oscar Núñez (2) - Marinella Farré (3)

Institute of Environmental Assessment and Water Research, Spanish National Research Council, Department of chemical engineering and analytical chemistry, University of Barcelona, Barcelona (1) - Serra Hunter Fellow, Generalitat de Catalunya, Department of chemical engineering and analytical chemistry, University of Barcelona, Barcelona (2) - Institute of Environmental Assessment and Water Research, Spanish National Research Council, Institute of Environmental Assessment and Water Research, Spanish National Research Council, Barcelona (3)

Keywords: cyanotoxins, microcystins, high-resolution mass spectrometry

Introduction:

Cyanobacteria are the components of regular microbial succession in periphyton formation, however, some species are known to produce toxic secondary metabolites (cyanotoxins), which vary in structure and harmful properties. During the past decades, an increase of cyanobacterial blooms was noticed in freshwater bodies. To monitor cyanotoxins' levels and prevent both human poisoning and wildlife damage, suitable analytical methods need to be developed.

Methods:

For sample pretreatment, SPE using 2 cartridges in sequence for multiple toxins has been optimized and employed. The chromatographic separation was achieved using a C18 analytical column (150x2.1 mm, 2 μ m) with acidified acetonitrile and water as mobile phase. The chromatographic separation was coupled to a Q-Exactive Orbitrap instrument (Thermo Fisher Scientific) and the MS data was acquired in both full scan and parallel-reaction monitoring modes (PRM).

Results:

Ultra-high performance liquid chromatography coupled to high-resolution mass spectrometry (UHPLC-HRMS) was developed. This method provides targeted analysis of cyanotoxins (microcystins, nodularin, cylindrospermopsin, and anatoxin-a) with instrumental limits of detection between 0.1 ng/L (4 toxins) and 1 μ g/L (2 toxins). Application of PRM gave an opportunity to identify the most abundant fragments for each toxin. Additionally, HRMS provides an assessment to the potential presence of transformation products and other non-targeted toxins in the samples. The developed method was applied for the study and characterization of cyanotoxins concentrations in Catalonia freshwater reservoirs.

Conclusions:

The developed method can be applied for identification and quantification of cyanotoxins of different chemical classes.

Novel Aspect:

A sensitive, fast and robust method for the analysis of cyanotoxins in freshwaters based on UHPLC-HRMS was developed.

Keywords: FT-ICR-MS, Ring Trial, human blood plasma, metabolomics

Introduction: A ring trial study of main blood plasma metabolites, in collaboration with over 17 different FT-ICR-MS laboratories worldwide, was organized and administrated at the Helmholtz Center Munich in a strong cooperation with Bruker Daltonics. The aim of this study is to investigate and to validate the implementation of several important ultra-high resolution FT-ICR-MS instruments for performing phenomics studies.

Methods: A novel standard operating procedure (SOP) was developed at the Helmholtz Center Munich, to assess deep metabolic information on human blood plasma samples[1]. Spiking studies with mixtures of chemical standards were performed to challenge the instruments' performance.

Results: The overlap of known and unknown metabolic compounds (features), reproducibly detected in all labs, is highlighted. In addition, key instrumental specificities between different FT-ICR-MS mass spectrometers are investigated, such as reproducibility, resolution, FWHM, peak shape, measurement sensitivity, dynamic range and mass measurement accuracy.

Conclusions: The study explores the capabilities of different FT-ICR-MS instruments with diverse ICR cells working under different magnetic field strengths, and with different operational cyclotron frequencies (1⁺ versus 2⁺ ion frequency measurements).

Novel Aspect: This study provides an unprecedented large-scale investigation to reliably perform accurate mass measurements for serving phenomics studies in the future.

1297 - SIMPLE WORKFLOW FOR PROTEOFORM SEPARATION AND ANALYSIS USING 2D GEL ELECTROPHORESIS-HIGH RESOLUTION MASS SPECTROMETRY.

Manasi Gaikwad (1)

University Medical Center Hamburg Eppendorf, Mass Spectrometric Proteomics Institute for Clinical Chemistry and Laboratory Medicine, Hamburg, Germany (1)

Keywords: 2D gel electrophoresis, mass spectrometry, proteoforms, post translational modification

Introduction:

In the early days of proteomics, it was assumed that each spot on a 2-dimensional electrophoresis (2DE) gel represent a single protein¹ due to the limitations of MALDI peptide mass fingerprinting for protein identification². The aim of this study was to answer the question how many proteins can be identified within one 2DE spot applying state of the art LC-MS/MS techniques and if additional information about proteoforms can be obtained due to separation of proteins by 2DE.

Methods:

Different 2DE-spots from a differential proteomics approach comparing human breast cancer cells before (control) and after perturbation (inhibition of mannosidase 1 with kifunensine) were analyzed. 60 spots were selected for further analysis after comparing the spot patterns of the 2DE gels. Selected spots were cut out and the proteins were proteolytically cleaved by trypsin. The peptides were analyzed by nano RPLC-ESI-MS/MS on a Q Exactive mass spectrometer.

Results:

Thousands of proteins and proteoforms were separated on the 2DE gel seen visually on the gel as multiple spots. The 60 spots subjected to bottom up LC-MS/MS analysis resulted in having greater insight into the number of proteins behind each spot and the distribution of proteoforms across 2DE gels. On average 125 proteins were identified per spot of the control 2D gel. Using this strategy, proteins could be identified unambiguously. About 42 % of the identified proteins were found in more than one gel spot which suggest that the proteins have varied in the post translational modifications (PTMs). Putative annexin A-2 like protein, desmoplakin and junction plakoglobin were proteins which are most commonly found in multiple spots. These multiple protein spots represent proteoforms having varied isoelectric points and molecular masses but are derived from same parent gene.

Conclusion:

The identification of proteins with state of the art LC-MS/MS from stained 2DE spots, which differ in their intensity in the comparison control vs. perturbed state gives information of proteoform changes associated with response to the perturbation. Combination of 2D gel separation and LC-MS/MS offers great potential in the proteome research focusing on proteoforms.

Novel aspect:

The workflow of 2DE followed by high resolution mass spectrometry represents a simple yet effective approach for identifying changes in the proteome on the level of proteoforms.

948 - RAPID AND EFFECTIVE MULTI-CLASS ANALYSIS OF ANTIBIOTICS IN FEEDINGSTUFFS AT CARRY-OVER LEVEL BY LC-MS/MS TECHNIQUES

Ilaria Di Marco Pisciotano (1) - Luigi Giannetti (2) - Bruno Neri (2) - Maurizio Fiori (3) - Cinzia Civitareale (4) - Paolo Stacchini (4) - Pasquale Gallo (1)

Istituto Zooprofilattico Sperimentale del Mezzogiorno, Department of Chemistry, Portici (NA) (1) - Istituto Zooprofilattico Sperimentale del Lazio e della Toscana, Department of Chemistry, Rome (2) - Istituto Superiore di Sanità, National Reference Laboratory for additives in feed, Rome (3) - Istituto Superiore di Sanità, Department of Food Safety and Veterinary Public Health, Rome (4)

Keywords: antibiotic, mass spectrometry, carry-over, feed.

Introduction

The rough clean up of pipelines after medicated feedingstuffs production can result in a cross-contamination of feed, known as “unavoidable carry-over for non target species”. This can expose farmed animals to undesirable administration of antibiotics, increasing the risk of induced resistance to microbials. Therefore, LC-MS/MS based multi-class methods have been developed and compared to determine up to 38 antibiotics in feed for target and untargeted species.

Methods

Purification of up to 38 antibiotics from feed (tetracyclines, sulphonamides, quinolones, macrolides, pleuromutilins, diaminopyrimidines, streptogramins) was performed by solid-liquid extraction. Determination was carried out by three different analytical systems: LC/ESI-QTRAP-MS/MS, UHPLC-Orbitrap-MS and UPLC-Xevo-TQ-MS. In all cases, chromatographic separation was performed on reversed phase columns, using linear gradient elution.

Results

The three test methods were in-house validated according to requirements of Commission Regulation 882/2004/EC [1] and Decision 657/2002/EC [2], evaluating the analytical performance parameters specificity, linearity, limit of quantification (LOQ), limit of determination (LOD), trueness, precision and ruggedness for each analyte. Specificity was assessed analyzing uncontaminated feed samples for poultry, cattle, pig, rabbit, sheep, goat and equine; no matrix interference was observed in the chromatograms at analyte retention times. Trueness as mean recoveries (%), and precision as RSD (%), were evaluated for each method by analyzing blank feed samples spiked at least at three concentration levels and were, respectively, in the range 76.3-107.7% and 1.6-22.8%. Linearity of each detector was verified by the correlation coefficient ($r^2 \geq 0.950$) of linear regression calibration curves of each analyte. The LOQ for all the antibiotics ranged from 0.010 to 0.100 mg/kg depending on the equipment; likely, LOD ranged from 0.002 to 0.030 mg/kg.

Conclusions

The multi-class and multi-drug methods we developed are all based on a rapid and simple cleanup, an effective chromatographic separation and a highly sensitive detection, allowing for simultaneous quantification and unambiguous identification of up to 38 antibiotics down to 0.010 mg/kg. These analytical methods fit with the requirements of the European Committee for the official control of antibiotics in feed at carry-over levels.

Novel Aspect

These analytical methods can replace single-class methods resulting in an optimization of work, costs and staff organization and in a more effective control activity.

Keywords: Organic Arsenic Species, High Resolution ES-MS/MS, Metabolomics, Fragmentation, Orbitrap.

Introduction:

Arsenic is unique among trace elements by exhibiting a rich organic chemistry spanning over 100 naturally occurring organoarsenic species in the environment. Organoarsenic species range from simple methylated arsenic acids through to arsenic-bound sugars and even more complex arsenic-containing lipids [1]. Here we report our most recent results employing high resolution mass spectrometry (HR-MS) to identify novel environmental arsenic compounds.

Methods:

We characterize the complex organoarsenical compositions in various environmental samples by means of positive ionisation HR electrospray Orbitrap MS/MS determination after separation of individual species by reversed-phase HPLC. The importance of tandem-MS as a powerful tool for the arsenic specific identification of unknown compounds is demonstrated and factors influencing the selectivity and sensitivity of the method discussed in detail.

Results:

The composition of the naturally occurring organoarsenic compounds are revealed by molecular HR-MS/MS measurements, whereby most of them show characteristic fragmentation. Among these, the most significant fragments $[M+H]^+$ have m/z of 104.9680 ($C_2H_6As^+$) and 122.9786 ($C_2H_8AsO^+$) originating from a common polar dimethylarsinoyl headgroup $(CH_3)_2OAs$. Furthermore, there is a variety of other fragmentation products supporting the identification of structural features such as arseno-ribosides with m/z 237.0102 ($C_7H_{14}AsO_4^+$), or arseno-phospholipids m/z 483.0607 ($C_{13}H_{29}PA_sO_{12}^+$). In dexterous combination with non-arsenic containing fragments such as e.g. 184.0733 ($C_5H_{15}O_4PN^+$) or corresponding neutral losses e.g. m/z 183.0660, we also show simple ways to identify even more complex arsenic compounds such as cholines or ethanol-amines.

Conclusions:

In our work we provide a sophisticated but still simple way for the determination of a wide range of organoarsenicals using high resolution mass spectrometry. Our method is not dependent on standard-compounds, and therefore has potential to open up the field for other scientists and assist in further research in this rapidly expanding field of environmental research.

Novel Aspect:

We present an approach to species independent, arsenic-specific determination without the necessity of an element-specific detector by using HR-ESMS/MS and monitor characteristic organoarsenic fragments.

500 - DIRECT GAS ANALYSIS USING A MULTI-TURN HIGH-RESOLUTION MASS SPECTROMETER

Masahiro Hashimoto (1) - M.J.(Marcel) van der Schans (2) - J.A. (Jeroen) Van der Meer (2) - Bram Van der Meer (3)

JEOL(EUROPE)SAS, European Application Group, Croissy-sur-Seine (1) - TNO, Defence, Safety and Security, Rijswijk (2) - JEOL(EUROPE)B.V., Sales Executive Science and Measurement Instruments, Nieuw-Vennep, (3)

Keywords: Gas analysis, High resolution, High mass accuracy, Multi-turn

Introduction: (Limit of 400 characters)

Small molecule gases such as CO, NO_x and SO₂ are analyzed by using a portable gas analyzer or a GC-MS. However, portable gas analyzers are only able to measure specific gases, and GC-MS is able to measure a variety of gases but requires special columns to separate small molecule gases. In this study, we measured complex gas mixtures by using the multi-turn HR-TOFMS without special columns.

Methods: (Limit of 400 characters)

We measured gas mixtures by using the multi-turn HR-TOFMS with three different sampling methods - gas mixing system, headspace and a tedlar bag. For the gas mixing system, a sample was mixed that contained benzene (1250 ppm) and arsine (40 ppm). The gases were introduced by using the MS vacuum system to draw the sample directly into the source with a short deactivated capillary column.

Results: (Limit 900 characters)

Target gases were observed, and their compounds were separated by the multi-turn HR-TOFMS perfectly. The mass error for the peaks were within 3.1 mDa. In the case of gas mixing system, the m/z difference of benzene and arsine is 0.1 Da (benzene, C₆H₆, M⁺ 78.04640; arsine, AsH₃, M⁺ 77.94452). The results showed that the overloaded peak for benzene (M⁺) and the smaller peak for arsine (M⁺) were perfectly separated and detected by the multi-turn HR-TOF MS. In addition, the arsine (M⁺) mass error was only 0.5 mDa.

Conclusions (Limit of 400 characters)

The multi-turn HR-TOFMS can separate complex gas mixtures by using high mass resolution and can identify elemental compositions by using the system's high mass accuracy. This means that the multi-turn HR-TOFMS is a powerful tool for analyzing complex gas mixtures.

Novel Aspect: (Limit of 150 characters)

Complex gas mixtures analysis by using a multi-turn HR-TOFMS.

1355 - LINEAR DYNAMIC RANGE IMPROVEMENT IN TOF-MS/MS MODE ON X500 QTOF SYSTEM

Feng Zhong (1) - Suya Liu (1) - Wen Jin (1) - Doug Simmons (1) - Nic Bloomfield (1) - Robert Haufler (1)

Sciex, Research, Concord, Canada (1)

TITLE

Linear Dynamic Range Improvement in TOF-MS/MS Mode on X500 QTOF system

KEYWORDS

HRMS TOFMS LDR QTOF Quantitation

INTRODUCTION

Linear Dynamic Range for MS-MS mode was improved by employing beam modulation. This technology was previously used in MS mode, but has now also been developed for MS-MS mode. This allowed the extension of LDR by increasing the upper limit of quantitation, with no changes to the lower limit of quantitation.

METHODS

17 standards were prepared by making 3-fold serial dilutions of 100 µg/mL Alprazolam/Atorvastatin in 50/50 acetonitrile/water containing 10ng/mL Alprazolam-D5/Atorvastatin-D5, respectively. The analyte concentration covered the range of 0.00077400 to 33,300 ng/mL.

Experiments ran alternating between modulation on and modulation off acquiring spectra in TOF-MS/MS mode.

RESULTS

In each case, the LLOQ was not affected by EDR, and the improvement of LDR is due to extension of ULOQ to higher concentration samples as expected. Accumulation times down to 25 ms were tested and did not show a significant impact on LDR. The average increase in the LDR was about 100 fold, from about 2.5 orders up to about 4-4.5 orders.

CONCLUSIONS

The EDR feature for MSMS improves the LDR performance for tested compounds and workflows by extending the ULOQ to higher concentration without effects on LLOQ.

Shorter accumulation, 25 ms and 35 ms in MSMS mode has not caused any loss of LDR performance comparing with 50 ms accumulation time.

1328 - APPLYING A NOVEL COMPONENT DETECTION ALGORITHM TO HELP ACCELERATE METABOLOMICS DISCOVERY WORKFLOWS

Christine Hinz (1) - Emily G Armitage (2) - Kirsten Hobby (2) - Neil Loftus (2) - Nicola Gray (3) - Manuel Y Schar (3) - Jeremy P E Spencer (3)

Shimadzu UK Limited, LCMS technical department, Milton Keynes, United Kingdom (1) - Shimadzu Corporation, Research and Development, Manchester, United Kingdom (2) - University of Reading, Department of Food and Nutritional Sciences, School of Chemistry, Food and Pharmacy, Reading, United Kingdom (3)

Key words: Component detection, Peak picking, Metabolomics, Untargeted analysis, Accurate mass

Introduction

In untargeted metabolomics workflows, data mining techniques are designed to identify differences between metabolite profiles from control and test groups, relating to specific clinical challenges or states. To accelerate metabolite detection we've developed the novel algorithm 'FIND' to locate components using high mass accuracy LC-MS TOF data. Here, it is applied to assess the impact of phenolic acids and avenanthramides in the diets of adult human volunteers.

Methods

Blood was provided before and after a 4-week intervention consuming a daily moderate dose of phenolic acids and avenanthramides in oats or a phenolic-low control. Extracted plasma was analysed using high mass accuracy LC-MS/MS TOF (Shimadzu Corporation, Japan). The FIND algorithm was applied to raw data with only an estimate of typical chromatographic peak width (FWHM) used. A collection of inbuilt logic is used to correctly identify masses of the unknown components.

Results

Untargeted discovery-based metabolomics workflows are designed to detect components from complex sample matrices. To help accelerate component detection in metabolomics workflows a novel algorithm has been designed to locate ion signals that are covariant and related in context (charge-state, isotope distribution, adducts, multimers) so that only a true monoisotopic mass of the component is reported.

Using a food-omics study as a model system, the component detection algorithm was applied to analysis of metabolite profiles from a human volunteer study exploring the impact of phenolic acids and avenanthramides in oats. In this study, the component detection algorithm was used to locate individual components in raw data files and to help verify metabolite detection between each test group following dietary exposure. The application of the component detection algorithm is simple, takes seconds to process, and does not require a complex method with many user parameters.

Conclusions

Adult volunteers provided blood before and after a 4-week intervention consuming a daily moderate dose of phenolic acids and avenanthramides in oats or a phenolic-low control diet in a crossover design. LC-MS/MS TOF was used to analyse extracted plasma and the FIND algorithm was applied to raw data to correctly identify the masses of the unknown components. A collection of inbuilt logic correctly identifies monoisotopic masses and related ions are grouped.

Novel aspect

Applying a novel algorithm to high mass accuracy LC-MS TOF data to locate individual components in complex samples.

1373 - COMPREHENSIVE ANALYSIS OF FLAME RETARDANTS AND OTHER HALOGENATED CONTAMINANTS IN DUST FROM AN E-WASTE RECYCLING CENTRE

Keywords: halogenated chemicals, GC × GC-HRMS, compound identification, GC-QTOFMS, dust analysis

Introduction

Consumer electronics typically contain halogenated flame retardant chemicals to comply with flammability standards. However, various negative health effects have been associated with the aforementioned compounds [1]. The focus of this study was analysis of selected dust samples from an e-waste dismantling facility in Toronto, Canada. The objective was to determine any halogenated additives present in the e-waste, and especially additives which may not yet be described in the literature.

Methods

The samples were extracted using solvent-liquid extraction and ultrasound-assisted extraction and did not undergo destructive clean-up.

The extracts were injected on a Waters Xevo G2-XS quadrupole time-of-flight mass spectrometer coupled to an Agilent 7890B GC with atmospheric pressure chemical ionization (APCI) in two configurations:

- “Fast GC”, using an Agilent DB5-HT 15m × 0.25mm internal diameter × 0.1µm film thickness; a (He) carrier gas flow of 3mL/min and a 10 min run time.
- Comprehensive two-dimensional gas chromatography (GC × GC), using a method with a slow temperature gradient and an Agilent DB-5 60m × 0.25mm × 0.25µm as the first dimension column and a Restek Rtx-17SIL (1m × 0.15mm × 0.15µm) second dimension column. The 2° oven was offset +15°C from the 1° oven.

Results

In the fast GC screening, the halogenated compounds tentatively detected were mainly flame retardants, such as polybrominated diphenyl ethers (and especially BDE-209, which was highly concentrated in some samples), TBBPA and BEHTBP (both present in very high amounts) and EHTBB. Polychlorinated biphenyls were also detected in the samples, but in lower amounts than the flame retardants.

The GC×GC data was further investigated for the presence of target compounds, by extraction of a selected ion chromatogram (SIC) for all target masses. Non-target compounds were also identified on the basis of visual inspection of Kendrick Mass Defect (KMD) plots, constructed using -H/+Cl substitution (34 Da)[2].

The list of halogenated isotopic clusters generated from the 1D-GC data was searched in the GC×GC data (GC Image HRMS v2.5) where, due to the higher separation of peaks, co-elutions with other analytes are less likely. Consequently, the spectra of the target and non-target compounds of interest were “pure”. Structure assignment was aided by NIST library searches. The (soft) nature of the ionization, i.e. APCI in the positive mode, typically provides the molecular ion peak as the base peak with few fragments. Despite this, the matches obtained with the NIST library (containing electron ionisation spectra) were quite good, because the search algorithm places more weight on the matches of higher molecular mass peaks/fragments.

Using this technique, a methoxy derivative of TBBPA was tentatively identified, as were a few dibromophenyl and tribromophenyl isomers. A few non-halogenated compounds were detected as well, mainly organophosphate esters. Among these, the tricresyl phosphates and other triaryl phosphates were in particularly high amounts.

Conclusions

The dust from an e-waste dismantling site contained a wide variety of flame retardants, so dust collected from these types of sites is a good indicator of which flame retardants are contained in various types of consumer electronics. The approach presented in this study has the benefits of providing quick information through the Fast GC screening. The enhanced separation of GCxGC provided in-depth information (viz. isobarically pure mass spectra and multidimensional GC retention behavior) at the cost of analysis time.

Novel Aspect

To the authors' knowledge, this is the first study using both a Fast GC screening and GC × GC for identification and confirmation of chemicals identified in e-waste dust samples.

317 - DEVELOPMENT OF AN LC-HRMS METHOD TO AID IN IDENTIFICATION AND CONFIRMATION OF CHLORINATED AND BROMINATED CONTAMINANTS

Alin IONAS (1) - Ana Miralles-Marco (1) - Garry Codling (1) - Simon Vojta (2) - Lisa Melymuk (1) - Jana Klánová (1)

Research Centre for Toxic Compounds in the Environment (RECETOX), Masaryk University, Brno (1) - Graduate School of Oceanography, University of Rhode Island, Kingston (2)

Keywords: halogenated chemicals, LC-HRMS, compound identification, Orbitrap Fusion, Data-dependent analysis

Introduction:

In human and environmental exposure, many of the compounds of concern for their environmental persistence and health risks are halogenated. The twelve initial persistent organic pollutants (POPs) included in the Stockholm Convention are all chlorinated. Many of the new POPs added subsequently are brominated, such as hexabromobiphenyl, (HBB), hexabromocyclododecane (HBCD), polybrominated diphenyl ethers (PBDEs, from the Tetrabrominated to Heptabrominated), or fluorinated, such as perfluorooctane sulfonic acid (PFOS), its salts and perfluorooctane sulfonyl fluoride (POSF) [1]. Furthermore, most chemicals listed in studies evaluating the potential of compounds to meet the criteria of being a POP, (persistence, bioaccumulative and ability to undergo long-range transport) are also halogenated [2,3,4].

For this reason, in the past few years there have been several studies trying to identify and highlight previously unknown halogenated chemicals of both natural and anthropogenic sources such as in stream sediments from southern Ontario [5], Atlantic dolphin blubber [6], and *Prymnesium parvum* haptophytes [7] and others.

In general, for this type of studies, the samples are usually acquired in full scan or data-independent analysis mode. This is followed by a lengthy data processing procedure, typically involving three steps:

- 1) Target screening / quantitative analysis step, where information about the levels of analytes present are confirmed with standards
- 2) Suspect screening step, where compounds of interest (for which standards are not available) are monitored
- 3) Non-target screening step, where the identification of other compounds is attempted.

For the confirmation of chemicals tentatively identified, tandem mass spectrometry information is necessary. To obtain it, an additional targeted MS_n analysis is often required, even if the initial acquisition mode was data-independent analysis, if the intensity of the peak of interest is not high enough to be selected for fragmentation. Consequently, the aim of this study is to develop an instrumental method designed to speed up and facilitate later data analysis by:

- 1) Incorporating an element of target and suspect screening in the acquisition method itself
- 2) Highlighting chemicals containing more than three atoms of chlorine and bromine, which are more likely to have an adverse effect on human health
- 3) Obtain MS₂ scans of the halogenated compounds of interest to use in their identification, without requiring subsequent instrument time.

Methods:

The instrument employed in the present study was a Shimadzu Nexera X2 UHPLC coupled to an Orbitrap Fusion MS detector (Thermo Fisher Scientific, Waltham, MA, USA). The detector was run at a resolution of 120,000 and was equipped with an atmospheric pressure chemical ionization (APCI) source. As source parameters, the negative ion discharge current was set at 10 μ A and the positive at 4 μ A. The sheath gas was set at 25 arbitrary units (equivalent to 3.17 L/min), and the auxiliary gas at 5 arbitrary units (corresponding to 5.08 L/min). The sweep gas was turned off. The ion transfer tube temperature was set at 250 °C and the vaporizer temperature at 325 °C.

A volume of 5 μ L of extract was injected, and separation was achieved using a Waters Acquity BEH C18 column (100 mm \times 2.1 mm i.d., 1.7 μ m particle size), fitted with a 5 mm matching Vanguard pre-column, with the same characteristics. The mobile phases employed were A: milliQ water and B: methanol, both with 5 mM ammonium

formate added. The flow rate was 0.3 mL/min and a linear gradient from 5% to 100% methanol in 8 min, followed by a 2 min hold before returning to the initial conditions for 4 min.

Standards were injected both in negative and positive polarity. For testing and development of the method, standards of brominated and chlorinated chemicals – mainly flame retardants – were employed. The “BDE-CM” mixture of PBDE congeners (28, 47, 99, 100, 153, 183 and 209) was purchased from Accustandard (New Haven, CT, USA), Hexabromocyclododecane (HBCD) from Wellington Laboratories (Guelph, ON, Canada) and three mixtures of novel FRs (From the INTERFLAB inter laboratory study [8]) were kindly donated by Wellington Laboratories. The mixtures contained 26 FRs in total: 2,4,6-Tribromophenyl allyl ether (ATE), 2,3,5,6-Tetrabromo-p-xylene (p-TBX), 2-bromoallyl-2,4,6-tribromophenyl ether (BATE), 1,2,3,4,5-pentabromobenzene (PBBz), Tetrabromo-o-chlorotoluene (TBCT), Pentabromotoluene (PBT), Pentabromoethylbenzene (PBEB), Tris(1,3-dichloroisopropyl) phosphate (TDCPP), 2,4,6-Tribromophenyl 2,3-dibromopropyl ether (DPTE), Hexabromobenzene (HBBz), Tris(2-butoxyethyl) phosphate (TBEP), Pentabromobenzyl acrylate (PBBA), 2-Ethylhexyl 2,3,4,5-tetrabromobenzoate (EHTBB), Tetrabromobisphenol A (TBBPA), 1,2-Bis(2,4,6-tribromophenoxy)ethane (BTBPE), Bis(2-ethylhexyl) tetrabromophthalate (BEHTBP), syn-Dechlorane Plus (s-DP), alpha-Dechlorane Plus (a-DP), Octabromotrimethylphenylindane (OBIND), Decabromodiphenyl ethane (DBDPE), α -Tetrabromoethylcyclohexane (aTBECH), β -Tetrabromoethylcyclohexane (bTBECH), α -1,2,5,6-Tetrabromocyclooctane (aTBCO), β -1,2,5,6-Tetrabromocyclooctane (bTBCO), 5,6-Dibromo-1,10,11,12,13,13-hexachloro-11-tricyclo[8.2.1.0^{2,9}]tridecene (HCDBCO) and Tris(2,3-dibromopropyl)isocyanurate (T23BPIC; abbreviations are those used by Wellington Labs) considered as current use compounds. All acronyms are as described in the certificates of analysis from the manufacturers and reference [8].

Results:

To achieve the aims described above, the detector needed to be fast enough to cycle between full MS acquisition and data-dependent MS₂ acquisition and the cycle time low enough to permit at least two cycles of MS₂ acquisition per peak. A cycle time of 0.8 seconds was chosen for this purpose.

Several filters were set after the initial Full MS scan, serving to select only the desired chlorinated and brominated ions to the latter type of acquisition.

The most relevant filters used to select just the ions with >3 atoms of Cl and/or Br for fragmentation and acquisition of MS₂ spectra were: 1) “Targeted Mass Difference” and 2) “Targeted Isotopic Ratio”. In the first filter, it was specified to select pairs of ions with a mass difference of 3.9941 Da 3.9959 for chlorinated and bromine-containing substances respectively. These values were chosen instead of the typical A/A+2 pair because of having the benefit of decreasing the number of false positives of non-chlorinated or brominated ions being selected for MS₂.

For the second filter, “Targeted Isotopic Ratio” the input was the typical ratios of isotopomers in a halogenated cluster of 3-14 atoms of Cl or Br. The ratios were calculated theoretically as described in a previous publication [9]. Some tests have also been done using an average value for these ratios and higher tolerance values, but this setup was less than ideal, as it generated higher numbers of false positives.

An exclusion list was defined by monitoring the most abundant ions coming from the mobile phase and the LC system. The list was uploaded into the “Targeted Mass Exclusion” filter, to prevent these ions from being selected for MS₂ fragmentation.

An “Intensity” filter was used as well, to eliminate ions close to background levels (filter set at 5E3).

The “Precursor Selection Range” was set at 250-1,200, to eliminate the 79/81 cluster and the 159.83 characteristic to many brominated analytes and thus highly unselective.

The “Dynamic Exclusion” filter had the purpose to ensure that ions from more than one halogenated cluster was selected for the data-dependent MS/MS scan, if more than one such cluster is present at the same retention time. This is accomplished by preventing an ion from triggering a second data-dependent scan, for 20 seconds after it had triggered the first one.

To increase the likelihood of obtaining high quality MS/MS data, the “Apex Detection” filter was used, to trigger the subsequent data-dependent MS/MS scans after the apex of the peak, when the intensity of the clusters of interest is at its highest. For this purpose, an expected peak FWHM of 3 seconds was found to be adequate, with a desired apex window of 15%.

A second data-dependent MS/MS was added, preceded by a “Targeted Mass Trigger”. This particular scan event was triggered whenever one of the masses on the list was detected. The ions observed in APCI negative mode for the analytes specified in the Materials and methods section were added to this list (targeted screening) and also accurate masses for other relevant analytes from the literature [9,10], such as 2,4,6-tris(2,4,6-tribromophenoxy)-1,3,5-triazine (TTBP-TAZ), for which standards were not available (suspect screening).

At the present stage of the method development process, the method correctly selects chlorinated and brominated clusters for data-dependent MS2 in over half of the cases examined. This can be easily improved by increasing the tolerances of parameters such as the isotope ratio, targeted mass difference, decreasing dynamic exclusion time and adjusting the parameters apex detection (or removing it entirely). However, doing so increases the number of false positives obtained. For example, for BEHTBP, the full scan MS spectrum was obtained, the most abundant isotopomer from the main cluster was automatically selected for the first data-dependent MS2 scan event and the same one was successfully selected as being on the list of the targeted mass trigger. But the same cannot be said for the second, less abundant isotopic cluster from the mass spectrum.

Conclusions:

As a conclusion, the method is accomplishing most of what it was intended for, but more fine tuning is needed for it to be fully suited for its intended purpose. Further studies on highly complex samples with this method are planned, after an additional tuning using indoor dust and waste water stream samples.

Novel Aspect:

To the authors' knowledge, this is the first study describing a method which provides targeted and suspect screening information, highlights halogenated chemicals in the chromatograms and provides MS2 information for the identification and confirmation of halogenated analytes, all in one run.

792 - COMBINATION OF DIFFERENT IONIZATION SOURCES EXPANDS THE ANALYSIS OF COMPLEX MIXTURES

Aikaterini Kondyli (1) - Wolfgang Schrader (1)

Max Planck Institut für Kohlenforschung, Mass Spectrometry, Mülheim an der Ruhr (1)

Keywords: atmospheric pressure ionization, crude oil, high resolution mass spectrometry

Introduction: (377)

Despite the great variety of ionization sources available, there is no single analytical technique for fully analyze a crude oil. Ion discrimination and ion suppression are limiting the compound detection [1,2]. While ESI is the method of choice for the detection of polar compounds, APPI and APCI favors the non-polar and low-to-medium polar compounds respectively. Until now, there is few information on the combination of different sources.

Methods: (394)

A light crude oil was dissolved and diluted in toluene/methanol (1:1) at a final concentration of 250 ppm. Mass spectrometric analysis was performed on an Orbitrap Elite. The spectra were collected in SIM mode with a mass resolution of 480000 (at m/z 400, 1.5s transient). ESI positive, APPI and APCI as well as the combination of ESI with APPI, or APPI with APCI were selected as ionization Methods: For APPI, a Krypton VUV lamp emitting radiation of 10 and 10.6 eV was used.

Results: (761)

The results obtained with different ionization methods show clearly that under ESI the ionization of nitrogen containing compounds is favored, while under APPI hydrocarbon species as well as oxygen containing compounds in both protonated and radical form were efficiently ionized. The combination of these two methods acted as an intermediate, allowing the ionization of non-polar to polar compounds. An overall increase was observed mainly in the O1 and O2 classes compared to the results obtained only from electrospray, while the classes of OS1 and S1 showed the highest population abundance after the combination of these Methods: On the other hand, in case of APCI, the hydrocarbon species as well as the N1, O1, O2, OS1 and S1 classes showed a higher abundance in their protonated form compared to the APPI. After their combination, an increase of the radical species in all the classes was observed.

Conclusions: (383)

Although each ionization method favors the detection of specific types of compounds, the combination of these methods gives the opportunity to utilize all the benefits of the individual Methods: The use of different ionization methods provides complementary information about the crude oil constituents. To obtain information on a molecular level, high resolution mass spectrometry is the method of choice for the analysis of such complex mixtures.

Novel Aspect: (123)

The effect of combining different ionization methods together for the analysis of complex mixtures is investigated on a molecular level by HRMS.

1178 - ABERRATION-BASED NUMERICAL OPTIMIZATION OF ION MIRRORS

Igor Kopaev (1) - Dmitriy Grinfeld (2) - Mikhail Monastyrskiy (3) - Makarov Alexander (2)

General physics Institute/T8, Krasnobogatyrskaya street., 44 home, 1 corps, 1 corps, Moscow, Russian Federation (1)
- ThermoFisher Scientific, Global Research LSMS, Bremen, Germany (2) - General Physics Institute, Optoelectronics
Departement, Moscow, Russian Federation (3)

Keywords: Mathematical modeling, multireflectron geometry optimization

Introduction: Synthesis and optimization of a multireflectron system based on ion mirrors

Mass-spectrometry systems based on ion mirrors have been introduced in 1973 [1] and now represent a perspective class of high-resolution MS equipment [2, 3]. The aim of this work is computer-aided optimization of aplanar-symmetric systems of meshless ion mirrors with the use of different numerical approaches.

Methods: Numerical approaches to optimization of planar-symmetric meshless ion mirrors

A part of the Matlab PDE Tollbox program code oriented to solve the Laplace equation was updated and tested. One of the main features of the newly developed code is a possibility of performing numerical optimization as applied to ion mirror simulation based on aberration theory.

Results:

The classes of ion mirror geometries satisfying the prescribed requirements have been found
The possibility of further minimization of the aberrations of interest has been shown
The alternative geometries have been studied and simplified

Conclusions

As a result of optimization calculations, a new geometry of the "stairs" type has been designed, which represents a compromise between different geometries based on rectangular electrodes
On the other hand, it is shown that the geometries with rectangular electrodes possess fairly small aberrations of interest and are the simplest among the geometries explored

Novel Aspect:

Computational optimization algorithms based on aberration theory to synthesize ion multireflectron systems with prescribed characteristics have been implemented.

655 - APPLICATION OF ETHCD FOR LEUCINE/ISOLEUCINE DISCRIMINATION IN PEPTIDES

Sergey Kovalev (1) - Miriam Tolpina (1) - Sergey Zhokhov (1) - Tatiana Samguina (1) - Albert Lebedev (1)

none, Moscow State University / Chemistry Department, Moscow (1)

Keywords: ETHcd, Orbitrap, peptidomics, leucine/isoleucine discrimination

Introduction:

For many years Edman degradation was a golden standard for peptide sequencing. However since 1990s mass spectrometry (MS) has become an effective alternative with significant advantages like possibility to uncover non-standard amino acids and post translational modification. One problem for MS in this field is isomeric leucine / isoleucine discrimination. The aim of our work is to develop reliable and efficient method exploiting ETD to overcome this difficulty.

Methods:

Experiments were carried out on Orbitrap Elite mass spectrometer with electrospray ionization source. Tryptic peptides of the human serum albumin, bacterial protein gp188, natural peptides isolated from skin secretion of *Rana ridibunda* frog and several synthetic peptides were introduced into the ion source using a syringe pump. Mass spectra were measured in a positive ionization mode in Orbitrap mass analyzer with 120,000 resolving power.

Results:

As a starting point we improved MS3 sequential ETD-HCD activation developed by our group earlier. To achieve maximum spectral quality and fragmentation efficiency all parameters of ion collection and fragmentation energy in MS3 ETD-HCD mode with maximum possible ion isolation width (600 Da) for peptides were optimized. The resulting ETD-HCD method, with "broad-band" activation made it possible to identify structure of 83 out of 93 leucine / isoleucine residues. Interfering process of radical site migration may be suppressed by a careful choice of the lowest possible energy for w-ion formation. The main disadvantage of "broad-band" activation is low efficiency of z-type ion formation for long peptides (with m/z more than 2000 Da). In the advanced version ETHcd was used to accelerate data acquisition. Besides it improved the spectra quality and had a greater sensitivity. Application of new method to a non-separated mixture of skin secretion peptides of frog *Rana ridibunda* allowed correctly identifying 60 of 66 Leu / Ile residues.

Conclusions:

New ETHcd method exhibiting nearly 90% efficiency was developed for reliable Leu/Ile discrimination in peptides. Aspects of ion optics tuning were studied and ETD, ETcaD, and ETHcd modes compared. Radical site migration interfering with Leu/Ile discrimination can be suppressed by careful choice of minimal NCE. The present version of the developed approach may constitute a basis for the creation of automatic sequencing protocol.

Novel Aspect:

The developed method is advantageous compared to existing ones. It has a potential for automation and coupling to LC to become a routine proteomics protocol.

MURAT KOZANLI (1) - NAFİZ ÖNCÜ CAN (1)

University, Anadolu University/Faculty of Pharmacy, Department of Analytical Chemistry, Eskisehir (1)

Keywords: apixaban, monolithic silica column, LC-ESI-MS/MS, pharmaceutical application

Introduction:

Apixaban (APX), a selective, reversible and direct inhibitor of factor Xa, is in use to reduce the risk of stroke and systemic embolism in patients with non-valvular atrial fibrillation [1]. In spite of some published methods for biological samples [2,3], there are very few methods on its determination in pharmaceutical preparations. The aim of this study was to develop a validated LC-MS/MS method for determination of APX in tablets.

Methods:

Analyses were performed using a Shimadzu LCMS-8040 (Japan) series LC-ESI-MS/MS instrument. APX and irbesartan (internal standard; IS) were separated on a monolithic high-resolution silica column using isocratic elution. The detection was performed in positive ion mode and the precursor-to-product ion transitions were monitored in MRM mode at 460.15 → 443.20 m/z for APX and 429.15 → 207.15 m/z for IS. The developed method was validated as per ICH Q2(R1) guideline.

Results:

For APX, linearity could be demonstrated over the concentration range of 2–20 µg/mL ($R^2 > 0.996$), and the calculated limit of quantification was about 1 µg/mL. Results for inter- and intra-day assay precision and trueness were obtained using internal quality control samples and remained within the acceptance criterion. External quality control samples were measured at the specified nominal values with inter- and intra-day precisions. Matrix effects were fully compensated by co-eluting IS, which in turn did not relevantly influence ionization efficiency.

Conclusions:

The method development was focused on the optimization of both LC and MS/MS conditions to obtain the best possible sensitivity and future applicability on regular LC-PDA systems. The proposed method was successfully applied on the real samples, possessing very high chromatographic efficiency.

Novel Aspect

The utilization of a monolithic high-resolution silica column, lower quantitation limits and use of IS are novel aspects of the study.

Keywords: multi-reflecting TOF MS, duty cycle, encoded frequent pulsing, folded flight path, artifact-free inverse transform

Introduction:

Multi-reflecting TOF MS incorporate extended ion flight paths to increase resolution, however this is at the expense of duty cycle. Upstream trapping to accumulate ions results in loss of mass accuracy. Alternatively, multiplexing of TOF spectra has been proposed by numerous researchers [1,2,3]. Here we describe the implementation of Encoded Frequent Pushing (EFP) [4, 5], where a repeated sequence of unique time interval pusher pulses is applied.

Methods:

In contrast to Hadamard transform methods, EFP involves a pattern of TOF start pulses where it's shifted replica does not coincide at more than one point (with a precision comparable to TOF peak width). Decoding by robust statistical verification of all data points produces no artefacts. The main parameter of the decoding algorithm is the ion population of multiplexed spectrum.

Data were acquired using a MR-TOF MS experimental system having a 46m long Folded Flight Path.

Results:

The 2 ms long time-of-flight spectra were acquired by a 1.8 Giga-samples/sec 12-bit ADC (X6 GPS Innovative Integration), with on the fly decoding performed using computational resources of the GPU card (NVIDIA). They demonstrated two orders improvement of duty cycle and hence sensitivity with no loss of resolution and with dynamic range reaching 5 orders of magnitude in a single ESI-spectrum.

There was no degradation of the mass accuracy when using EFP recorded over the mass to charge range 300 to 3000 (using 2-points for internal calibration). In fact, for weaker peaks within the data, inclusion of more ions helped to improve the accuracy of the mass measurement.

We also found that EFP does not introduce deviations to the relative intensities of various spectral peaks, except when the signal was at the minimal detectable level.

Conclusions

The method is artefact free and provides duty cycles comparable with conventional, non MR-TOF systems without affecting MR-TOF resolution and mass accuracy.

Novel Aspect:

High duty cycle multi-reflecting OA-TOF-MS using artefact-free multiplexed data acquisition method without compromising mass accuracy and resolving power.

1389 - METABOLOMIC AND N-GLYCAN CHARACTERIZATION OF SKIN FIBROBLASTS FROM AGED AND YOUNG DONORS

Anna Karen Carrasco Laserna (1) - Bao Hui Ng (1) - Jeyakumar Masilamani (2) - Toan Thang Phan (2) - Fong Yau Sam Li (1)

National University of Singapore, Department of Chemistry, Singapore, Singapore (1) - CellResearch Corporation, National University of Singapore/ Department of Surgery, Singapore, Singapore (2)

Keywords: skin fibroblasts, aging, metabolomics, N-glycans

Introduction:

Fibroblasts are cells that play an important role in wound healing. They are responsible for excreting extracellular matrix at the site of injury and in their myofibroblast form, cause wound contraction and deposit collagen[1]. Delayed wound healing is commonly observed with aging and a major contributing factor is the dysfunction of the fibroblasts [2]. In this study, we explore the metabolic and protein glycosylation changes in skin fibroblasts with aging.

Methods:

Skin fibroblasts were collected from young (YSF) and aged (ASF) donors, cultured to $\sim 1 \times 10^6$ cells, and extracted by sonication with 80% methanol. The supernatant was obtained and analyzed using reverse phase (RP) and HILIC LC-MS in positive and negative ESI modes. Precipitated proteins were separated from cell debris, deglycosylation was performed and the N-glycans were labeled using 2-AB. The samples were also analyzed using RP and HILIC LC-MS in positive ESI mode.

Results:

Initial multivariate analysis using Principal Components Analysis (PCA) of metabolomic LC-MS data from positive ESI HILIC and RP modes showed distinct differentiation of ASF and YSF. Orthogonal Projection to Latent Squares-Discriminant Analysis (OPLS-DA) was also performed to identify features that are significantly contributing to the differentiation of the ASF and YSF. Identification of differentiating features revealed that certain phospholipids were lower in ASF samples while acylcarnitines were found to be in higher levels in ASF. This could be indicative of higher rate of lipolysis and reduced mitochondrial fatty acid oxidation in ASF. N-glycan LC-MS analysis also revealed differences in the glycan profile for the ASF and YSF samples. Identification of the significantly differentiating glycans is on-going.

Conclusions:

Preliminary results revealed significant differences in the metabolic and N-glycan profile of skin fibroblasts from young and aged donors. Skin fibroblasts from aged donors were found to have lower phospholipid levels and higher acylcarnitine levels indicating higher rate of lipolysis and reduced mitochondrial fatty acid oxidation function.

Novel Aspect:

We characterized the metabolic and N-glycan profiles of skin fibroblasts from a single set of sample extraction revealing significant changes in skin fibroblasts with aging.

470 - SCREENING FOR ANTHRAQUINONES IN CHILEAN MUSHROOMS BY HPTLC - NEGATIVE ION DESI HIGH-RESOLUTION MASS SPECTROMETRY

Annegret Laub (1) - Ann-Katrin Sendatzki (1) - Götz Palfner (2) - Norbert Arnold (1) - Ludger Wessjohann (1) - Jürgen Schmidt (1)

Leibniz-Institute of Plant Biochemistry, Bioorganic Chemistry, Halle (1) - Universidad de Concepcion, Departamento de Botanica, Concepcion (2)

Keywords: HPTLC-negative ion DESI-HRMS/MS, mushrooms, anthraquinones

Introduction:

Desorption electrospray ionization mass spectrometry (DESI-MS) is a powerful ambient ionization mass spectrometric technique [1]. Its coupling with high-performance thin-layer chromatography (HPTLC) provides a simple and robust methodological approach for separation and highly-sensitive detection of natural compounds in plants and fungi [2]. Moreover, high-resolution mass spectrometry (HRMS) ensures an outstanding selectivity and specificity of this technique. This methodology can be also used in natural product research for a fingerprint analysis in crude extracts [3]. We have applied a combination of a normal phase HPTLC with DESI-HRMS for profiling of anthraquinones in Chilean *Cortinarius* species.

Methods:

Crude methanolic extracts of seven *Cortinarius* species were investigated by thin layer chromatography using 10x10 cm Silica 60 F254 HPTLC plates. The plates were developed in a horizontal CAMAG chamber using toluene/ethyl formiate/ formic acid (10:5:3 v/v/v) as solvent system. The DESI-MS analysis was performed by an Orbitrap Elite mass spectrometer (Thermo Scientific, Bremen, Germany) combined with a 2D-DESI-source (Omnispray System OS-3201, Prosolia Inc., Indianapolis, USA) and operated in the negative ion mode. The MS and MS² spectra were acquired with the resolution of 30000 by scanning of individual TLC bands in the x-direction at a surface velocity of 200 µm/s. The data were evaluated using Xcalibur 2.2 SP1 software.

Results:

We present HPTLC-negative ion DESI-HRMS results of the analysis of complex crude extracts from seven Chilean species of the genus *Cortinarius* concerning the occurrence of anthraquinones. These compounds are known as potential chemotaxonomic markers in fungi [4]. Using this method physcion, emodin, dermolutein, hypericin, skyrin, 7,7'-emodinphyscion, and flavomannin C were identified by their elemental composition and partly by their characteristic fragmentation patterns in comparison with reference compounds. It should be pointed out, that the HRMS approach also allows a mass spectral distinction of isobaric ions. This was demonstrated for the detection of some investigated anthraquinones whose nominal mass is accompanied by other compounds in the crude extracts.

Conclusions:

HPTLC-negative ion DESI-HRMS was shown to be a powerful method for the analysis and profiling of anthraquinones in complex crude extracts of different Chilean fungi of the genus *Cortinarius*. Using this method six anthraquinones were identified by their elemental composition and partly by their characteristic fragmentation patterns in comparison with reference compounds. High-resolution mass spectrometry (HRMS) also allows a mass spectral

distinction of isobaric ions which could be demonstrated for the detection of some investigated anthraquinones whose nominal mass is accompanied by other compounds in the crude extracts.

Novel Aspect:

HPTLC-DESI-HRMS/MS as a powerful tool for chemotaxonomic analysis of Chilean mushrooms

1243 - LEAN APPROACH OF AUTOMATED SAMPLE PREPARATION FOR LC-MS OF INTACT PROTEINS ON A LIQUID HANDLING ROBOT

Katharina List (1) - Dorothee Wetzel (1) - Martin Pauers (1)

Boehringer Ingelheim GmbH & Co. KG, Biologicals Development, Biberach, Germany (1)

Keywords: Automation, Sample Preparation, Intact Protein, Handling Robot, Biotherapeutics

Introduction:

The preparation of samples for LC-MS analyses is elaborate and time consuming. Due to more routine utilization of LC-MS in biotherapeutics development, the amount of samples rises, raising the need to automate sample preparation. An automated process will enable faster sample preparation and higher reproducibility and repeatability of the sample.

Methods:

A manual sample preparation protocol, consisting of dilution steps, was transferred to a robotic liquid handling system (Tecan, Fluent). An internal standard was used and added into the samples before the dilution steps for protein concentration determination by LC-MS (Waters Acquity UPLC coupled to a Waters SYNAPT G2-S). Additionally the protein concentration was determined by UV-photometer.

Results:

LC-MS data confirms the UV data and shows that automated sample preparation presents higher quality in repeatability, reproducibility and comparability in contrast to manual sample preparation. Regardless of the initial concentration of the samples the robotic system is able to generate dilutions fitting more precisely to the target concentration. Furthermore it manages to reproduce the same concentration of a sample that was diluted earlier with only minimal deviation and still more exactly as if diluted manually. In addition the concentrations of the automated prepared dilutions are more accurate from sample to sample meaning an increase of comparability between the samples compared to manual sample preparation. The robotic liquid handling system from Tecan is capable of handling complex and high numbers of protein samples.

Conclusions:

The sample preparation protocol was successfully transferred to a robotic liquid handling system. LC-MS data demonstrated that automated sample preparation is highly reproducible, repeatable and comparable. Further complex sample preparation, such as peptide mapping protocol, is planned to be transferred to the robot.

Novel Aspect:

Reproducible implementation of automated sample preparation on a robotic liquid handling system was achieved.

1268 - COMBINATION OF CHEMICAL IONIZATION (CI) AND LOW-ENERGY ELECTRON IONIZATION WITH HIGH-RESOLUTION GC/Q-TOFMS

Viorica Lopez-Avila (1) - Sofia Nieto (2) - Harry Prest (2) - Jeffrey Kernan (2) - George Yefchak (2) - Robert Clark (2) - Nathan Eno (2) - Jim Oppenheimer (2) - Bill Russ (2) - Nicola Cimino (3)

Agilent Technologies, Mass Spectrometry, Santa Clara, United States (1) - Agilent Technologies, MSD, Santa Clara, United States (2) - Agilent Technologies, EMEAI, Rome, Italy (3)

Keywords: chemical ionization, low-energy electron ionization, gas chromatography, Q-TOF mass spectrometry

Introduction:

GC/Q-TOF mass spectrometry (MS) with low-energy electron ionization (EI) and chemical ionization (CI) have developed into versatile analytical tools for the compound identification due to the enhancement in the relative abundance of the molecular ions or their adducts, respectively, as compared to the standard EI. The latter technology offers additional advantages as the ionization process can be controlled with various reagent gasses. The use of combination of CI and GC/Q-TOFMS will be shown here with several compound classes including organochlorine and organophosphorus pesticides.

Methods:

Experiments were done with an Agilent 7250 GC/Q-TOF equipped with a low-electron energy EI and an interchangeable CI source. The test compounds included: organochlorine (OCP) and organophosphorus (OPP) pesticides, chlorinated acids and a few conazoles. The GC separation was on a 30 m x 0.25 mm id x 0.25 μ m HP-5MS capillary column using He at 1.2 mL/min. The injector temperature and the MS interface were set at 280°C. Methane (99.99%) was used as reagent gas. For positive CI, the methane flow was set at 20% and for negative CI at 40%. For NCI, the source and the quadrupole temperatures were set at 150°C. For PCI, the source temperature was set at 280°C and the quadrupole temperature at 150°C. The spectral data were acquired at 5 Hz and the mass range was 50-650 m/z. 2H-Perfluoro-5,8-dimethyl-3,6,9-trioxa-dodecane (PFDTD) was used to tune the mass spectrometer in the CI mode. Data analysis was performed using Agilent MassHunter (MH) Qualitative Analysis software version B.08 as well as MH Quantitative Analysis software version B.09.

Results:

Low-energy EI provided an increase in relative abundance of molecular ions for halogenated dienes like hexachlorobutadiene and hexachlorocyclopentadiene, halogenated aliphatic ethers, and some phthalate esters. The interchangeable prototype CI source was evaluated with selected OCPs and OPPs in negative mode using methane as reagent gas. Significant decrease in fragmentation was observed for the OCPs, OPPs, and the chlorinated acids as methyl esters, when using negative CI, although the molecular ion was not always the base peak for these compounds. Nonetheless, fragmentation in CI leads to larger m/z fragment ions that helps in both compound identification as well as targeted analysis. The NCI spectra of a series of 14 conazoles including aza-, eta-, propi- and difenoconazole will be presented. NCI has a different fragmentation mechanism than EI and with high resolution Q-TOF such differences between the two ionization mechanisms can be easily explained.

Conclusions

Benefits of the 7250 GC/Q-TOF system equipped with a low energy-capable EI source as well as an interchangeable prototype CI source were explored for targeted and untargeted analysis applications.

Chemical ionization alone or in combination with low-energy EI and a high-resolution GC/Q-TOF provides new opportunities in compound identification.

Novel Aspect:

Use of high-resolution GC/Q-TOFMS with interchangeable low-energy EI or prototype CI sources in positive or negative mode

1348 - LIQUID CHROMATOGRAPHY COUPLED TO QUADRUPOLE-ORBITRAP HIGH RESOLUTION MASS SPECTROMETRY BASED METHOD FOR TARGET ANALYSIS AND SUSPECT SCREENING OF NON-IONIC SURFACTANTS IN TEXTILES

Luo Xin Luo (1) - Niu Zengyuan Niu (1) - Ye Xiwen Ye (1) - Tang Zhixu Tang (1) - Zhang Li Zhang (1)

Qingdao Customs, Inspection and Quarantine Technical Center, Qingdao, China (1)

Keywords: Alkylphenolpolyethoxylates (APEOs), Alcohol polyethoxylates (AEOs), Orbitrap, High resolution mass spectrometry, Textiles

Introduction:

Non-ionic surfactants such as alkylphenolpolyethoxylates(APEOs) and alcohol polyethoxylates (AEOs) are widely applied in textile industries. They are potential sources of environmental pollution. In recent years, APEOs and AEOs have been detected and reported frequently in environmental samples, such as water and sediments. In this study, we describe a high-throughput and sensitive method for textiles analysis, using liquid chromatography coupled to quadrupole-Orbitrap high resolution mass spectrometry(LC-Q-Orbitrap HRMS), for the simultaneously quantitative analysis of 40 target AEO oligomers with reference standards and screening of 160 AEO oligomers without standards in textiles.

Methods:

The APEOs contain nonylphenol ethoxylates (NPEOs) and octylphenol ethoxylates (OPEOs) with an EO number of ethylene oxide of 1-20, while AEOs focus on C11EOs-C18EOs with an EO number of 1-20. After ultrasonic extraction in methanol, the extract was directly separated using a core-shell CORTECS C18+ column and analyzed by Full MS/dd-MS2 (data dependent acquisition) scan in ESI positive mode. Two best sensitivity experimental conditions for APEOs with short EO chains (AP(EO)1-2) and long EO chains (AP(EO)3-20) were investigated, respectively.

Results:

Most APEO oligomers had wide concentration ranges and the correlation coefficients (R^2) were higher than 0.999. The limit of quantitation (LOQ) values for NP(EO)3-20 oligomers range from 16.00 to 52.80 $\mu\text{g}/\text{kg}$ and for OP(EO)3-20 oligomers is from 2.40 to 8.00 $\mu\text{g}/\text{kg}$. LOQ for NP(EO)1 and NP(EO)2, OP(EO)1 and OP(EO)2 was 2.40 mg/kg and 0.24 mg/kg, 1.20 mg/kg and 0.16 mg/kg, respectively. The average recovery for each APEO oligomer in cotton and polyester matrix was between 78% and 110% at three spiked levels and the relative standard deviation (RSD %) was below 10%. Theoretical m/z and assignments for MS/MS product ions of AP(EO)1-20 were predicted, the fragmentation regularity was divided into 7 groups according to different structures and three typical ions were listed. At the same time, based on the similarity of APEOs and AEOs in structure as well as previous reports on these two kinds of non-ionic surfactants, three typical product ions of APEOs were selected for confirmation of AEOs without reference standards. Then for AEOs suspects, a HRMS compound database containing 160 AEO oligomers was built and several parameters such as exact m/z , isotopic patterns, predicted product ions and predicted retention time were used for screening and confirmation. The established method was successfully applied for analysis of 40 commercial textile samples. Compared with OPEOs, NPEOs, especially NP(EO)3-15 oligomers, were widely detected in samples and the total concentration ranged from 1.56 to 1376.31 mg/kg. AEOs were also found in most samples, among which C12-14, C16 and C18 compounds appeared more frequently and the EO chains mainly ranged from 3 to 15.

Conclusions:

A high-throughput and sensitive LC-Q-Orbitrap HRMS method has been established for simultaneously quantitative analysis of 40 APEOs and screening of 160 AEOs in textiles. Under two optimized chromatographic and mass spectrometric conditions, all oligomers with EO chains from 1 to 20 can be analyzed with high sensitivity. The method has been successfully applied to analyze 40 textile samples. NP(EO)3-15 and AEO homologs of C12-14, C16 and C18 with EO chains ranging from 3 to 15 were frequently detected in samples. This method is rapid, high throughput and sensitive. Moreover, any other potential APEOs and AEOs oligomers interested can be added into the compound database and retrospective analysis of them is feasible for present method.

Novel Aspect:

40 APEOs targets and 160 AEOs suspects in textiles were simultaneously analyzed.

APEOs with both short and long EO chains can achieve high sensitivities.

Exact m/z and fragmentation pathways of main APEOs fragments were predicted.

Fragmentation regularities of APEOs were used for confirmation of AEOs suspects.

Method was applied on 40 textile samples and oligomers detected were concluded.

draft

1122 - LIFE AT THE FRONTIER: 21 TESLA FOURIER TRANSFORM ION CYCLOTRON RESONANCE MASS SPECTROMETRY

Department of Chemistry & Biochemistry, Florida State University, 95 Chieftain Way, Tallahassee, FL 32306 (1) - Ion Cyclotron Resonance Program, National High Magnetic Field Laboratory, 1800 East Paul Dirac Drive, Tallahassee, FL 32310 (2) - Florida State University Future Fuels Institute, 1800 E. Paul Dirac Dr., Tallahassee, FL 32310 (3)

Keywords: 21 tesla FT-ICR MS, top-down MS/MS, monoclonal antibodies, hemoglobin variants, petroleomics

Introduction: (388/400 characters without spaces)

FT-ICR MS offers at least 10X times higher mass resolving power than any other mass analyzer, and is thus the mass analyzer of choice for “omics” applications. 21 tesla FT-ICR MS [1] enables ultrahigh mass resolving power at on-line HPLC speed (< 1 second per acquired transient) for high-throughput analysis of complex organic mixtures: e.g. assignment of >450,000 distinct elemental compositions from a single LC FT-ICR mass chromatogram of Atjabsca bitumen.

Methods: (399/400 characters without spaces)

We perform protein top-down and middle-down MS/MS (front-end ETD [2], CID, or UVPD; in-cell IRMPD). Our ICR cell is dynamically harmonized, with 120° azimuthal excitation/detection (for improved S/N and elimination of 3rd harmonics) and segmented electrodes (for 3X ICR frequency detection, and thus mass resolving power equivalent to 3X magnetic field strength). Broadband phase correction yields absorption-mode mass spectra (for 2X LC/MS mass resolving power).

Results: (804/900 characters without spaces)

Based on various front-end extraction/chromatography procedures, we identify up to 10X more elemental compositions in petroleum than from any single broadband mass spectrum. For intact proteins, we report monoisotopic mass measurements 10x more accurate than commercial average-based Methods: For example, we identify the class, sequence variants, and multiple glycoforms of monoclonal antibodies from multiple myeloma patient serum, with 100% match to DNA germline sequencing, and without false negatives due to incomplete bone marrow aspiration. For human hemoglobin, we are able to identify sequence variants as well as thalassemia (from, e.g., the abundance ratio of delta chain/beta chain). Work supported by NSF Division of Materials Research through NSF DMR-11-57490 and DMR-1644779, The Gulf of Mexico Research Initiative to the Deep-C Consortium, the Florida State University Future Fuels Institute, and the State of Florida.

Conclusions (395/400 characters without spaces)

FT-ICR mass resolving power and data acquisition speed increase directly with magnetic field strength, B_0 . Also, mass accuracy, dynamic range, and peak non-coalescence scale as B_0^2 . This talk will present new benchmarks for FT-ICR MS performance, based not only on 21 tesla magnetic field (highest in the world), but also on recent advances in front-end separations and MS/MS, ICR excitation and detection, and data reduction (mass calibration; phase correction).

Novel Aspect: (132/150 characters without spaces)

21 tesla FT-ICR MS [1], with front-end ETD [2], dynamically harmonized ICR cell with 120° azimuthal excitation/detection and tripled frequency detection

829 - THE ADVANTAGES OF USING AN MRMHR ACQUISITION FOR INCREASED SENSITIVITY FOR TARGETED ANALYSIS USING A QTOF INSTRUMENT

Daniel McMillan (1) - Phil Taylor (2) - KC Hyland (3) - Chris Borton (4)

SCIEX, Business Development, Warrington (1) - SCIEX, Marketing, Warrington (2) - SCIEX, Application Development, Redwood Shores (3) - SCIEX, Application Development, Framingham (4)

Keywords: QTOF, Targeted, MRM, Sensitivity

Introduction:

When attempting to quantitate with a QTOF instrument using a fragment ion instead of the signal from the TOF acquisition is that the collision energy for a given fragment is not formed at an optimum collision energy. A novel feature of the SCIEX X500R QTOF System is the ability to acquire specific MRM pairs just as are acquired in a triple quadrupole instrument thus improving the sensitivity of the method. This presentation discusses the concept of an MRMHR experiment and demonstrates the advantage of this technique.

Methods:

A set of standards were analyzed using a standard data dependent scan where the parent ion of each compound is selected for fragmentation in Q1 and the ion is fragmented using a collision energy of 35 volts. A quantitation method was created using the two most intense fragment ions and an instrumental detection limit was determined. The same set of standards was re-analyzed using an MRMHR scan. The instrumental detection limit from the MRMHR data was determined and compared to the previous fragmentation data. The SCIEX X500R QTOF system has the unique ability to acquire MRM transitions with optimized collision energies resulting in triple quadrupole sensitivity but allows for the acquisition of full scan MS/MS for compound identification without sacrificing cycle time, and we will discuss the features of MRMHR

Conclusions:

A limitation of traditional triple quadrupole mass spectrometers for quantitative applications is that compound identification relies on a ratio of two ions from the compound fragmentation. Interference from the matrix frequently causes this ratio to be unreliable for compound identification resulting in both false positive and false negative results. The slow speed of acquiring full scan MS/MS spectra from a triple quadrupole instrument prohibits the acquisition of useful spectra for compound identification due to degraded cycle times. One of the advantages of QTOF instruments is the speed of acquiring full scan MS/MS spectra during sample analysis without the slow cycle times observed for triple quadrupole instruments. Unfortunately, quantitation is accomplished using fragments from a full scan MS/MS where the collision energy is not optimized for a given transition.

Novel Aspect:

This is the first demonstration of using a QTOF to acquire MRM transitions with optimized collision energies

835 - CONTEXTUALIZATION OF DARK MATTER IN MS1 FT-ICR MS¹ DATA.

³Chair of Analytical Food Chemistry, Technische Universität München, Alte Akademie 10, 85354 Freising-Weißenstephan, Germany.

Keywords: FT-ICR-MS, Dark Matter, Annotation, Metabolomics

Introduction(Limit of 400 characters without spaces):Major proportions (70-95%) of ultra-high resolution MS-signals with known molecular formula cannot be found in metabolomic databases.This mass spectrometric dark matter [1, 2, 3] exhibits statistical significance and is usually not identifiable via MS/MS. This lack of biological MS¹-signal contextualization deems major parts of data useless. Interpretation methods that go beyond mere m/z-to-database matching are required to tackle this problem.

Methods(Limit of 400 characters without spaces): Ultra-high resolution MS data on *Populus X. canescens* were annotated by virtue of mass difference network propagation. Mass difference enrichment analyses (MDEAs), mapping to databases via MDs and compositional similarity and PLS regression were used to extract molecular patterns in association to Isoprene synthase knockdown and experimental perturbations. SIM-STITCH MS² scans were employed to investigate the plausibility of predictions [4].

Results(Limit of 900 characters without spaces):4,335 m/z peaks that obtained molecular formula annotation occurred non-randomly across 211 mass spectra. Merely 129 molecular formulas (3%) matched to KEGG pathways, while several hundreds of peaks discriminated wild type plants from ISPS knock-downs. MDEAs highlighted the molecular building blocks that were used to build up either class's biomass. The usage patterns of the building blocks implied by MS¹ were consistent with SIM-STITCH MS² results. MDEA confirmed prior knowledge on the effects of ISPS knock-downs.The highlighted mass difference building blocks (MDBs) were used to connect the mass spectrometric dark matter to KEGG database entries, which resulted in consistent transformation patterns, explaining how the different genotypes transform KEGG compound classes and metabolites from other databases into biomass. Compound class conserving MDs were elaborated. Compound class distributions were in-line with results from compositional similarity approaches with the power to contextualize almost 100% of the obtained data.

Conclusions(Limit of 400 characters without spaces):The mass-difference space in MS¹ spectra contains valuable information on usage patterns of molecular building blocks.MDEA can highlight the processes that drive the synthesis of biomass after fundamental perturbations to systemic carbon flux. Dark matter contextualization will help narrowing down fruitful fields of research by highlighting compound classes that change systematically.

1376 - COMPREHENSIVE ANALYSIS OF MULTI-CLASS HAZARDOUS CHEMICALS IN PLASTIC PRODUCTS USING HIGH RESOLUTION MASS SPECTROMETRY

Niu Zengyuan Niu (1) - Luo Xin Luo (1) - Ye Xiwen Ye (1) - Tang Zhixu Tang (1) - Zhang Li Zhang (1)

Qingdao Customs, Inspection and Quarantine Technical Center, Qingdao, China (1)

Keywords: multi-class, hazardous chemicals, plastic products, high resolution mass spectrometry

Introduction:

With the increasing awareness of the safety of consumer goods, the relevant restrictions on the number of hazardous chemicals are increasing. Simultaneous detection for multi-class targets and non-targets is becoming a more popular and difficult topic.

Methods:

Present work established a novel method for the comprehensive analysis of 41 chemical hazards (20 targets and 21 non-targets) in plastic products (including plastic toys, electrical and electronic plastic parts, polymeric food contact materials, etc.). Compounds studied here belong to four classes, mainly including phthalic acid esters (PAEs), organotins (OTs), perfluorochemicals (PFCs) and flame retardants (FRs), et al. According to the sample material, appropriate organic solvents were selected for ultrasonic extraction, and methanol was used to precipitate the polymer. After standing for some time, the extract was separated by the core-shell particle column and analyzed by the Orbitrap high resolution mass spectrometry.

Results:

The results were confirmed by multidimensional identification of the parameters such as the m/z of the parent ion, the isotope ratio, and the exact m/z of fragments. Method validation for 20 compounds was evaluated. The limits of quantitation ranged from 2 mg/kg ~ 200 mg/kg, the recovery was 74% ~ 120% and the precision was less than 13%. Present method was applied for simultaneous detection both targets and non-targets in 34 plastic samples, among which di(2-ethylhexyl) phthalate (DEHP), dibutyl phthalate (DBP) and diisobutyl Phthalate (DIBP) were detected quantitatively and tetrabromobisphenol A (TBBPA) was detected qualitatively.

1393 - HIGH RESOLUTION MASS SPECTROMETRY BASED METHOD FOR SCREENING AND IDENTIFICATION OF 48 PROHIBITED DYES IN TEXTILES USING DATA-DEPENDENT ACQUISITION MODE

Niu Zengyuan Niu (1) - Luo Xin Luo (1) - Tang Zhixu Tang (1) - Ye Xiwen Ye (1) - Qu Lianyi Qu (1)

Qingdao Customs, Inspection and Quarantine Technical Center, Qingdao, China (1)

Keywords: high resolution mass spectrometry; screening and identification; dyes; textiles; data-dependent acquisitionmode

Introduction:

Various prohibited dyes are often misused or even deliberately used for pursuit of economic interest in textile industries. Owing to their widespread use, toxicity on human health, as well as destruction to the ecological environment, some international authoritative consumer laws have strictly limited their use. Dyes used in textiles often contain synthetic intermediates, dispersants and other impurities, making their composition very complex. While traditional analysis usually focus on single group of compounds, and false positive identifications might be possible due to the low selectivity of methods

Methods:

The currently presented work firstly developed a high-throughput screening and identification method for simultaneous analysis of 48 prohibited dyes, belonging to 5 different groups, in textiles. After extraction in pyridine/water (1/1, V/V) water bath at 95 °C, the extract was filtered with 0.22 µm membrane, then directly separated using a C18 column and analysed by Full MS/dd-MS2 (data-dependent acquisition) scan using electrospray ionization probe (ESI) operating in positive and negative mode. The retention time, exact mass of each precursor and MS2 fragment, as well as the isotopic pattern of precursors were used for the simultaneous analysis of targeted dyes. Moreover, for the identification of complex components within certain dyes such as disperse blue 35, software of ACD/Labs were also used for the prediction of MS2 fragment assignments and calculation of the theoretical accurate mass, which greatly improve the identification reliability and accuracy of the presented method.

Results:

All 48 dyes had wide concentration ranges and the correlation coefficients (R²) were higher than 0.99. The limit of quantitation (LOQ) values ranged from 0.01 mg/kg to 10 mg/kg. The average recovery for each analyte in representative cotton and polyester matrix was between 62% and 120% at three spiked levels and the relative standard deviation (RSD%) was below 15%. The established method was successfully applied for analysis of 40 commercial textile samples with various fiber types, among which disperse orange 37 was detected. This method is rapid, sensitive and accurate, which could be applied on the high throughput analysis of prohibited dyes in textiles.

353 - SIMULTANEOUS DETERMINATION OF NINE WATER-SOLUBLE SYNTHETIC COLORANTS IN COSMETICS BY LC-Q-TOF/MS AND LC-MS/MS

Seongsoo Park (1) - Jun Hyung Kim (1) - Gihaeng Kang (1) - Ayoung Min (1) - Ji Hyun Lee (1) - Hyoung-Joon Park (1) - Taeik Hwang (1) - Seok Heo (1) - Kwon Yong Eom (1) - Dong Woo Shin (1) - Sung-Kwan Park (1) - Hoil Kang (1)

National Institute of Food and Drug Safety Evaluation, Division of Advanced Analysis, Chungcheongbuk-do (1)

Keywords: synthetic colorants, cosmetic, LC-Q-TOF/MS, LC-MS/MS

Introduction:

In this study, LC-Q-TOF/MS and LC-MS/MS method were developed to identify and measure the illegally adulterated synthetic colorants (Acid yellow 9, Brilliant black BN, Orange GGN, Yellow 2G, Red 2G, Green S, Carmoisine, Erythrosin B, Patent blue V) that may be found in cosmetics circulated in Korea..

Methods:

We have established and optimized the simultaneous analysis of nine water-soluble synthetic colorants in facial toner using LC-Q-TOF/MS and LC-MS/MS. Colorants-spiked facial toner samples(0.2 g) were prepared with 50 mL of 20% methanol:chloroform(9:1) into a Teflon centrifuge tube. Sample extraction was performed by vortexing the sample for 2 min and ultrasonication for 30min. The extract was centrifuged for 5min at 3000 rpm and upper layer was collected in volumetric flask of 50mL. All solutions were filtered through a 0.22 µm syringe filter(PVDF) prior to LC-Q-TOF/MS and LC-MS/MS analysis.

Results:

The method was validated for specificity, linearity, limit of detection (LOD), limit of quantification (LOQ) and recovery. The linear correlation coefficients were good (>0.99), the limits of detection and quantitation of the method ranged from 0.0039 to 0.0625 µg/mL and from 0.0117 to 0.1875 µg/mL, respectively. The recovery for this LC-MS/MS procedure was 82.5–104.7%, with an RSD less than 15% (n=3).

Conclusions :

In this study, a fast, simple, and accurate method was developed for the identification and quantification of nine water-soluble synthetic colorants in facial toner by using LC-Q-TOF/MS and LC-MS/MS. The method was completely validated showing satisfactory data for specificity, linearity, limit of detection, limit of quantification and recover. Therefore, this study will be helpful for comprehensive analysis and monitoring synthetic colorants in cosmetics.

Novel Aspect:

In this study, we have developed analytical methods for illegally adulterated synthetic colorant in cosmetics circulated in Korea. The high sensitivity, high resolution and accurate mass determination, LC-Q-TOF/MS method is a useful analytical tool for synthetic colorants. Also, the results indicated that the method can be used for rapid and accurate screening of synthetic colorants present in cosmetics

1113 - SINGLE CELL METABOLOMICS WITH LAESI-21T-FTICR-MS

Ljiljana Pasa-Tolic (1) - Christopher R. Anderton (1) - Dusan Veličković (1) - Sylwia A. Stopka (2) - Laith Samarah (2) - Rikkita Khattar (2) - Jared B. Shaw (1) - Beverly J. Agtuca (3) - Gary Stacey (3) - Akos Vertes (2)

Pacific Northwest National Lab, Environmental Molecular Sciences Lab, Richland (1) - The George Washington University, Department of Chemistry, Washington (2) - University of Missouri, C. S. Bond Life Sciences Center, Columbia (3)

Keywords: MSI, FTICR, LAESI, plant-microbe

Introduction:

The ability to visualize complex metabolic behavior of living organisms in situ and at the single cell level represents a bioanalytical grand challenge that has yet to be fully realized. Herein, we present the combination of fiber-LAESI with fluorescence microscopy and ultrahigh resolution 21T-FTICR-MS to address these needs.

Methods:

To provide simultaneous spatial distributions for hundreds of metabolites in biological tissues, an LAESI ion source was coupled with a 21T FTICR-MS system. Utilizing the ultra-high mass resolving power, isotopic fine structure readout was used for metabolite annotations. Single-cell spatial resolution was achieved by delivering mid-IR laser pulses through a sharpened optical fiber, while a dual modality microscopy allowed for precise targeting of cells.

Results:

Spatial heterogeneity was tackled using LAESI coupled with the 21T-FTICR-MS. This unique instrumental configuration provides exquisite mass and spatial resolution, down to the single cell level. A dual channel microscope capable of both simultaneous brightfield and fluorescence imaging was combined with the fiber-LAESI-MS to enable selection of specific cells. For instance, cells in a soybean root nodule infected by GFP labeled soil bacteria were targeted for analysis in a heterogeneous population of infected and uninfected cells. The superior mass resolution and accuracy offered by the 21T FTICR-MS facilitated identification of differentially abundant metabolites in soybean root nodule cells infected by wt and nifH- rhizobia. Notably, this novel capability facilitated characterization of organometallic molecules due to their natural isotope patterns (e.g. ^{57}Fe isotopologues). Preliminary data indicates significantly lower abundance of heme b, disaccharide, and S-adenosylmethionine in the nifH- mutant.

Conclusions

We demonstrate that LAESI coupled with the 21T FTICR-MS holds tremendous potential for in-situ single cell metabolomics as illustrated by the study of plant-microbe interactions.

Novel Aspect:

In situ single cell analysis by fiber-LAESI-MS promises new insights into cellular heterogeneity and metabolic noise.

581 - SFC-QTOF-ESI-MS: DEVELOPING AN INNOVATIVE ONE-RUN METHOD FOR CHOCOLATE QUALITY AND AUTHENTICITY CONTROL

Michaela Rektorisova (1) - Vojtech Hrbek (1) - Monika Tomaniova (1) - Jana Hajslova (1)

University of Chemistry and Technology, Prague, Department of Food Analysis and Nutrition, Prague (1)

Keywords: High-resolution mass spectrometry, Parallel reaction monitoring, Triacylglycerols, Cocoa butter equivalents, Cocoa solids

Introduction:

To assess chocolate quality and authenticity, a combination of various analytical procedures is involved, thereby making the process time-consuming and costly.[1] Thus, we investigated the potential of supercritical fluid chromatography coupled to quadrupole-time of flight mass spectrometry (SFC-QTOF-MS) to replace 'classic' Methods: Its specific separation character and selective detection make this technique suitable for authentication of fatty foods.

Methods:

Samples were prepared by sequential extraction using hexane in the first step, followed by water extraction of the residue. Analysis of combined extracts was performed by Waters SFC-QTOF-MS with electrospray ionization (ESI). To obtain most comprehensive information about sample composition, the MS method comprised a full MS1 scan to detect potential unpredicted compounds, and several time-scheduled targeted MS/MS functions (parallel reaction monitoring).

Results:

A single 8 minute analytical run enabled us (i) to determine the presence of cocoa butter equivalents and milk fat according to triacylglycerols, (ii) to calculate dry non-fat cocoa solids based on theobromine and caffeine content, and (iii) to screen sugars, i.e. the key components involved in legislation. Optimizing parameters in the individual MS/MS functions (scan time, target enhancement, collision energy) led to a significant adjustment in analyte responses according to their concentration range in samples, e.g. decreased response of 3 major triacylglycerols of cocoa butter in contrast to increased response of minor triacylglycerol specific for milk fat. Attention had to be paid to background contamination (e.g. phthalates) to avoid the suppression of target ion intensity. Thus, in addition to an effort to minimize such contamination, it was useful to acquire a full MS scan not only to obtain comprehensive information about samples, but also to prevent quantification errors caused by abrupt changes in background intensity.

Conclusions:

SFC-QTOF-MS has proved to be a powerful tool to assess chocolate quality and authenticity, enabling fast, simultaneous determination of cocoa butter equivalents, non-fat cocoa solids and sugars. We have demonstrated a unique separation (compared to reversed-phase liquid chromatography) and advantages of using parallel reaction monitoring for targeted analysis. In addition, we have shown the importance of acquiring a full MS scan to aid interpreting the results.

Novel Aspect:

Fast and cost-effective method for the assessment of several chocolate quality and authenticity parameters that are usually analyzed by a combination of standard Methods:

1063 - USING ATOMIC LAYER DEPOSITION (ALD) TO ENHANCE MCPs FOR MASS SPECTROMETRY

Matthew Breuer (1) - Paula Holmes (1) - John Harper (2)

Photonis, Research and Development, Sturbridge, MA (1) - Photonis, Research and Development, Brive (2)

Keywords: Microchannel plate (MCP), Atomic Layer Deposition (ALD), detector

Introduction:

A microchannel plate (MCP) is an array of identical parallel open channels with diameters typically between 5 and 25 microns in a glass plate with a thickness that is typically 40-60 times the channel diameter. MCPs are made of a special lead-silicate glass that, when properly processed, makes the MCP an excellent ion detector and electron multiplier, capable of high gain and low noise. While it has long been possible to coat the input and output surfaces of MCPs to enhance their performance, historically it has been prohibitively difficult to use a coating to affect the inner channel surface that is responsible for electron multiplication. Atomic layer deposition (ALD), which is a process that builds conformal coatings one atomic layer at a time using a sequence of self-terminating gas-solid reactions, offers an opportunity to coat these high aspect ratio surfaces with high uniformity and enhance some aspects of the MCP performance as a result.

Methods:

Standard and coated MCPs were fabricated and their relevant performance characteristics were characterized using industry standard test methods for MCPs. These characteristics include overall gain, gain stability (lifetime), and linear current output. In addition, coated and uncoated MCPs were assembled in detector assemblies intended for mass spectrometry and their instrument-specific characteristics were evaluated using the instrument tune sequences.

Results: Coatings of high electron yield materials such as aluminum oxide can result in higher overall gains when the MCPs are operated at high voltage and lower gains when the MCPs are operated at lower voltages. This is in line with expectations based on the dependence of the kinetic secondary electron emission yield curves as a function of primary electron energy. Coated MCPs have good gain stability during operation at typical vacuum levels ($<1E-5$ Torr) similar to uncoated MCPs. When used in time of flight detector assemblies, aluminum oxide coated MCPs generally tune at a lower voltage. Aluminum oxide coatings can also be used to form an inert barrier layer on standard MCPs. This can affect long-term resistance stability when the MCPs are exposed to air or dry nitrogen. It is typical for the overall resistance of uncoated MCPs to increase gradually over time. Coating of the MCPs can reduce this effect.

Conclusions

ALD can be used to uniformly coat the high-aspect ratio inner channel surfaces of MCPs and affect their electron multiplication behavior. This provides an additional method for tailoring MCPs to meet the required performance characteristics of particular applications.

Novel Aspect:

An alternate electron multiplication coating can be applied to MCPs to enhance performance.

742 - THE COMBINATION OF HYDROPHILIC INTERACTION LIQUID CHROMATOGRAPHY AND ION MOBILITY MASS SPECTROMETRY FOR DIESEL FUEL ANALYSIS

Elize Smit (1) - Stefan De Goede (2) - Egmont Rohwer (3)

University of Johannesburg, Department of Chemistry, Johannesburg (1) - SASOL Energy, Energy Technology, Sasolburg (2) - University of Pretoria, Department of Chemistry, Pretoria (3)

Keywords: High resolution mass spectrometry, Hyphenated techniques, Hydrophilic Interaction Liquid Chromatography, Ion Mobility, Petroleomics

Introduction:

The characterization of trace polar species in fuels is important due to their influence on the fuel's physical properties, which has given rise to the field of petroleomics [1]. Due to the complex nature of diesel and other crude-derived fuels its chemical composition is often investigated by considering classes of compounds rather than individual chemical species [2,3,4].

Methods:

The chromatographic separation of diesel fuel extracts using hydrophilic interaction liquid chromatography (HILIC) was combined with high resolution mass spectrometry (TOFMS). Selective ionization of trace polar species was achieved with electrospray ionization and atmospheric pressure chemical ionization. Furthermore, ion mobility mass spectrometry was used to obtain additional chemical information.

Results:

The separation of the polar fraction of diesel into classes of compounds, i.e. based on functionality, was achieved. Complementary information was obtained by considering both positive and negative ion mass spectra. Separation of species that readily formed positive ions was influenced by heteroatom content as well as degree of unsaturation (or DBE). Visualisation of the multidimensional data was explored in order to facilitate the interpretation of chemical information obtained. More than half of the detected m/z values were observed to show isomers separated by drift and/or retention time. A large amount of structural information is therefore gained by pre-separation despite the loss in sensitivity. A novel graphical representation has been introduced where Kendrick mass defect (instead of m/z values) is plotted against drift time to visualise information regarding heteroatom content and double bond equivalents (DBE) against structural information, resulting in an orthogonal system.

Conclusions:

Hydrophilic interaction liquid chromatography was used to separate methanol extracts of diesel fuel in terms of heteroatom content (i.e. group-type separation). Ion mobility mass spectrometry provided additional chemical information of species in diesel fuel extracts. The multidimensional data obtained from hyphenated techniques can be visualized in unique ways to facilitate interpretations.

Novel Aspect:

The group-type separation of diesel fuel extracts was achieved with hydrophilic interaction chromatography. Mobilograms were modified to incorporate mass defects.

898 - COMPREHENSIVE HIGH-RESOLUTION MASS SPECTROMETRIC EVOLVED GAS ANALYSIS IN THE CONTEXT OF PETROLEOMICS: ANALYSIS OF BITUMEN, HEAVY CRUDE OILS AND ASPHALTENES

Christopher Ruger (1) - Anika Neumann (1) - Christoph Grimmer (1) - Uwe Kafer (2) - Martin Sklorz (1) - Thomas Groger (2) - Thorsten Streibel (1) - Ralf Zimmermann (1)

University of Rostock, Institute of Chemistry, Rostock (1) - Helmholtz Zentrum Munchen, Comprehensive Molecular Analytics, Munchen (2)

Keywords: evolved gas analysis, high resolution mass spectrometry, Petroleomics, atmospheric pressure ionization, photo ionization

Introduction:

Petroleomic materials remain to be one of the greatest challenges in chemical analysis. The conversion of heavy oils or exploration of alternative sources raises new challenging issues, such as the formation of deposits or efficient processing of residues. Thermal analysis using evolved gas analysis coupled to mass spectrometry is one powerful approach for deciphering these materials.

Methods:

For this purpose, several thermal analysis systems coupled to different mass spectrometric analyzers, such as ultra-high resolution FT-MS [1,2] and TOF-MS, were applied to study low-viscous and solid petroleomic materials. The setups varied in ionization techniques covering soft vacuum and atmospheric pressure approaches, and hard electron impact allowing in combination an in depth-chemical description of the desorbed and pyrolyzed material. [3]

Results:

Besides the description of heavy oils and bitumen, asphaltenes were in the primary focus of the study. Generally, for the intended pyrolysis of the asphaltenes, an ultra-complex molecular pattern is revealed. This molecular space could be comprehensively analyzed by ultra-high resolution mass spectrometry equipped with atmospheric pressure chemical and photo ionization revealing the highly aromatic and Sulphur-containing core structures, whereas vacuum single photon ionization was able to analyze the thermally fragmented side chain distribution. Moreover, a vacuum direct inlet probe equipped with electron ionization was able to broaden the picture by evaporating larger components prior thermal decomposition and thereby allow for additional structural information.

Conclusions

Summarizing, mass spectrometric evolved gas analysis has shown to be an efficient technique for Petroleomics. Most importantly the data combination of various setups enabled an in-depth chemical and structural analysis and hypothesizing of macromolecular structural features. Future work will focus on data integration as well as on structural information by adding a chromatographic separation between thermal release and mass spectrometric detection.

Novel Aspect:

Data integration of several mass spectrometric evolved gas analyzer allowing comprehensive chemical analysis and structural motives of complex petrochemical materials.

426 - APPLYING HIGH-RESOLUTION MASS SPECTROMETRY TO ELUCIDATE THE FORMATION AND FATE OF OZONATION TPS IN WASTEWATER TREATMENT

Jennifer Schollee (1) - Rebekka Gulde (1) - Marc Bourgin (1) - Moreno Rutsch (1) - Julian Fleiner (2) - Marc Boehler (2) - Juliane Hollender (1) - Urs von Gunten (3) - Christa McArdell (1)

Eawag, Environmental Chemistry, Duebendorf (1) - Eawag, Process Engineering, Duebendorf (2) - Eawag, Water Resources & Drinking Water, Duebendorf (3)

Keywords: Non-target screening, Ozonation, Transformation products, Advanced wastewater treatment

Introduction: (Limit of 400 characters without spaces)

Ozonation has increasingly been applied for micropollutant abatement in wastewater and high removal rates have been observed for most known micropollutants. However, the formation and fate of ozonation transformation products (OTPs) is not well understood. High resolution tandem mass spectrometry (HRMS/MS) with non-target analysis was applied to study unknown OTPs in real wastewaters in Switzerland.

Methods: (Limit of 400 characters without spaces)

Samples were collected from two wastewater treatment plants (WWTPs) before and after ozonation and measured with Orbitrap HRMS/MS coupled to reverse-phase liquid chromatography (RPLC). Hierarchical cluster analysis grouped features based on intensity patterns and the fate of likely OTPs was investigated. Additionally, a method was developed for HRMS coupled to hydrophilic interaction liquid chromatography (HILIC) to measure highly polar OTPs.

Results: (Limit 900 characters without spaces)

Out of approximately 8000 HRMS features detected at one WWTP, 600-700 features (9%) were determined to be likely OTPs based on their intensity patterns. In subsequent post-treatment, 54-83% of likely OTP features were well-removed, with granular activated carbon (GAC) filters (run up to 40,000 bed volumes) performing slightly better than the biofilters investigated. It is speculated that sorption in the GAC filters accounted for the higher OTP abatement compared to biofilters, where biodegradation was the primary mechanism for OTP abatement. It was also found that OTPs that were well-removed in post-treatment had significantly higher retention times in RPLC ($p < 0.05$, Mann-Whitney U-test), suggesting recalcitrance of polar OTPs. To get information on highly polar OTPs, a new method combining HILIC with HRMS/MS was developed and preliminary results indicate that previously undetected OTPs can now be investigated with this method. Formation of OTPs from 50 micropollutants is being further studied with HILIC- and RPLC-HRMS/MS.

Conclusions (Limit of 400 characters without spaces)

The combination of HRMS with non-target analysis provides a more comprehensive picture of the formation and abatement of OTPs. By developing a HILIC-HRMS/MS method, unknown highly polar OTPs can also be evaluated. The ability to monitor OTPs in WWTPs is critical to elucidate persistent OTPs that might make their way to the aquatic environment.

Novel Aspect: (Limit of 150 characters without spaces)

Novel analytical and data analysis methods applied to HRMS/MS data were used to evaluate the formation and abatement of OTPs during advanced wastewater treatment.

858 - ANALYSIS OF CATIONIC POLAR PESTICIDES IN BABY FOOD USING ION CHROMATOGRAPHY AND MS/MS OR HIGH RESOLUTION ACCURATE MASS SPECTROMETRY

Frans Schoutsen (1) - John E Madden (2) - Jeffrey S Rohrer (2) - Jonathan Beck (3)

Thermo, takkebijsters 1, Breda (1) - TFS, CA, Sunnyvale (2) - TFS, CA, San Jose (3)

Keywords: LCMS, HRAM, Ion Chromatography, Chlormequat, QuPPE

Introduction:

In this publication we demonstrate analysis of quaternary amine pesticides in baby food samples using cation-exchange chromatography Polar cationic pesticides such as chlormequat, diquat, mepiquat, paraquat, morpholine, trimethylsulfonium, and propamocarb may occur as residues in food, but may be excluded in pesticide monitoring programs due to challenges using generic multi-residue Methods:

Methods:

Cation-exchange chromatography with serial detection by suppressed conductivity and mass spectrometry. These techniques are demonstrated by targeted MS/MS on a triple quadrupole mass spectrometer and by high resolution accurate mass spectrometry (HRAM MS)

Results:

A chromatographic separation was demonstrated on a prototype column. The six pesticides had good accurate mass, meeting the SANTE requirements of <5 ppm. Native cationic pesticides of interest were not found in the samples. Sensitivities in the low $\mu\text{g/L}$ were determined by spiking pesticides in the samples. Good accuracy was found, with recoveries between 80-120%.

Conclusions

Ion chromatography coupled with HRAM mass spectrometry demonstrated clear benefits for challenging cationic pesticide separation and identification.

Novel Aspect:

Ion chromatography coupled with HRAM mass spectrometry demonstrated clear benefits for challenging cationic pesticide separation and identification.

206 - AN AUTOMATED WORKFLOW FOR HIGH-THROUGHPUT NICOTINE QUANTITATION USING HIGH PERFORMANCE LIQUID CHROMATOGRAPHY COUPLED TO HIGH RESOLUTION ACCURATE MASS SPECTROMETRY FOR PROTOTYPE TESTING.

Sandra Sendyk (1) - Quentin Dutertre (1) - Arno Knorr (1) - Julia Hoeng (1) - Mark Bentley (1)

Philip Morris, Science & Innovation, Neuchatel (1)

Keywords: Mass spectrometry, high-throughput, automation, method validation

Authors: S. Sendyk, Q. Dutertre, A. Knorr, J. Hoeng, M. Bentley

Introduction: (Limit of 400 characters)

Human organotypical 3D tissue cultures are routinely used for in vitro toxicological assessment of the biological impact upon exposure to smoke from a reference cigarette 3R4F and aerosol from heat-not-burn products at the air-liquid interface using the Vitrocell® system. Nicotine, one of the major constituent of tobacco can be used as biomarker of exposure.

Methods: (Limit of 400 characters)

Cigarette smoke or aerosol of heat-not-burn products was deposited at Phosphate Buffer Saline solution (PBS), serving as a surrogate matrix in the Vitrocell® system. A reverse phase high-performance liquid chromatography coupled to high resolution accurate mass spectrometry was used.

The procedure was automated using a protocol developed in Pipeline Pilot (Biovia®) from acquisition to reporting.

Results: (Limit 900 characters)

The method was designed enabling analysis of a large number of samples within a short time.

Selectivity of chromatographic separation was proven for nicotine and its internal standard (nicotine-methyl-d3), separated from other interferences.

A high-throughput method was designed and enables quantitation of nicotine within a dynamic range of three orders of magnitude. The method was validated within a working range from 50 ng/mL to 2000 ng/mL in PBS. Linearity of the method was achieved by a 8-point calibration curve. Furthermore accuracy, precision and instrumental repeatability were assessed.

Quantitation was performed by isotopic dilution technique using stable isotope labelled nicotine as internal standard. The method is reliable for the analysis of subsequent sample batches and demonstrated high robustness in practical applications.

Conclusions: (Limit of 400 characters)

An automated workflow for high-throughput nicotine determination was established delivering robust and accurate data. The method was validated testing accuracy, linearity, instrument repeatability and stability matching acceptance criterion according to standard regulation [1, 2]. It shows suitable performances for routine based application to accurately determine nicotine concentration in PBS.

Novel Aspect: (Limit of 150 characters)

An automated workflow for high-throughput PBS exposed samples analysis by liquid chromatography coupled to high resolution accurate mass spectrometry.

Keywords: Fosamprenavir calcium, Stress studies, Degradation products, Orbitrap, ADMET Predictor™

Introduction:

Stress testing is an essential part of a regulatory-compliant stability program for all types of drugs [1]. It involves i) subjecting the drug to a variety of conditions, ii) separation of degradation products (DPs) by a stability-indicating method (SIM), and iii) characterization of DPs with the help of advanced spectroscopy tools [2]. These studies were systematically accomplished on fosamprenavir calcium (FPV), a protease inhibitor used to cure HIV [3].

Methods:

The drug was subjected to stress under hydrolytic, oxidative, photolytic and thermal conditions. It proved stable in the latter three conditions. The hydrolytic DPs were separated using a SIM, and were initially characterized from mass results obtained by employing UHPLC-Thermo Q-Exactive™ Plus Orbitrap and LC-LTQ XL™ spectrometers. Toxicity of each DP was predicted using ADMET Predictor™ software (Simulation Plus).

Results:

Six DPs (DP 1-DP 6) were formed on acid and base stress. DP 1, DP 2, and DP 4-DP 6 were generated in acid (2N HCl, 75 °C, 6 d), while DP 3 was the lone DP in basic (2N NaOH, 75 °C, 1 d) condition. DP 2 was a common product. Mass studies revealed that the drug was protonated at two different sites, each following a separate fragmentation route. HRMS and MSn data allowed suggesting comprehensive fragmentation pathways of the drug as well as its DPs. The information allowed successful delineation of structures of all DPs. Major hydrolytic routes were cleavage of carbamate ester of the drug to form DP 2, and dephosphorylation of both the drug and DP 2 to form DP 5 and DP 1, respectively. Methylation of the drug in presence of methanol resulted in DP 6 (at aniline nitrogen) and DP 3 (upon replacement of THF moiety). DP 6 underwent carbamate ester cleavage to result in DP 4. Toxicity predictions highlighted that DP 1 was associated with propensity for phospholipidosis, DP 2-DP 4 had susceptibility towards skin sensitization, while DP 5 was associated with reproductive toxicity.

Conclusions:

Stress degradation study on FPV provided significant information on its degradation behavior. The drug was found to be susceptible only to acid/base hydrolysis. A total of six DPs were formed, which were characterized using HRMS and MSn data. The DPs were also evaluated for their in silico toxicity using ADMET Predictor™ software.

Novel Aspect:

Degradation profile of FPV was established and justified through relevant mechanistic explanations. In silico prediction studies highlighted added toxicities of DPs.

1231 - QUANTITATION OF SERUM CREATININE IN MICE USING HYDROPHILIC INTERACTION LIQUID CHROMATOGRAPHY (HILIC) COUPLED WITH HIGH-RESOLUTION ACCURATE-MASS (HRMS) ORBITRAP MASS SPECTROMETER

Hidenori Takada (1) - Yuko Ube (2) - Mariko Sakai (2) - Yoko Hasegawa (1) - Tetsuya Kitayama (2) - Yuji Yamazaki (3) - Tatsuo Uchimura (1)

Kyowa Hakko Kirin Co., Ltd, Translational Research Unit, R&D Division, Sunto-gun, Japan (1) - Kyowa Hakko Kirin Co., Ltd, Nephrology R&D Unit, R&D Division, Sunto-gun, Japan (2) - Kyowa Hakko Kirin Co., Ltd, Nephrology R&D Unit, R&D Division, Machida, Japan (3)

Keywords:

Creatinine
HILIC
HRMS
Biomarker
Cyanoacetic acid

Introduction:

Serum creatinine level (SCR) is widely used as a biomarker of renal function. The SCRs are lower in normal mice than in human, dogs and rats. Colorimetric methods (Jaffe method and enzymatic method) commonly used in laboratory and clinic are insufficient from perspectives of accuracy and sensitivity for determination of the mouse SCR. A highly accurate and sensitive analytical method using LC/MS/MS for determination of mouse SCR has been developed.

Methods:

Creatinine was separated in HILIC mode using cyanoacetic acid as an acidic additive in LC mobile phase and detected by parallel reaction monitoring (PRM) in positive ESI mode using hybrid quadrupole-orbitrap mass spectrometer (Q Exactive Focus, Thermo Fisher). The SCR in mice with renal ischemia-reperfusion (I/R) and sham operation were determined using the novel HILIC/HRMS method and the colorimetric methods and compared with blood urea nitrogen (BUN).

Results:

In the HILIC/HRMS method, cyanoacetic acid, whose decarboxylation occurs by heating at temperature higher than 160°C and produces acetonitrile with carbon dioxide, resolved the matrix effect with decrease in MS response of creatinine in mouse serum observed using formic acid as an acidic additive. The selectivity of creatine in the blank serum was evaluated using peak area ratio of quantifying ion mass (m/z 86.07) to qualifying ion mass (m/z 72.04) (Quant/Qual ratio), and the issue was minimal. The intra- and inter-assay accuracy and precision, and the results in stability testing (storage at -20°C for 95 days and freezing and thawing) were preferable. In I/R model and sham-operated mice, the correlation of SCR by the HILIC/HRMS method with BUN was better than those of SCRs by colorimetric methods (Jaffe method and enzymatic method) with BUN. In particular, the deviations from the correlation of SCR by the HILIC/HRMS method were smaller at lower levels in normal mice or mice with mild renal failure than that of SCR by enzymatic method.

Conclusions:

The novel analytical method for determination of serum creatinine in mice has been developed and utilizes separation in HILIC mode using cyanoacetic acid as an acidic additive of LC mobile phase and HRMS detection in

positive ESI mode. Cyanoacetic acid resolved the matrix effect in MS response of creatinine in mouse serum. The developed method showed potentials of highly accurate determination for lower SCR (≤ 0.3 mg/dL) in normal mice or mice with mild renal failure.

Novel Aspect:

The novel HILIC/HRMS method showed accurate and precise determination of mouse serum creatinine. Cyanoacetic acid showed a novel potential for LC/MS detection in ESI mode.

1104 - QUADRUPOLE-RESOLVED ALL IONS MS/MS FOR RELIABLE QUANTITATION OF PESTICIDES IN COMPLEX MATRICES USING UNTARGETED ACQUISITION

László Tölgyesi (1) - Christian Klein (2) - Tom Knotts (2) - Dorothy Yang (2) - Bill Frazer (2) - Tarun Anumol (3) - John Lee (4) - William E. Barry (2)

Agilent Technologies Sales & Services GmbH & Co. KG, Global Laboratory Solution Sales (LSS) Marketing, Waldbronn (1) - Agilent Technologies, Inc., R&D, Santa Clara, CA (2) - Agilent Technologies, Inc., Segment Marketing, Little Falls, DE (3) - Agilent Technologies, Inc., Segment Marketing, Bracknell, Berkshire (4)

Keywords: QTOF, untargeted screening, pesticides, HRMS

Introduction:

For pesticides screening, untargeted data collection utilizing LC/MS High Resolution Mass Spectrometry allows labs to continually evolve the scope of targets without the need to change a base method. Measurement of fragment ions can sometimes suffer from interferences, effecting the reliability of ion ratio and ultimately the ability to detect much reduced fragments. To overcome this, precursors are resolved into smaller bands of ions on a prototype QTOF.

Methods:

The quadrupole isolation windows are adjustable by changing DAC values ranging from 0 to 255, effecting the applied RF values. By using calibrant ions, the isolation window width and rectangularity could be determined. Multiple acquisition methods were generated, dividing the mass range into sections between 10amu and up to several hundred amu. For proof of concept, avocado and black tea QuEChERS extracts, spiked to 2 and 10 ppb with pesticides, were evaluated.

Results:

The rectangularity of the quadrupole window width needed to be determined, because the shape of the isolated window determines the necessary overlap when moving from one window to the next. Generating empirically the needed DAC values for a 30 amu and a 50 amu window, and scanning the quad in 0.1Da steps, less than 1 amu was needed to reach FWHM on both sides of the isolation window. Calibrant mass 322 was used to establish beginning, end and half maximum of the window.

In the case of Imazalil, however, the All Ion(AI) spectra showed a matrix interference of one of its fragment ions, leading to a mass shift as well as an EIC height which was overlaid with the matrix contribution. The effect of matrix contribution went up with lower concentration of the pesticide. By using 30 amu isolation window width, the matrix interference was completely removed, allowing the reliable quantitation of Imazalil in both avocado and black tea matrices with identical ion ratio compared to the standard in neat solvent matrix.

Conclusions:

Comparing the analyses of AI MS/MS alone with quadrupole resolved All Ions MS/MS on the spiked pesticide samples, we have noticed that the fragmentation spectra looked substantially cleaner compared to All Ions MS/MS spectra. Nevertheless, in multiple cases ion-ratio of fragment ions remained the same. The dependence of pesticide concentration, quadrupole window width (fixed and variable) as well as matrix complicity will be further evaluated and presented.

Novel Aspect:

Increased confidence in compound qualification and quantitation on a Q-TOF mass spectrometer by utilizing TQ-like post-processing criteria using untargeted acquisition.

983 - IDENTIFICATION OF ELECTROCHEMICAL DEGRADATION PRODUCTS OF SELECTED PHARMACEUTICALS BY HIGH RESOLUTION MASS SPECTROMETRY

Andrea Vojs Stanova (1) - Andrea Vojs Stanova (2) - Erika Medvecká (2) - Adam Borik (1) - Roman Grabic (1) - Pavel Skvara (2) - Tomas Mackulak (3) - Marian Marton (4) - Marian Vojs (4)

Keywords: mass spectrometry, boron doped diamond electrodes, pharmaceuticals, wastewater treatment

Introduction

In recent years, pharmaceuticals are becoming more frequently found in the aquatic environment[1]which indicates limitations of their removal in conventional wastewater treatment plants[2]. Therefore, new treatment processes that are more efficient and notharmful for the environment are developed. Among different technologies for advanced water treatment belongs boron doped diamond (BDD) [3,4].

Methods

Residual pharmaceuticals and their metabolites produced during the electrochemical degradation process were determined using TSQ Quantiva LC/MS/MS (Thermo Fisher Scientific, San Jose, CA, USA). For the identification of electrochemical degradation products high-resolution mass spectrometers Q-Exactive MS (Thermo Fisher Scientific) and IT-TOF-MS (Shimadzu, Kyoto, Japan) were used.

Results

Electrochemical degradation of selected pharmaceuticals was performed in electrochemical cell with two parallel BDD electrodes. Based on our preliminary results, different types of BDD electrodes (grown with different deposition parameters, like CH₄/H₂, B/C in gas phase) were used for water treatment in the first part of this study. Obtained results indicate that this method is able to effectively degrade a wide spectrum of pharmaceuticals that are insufficiently removed by traditional processes at WWTP. Micropollutants such as caffeine, sulfamethoxazole, diclofenac, carbamazepine, valsartan, trimethoprim and venlafaxine were degraded with more than 50% efficiency. In the second part of our study we focused on the identification of electrochemical degradation products. To identify potential electrochemical degradation products two different high resolution mass spectrometers were used.

Conclusions

This work deals with the possibilities of boron doped diamond electrodes for electrochemical degradation of different pharmaceuticals in wastewater. Using high resolution mass spectrometry, it was possible to identify the products of electrochemical degradation of selected pharmaceuticals.

Acknowledgements

This work was supported by the grant of the Slovak Research and Development Agency (APVV-16-0124).

Novel Aspect

Identification of electrochemical degradation products of selected pharmaceuticals by high resolution mass spectrometry.

867 - REMOVAL OF ISOBARIC INTERFERENCES BY LASER RESONANCE IONIZATION MASS SPECTROMETRY FOR DETERMINATION OF $^{126}\text{Sn}/^{121}\text{mSn}$ RATIO

Wenliang Wang (1) - Xiaopan Shen (1) - Lihua Zhai (1) - Hu Deng (1) - Zhiming Li (1)

Northwest Institute of Nuclear Technology, applied physics and chemistry department, Xi'an (1)

Keywords: Laser resonance ionization mass spectrometry; Isobaric interference; Isotope ratio; Fission product; Spent fuel reprocessing solution

Introduction:

As fission product, ^{126}Sn and ^{121}mSn are considered as important nuclides to monitor the nuclear contamination [0]. The common methods for determination of $^{126}\text{Sn}/^{121}\text{mSn}$ ratio are inductively coupled plasma mass spectrometry (ICP-MS) [0], thermal ionization mass spectrometry (TIMS) [0], and accelerator mass spectrometry (AMS) [0]. However, the isobaric interferences caused by ^{126}Te and ^{121}Sb are the main difficult problem in the those Methods: A complicated sample preparation chemistry procedure is commonly adopted to separate the interfering species, which may cause a waste of sample and introduce new interferences.

Laser resonance ionization mass spectrometry (LRIMS) has both advantages of laser resonance ionization spectroscopy and mass spectrometry. By selectively ionizing only one element at a time through a resonance excitation process, isobaric interferences are essentially eliminated [0]. In this paper, a LRIMS method of measurement of $^{126}\text{Sn}/^{121}\text{mSn}$ ratio in the sample extracted from the spent fuel reprocessing solution was proposed. The removal of isobaric interferences in this method was confirmed by analysis of a tin-antimony-tellurium mixture sample.

Method:

Our LRIMS device developed indigenously mainly includes laser system, atomization source, electromagnet analyzer, data acquisition and processing system. The basic process of the proposed LRIMS method is as follows: firstly, the sample is atomized by electric heating; secondly, the atoms are selectively ionized by the dye lasers with specific wavelengths; lastly, the ions are drawn into the electromagnet analyzer for isotopic ratio analysis.

The laser system consists of three tunable dye lasers pumped by 532 nm Nd:YAG solid-state lasers with pulse frequency of 10 kHz. The tunable wavelength range is 550 ~ 850 nm, which can be extended to shorter wavelength (275 to 425 nm) by frequency doubling method.

The atomization source is designed by electric heating tantalum filament with 18 mm long, 0.7 mm width, and 0.045 mm thickness. A grid electrode is mounted behind the atomization source to shield the ions produced by the thermal surface ionization. The detection efficiency of the sample with and without grapheme oxide solution are compared. Three laser beams are coupled into the 3×1 fiber combiner, and focused by achromatic lens. Through carefully adjustment, the special overlap between the laser beam and atomic beam is maximized. The electromagnetic analyzer with the mass resolution of 500 and the abundance sensitivity of 2×10^{-6} is used to measure tin isotopic ratios.

In order to evaluate the isobaric interference in LRIMS method, a mixed sample of Sn, Sb and Te with a ratio of 1:1:1 is prepared to evaluate the isobaric interference. The $^{126}\text{Sn}/^{121}\text{mSn}$ isotopic ratio in a tin sample extracted from the spent fuel reprocessing solution is determined.

Results:

The auto-ionization energy spectrum of tin atom is obtained by laser resonance ionization spectrometry. According to the LRIMS signal of tin ions as a function of each laser wavelength, an efficient three-color-three-photon resonance ionization scheme of tin is confirmed. The laser wavelengths of each excitation/ionization step are optimized as $\lambda_1=286.42$ nm, $\lambda_2=811.63$ nm, $\lambda_3=823.72$ nm. In order to achieve saturated resonance excitation and ionization, the laser average power is set as 18 mW, 230 mW, and 1700 mW respectively. The linewidth of each laser is tuned as about 10 pm to reduce the isotopic discrimination effect.

The temperature of the filament required for adequate neutral tin species production is optimized as 600-700°C. The total detection efficiency of 1 μg tin sample is measured as about 3×10^{-5} by mixing samples with grapheme oxide solution, which is as 4.5 times higher as the sampling without grapheme oxide solution. The results show that a layer of grapheme oxide gives better control of evaporation and reduces loss of sample as molecular oxide species.

The tin isotopic ratios in a tin-antimony-tellurium mixture with a ratio of 1:1:1 are measured. The major tin isotope ratios in the sample are determined and the relative standard deviations of $^{116}\text{Sn}/^{120}\text{Sn}$, $^{117}\text{Sn}/^{120}\text{Sn}$, $^{118}\text{Sn}/^{120}\text{Sn}$, $^{119}\text{Sn}/^{120}\text{Sn}$ are all less than 1%. There are no signal at $M/Z=121$ (^{121}Sb) and 126 (^{126}Te) during the experiment indicating a selectivity factor for Sn exceeding 108. Results show that the isobaric interferences from Sb and Te are effectively eliminated in the LRIMS method.

A tin sample extracted from the spent fuel reprocessing solution is measured by the LRIMS method. The ratio of ^{126}Sn and ^{121}mSn is measured as 49.78 without sample preparation chemistry procedure.

Conclusions:

Based on the LRIMS device developed in the laboratory, a new attempt has been made for measurement of $^{126}\text{Sn}/^{121}\text{mSn}$ ratio in the spent fuel reprocessing solution. The isobaric interferences are eliminated in this method. The results show that LRIMS may be the most appropriate technique to correctly determine isotope ratios if isobaric interferences exist from other elements in the sample.

Novel Aspect:

Based on the LRIMS device developed in the laboratory, the auto-ionization energy spectrum of tin atom is obtained, and an efficient three-color-three-photon resonance ionization scheme of Sn is confirmed. A LRIMS method of measurement of $^{126}\text{Sn}/^{121}\text{mSn}$ ratio in the sample extracted from the spent fuel reprocessing solution is proposed, in which the isobaric interferences caused by ^{126}Te and ^{121}Sb are eliminated.

1230 - ULTRASENSITIVE DETECTION OF PROTEIN BIOMARKERS BY SIGNAL AMPLIFICATION MASS SPECTROMETRY

Yuning Wang (1) - Ruijun Du (1) - Liang Qiao (1) - Baohong Liu (1)

Department of Chemistry, Fudan University, Shanghai, China (1)

Keywords: biomarker, membrane protein, mass spectrometry, signal amplification

Introduction:

Proteins are essential biomolecule in revealing biological activities, while abnormal expression of proteins is often related to various diseases.[1, 2] However, protein biomarkers expressed in cells can be exceedingly rare. Moreover, unitary biomarker is usually expressed by more than one type of disease.[3, 4] Thus, sensitive and accurate detection of multiple biomarkers is indispensable for clinical diseases diagnosis.

Methods:

Herein, we propose a novel mass spectrometry (MS) signal amplification method to detect low-abundance protein biomarkers using mass labels (MLs)-modified Au nanoparticles (AuNPs), based on our previous work.[5] AuNPs modified with specific antibodies against protein biomarkers and multiplexed MLs were introduced to recognize the biomarkers through a sandwich protocol.

Results:

By analyzing the abundant MLs with laser desorption ionization time-of-flight (LDI-TOF) MS, presence of the biomarkers can be confirmed. As the types of ML increased, a variety of protein biomarkers could be analyzed simultaneously. In this assay, protein biomarkers of epithelial cell adhesion molecule (EpCAM) and cytokeratin 19 (CK19) were selected as exemplified, 2 z mole of which could be specifically and accurately identified. Meanwhile, utilizing this method, EpCAM and CK19 with the amount of 20 z mole were simultaneously detected.

Conclusions

In conclusion, a novel MS based approach has been developed to co-detect multiple biomarkers using numerous MLs-labeled AuNPs. Protein biomarkers, EpCAM and CK19, were simultaneously identified when their amount were lower to 20 z mole. In view of the advantages of ultrahigh sensitivity and specificity, the protocol possesses promising value in cell characterization, cell signaling behavior measurement, and the monitoring of disease formation and progression.

Novel Aspect:

By analyzing various MLs with LDI-TOF MS, multiple protein biomarkers could be analyzed simultaneously and sensitively.

1010 - IMPROVING COVERAGE IN TRANSMEMBRANE DOMAINS OF INTEGRAL MEMBRANE PROTEINS WITH ULTRA-VIOLET PHOTODISSOCIATION

Julian Whitelegge (1)

University of California Los Angeles, The Pasarow Mass Spectrometry Laboratory, Los Angeles (1)

Keywords: membrane protein, FTMS, electron-capture dissociation, electron-transfer dissociation

Introduction:

The most common structural feature of membrane proteins is the bilayer embedded alpha helix. Mass spectrometric coverage during dissociation experiments is frequently limited due to lack of charged residues and retention of structure in the gas phase. In this presentation we explore new strategies for improving coverage in transmembrane domains using FTICR and other high-resolution instruments, including ultra-violet photodissociation (UVPD).

Methods:

Samples were typically dissolved in formic acid immediately prior to separation by reverse-phase chromatography on polymeric stationary phase at 40 °C (PLRP/S, Agilent) or size-exclusion in chloroform/methanol/aqueous formic acid (4/4/1). Samples were selected for high-resolution top-down mass spectrometry directed by low-resolution MS data and analyzed by static infusion freeing us from the constraints of chromatographic timescales.

Results:

Samples were subjected to positive-ion nano-electrospray ionization mass spectrometry using either a 7 Tesla FTICR instrument (LTQFT Ultra with ECD and IRMPD) or an orbitrap (Lumos ETD with a solid state UV laser (213 nm) for UVPD). Addition of supercharging reagents shifted the predominant molecular ion to higher charge states, improving yield of product ions in ECD though it is unclear whether this was due to increased abundance of the precursor or denaturation by the supercharging reagent. We tested dissociation of the two transmembrane helix c-subunit of the ATP-synthase. The 7997.36 Da (monoisotopic) protein isolated from *S. oleracea* retained its initiating formyl-Met residue and yielded either 4- or 5-charge ions (m/z 2001 and 1334 respectively) both of which were analyzed by static nano-electrospray to yield a precursor intensity of $1e6$. These ions were subjected to various dissociation techniques including higher energy collisional (HCD), electron transfer (ETD), the binary mixture these two (ETHcD) for comparison with UVPD.

Conclusions

Modern dissociation strategies are giving excellent coverage in transmembrane domains of integral membrane proteins. While ETHcD enabled coverage above 50% for single charge states compared with CAD, HCD and ETD, UVPD gave 70 - 80% coverage. Summing UVPD data for two charge states gave close to 100% coverage.

Novel Aspect:

UVPD and ETHcD appear especially effective for detailed structural characterization of the transmembrane domains of integral membrane proteins.

149 - STUDY FOR MASS RESOLUTION OF QUADRUPOLE MASS SPECTROMETERS ACCORDING TO THE ROD ELECTRODE ALIGNMENT

Kiyomi Yoshinari (1) - Yasushi Terui (2)

Hitachi, Ltd. Research & Development Group, Center for Technology Innovation - Controls, 1-1, Omika-cho 7 chome, Hitachi-shi, Ibaraki-ken (1) - Hitachi High-Technologies Corporation, Science & Medical Systems Business Group, 882, Ichige, Hitachinaka-shi, Ibaraki-ken (2)

Study for Mass Resolution of Quadrupole Mass Spectrometers According to the Rod Electrode Alignment

Keywords: Quadrupole Mass Spectrometers, mass resolution, multipole electric field, rod electrode alignment, BEM

Introduction: (Limit of 400 characters)

Radio frequency (RF) quadrupole mass spectrometers (QMS) have come to be used in various fields because of their compactness. Ionized specimens are separated while passing through a QMS in accordance with their m/z values. The mass resolution of QMS must be raised to identify species with high accuracy. The mass resolution is related to the alignment of a QMS's four rod electrodes [1].

Methods: (Limit of 400 characters)

We developed our original simulation program PISA-QMS, in which ion motions in an RF electric field can be calculated using the BEM [2],[3] for an electric field and using the Shanks method for ion motion [4] within 0.01% error. PISA-QMS was applied to a QMS varying r/r_0 from 1.063 to 1.145, where r and r_0 indicate the radius of one rod and the inscribed circle between four rods. The relationship between mass resolution and r/r_0 values was investigated using PISA-QMS.

Results: (Limit 900 characters)

The relationship between mass resolution (FWHM) and r/r_0 values showed a range of r/r_0 values with high mass resolution ($\text{FWHM} \leq 0.5$). The range of r/r_0 values giving high resolution ($\text{FWHM} \leq 0.5$) was $1.124 \leq r/r_0 \leq 1.13$. To clarify the mechanism of high mass resolution in such r/r_0 values, we calculated the electric fields between four rod electrodes and expanded them into multipole components ($n=1-6$). According to the values, the generation % of quadrupole components ($n=2$) and others ($n \neq 2$) changed. When r/r_0 was 1.127, the generation % ($n=2$) became almost 100% because the other multipole components totally canceled each other. The values of r/r_0 giving high resolution ($\text{FWHM} \leq 0.5$) show good agreement with the range of r/r_0 giving a high % of quadrupole component generation ($\geq 99.8\%$). High resolution could be obtained even when the rod electrode surfaces were not hyperboloid by generating a quadrupole electric field component greater than 99.8% and by canceling other components to no less than 0.2%.

Conclusions (Limit of 400 characters)

An electric field, ion motions, and mass spectra were calculated by applying our simulation program PISA-QMS to QMS varying r/r_0 values. The results showed the mechanism of mass resolution is determined by quadrupole components % among the generated electric field. High resolution could be obtained even when the rod electrode surfaces were not hyperboloid by generating an electric field so as to make the quadrupole component $\geq 99.8\%$ and the other components $\leq 0.2\%$.

Novel Aspect: (Limit of 150 characters)

High resolution can be obtained by generating an electric field so as to make the quadrupole component $\geq 99.8\%$ and the other components $\leq 0.2\%$.

624 - A HIGH-RESOLUTION ION MOBILITY SPECTROMETER COUPLED TO A TIME-OF-FLIGHT MASS SPECTROMETER

Maria Allers (1) - Laila Timoumi (1) - Ansgar T. Kirk (1) - Florian Schlottmann (1) - Stefan Zimmermann (1)

Leibniz Universität Hannover, Institute of Electrical Engineering and Measurement Technology, Department of Sensors and Measurement Technology, Hannover (1)

Keywords: High-resolution ion mobility spectrometer; Gated IMS-MS interface

Introduction:

Over the last years, we have developed compact high-resolution drift tube ion mobility spectrometers (IMS) combined with different ion sources reaching high resolving power up to $R=250$ [1,2]. High-resolution IMS allow fast separation of ion species by size, shape and charge, yielding structural information complementary to molecular mass. To keep such high IMS resolving power when coupling the IMS to a time-of-flight mass spectrometer (TOF-MS), here a Bruker micrOTOF II, several aspects have to be considered, such as the ion transfer and IMS-MS synchronization.

Methods:

Usually, when coupling IMS to TOF-MS data acquisition of both instruments is synchronized resulting in two-dimensional data containing ion mobility and mass spectra. However, due to the short temporal peak widths of just $60 \mu\text{s}$ in our high-resolution IMS with $R=100$, this technique is not applicable due to significant peak broadening during the ion transfer into the MS and an insufficient data acquisition rate of the MS. Thus, a simple gated interface has been designed to transfer selected peaks of the ion mobility spectrum into the TOF-MS. The interface is realized by replacing the Faraday plate of the IMS with a Faraday grid that is shielded by two additional aperture grids. By directly inserting the interface into the capillary shield of the MS, the IMS can be operated at ambient pressure and easily adapted to the MS inlet capillary.

Results:

Coupling our high-resolution IMS to a TOF-MS as described above does not affect IMS resolving power. The novel interface allows both, recording full ion mobility spectra and transferring selected ion peaks or time domains of the ion mobility spectrum into the MS to analyze selected ion species formed in the IMS. Furthermore, due to high grid transparency, ion losses in the interface are minimized. The investigation of the positive reactant ions, ketones and alcohols show the occurrence of ion cluster dissociation and ion fragmentation processes inside the transfer stage of the Bruker micrOTOF II. As proof-of-concept study, the presented IMS-MS is used to investigate the product ions of benzene, toluene and m-xylene in dry, purified air using a 3H source. Besides the well-known product ions M^+ and $M\cdot\text{NO}^+$, for high concentrations a dimer ion is also observed for benzene and toluene, consisting of two molecules and three further hydrogen atoms.

Conclusions:

A simple interface to couple high-resolution IMS to APCI-TOF-MS while keeping full IMS resolving power is presented. Due to its fast gating capability this interface can be used to investigate ion species of a certain peak in the ion mobility spectrum and to explore the ionization processes in IMS. In particular, coupling our IMS to a Bruker micrOTOF II allows investigating the ion chemistry of different ion sources.

Novel Aspect:

Simple interface for coupling high-resolution IMS operated at atmospheric pressure to TOF-MS, minimizing ion losses, recording full ion mobility spectra and enabling a gated transmission of ions into the MS.

Title (20 Words):

Application of PASEF MS/MS scans to monoclonal antibody peptide mapping

Introduction (120 Words):

Peptide mapping is an essential method for evaluating monoclonal antibodies (mAb) heterogeneity and their response to stress conditions. The demands placed on this assay have drastically evolved from initially checking the primary sequence to the localization of post translational modification and the determination of low level heterogeneities such as amino acid misincorporation. Because of this, there is a lot of interest in developing platform methods that are faster or able to provide more information.

Parallel serial fragmentation (PASEF) scans use ion mobility as a method to accumulate and select precursors for data dependent scans. This makes it possible to separate peptides that do not separate in the chromatography dimension, leading to improved sensitivity and new opportunities to improve peptide maps.

Methods (120 words):

The NISTmab reference material (SRM8671) was incubated under high pH for 24 and 48h. The stressed samples and a control were alkylated and digested with trypsin before UHPLC separation using gradient lengths from 5 to 45 min. The data acquisition was conducted on a timsTOF Pro (Bruker) using the PASEF scan mode. The resulting data was processed with Byonic/Byologic (Protein Metrics) and the ability to detect deamidated peptides was systematically evaluated for the various gradient lengths.

Preliminary Data (300 Words):

Rapid gradient:

Sequence coverage upward of 95% was achieved for the unstressed NISTmab sample with an HPLC gradient length of 5min and detection using the PASEF scan mode. Despite the short run time, multiple deamidation sites were detected.

Detailed characterization:

The traditional peptide map method using an extended 120 min gradient combined with the PASEF scan mode allows the detection of low level heterogeneities down to 1-10 ppm of the NISTmab such as beta-microglobulin.

Now ongoing:

We are now running a systematic evaluation of the performance of the method with gradient lengths of 5, 15, 30 and 45 min, while optimizing of the mobility and MS/MS parameters to take in account the increasing amount of coeluting precursors as the HPLC gradient length is reduced.

Novel Aspect (20 Words):

Impact of PASEF scans on the ability to detect deamidation in peptide mapping

821 - A CLIP ON ION MOBILITY DEVICE. ENABLING GAS PHASE IONS SEPARATION AND COLLISION CROSS SECTION MEASUREMENTS TO ANY MASS SPECTROMETERS.

Bruno Bellina (1) - Jan Commandeur (2) - Perdita Barran (1)

University of Manchester, Manchester Institute of Biotechnology, Manchester (1) - MS Vision, MS Vision, Almere (2)

Keywords: Ion mobility, Instrumentation, Retrofitted

Introduction:

Ion Mobility is a powerful gas phase separation technique that is used to distinguish ions as a function of their sizes/shapes; leading to molecule identification directly from the measurement of their mobilities. When coupled to mass spectrometry, IM-MS technique brings in a new dimension and numerous applications. We are developing a clip-on device that would be adaptable to any mass spectrometer to enable ion mobility separation and CCS measurements.

Methods:

The developed prototype utilise a resistive glass tube to generate an absolute and linear electric field, needed for direct collision cross sections (CCS) measurements. The entrance and the exit caps have been specially designed to minimize hardware modifications on the host MS instrument. A single gas inlet is needed along with a total of only eight simple electrical connectors.

Results:

The first generation will be fitted to a WATERS Q-ToF-Ultima. The only necessary modification will consist into shortening the second ion guide, prior to the quadrupole region; retaining the original footprint of the instrument. An ion funnel has been designed and mounted on the exit cap allowing efficient refocusing of the ion beam post drift. A second generation will embed an ion mobility gating region (necessary for ion pulsing) along with the ion funnel region. Both have been developed to minimize the imprint on the host system and will be mounted and part of the entrance and exit caps. SIMION simulations have been successfully run on various types of model systems ranging from Leucine Enkephalin (low mass singly charged) to Cytochrome C (High mass, multiple charges). The maximum theoretical resolving power at different drift voltages at ambient temperature is evaluated with a maximum operating voltage of 20 V/cm.

Conclusions

A portable ion mobility device has been developed to enable gas phase separation and CCS measurement on any mass spectrometer (Q-ToF, FT and Ion Trap). The device is designed to minimize its imprint on the host, embedding trapping, drifting and refocusing regions in a single assembly. The simulations undertaken show very promising results for a large range of ions.

Novel Aspect:

The novelty resides in the device flexibility. The length of the ion mobility drift region is easily adjustable and the device can be fitted to any MS instruments.

1380 - TIMSTOF PRO AND PASEF

MULTIPLYING SEQUENCING SPEED AND SENSITIVITY IN MASS SPECTROMETRY-BASED PROTEOMICS

Andreas-David Brunner (1) - Florian Meier (1) - Scarlet Beck (2) - Heiner Koch (2) - Markus Lubeck (2) - Niels Goedecke (2) - Michael Krause (2) - Nicole Drechsler (2) - Juergen Cox (3) - Oliver Raether (2) - Matthias Mann (1)

Max Planck Institute of Biochemistry, Department for Proteomics and Signal transduction, Planegg, Germany (1) - Bruker Daltonik GmbH, R&D, Bremen, Germany (2) - Max Planck Institute of Biochemistry, Systems Biochemistry, Planegg, Germany (3)

Keywords: Trapped ion mobility spectrometry, High sensitivity, High speed, Proteomics

Introduction:

Applications of proteomics technologies to biomedical research require further developments of mass spectrometry (MS) technology to overcome longstanding limitations in speed, sensitivity, and robustness. Trapped ion mobility spectrometry (TIMS) coupled to a quadrupole time-of-flight (qTOF) analyzer in combination with the 'Parallel Accumulation – SErial Fragmentation' (PASEF) scan mode has shown much promise in this regard. [1]

Methods:

TIMS separates ions based on their mobility and releases them sequentially into the MS. PASEF synchronizes the MS2 precursor selection with the TIMS elution time - multiplying sequencing speed and sensitivity by multiple precursor selection per TIMS scan [2]. An algorithm that detects precursors in 4 dimensions was developed. Data analysis is implemented in MaxQuant. We evaluated the TIMS-TOF Pro performance with regard to sensitivity, speed, and reproducibility.

Results:

In 2h single-shot measurements of 200ng HeLa digest, our setup detected more than 350,000 multiply charged features and identified more than 6,000 protein groups with an high quantitative reproducibility between replicates ($R^2 = 0.97$) and a scan speed of >120 Hz. From only 10 ng of HeLa digest, which converts to approximately 30 HeLa cells, we identified more than 2,400 protein groups in 60 min and more than 2,450 protein groups in only 30 min, highlighting the sensitivity and sequencing speed of our setup. [3] We demonstrate the combination of the exceptional scan speed and high sensitivity of our mass spectrometry setup for turbo protein-protein interactome studies in yeast pulldown experiments. We identify all known interaction partners from protein complexes distributed across the whole protein copy number range and from only 50-100 ng of input material in 23 min measurements.

Conclusions

The additional separation of co eluting ions and signal compression in sharp ion mobility peaks in the additional TIMS dimension increases sensitivity and dynamic range. This allows high speed and high sensitivity applications, and routine large-scale measurements of peptide collisional cross sections (CCS), reflecting their 3D structure, which adds a new and yet underexplored level of information to conventional bottom-up proteomics workflows.

Novel Aspect:

Robust, high sensitivity and high speed shotgun proteomics on a novel TIMS-qTOF platform combined with the PASEF scan mode.

Keywords: IMS-MS, CCS, clusters, phosphoric acid

Introduction:

The coupling of ion mobility and mass spectrometry (IMS-MS) is spreading as a supplemental method of structural characterization to mass spectrometry. Several IMS-MS techniques necessitate the use of reference ions and calibration to measure the collision cross section (CCS) of the but the pool of reference ions is limited. Since a first study in 2014[1], we study phosphoric acid cluster ions in view of investigating their potential as calibrants.

Methods:

Phosphoric acid solutions (5 to 50 mM) in water and acetonitrile were analyzed using electrospray ionization in the negative ion mode. Collision cross section were measured in helium drift gas using an Agilent 6560 drift tube ion mobility (DTIMS) Q-TOF instrument, equipped with an electrospray ionization source. Ion mobility mass spectrometry measurements were also carried out on a SYNAPT G2 HDMS (Waters), that operates a travelling wave ion mobility device.

Results:

Collision cross sections from drift tube ion mobility spectrometry in helium gas were obtained for singly, doubly and triply charged phosphoric acid cluster anion. We studied the relation between collision cross sections and the aggregation number. Phosphoric acid clusters were modelled by non-overlapping spheres that adopt a tight three dimensional packing and collision cross sections were calculated using the projection approximation method. Using such minimal clusters of spheres as rough models for the cluster of phosphoric acid molecules, we could reproduce the growth of the CCS of the clusters by adapting the radius of the spheres that represent the phosphoric acid molecules.

Collision cross sections in helium were correlated to the collision cross sections in nitrogen, and their spherical models compared.

Both collision cross sections in helium and nitrogen were used to calibrate a travelling wave ion mobility instrument, and the resulting accuracy were compared using published reference compounds.

Conclusions

As phosphoric acid cluster anions are isotropic clusters that can be regarded as nanodroplets of a very accessible and simple compound, they could be used as universal calibrants for collision cross section measurement for ion mobility mass spectrometry.

Novel Aspect:

Universal calibrants for ion mobility mass spectrometry using isotropic clusters.

886 - EXPLORING THE CHEMICAL COVERAGE AND STRUCTURAL ASSIGNMENT OF NATURAL PRODUCTS BY ION MOBILITY SPECTROMETRY COMBINED WITH ULTRA-PERFORMANCE LIQUID CHROMATOGRAPHY/MASS SPECTROMETRY

Fausto Carnevale Neto (1) - Joseph Egan (2) - Leticia Veras Costa-Lotufo (3) - Norberto Peporine Lopes (1) - Roger Linington (2)

N/A, Faculdade de Ciencias Farmaceuticas de Ribeirao Preto - USP, Ribeirao Preto (1) - N/A, Simon Fraser University, Burnaby (2) - N/A, Universidade de Sao Paulo, Sao Paulo (3)

Keywords: Ion mobility-mass spectrometry, Natural products, CID fragmentation, Collisional cross section.

Introduction:

The major goal in Natural Products (NP) research is to interrogate complex biological extracts for the purposes of metabolic exploration and natural products discovery. In order to achieve this objective, NP studies rely on accurate and selective acquisition of all possible chemical information, which includes maximization of the number of detected metabolites and their correct molecular assignment [1-3].

Methods:

In this work, we investigated the capabilities of liquid chromatography coupled to ion mobility high-resolution mass spectrometry in the context of natural products. In other words, we addressed the use of comprehensive four-dimensional data (chromatographic retention time, drift time, mass-to-charge and ion abundance) as a way of detect and elucidate NP in complex biological extracts at nanoscale.

Results:

In order to demonstrate the performance of ion mobility for larger chemical coverage, we investigated the behavior of distinct NPs (or NP-inspired molecules) on UHPLC within hybrid Travelling Wave Ion Mobility (TWIM) QTOF system, considering sensitivity and selectivity, LC-deconvolution and conformation space (correlation between m/z and drift time) filtering. The procedure focused on two types of MS/MS data acquisition; data-dependent acquisition (DDA) or auto-MS/MS, and data-independent acquisition (DIA) or all-fragment-ion technique. We evaluated the influence of the "precursor ion isolation width" on chemical coverage, using both approaches, and the impact of additional ion mobility dimension on molecular detection and spectral-quality information. The observations were further explored in a partially characterized sample from a bank of marine bacterial extracts, spiked with the mixture of STDs at the two ranges of concentrations.

Conclusions:

The use of ion mobility (IMS) as orthogonal information on LC-MS method can improve both metabolite detection and chemical characterization for natural products by separating ions in the gas-phase and adding coarse-grained structural information based on shape and collision cross sectional area (CCS).

Novel Aspect:

The application of IMS-MS can improve both metabolite detection and chemical characterization of complex samples in the field of Natural Products.

315 - INFLUENCE OF PROTOMERS ON DISSOCIATION OF SEQUENCE-DEFINED OLIGO(ALKOXYAMINE AMIDE)S

Christophe Chendo (1) - Salomé Poyer (2) - Didier Siri (2) - Jean-François Lutz (3) - Laurence Charles (2)

Fédération des Sciences Chimiques (FR1739), Aix Marseille Université, Marseille (1) - Institut de Chimie Radicalaire (UMR7273), Aix Marseille Université, Marseille (2) - Institut Charles Sadron, CNRS - Chimie Moléculaire de Précision (UPR22), Université de Strasbourg, Strasbourg (3)

Keywords: Protomers; dissociation mechanism; ion mobility; sequence-defined polymers; MS/MS

Introduction:

Poly(alkoxyamine amide)s are sequence-defined synthetic polymers in which binary information can be written thanks to a 0/1 coding system based on the mass of two amide synthons that alternate with a nitroxide moiety [1]. They can be easily sequenced by MS/MS since they mainly dissociate via homolysis of all fragile C–ON bonds between a coding unit and a nitroxide moiety. Surprisingly, each of these cleavages does not produce the two expected complementary products.

Methods:

Oligo(alkoxyamine amide) trimeric models were ionized in positive ion mode electrospray. Tandem mass spectrometry and ion mobility spectrometry (IMS) experiments were performed with a Synapt G2 HDMS instrument. Geometry optimization was done after DFT calculations using M06-2X functional with the 6-31G(d) basis set implemented in the Gaussian-16 program. The MOBCAL software was used to convert Cartesian coordinates in collision cross section (CCS) values.

Results:

Production of only one fragment upon homolysis of one X-T bond in a protonated α -X-T-X-T-X- ω trimer (where X stands for the coding amide moiety and T the TEMPO nitroxide) strongly suggests that, although not directly involved in the mechanism of this charge-remote reaction, the adducted proton has an influence on its occurrence [2]. Protonation of the nitrogen atom in nitroxide was demonstrated to induce an increase of the dissociation energy of the C–ON bond [3]. Accordingly, homolysis of the first X-T bond would occur only when the second T nitroxide was protonated, and vice versa. This assumption implies that each precursor ion would exist as two protomers. Ion mobility experiments indeed showed two distinct conformations for all protonated trimers but those with a 1 coded unit in the second monomer, which were shown to have the same CCS regardless of the proton location. However, although a single C–ON bond homolysis was expected for each protomer, MS/MS spectra recorded after IMS separation still showed homolysis of the two C–ON linkages.

Conclusions

Positive ion mode electrospray ionization was shown to produce different protomers of sequence-defined oligo(alkoxyamine amide)s. By combining ion mobility data and molecular modeling, conformation of these protomers was demonstrated to be sequence-dependent. However, the actual influence of proton location on the occurrence of alkoxyamine bond homolysis is still unclear and is currently investigated with theoretical calculations.

Novel Aspect:

Protomer-specific conformations and their influence on dissociation of small sequence-controlled polymers

1191 - IMS-MS AS A MEANS OF REVEALING NEW STATES DURING THE MELTING OF PROTEINS

David Clemmer (1) - Tarick El Baba (1) - Daniel Woodall (1) - Shannon Raab (1)

School of Public Health-Bloomington, Indiana University (1)

Introduction

One of the most challenging problems in biochemistry involves understanding the structures of non-native proteins that are sometimes intermediates during protein folding and unfolding events. After more than 50 years of work, experimental characterization of protein folding and unfolding usually leads to results which are described as a cooperative, two phase, transition between the folded and unfolded states – i.e., the protein appears to melt and no information about non-native states is obtained

Methods:

Here we present new data from an IMS-MS analysis of simple proteins that are electrosprayed from a temperature controlled source. In this approach the source temperature is varied and IMS-MS is used to read out changes in conformations as a function of temperature. Droplets undergo an evaporative cooling phenomenon during shrinkage and this appears to trap solution structures that are not easily observed with other techniques. The IMS distributions change as the shapes of protein conformers change as the MS charge state distributions.

Results:

The results suggest that the cooperative two state behavior involves other states that are captured in the IMS-MS analysis. In some examples, we find evidence for at least 10 structures that arise at slightly different transition temperatures. To date we have investigated several peptides, proteins, and protein complexes.

Conclusions:

The ability to experimentally capture information about new states that are involved in folding and unfolding events may help guide theoretical efforts to model folding and unfolding processes.

Novel Aspect:

IMS-MS techniques are used to capture information about non-native protein populations and structures from solution.

152 - TRAPPED ION MOBILITY SPECTROMETRY AS NOVEL SEPARATION TECHNIQUE FOR THE INVESTIGATION ON ISOMER FORMATION DURING THE SIMULATION OF PHASE I METABOLISM BY MEANS OF ELECTROCHEMISTRY/MASS SPECTROMETRY

Jens Fangmeyer (1) - Simon Gereon Scheeren (1) - Robin Schmid (1) - Uwe Karst (1)

University of Muenster, Institute of Inorganic and Analytical Chemistry, Münster (1)

Keywords: Electrochemistry, Metabolism, Trapped Ion Mobility Spectrometry, Liquid chromatography, Hyphenation

Introduction:

Electrochemistry/mass spectrometry (EC/MS) has evolved as a valuable and purely instrumental approach in mimicking the phase I metabolism of xenobiotics. Due to the formation of isomers after the electrochemical treatment, the development of a separation method in order to distinguish between them is required. For this purpose trapped ion mobility spectrometry (TIMS) enables a novel and faster approach for the separation of oxidation products.

Methods:

The generation of metabolites was performed in an electrochemical cell equipped with a boron-doped diamond working electrode applying a potential ramp. The EC cell was coupled online to ESI-HR-MS. The results were plotted in three-dimensional mass voltammograms. Mobile voltammograms for each m/z were recorded and visualized as a contour plot, which shows the signal intensity versus the applied potential and the inverted reduced mobility ($1/k_0$) of the analyte ions.

Results:

With the recorded mass voltammograms different oxidation products of the model compound metoprolol were identified via their accurate masses, e.g. N-dealkylated or hydroxylated products. Especially hydroxylations are typically possible at different molecular positions. The mobile voltammograms for each m/z reveal isomer formation regarding hydroxylation of metoprolol. Two different hydroxylation products can be distinguished in the mobile voltammograms via differences regarding their reduced mobility referring to different collisional cross sections. Additionally MS/MS experiments after TIMS separation were carried out in order to give structural information of both compounds. Further fragmentation experiments after HPLC separation show the same results in fragmentation pattern and isomer distinction. Accordingly, by coupling EC with TIMS the analysis time can be reduced by at least the factor of five compared to conventional HPLC separations.

Conclusions:

The ability to distinguish between different electrochemical metabolite isomers proves that EC/TIMS/ESI-HR-MS is a fast and powerful tool for the simulation of xenobiotic phase I metabolism including identification of the metabolites via MS/MS experiments. The time-consuming HPLC separation development process was replaced by the implementation of TIMS resulting in a faster analysis.

Novel Aspect:

The new and fast separation technique TIMS has been implemented in the electrochemical simulation of phase I metabolism in order to investigate isomer formation.

44 - PRION PROTEIN CONFORMATIONAL LANDSCAPE STUDIED BY MASS SPECTROMETRY AND ION MOBILITY.

Frédéric Halgand (1) - Guillaume Van der Rest (2) - Human Rezaei (3)

CNRS, Chemistry, Orsay (1) - Université Paris-Sud, Chemistry, Orsay (2) - INRA, Biology, Jouy-en-Josas (3)

Prion protein conformational landscape studied by mass spectrometry and ion mobility.

Van der Rest G (1), Rezaei H (2), Halgand F (1),

(1) CNRS-Université Paris Sud, Laboratoire de Chimie Physique, Orsay, France.(2) INRA, Laboratoire VIM-MAP2, Jouy-en-Josas, France.

Keywords: prion, native mass spectrometry, ion mobility, conformational landscape

•Introduction: MS has proved to be an efficient way to analyze “native” complexes. More recently, the commercial availability of instruments coupled to ion-mobility devices has led to renewed interest of structural biologists with access to conformational landscape of proteins. Recent studies suggest that different prion conformers might coexist in solution. We therefore decided to screen the ovine and human PrP monomers using ion mobility coupled to mass spectrometry.

•Methods: Shortly, ion mobility and MS data were recorded under direct infusion of the prion protein in TEAA 20 mM pH 3.3 buffer on a Synapt G2-Si. Then collision cross section calibration was performed following the procedure of Bush et al for data comparison. For data mining we used an automated data extraction pipeline for which we developed a Python/Qt script base interface.

•Results: Data showed that at least three PrP conformers are observed in the gas phase. PrP monomers are known to lead to the formation of oligomeric species in specific conditions not compatible with MS. We developed a SEC-IMS-MS setup with the aim to study the oligomers produced in these conditions. The development of this methodology allowed us to achieve CCS calibration with standards and successfully observed the small (O3) oligomeric species ((O3 ~9-mer). One key observation in this process was that the relative abundance of the gas phase monomeric conformers changed upon SEC elution. This suggest that conformer family abundances were related to protein concentration. Thus we probed the effect of protein concentration upon conformer relative abundances. Results allowed us to clearly demonstrate that monomer concentration has an effect on the ratio of conformers present in solution, which could be related to the occurrence of structural information transfer occurring through the formation of discreet polymeric objects.

•Conclusions: Here we demonstrated that ion mobility coupled to mass spectrometry can be a highly efficient tool, not only to qualitatively describe the conformational landscape but also to quantitatively follow conformers dynamic. Our results, opened new ways for biological interpretation of prion pathologies.

•References: Van der Rest, G. and F. Halgand, Size Exclusion Chromatography-Ion Mobility-Mass Spectrometry Coupling: a Step Toward Structural Biology. *J Am Soc Mass Spectrom*, 2017. 28(11): p. 2519-2522. Van der Rest, G., H. Rezaei, and F. Halgand, Monitoring Conformational Landscape of Ovine Prion Protein Monomer Using Ion Mobility Coupled to Mass Spectrometry. *J Am Soc Mass Spectrom*, 2017. 28(2): p. 303-314.

•Novel Aspect: First evidence of conformers in the gas phase that keep part of solution properties and helped deciphering prion pathologies.

UMONS, Université de Mons, Mons (1)

Keywords: Peptoids, Secondary Structures, Ion Mobility

Introduction:

Peptoids are peptidomimetic polymers of N-substituted glycine units that differ from amino acid building block by the side chain position present on the nitrogen atom [1]. Peptoids can adopt secondary structures, such as helix, which are dependent on cis/trans amide conformation, itself related to the composition [2]. Nowadays a great care is raised to the peptoid structure especially since the helicoidal folding possibly induces enantioselective properties [3].

Methods:

(S)-phenylethyl peptoids are synthesized using a well-described solid-phase protocol involving a series of repeated acylation and nucleophilic displacement steps [4]. Mass spectrometry experiments have been completed using the Waters Synapt G2-Si instrument integrating the traveling wave ion mobility technology. The interpretation of experimental collisional cross sections is supported by Molecular Modeling with optimized force field.

Results:

To try deciphering the gas-phase secondary structure of ionized peptoids, Ion Mobility Mass Spectrometry (IMMS) and Molecular Modeling techniques are combined. The helicoidal structure adopted by (S)-phenylethylamine homopeptoids (Nspe) is confirmed in solution justifying the choice of this side chain as model compound [5]. The Collisional Cross Sections (CCS) of protonated Nspe peptoids from one to fifteen monomer units are measured. Interestingly, when the CCS values are reported in function of the polymerization degree, a linear correlation appears, potentially attributable to the helicoidal conformation. However, comparing the CCS and analyzing the relative energies, a charge-induced loop structure seems to be a more relevant gas phase structure. Acetylation of terminal amine function is therefore envisaged to hinder the specific charge positioning at the amine terminal function. The IMMS results obtained for AcNspe peptoids shows a totally new trend.

Conclusions

Peptoids are an emergent class of biomimetic polymers [1]. Numerous in-solution studies describe their ability to fold as a helix despite the fact that the amide conformational equilibrium drastically complicates the data interpretation [2]. Mass spectrometry represents an elegant alternative although the ionization/desolvation processes may denature the solution phase structures.

Novel Aspect:

In contrast to peptides, the H-bond suppression in peptoids induced by the side chain position questions all the considerations about the structure conservation upon ESI.

1330 - CROSS SECTION OF SELECTED EXTRACTABLE AND LEACHABLE COMPOUNDS: INFLUENCE OF MOBILE PHASE COMPOSITION

Vincent Hanot (1) - Rodrigo Feliciano (2) - Peifeng Hu (3) - Christopher Jones (3)

Baxter, Mass Spectrometry, Braine L'alleud, Belgium (1) - Baxter, Mass Spectrometry, Braine L'Alleud, Belgium (2) - Baxter, Mass Spectrometry, Round Lake, United States (3)

Keywords: Ion Mobility, CCS, E&L, Identification, Mobile Phase

Introduction: (Limit of 400 characters without spaces)

Ion mobility coupled to mass spectrometry (IM-MS) allows the separation of molecular species based on their mass, charge and shape, providing an additional separation dimension to chromatography. In this work, we compare the reproducibility of collision-cross section (CCS) measurements for analytes separated using different liquid chromatography (LC) mobile phase conditions to evaluate the robustness of LC-IM-MS for extractables identification.

Methods: (Limit of 400 characters without spaces)

In order to study the impact of pH on adduct formation of known impurities from pharmaceutical packaging material by IM-MS, several aqueous mobile phases with different pH were evaluated. IM-MS detection was performed on a Waters VION in positive and negative modes between m/z 80-1000. Each mixture of standards analysed in triplicate was bracketed by QC analysis ($n=5$) and CCS values for each compound were collected.

Results: (Limit 900 characters without spaces)

The reproducibility of CCS values has been measured for analytes originating from different LC mobile phases. Different pH were evaluated (10 mM ammonium acetate + 0.05% CH₃COOH, 0.1% HCOOH and 0.001% HCOOH) using methanol as organic mobile phase during a 35 min gradient method. 10 μ L of standards or QC samples were injected into an Agilent Zorbax Eclipse Plus, 2.1 x 100 mm at 40°C with a 0.5 mL/min flow. All molecules were detected in negative mode as [M-H]⁻. In positive mode, each analyte was detected as [M+H]⁺, [M+Na]⁺, [M+K]⁺, [M+NH₄]⁺, or different combinations of these adducts. The precision of CCS values was $\leq 1.13\%$ and $\leq 0.57\%$ for QC and samples, respectively. The difference between expected and observed CCS (Δ CCS) ranged between [-1.60; 1.02%] and [-1.94; 1.30%] for QC and samples, respectively. A very good precision and "accuracy" were measured independently of the pH of the mobile phase. The results of this study also showed that the relationship between the adduct formed and the measured CCS value is not straightforward.

Conclusions

These results showed that CCS values for small organic ions are pH-independent, unlike the retention time. The very good reproducibility of CCS values highlighted the usefulness of CCS values in identifying compounds and can serve as a complementary fingerprint for the identification of unknown compounds in E&L studies. In the identification process, the adduct formation should be considered as it will impact the measured CCS value.

Novel Aspect: (Limit of 150 characters without spaces)

This work highlights the relevance of using CCS values as an additional dimension to identify unknown compounds in E&L studies.

412 - COLLISION CROSS SECTION (CCS) AS A COMPLEMENTARY PARAMETER TO CHARACTERIZE HUMAN AND VETERINARY DRUGS: CREATION OF A DATABASE

Carmen Tejada-Casado (1) - Maykel Hernández-Mesa (2) - Fabrice Monteau (2) - Francisco J. Lara (1) - Monsalud del Olmo-Iruela (1) - Ana M. García-Campaña (1) - Bruno Le Bizec (2) - Gaud Dervilly-Pinel (2)

University of Granada, Department of Analytical Chemistry - Research group FQM302, Granada (1) - École nationale vétérinaire, agroalimentaire et de l'alimentation de Nantes-Atlantique (Oniris), Laboratoire d'Etude des Résidus et Contaminants dans les Aliments (LABERCA), Nantes (2)

Keywords: Ion mobility mass spectrometry; human and veterinary drugs; fragmentation patterns, urine samples

Introduction:

Ion mobility spectrometry (IMS) in combination with mass spectrometry (MS) provides complementary information on m/z , the so-called collision-cross-section (CCS, Ω (Å²)), which may be useful for the identification of human and veterinary drugs [1]. So far, only a reduced number of these drugs has been characterized in terms of CCS, limiting its application as identification parameter [2,3]. Moreover, in the field of metabolomics where a wide number of compounds from different chemical families are detected, the creation of CCS databases is crucial for molecular identification.

Methods:

IMS-MS analysis were carried out on a hybrid quadrupole/traveling wave ion mobility/orthogonal acceleration time-of-flight (ToF) geometry instrument (Synapt G2-S HDMS). CCS characterization of human and veterinary drugs was accomplished under flow injection analysis (FIA) and positive electrospray ionization (ESI) conditions. Nitrogen was used as drift gas in the ion mobility cell. In this work, 7 families of drugs (i.e. 18 benzimidazoles, 11 5-nitroimidazoles, 11 aminoglycosides, 19 quinolones, 18 β -lactams, 10 sulfonamides and 5 tetracyclines) have been identified and characterized in terms of m/z and CCS.

Results:

CCS is a molecular characteristic closely related to m/z , so linear correlation between both parameters is expected for compounds belonging to the same chemical family and with similar structural composition. The developed data set includes the CCS of 173 ions considering both $[M+H]^+$ and $[M+Na]^+$ species. High correlation between m/z and CCS is observed for $[M+H]^+$ ($r=0.9756$, $n=91$) and $[M+Na]^+$ ($r=0.9558$, $n=82$) ions. As expected, CCS values for sodium adducts are greater than for protonated molecules because they present higher molecular weight. However, sodium adducts of aminoglycosides, β -lactams, and of several quinolones and benzimidazoles, present lower CCS values than expected, that can be interpreted as these ions are more compact than their related protonated molecules. The main fragment ions for most compounds have also been characterized in terms of CCS and included in the database as additional interesting piece of information. Finally, 11 veterinary drugs in bovine urine samples were analyzed showing no influence of matrix on the CCS values.

Conclusions

This work proposes a CCS database for human and veterinary drugs. It includes 92 compounds of which 37 of them have been characterized in terms of CCS for the first time. In traditional LC-MS workflows, this database can be used for identification together with other well established identification criteria such as precursor ion, accurate mass, fragment ion, isotopic pattern and retention time.

Novel Aspect:

Additional information for the identification of a wide range of contaminants and other residues is provided as required by new trends in global and/or untargeted analysis.

École nationale vétérinaire, agroalimentaire et de l'alimentation de Nantes-Atlantique (Oniris), Laboratoire d'Etudes des Résidus et Contaminants dans les Aliments (LABERCA), INRA UMR 1329, Nantes (1) - University of Granada, Department of Analytical Chemistry - Research Group FQM302, Granada (2)

COLLISION CROSS SECTION AS A NOVEL PARAMETER FOR THE CHARACTERIZATION OF STEROIDS

Keywords: collision cross section, ion mobility spectrometry, mass spectrometry, steroids, biological samples

Introduction:

Steroids play important roles in biological processes, thus, steroid profiling enhances the knowledge about metabolic mechanisms and the effects of chemical exposures on human health [1]. The integration of ion mobility spectrometry (IM) in LC-MS workflows provides additional information to steroid profiling by adding an extra separation dimension and measuring the molecular collision cross section (CCS) [2].

Methods:

A total of 300 compounds belonging to different steroid families (i.e. androgens, estrogens, progestogens and corticosteroids) and involving 1080 ions (i.e. protonated and deprotonated molecules, fragment ions, sodium adducts, dimers) have been identified and characterized in terms of m/z and CCS. A hybrid quadrupole/traveling wave ion mobility/time-of-flight mass spectrometry instrument (Synapt G2-S HDMS) was employed for CCS characterization. Urine samples containing steroid glucuronides and sulfates have been analyzed by LC-ESI-IM-MS.

Results:

High correlation has been observed between m/z and CCS for steroids. However, several steroids with large moieties such as steroid glucuronides and steroid esters resulted in more compact or elongated molecules than predicted from the large set of steroids analyzed. In addition, steroids present different structural properties depending on the number of carbons of their steroid skeleton with consequences on their spatial size as evidenced by the CCSs observed. Structural differences of $22.8 \pm 5.9 \text{ \AA}^2$ have been observed between the protonated molecule and the sodium adduct of steroids. Certain protonated molecules and sodium adducts present a CCS deviated from the expected value which results in valuable information for steroid identification in untargeted analyses. Moreover, several isomeric steroid pairs (e.g. 5β -androstane-3,17-dione and 5α -androstane-3,17-dione) have been separated based on their CCS differences.

Conclusions:

CCS provides additional information to retention time and mass spectra for supporting steroid profiling and gives more confidence to the results obtained in the routine analysis of steroids. The CCS of steroids in urine samples can be measured with high confidence considering a variation $< 2\%$ in relation to the values obtained in standards.

Novel Aspect:

This work proposes the first CCS database for 300 steroids (i.e. endogenous, including phase I and phase II metabolites, and exogenous synthetic compounds).

Keywords: travelling wave ion mobility, isobaric isomers, polarizable drift gases, environmental samples

Introduction:

The oxidation of volatile organic compounds in the atmosphere leads to secondary organic aerosol compounds (SOA) that partition into ambient particulate matters. Owing to lack of authentic standards, their structural analysis mostly relies on MS_n experiments though the information tends to be limited to the presence of functional groups. Here we show the application of travelling wave mass spectrometry with polarizable drift gas for their structural analysis.

Methods:

The extracts of PM samples collected in Chengdu, China were analysed using a Waters Acquity UPLC coupled to SYNAPT G2 HDMS (UPLC/(-)ESI-IMS-QTOFMS). An Acquity UPLC HSS T3 column (100 x 2.1 mm, 1.8 micrometer) was used for the separation of the sample. The ability to separate small isobaric isomer compounds was compared for N₂ drift gas and CO₂ drift gas.

Results:

Among SOA compounds detected in the chromatograms, we focus on a series of isobaric isomer compounds detected at m/z 294 (m/z 294.0647, C₁₀H₁₆NO₇S⁻). Based on the number of carbon and hydrogen atoms, they are thought to originate from monoterpenes. Common m/z values in MS₂ spectra were m/z 247 (C₁₀H₁₅O₅S⁻), and m/z 95 (·SO₄⁻). Two of the isomers showed m/z 231 (C₁₀H₁₅O₄S⁻), whereas the one peak showed m/z 233 (C₈H₁₁NO₅S⁻) instead. The presence of m/z 95 (·SO₄⁻) in MS₂ suggests that precursor monoterpenes contain a tertiary carbon where a sulfate group can be attached. In the drift time of CO₂-IMS-MS, the m/z 247 fragment in the peak at 9 min showed a larger drift time (6.8 msec) than the peak eluting at 8.5 min (6.5 msec). This difference was not visible for the N₂ drift gas. This indicates that the CCS of the precursor monoterpene is larger for this peak than the other peak. While this information alone is not sufficient to determine their structures or precursors, it provides an important piece of information to narrow down their possible structures.

Conclusions

In this work, we showed that IMS-MS separation with CO₂ drift gas can be useful for obtaining additional structural information to MS₂ data. The technique is potentially useful in obtaining structural information for other environmental compounds that have no authentic standard compounds.

Novel Aspect:

Application of highly polarizable drift gas in IMS-MS to elucidate structures of unknown small molecules.

815 - PROFILES OF ARRIVAL TIME DISTRIBUTIONS IN DIFFERENT DRIFT GASES AS A TOOL FOR IDENTIFICATION OF ISOMERS

Lucie Borovcová (1) - Jana Ondruchová (1) - Vladimír Havlíček (2) - Karel Lemr (1)

Palacký University, Regional Centre of Advanced Technologies and Materials, Department of Analytical Chemistry, Faculty of Science, 17.listopadu 12, Olomouc (1) - Institute of Microbiology ASCR, v.v.i., Laboratory of Molecular Structure Characterization, Vídeňská 1083, Prague (2)

Keywords: ion mobility, mass spectrometry, isomers, new psychoactive substances, saccharides

Introduction:

Ion mobility coupled to mass spectrometry improves selectivity[1] but available instruments provide relatively low resolving power. Change of drift gas can enhance separation[2] or peak fitting can reveal isomers in their mixture [3]. Although strongly overlapped peaks were distinguished by the fitting very similar peak shapes can limit its efficiency. Three drift gases were used to distinguish isomers comparing not only their drift times but also peak profiles.

Methods:

Experiments were carried out using a Q-TOF instrument equipped with ion mobility (Synapt G2-S, Waters, Manchester, UK). A custom-made gas controller (Chromservis, Prague, Czech Republic) allowed switching between different drift gases (N₂, Ar or CO₂). Sample solutions were directly infused into an electrospray ion source. Isobaric or isomeric new psychoactive substances and isomeric hyaluronan-derived oligosaccharides were used as testing compounds.

Results:

Using three drift gases (N₂, Ar, CO₂), ion mobilograms of standards were acquired to get the reference drift time values and arrival time distribution (ATD) profiles. In some cases the change of drift gas allowed separation of isomeric or isobaric analytes and individual peaks were observed in mobilograms. Some critical pairs were not separated sufficiently in any tested drift gas. Nevertheless, differences in ATD (peak) profiles of some unseparated analytes were evident which allowed to distinguish them. For example for drugs of abuse, two isomers (3-FMC, 4-FMC) were well separated from isobaric 2C-H in N₂ but both isomers showed practically identical drift time values as well as ATD profiles and could not be identified. Applying CO₂, the isomers were not separated sufficiently but their ATD profiles were different and helpful for the identification. ATD profiles of some individual compounds could also be extracted from a mobilogram of their mixture and peak areas corresponding to individual compounds were determined.

Conclusions:

In ion mobility, individual analytes are identified using their drift times or collision cross sections. Selectivity can be changed by applying different drift gases but drift times of compounds can still remain too close. Even in such cases, ATD profiles of individual compounds can be characteristic and useful for the identification. Since ATD profiles of analytes can be similar in one drift gas application of different gases can improve the identification ability.

Novel Aspect:

In addition to drift time values, ATD profiles acquired in different drift gases were successfully used to identify isomers.

Keywords: Alzheimer's disease, beta-amyloid, structural changes by ligands, ion-mobility, LILBID-MS

Introduction:

Spontaneous aggregation of proteins can be the reason for a diversity of diseases e.g. Alzheimer's Disease (AD) and Parkinson. The proteins involved in these diseases (beta-amyloid (A β 42) and α -Synuclein, respectively) show the ability of spontaneous aggregation, leading to fibrils formation [1,2]. It is now generally accepted that the small oligomers rather than fibrils are the toxic species in the emergence of those diseases [3].

Methods:

Laser-induced-liquid-bead-ion-desorption (LILBID) MS is an ionization technique which has the ability to conserve non-covalent interactions. Thereby, tiny droplets are transferred into vacuum and irradiated by IR laser pulses. This leads to release of the analyte-ions which are then mass-analysed by time-of-flight. Electrospray-ionization (ESI) combined with IMS allows to correlate the oligomerization of A β 42 to structural changes of the amyloid peptide.

Results:

We present the differences, advantages and disadvantages of both methods for studying amyloids. By combining the two complementary techniques it is possible to analyze oligomerization, ligand binding and structural changes of the aggregating proteins in dependence of different ligands for a better understanding of the amyloid's behavior. We use LILBID to study the kinetics of the oligomerization of A β 42 and α -Synuclein by time-resolved measurements and the effect of molecules which influence the oligomerization. We show examples of molecules which inhibit or even reverse the oligomerization. Furthermore, we use ESI MS and IMS to study the peptide structure. We are able to correlate experimentally determined CCS values to the structure of aggregating peptides to detect changes of the structure induced by ligand molecules. Thereby we can gain insights into amyloid formation as well as the effect of different kinds of ligands.

Conclusions:

LILBID-MS is a well-suited tool to study the kinetics of amyloid behavior allowing to follow the oligomerization of amyloids in terms of disease-relevant oligomers in dependence of the presence of inhibitors. ESI-IMS can give complementary information on how different binding partners affect the conformation of A β 42. By correlating both methods we can gain an insight on the mechanism of oligomerization.

Novel Aspect:

Combining two mass spectrometry techniques to gain orthogonal information (structure and oligomeric state) of amyloidogenic peptides

Keywords

Differential Mobility Separation Bile Acids

Introduction

Bile acids are involved in a wide range of biological functions including lipid resorption, immunological functions and metabolic regulation. Through metabolic transformations, isomeric and isobaric variants are generated, which makes the unequivocal identification and quantification of individual chemical species difficult.

Here we introduce Differential Mobility Separation (DMS) as a methodology for the separation of bile-acid isomers. DMS is an ion mobility technology which separates molecules based on their dipolar moment. We show DMS separation in conjunction with chromatographic separation (LC-DMS-MS) as well as with direct infusion (DMS-MS). While the combination with chromatographic separation may improve selectivity, the separation power of SelexION is sufficient for a clear separation of isomers, allowing for infusion-based fast quantification without the need for LC development.

Methods

Bile acid standards were prepared in 10% DMSO at a stock solution of 1 mM. Two groups were used: taurodeoxycholic acid (TDCA), taurochenodeoxycholic acid (TCDCA), tauroursodeoxycholic acid (TUDCA) with monoisotopic mass of (499.2967) and formula (C₂₆H₄₅NO₆S) and glycodeoxycholic acid (GDCA), glycochenodeoxycholic acid (GCDCA) and glyoursodeoxycholic acid (GUDCA) with monoisotopic mass of (449.3141) and formula (C₂₆H₄₃NO₅). For direct infusion, compounds were prepared in water/methanol 50/50, 0.1% FA at a concentration of 1 μM. For LC-separation preparation was done in the same solvent at a concentration of 0.1 nmol/ml with 1 μl injection volume. The samples were measured on a QTRAP® 6500 LC-MSMS system equipped with a SelexION® (DMS) device and coupled to an ExionLC™ system for the LC experiments.

Preliminary results

Using the DMS technology, we directly infused the bile acid standards individually and as mixtures to determine the CoV values of the different isomers. To this end, the compensation voltage was ramped over a range between -30V to 0V. The results showed almost baseline separation of the different isomers.

The next aim was to combine DMS with chromatographic separation. The combination of DMS with chromatography has several advantages: Firstly, DMS showed a marked reduction of chemical background for better quantification, resulting in improvement of the signal to noise ratio (give a value NNN). A further advantage is less requirement for development of chromatographic separation, which was shown by the elimination of isomers from extracted ion chromatograms. This also eliminated the requirement for retention time assignment and less reliance on compound specific fragments which may be low abundant. For example, DMS allows to use a highly abundant fragment without the need for compound specificity.

Novel aspects

Differential mobility separation, increased selectivity of bile acid separation by LC-DMS-MS

Keywords:

Collision Cross Section, Ion Mobility, Steviol Glycosides, Screening Libraries, CCS Fingerprints

Introduction

CCS data bases are being developed across multiple application areas.¹⁻⁶ A method using Ion Mobility Mass Spectrometry has been developed to screen/distinguish steviol glycoside isomers. A quantitative assessment of long-term CCS measurement stability and an intersite comparison is presented. In addition to illustrating how CCS fingerprints can be produced to enhance cumulative identification specificity within screening libraries.

Methods

Reversed phase separation was performed (2ul/min), using a microfluidic PCA (post column addition) separation device (40°C), incorporating a 1.7 µm, ACQUITY UPLC BEH C18 stationary phase in a 150 µm diameter separation channel, with integrated ESI emitter (-2.6 kV). The source enclosure was interfaced to a SYNAPT® G2-Si mass spectrometer and generic ion mobility separation performed in negative ion HDMSE mode, at 20000 FWHM (m/z 50-2000).

Results

55 food commodity samples labeled as containing stevioside sweeteners were screened using a steviol glycoside CCS library. Analyses produced CCS values, enabling the unequivocal identification of steviol glycosides and isomeric pairs. Retrospective data analysis revealed coeluting isomeric species comprising, (steviol glycosides, formate adducts, labile fragment ions, doubly de-protonated dimers, multiply charged species) and have been differentiated using CCS, generating specific isomeric analyte fingerprints.

Short term precision/repeatability CCS measurement RSD's between 0.11 and 0.21% were obtained. For an inter-site comparison (UK/Belgium), the CCS difference was <0.7%. For long term performance, over a 45 days (24/7, one calibration), samples comprised of solvent standards (1-1000 pg/µL) and a commodity subset. 18,974 steviol glycoside detections were measured. The determined CCS error was <1%, with RMS error of 0.26%.

Conclusions

Inter-site and short/longterm term precision of CCS measurements indicate that CCS is a reliable metric that can be added to searchable screening libraries, enabling an additional complimentary metric to be used in conjunction with retention time and accurate mass measurement. CCS fingerprints can be used as an additional metric to enhance identification specificity, even where no product ion information is available and retention time shifts occur.

Novel Aspect

Micro UHPLC MS sensitivity and CCS retrospective data review, enabled multiple analyte specific isomeric species (CCS fingerprints) to enhance searchable databases.

Keywords: CCS, Libraries, DMPK, Unknowns, Matrices

Introduction

A primary challenge in characterizing metabolic fate is distinguishing drug-related material in the presence of the complex matrix. A commonly used approach is to filter components based on parent drug properties. However, identification of drug-related, unexpected metabolites remains a limiting issue. By characterizing the native complement of biological matrices in a library based on m/z, CCS and product ions, we can flag components in samples that are unlikely to be drug metabolites.

Methods:

Hepatocyte incubations were analysed using ion mobility enabled data independent acquisition (HDMSE) LC/MS data were acquired with two different reversed phase gradient Methods: The data were co-detected across all samples in the m/z, RT, and CCS dimensions. An aggregate peak list file was developed from which an initial query library was created. Through an iterative search and (Kendrick) filtering process, the content of the known-unknown library was curated and appropriate query parameters derived.

Results:

Five technical replicate LC-MS experiments of each incubation were conducted per gradient method. Four of the five replicates were used for library creation and the remaining replicate was used for testing and evaluation. The initial library comprised components that were consistently detected across all runs with regard to m/z, retention time and drift time reproducibility. No restrictions were applied at this stage with respect to intensity and/or number of fragment ions per product ion spectrum. Appropriate search tolerances were readily obtained by considering every possible match parameters, resulting in a set of parameters that are equivalent to those typically applied in studies where the structure and/or elemental composition of the target molecules are known. The curation process also allowed for the estimation of the contribution of each analytical parameter, either individually or combined, to the overall specificity of a compound search. In addition, two methods were considered and evaluated that express normalized specificity metrics either as a function of the number of detections or curated library entries, respectively.

Conclusions

The application of the known-unknown library and the ability to estimate FDR will be demonstrated by hepatocytes incubation matrices spiked with known compounds and metabolites. The development and evaluation additional known-unknown libraries of other biological matrices is currently underway as well as the identification of commonly detected unknown compounds in different biological drug incubation matrices.

Novel Aspect:

Our approach shows the benefit of integrating CCS values even for unknown compounds in known-unknown libraries which has the potential to accelerate metabolite identification in DMPK workflow

Keywords: Protein Structure, Ion Mobility, HDX, DMS, Gas Phase Structure

Introduction:

Native electrospray offers the ability to maintain structural characteristic of the proteins prior to MS analysis. In recent years, the coupling of conventional mobility has also proven to be useful at interrogating the various conformation that may exist in the gas phase associated with intact proteins. More recently, differential mobility separation (DMS) has also been used to effectively separate isoforms and isomers prior to analysis. Here we report of the use of DMS to augment the separation of intact protein under native- LC conditions.

Methods:

All proteins and peptide standards were acquired from SIGMA and used without any further purification. LC was performed using a Shimadzu Nexera UFLC system operated at a flow rate of 400uL/min with a 2x150mm Yara 3u SEC-3000 (Phenomenex) over 15 minutes. All samples were analysed using a TripleTOF[®] 5600+ system equipped with a SelexION[®] (DMS system) using a Turbo V source.

Results:

Cytochrome-c was used as model protein to assess the DMS and source condition required for successful detection of various conformations. Under 'native like' infusion conditions, it was found that the DMS can be operated at medium temperature (225°C) and varying SV values to reveal multiple transmission optima (n=3) for the +8 charge state. Prior publications have observed and attributed multiple conformers to this particular charge state. These conformers were also observed under LC conditions as long as the source temperature was kept below 300°C. Though CCS measurement may not be directly obtained from the CoV values, HDX in the gas phase after the DMS separation confirmed that the conformations had differences in exchange rate that are consistent with compact and extended structure. When the spray and solution conditions were modified to induce conformational changes in the solution phase, the CoV optima for that charge state changed. These results are consistent with conformational changes that can be detected by DMS separation.

Conclusions

Differential mobility provides an orthogonal separation to mass spectrometry and LC technology. The work presented here opens up an avenue of structural biology, with the interrogation of compact and extended conformations. The addition of gas phase HDX provides further evidence that the ions are entering the gas phase with a level of solution phase structure. Importantly the observed species are supported through previous publications.

Novel Aspect:

'Native like' structure analysis with differential mobility and LC separation

1045 - ION GUIDE WITH VERY STRONG AXIAL TRANSPORTING FIELDS

Sergey Poteshin (1) - Anna Burykina (1)

NRNU MEPhI, Molecular physics, Moscow (1)

Keywords:

Ion transport, ion transport, Collision Cell with axial field

Introduction:

The main task of this investigation is the searching of geometrical and RF power supplying modes for RF-only stacked ring ion guide with traveling waves for providing very high axial transporting fields. It can be attractive for 1) high-speed, high-pressure collisional cell, 2) the lifting of ions from low to high pressure area for Quadrupole/IMS applications.

Methods:

For a theoretical calculation of effective potentials for the stack of ring electrodes with RF supplying we can use comprehensive work of Berdnikova A. S. [1]. Also we calculate ions trajectories in gas with using SIMION 8.1 with own modified HS1 code. The modification allows to significantly accelerate the calculation of trajectories at the high pressure without loss of accuracy.

Results:

As a basic version of stacked ring ion guide we chose a 4 times the electrode pitch which repeated along axis. Thus we needed only 4 RF power signal for applying to $N=1..4$ electrodes. RF signal is a combination high frequency V_{rf+} and low frequency (LF) signal providing traveling waves field. The LF voltages have an amplitude V_{tw} and are phase shifted by $\pi/2N$.

The inner diameter of the electrodes was chosen quite small $R_0 \sim 1$ mm, to produce straight axis field caused by TW potentials. The thickness of electrodes was 0.2 mm and the gap between of them is 0.2 mm.

Numerical simulation shows the good ion transport efficiency at wide pressure range 0-100 Torr with different RF power supplying regime. At low pressure we have to apply higher amplitude with higher frequency V_{rf+} and for high pressure we can leave only LF supplying signals for the traveling waves.

Also simulation shows excellent ability for a high speed axial ion transporting.

Conclusions

The ability of ion guide based on stacked ring with traveling waves to operate at wide pressure range 0-100 Torr with high axial transporting speed of 100 m/s (at 100 Torr) is shown. Thus our ion guide can operate as ions passing system from low to high pressure ~ 10 -100 Torr for realizing Quadrupole/IMS devices.

Also it will be shown that the presented ion guide is effective as a very high speed at operating rate collision cell.

Novel Aspect:

Presented ion guide can be used for 1) ions passing system from low to high pressure for Q/IMS devices or high pressure collision cell 2) very high speed operating rate collision cell.

1046 - THERMAL DENATURATION OF PROTEINS BY VARIABLE-TEMPERATURE ELECTROSPRAY IONIZATION PAIRED WITH ION MOBILITY SPECTROMETRY-MASS SPECTROMETRY

Shannon Raab (1) - Tarick El-Baba (1) - Daniel Woodall (1) - David Clemmer (1)

Indiana University, Department of Chemistry, Bloomington (1)

Keywords: IMS-MS, vt-ESI, protein folding, structure

Introduction:

Protein folding is difficult to study due to the lack of sensitive techniques that can detect all populated structures on a folding pathway. Ion mobility spectrometry-mass spectrometry (IMS-MS) paired with a variable-temperature electrospray ionization (vt-ESI) source has elucidated multiple folding structures based on changes in collision cross section (CCS) upon protein denaturation[1]. Here, this method is used to study protein folding and assembly.

Methods:

Experiments were carried out using nested IMS-TOF instruments fitted with a custom vt-ESI source that maintains a solution temperature up to ionization and analysis. Wild-type and point-mutated chymotrypsin inhibitor 2 (CI2) were expressed in *E. coli* and purified by existing techniques. Avidin was purchased from Lee BioSolutions and all other reagents were purchased from Sigma Aldrich. Samples were made to ~30 μM with varying amounts of ammonium acetate buffer.

Results:

We monitored the unfolding of CI2, a single-domain protein previously reported to fold by a two-state cooperative transition[2]. Changes in the charge state distributions suggest the melting transition follows a two-state transition; our melting temperatures (at several solution pH values) are within 1% of calorimetric data. However, the mobility distributions within each charge state reveal several structures that behave differently with increased temperature (i.e., multiple folding states). Point-mutated CI2 variants were melted and compared to the wild-type protein to determine the contribution of specific residues to the overall folding behavior. Preliminary experiments studying the homotetrameric protein avidin show interesting melting behavior. For example, the compact tetramer is favored until ~82 °C; beyond this point the tetramer appears to dissociate into folded monomers. Further increases in temperature result in unfolding of the monomers by what appears as a two-state process.

Conclusions:

Despite the two-state behavior observed in the mass spectral data, CCS structures provide a clear indication that two-state behavior is a composite of many structures. CCS data show a minimum of two native states and four denatured states for CI2. The results for avidin show an example of multiple cooperative transitions hidden within a complex dissociation and unfolding transition – the tetramer first dissociated, followed by monomer unfolding.

Novel Aspect:

Multiple structures are involved in a protein typically thought to unfold via a two-state transition.

Leibniz Universität Hannover, Institute of Electrical Engineering and Measurement Technology, Sensors and Measurement Technology, Hannover (1)

Keywords: ultra-high resolution drift tube ion mobility spectrometry, isotopes, isotopologues, collision cross section, atmospheric pressure ionization

Introduction:

In drift tube ion mobility spectrometry (IMS), ions are driven through a drift tube by a homogenous electric field and collide with neutral drift gas molecules. The separation mainly depends on the ion-molecule collision cross section (CCS). Therefore, in more and more applications IMS are used for pre-separation of isomers that cannot be distinguished by their mass-to-charge ratio (m/z) in mass spectrometers (MS). One major benefit of IMS is the fast separation within a few milliseconds revealing the CCS.

Methods:

The ultra-high resolution drift tube IMS used in this work has a resolving power of $R_p=250$, which is defined as the full width at half maximum (FWHM) divided by the drifttime. To achieve such high resolving power in IMS a drift voltage of 25 kV is used. Nevertheless, the length of the drift tube is just 15 cm. For ionization, atmospheric pressure chemical ionization with a miniature soft X-ray source is used as well as atmospheric pressure photo ionization (APPI) with 10.6 eV.

Results:

In previous work, we demonstrated the separation of several isotopologues with the instrument used. [1] Here, isotopes with small differences in CCS are separated. The percentage difference in CCS is defined as the difference of the CCS divided by the average CCS and multiplied by one hundred. Calculating the percentage difference that can be resolved with $R_p=250$ yields a minimum percentage difference in CCS of 0.8%. [2] For example, the isomers 2-picoline and 3-picoline are clearly separated using an APCI ionization source. Whereas these substances can hardly be resolved with GC-MS. [3]

Conclusions:

The separation of isomeric compounds is of major interest, especially in pharmaceutical science. With ultra-high resolution drift tube IMS and IMS-MS small percentage differences in CCS can be resolved.

Novel Aspect:

Separation of isotopes with differences of only 0.8% in CCS using ultra-high-resolution DT-IMS.

174 - ION MOBILITY-DERIVED COLLISION CROSS SECTION FOR MYCOTOXINS: AN INTERLABORATORY STUDY.

Laura Righetti (1) - Lee Gethings (2) - Sara Stead (3) - Chiara Dall'Asta (1)

University of Parma, Department of Food and Drug, Parma (1) - Waters Corporation, Wilmslow, Wilmslow (2) - Waters Corporation, Wilmslow, Manchester (3)

Ion Mobility-Derived Collision Cross Section for Mycotoxins: an interlaboratory study.

Laura Righetti¹, Lee Gethings², Sara Stead² & Chiara Dall'Asta¹

¹Department of Food and Drug, University of Parma, Parco Area delle Scienze 95/A-43124 Parma (Italy)

²Waters Corporation, Altrincham Road, UK-SK9 4AX Wilmslow, United Kingdom.

Keywords: Travelling wave ion mobility spectrometry; CCS database; Interlaboratory comparison; Mycotoxins.

Introduction:

Ion mobility mass spectrometry (IM-MS) is spreading rapidly as a promising technique for simultaneous screening, quantification and identification of a large number of food contaminants. Collision cross section (CCS) measurements resulting from ion IM-MS experiments provide a promising orthogonal dimension of structural information in MS based analytical separations. As with any molecular identifier, interlaboratory standardization must precede broad range integration into analytical workflows [1].

Methods:

More than 60 mycotoxins were analyzed both in standard solution and in matrix to demonstrate the reproducibility of this new molecular identifier. The reproducibility of CCS values was evaluated across two traveling wave ion mobility mass spectrometers (Synapt G2 HDMS and Vion IMS QTOF) located in different laboratories.

Results:

A database containing TWIMS-derived CCS values of parent and modified mycotoxins is hereby presented. CCS measurements showed high intra- and inter-day repeatability (RSD <1.8%), they were not affected by the complexity of the investigated matrices (i.e. malt, corn flakes, maize feed, wheat) ($\Delta\text{CCS} \leq 2\%$) and they resulted independent from the concentration [2]. In addition, they were not influenced by instrument settings. CCS values derived from Synapt G2 HDMS and Vion IMS QTOF mass spectrometers were highly reproducible with interlaboratory RSD <5%. Furthermore, the novel geometry of the Vion system allows to elucidate fragmentation that might occur for labile mycotoxins during different stages of the ESI-TWIMS QTOF analysis. Indeed, it is possible to state if dissociation occurs before (fragments would present shorter drift times than precursor ion) or after the TWIMS cell (drift time of the fragment ions would match that of the precursor ion). This is useful to understand which parameter has to be properly set to avoid/promote analyte fragmentation.

Conclusions:

Overall, our study demonstrates the reproducibility of CCS across different instrumentations and analytical conditions. The addition of CCS in the mycotoxins screening workflows improves the accuracy and precision of analysis and would provide a higher degree of confidence in the identification workflow compared to traditional analytical approaches. Thus, many false-positive detections could be avoided by applying a maximum ΔCCS tolerance of 2%.

Novel Aspect:

The low RSD observed in this interlaboratory study illustrate the potential of CCS as a molecular identifier that can be used alongside the traditional molecular identifiers.

370 - DECONVOLUTION OF DIRECT INFUSION TIMS-MS ANALYSES

Peter Sander (1) - Sven Meyer (1)

Bruker Daltonics, R&D, Bremen (1)

Keywords: Trapped Ion Mobility Spectrometry; deconvolution; isobaric compounds; CCS determination

Introduction:

The combination of ion mobility separation with mass spectrometry offers increased capabilities for determining the structure of molecules. In these scenarios, ion mobility initially delivers a separation based on molecule sizes. Yet, often even simple molecules or molecule mixtures show ambiguous mobilities which cannot easily be resolved further, e.g., by chromatography.

An algorithm has been developed to deconvolute these overlapping signals in the mobility vs. m/z domain of a direct infusion experiment. The result are compounds comprising each of a clean mass spectrum and a mobilogram. Optionally, a fragment mass spectrum is extracted.

Methods:

A mixture of isobaric lipids has been analyzed using direct infusion trapped ion mobility spectrometry (TIMS) coupled with an orthogonal time-of-flight mass spectrometer.

The algorithm developed here is evaluating such analyses. It is a further development of an algorithm initially developed for deconvolution of compounds of a chromatographically separated LC/MS analysis. [1]

The basic idea of this algorithm is the comparison of all extracted ion mobilograms to detect and deconvolute compounds. The key to success is the usage of fuzzy logic for the decision if any of two ions belong to the same compound or to different, partly overlapping compounds. Each compound is then associated with a clean compound mass spectrum, deconvoluted by any overlapping compounds and background subtracted. In extension to that fragment spectra at the same mobility are also associated to that compound.

Finally, the collision cross section of each compound is determined from the m/z ratio of the most intense ion and its charge state.

Results:

The mobility- m/z heatmap of a measurement of a mix of lipids reveals several partly overlapping signals. The direct infusion analysis was acquired over one minute and was performed on the Bruker timsTOF Pro instrument.

Applying the algorithm delivers compounds, each of a clean mass spectrum and a mobilogram. Signals are clearly separated and contain no signals from overlapping compounds or any background signals. Since charge state and molecular weight are also determined, collision cross section (CCS) values are calculated as well and the mobilograms can be directly depicted on a CCS scale.

Summarizing the results shows that also isomeric lipids were separated, each measured with a distinct CCS value.

Conclusions:

Ion mobility separation has already proved to be a valuable combination with mass spectrometry. In the task of structure elucidation however, even simple mixtures of isobaric compounds can show complex and ambiguous signals in a direct infusion experiment. This algorithm (DissectTIMS) deconvolutes these signals into compounds, each of a clean mass spectrum, a mobilogram and a CCS value.

Novel Aspect:

Deconvolution of overlapping signals in a direct infusion TIMS-MS experiment delivering clean mass spectra, mobilograms and CCS values.

366 - ION MOBILITY MASS SPECTROMETRY FOR PROFILING AND STRUCTURAL CHARACTERIZATION OF HUMAN HIPPOCAMPUS GANGLIOSIDES

Mirela Sarbu (1) - Željka Vukelić (2) - David Clemmer (3) - Alina Diana Zamfir (1)

National Institute for Research and Development in Electrochemistry and Condensed Matter, Timisoara, Romania, Department of Condensed Matter, Timisoara (1) - University of Zagreb Medical School, Department of Chemistry and Biochemistry, Zagreb (2) - Indiana University, Department of Chemistry, Bloomington (3)

Keywords: ion mobility separation mass spectrometry; gangliosides; human fetal hippocampus; collision-induced dissociation; cholinergic activity.

Introduction:

The structural analysis of gangliosides (GGs), a particular class of glycosphingolipids highly expressed in central nervous system, experienced a new level due to the rapid advances in ion mobility separation mass spectrometry (IMS MS) [1]. In view of the direct correlation of GGs with neurogenesis and synaptogenesis, in this work we have implemented IMS MSn for the first time in the study of a highly complex native mixture originating from human fetal hippocampus [2].

Methods:

The GG mixture was purified from a 17-th gestational week fetal hippocampus (FH17) using the method of Svennerholm and Fredman and modified by Vukelić et al [4]. The sample dissolved in methanol to 5 pmol/ μ L concentration was infused at 2 μ L/min flow rate and 2 kV ESI voltage into the Synapt G2s. To enhance the separation IMS wave velocity was set at 650 m/s, IMS wave height at 40 V and IMS gas flow at 90 L/min. CID was performed in the transfer cell, using energies between 10-45 eV.

Results:

The ionization and detection of low abundant species was possible due to IMS that allowed the differentiation of GGs based on the carbohydrate chain length and degree of sialylation. These findings provided a more reliable insight into the expression of polysialylated structures, which might constitute markers of brain development. By IMS MS, after six minutes of signal acquisition, no less than 134 distinct GGs were identified, a number nine times higher than the number of GGs previously reported in FH following chip nanoESI QTOF MS analysis without prior separation (only 14 structures) [3]. Moreover, IMS MS evidenced no less than 54 different species modified by either carbohydrate or non-carbohydrate type of attachments. Of these, 25 ions correspond to GG structures modified by CH₃COO⁻ attachment, novel species never reported before. CID MSn experiments conducted after mobility separation provided a detailed structural characterization of CH₃COO⁻ GT1b(d18:1/18:0), a biologically relevant compound.

Conclusions

The screening of FH17 by IMS MS provided data related to the expression and role of GGs in fetal hippocampus, with a particular emphasis on their cholinergic activity by the discovery for the first time of novel species modified by CH₃COO⁻ attachment. In view of the present findings, we may conclude that IMS MS and CID MSn proved their high efficiency for unequivocal detection and characterization of these low abundant species, with a significant biological role.

Novel Aspect:

First implementation of IMS MS for GG determination in FH and discovery of CH₃COO⁻ modified species, correlated with the cholinergic activity of GGs in central nervous system.

478 - FAIMS-MS-IR SPECTROSCOPY WORKFLOW: A MULTIDIMENSIONAL PLATFORM FOR THE ANALYSIS OF MOLECULAR ISOFORMS

Baptiste Schindler (1) - Isabelle Compagnon (1) - Franck Lépine (1)

Institut Lumière Matière, Université de Lyon, Lyon (1)

Keywords: FAIMS, IRMPD spectroscopy, isomers, hyphenated techniques, multidimensional analysis

Introduction:

The analysis of isoforms is challenging by mass spectrometry and ion mobility spectrometry is gaining momentum for this purpose. However IMS technologies suffer from the absence of detailed structural information. On the other hand, IRMPD spectroscopy (Infrared Multiple Photon Dissociation) is able to resolve subtle isomerisms on pure sample. We propose to combine FAIMS separation, mass spectrometry and IRMPD spectroscopy for multidimensional analysis.[1]

Methods:

This new instrument consists of an ultraFAIMS (Owlstone) device interfaced to a linear ion trap (LTQ XL Thermo Scientific) which was modified for IRMPD spectroscopy. The combination of FAIMS separation, mass spectrometry and infrared spectroscopy in a single instrument allows various possibilities of multidimensional analysis, especially for mixture of isomers.

Results:

For a given mass-selected ion, two different modes using FAIMS separation and IRMPD spectroscopy are enabled to characterize the composition of a mixture of isomers. They are demonstrated on an isomeric mixture of paracetamol and 2-phenylglycine. In the first mode, a FAIMS (high-Field Asymmetric waveform Ion Mobility Spectrometry) separation of the isomers is performed with a static compensation field for mass- and isomer-selective ion spectroscopy. In the second mode, the compensation field is scanned while the ions are irradiated at a fixed wavenumber allowing selective photofragmentation of a chosen species.

The FAIMS-MS-IR workflow allows separation and identification of mixtures of isomers using an appropriate database of IRMPD spectra and without the use of standards for calibration purpose. Alternatively for such isomeric mixture, IRMPD spectroscopy alone yields a convoluted spectrum. By adding a FAIMS dimension, it is possible to retrieve individual spectroscopic signature for each isomer present in the mixture.

Conclusions:

This configuration of IMS-MS-IR workflow constitutes an attractive alternative to more elaborate approaches for ion spectroscopy of mass-selected and isomer-selected ions. In the field of analytical chemistry, we hope that this type of multidimensional analysis will be a valuable tool for a broad range of biological/medical/pharmaceutical applications where the identification of isoforms is critical.

Novel Aspect:

A new multidimensional analysis workflow combining FAIMS separation and IRMPD spectroscopy for analytical purpose or structural analysis.

1079 - PROTEIN ANALYSIS USING ION MOBILITY MS AND IN-SOURCE ION ACTIVATION COMBINED WITH ECD ION FRAGMENTATION

Ruwan Kurulugama (1) - Valery Voinov (2) - Kenneth Newton (1) - Christian Klein (1) - Nathan Lopez (3) - George Stafford (1) - Joe Beckman (2) - John Fjeldsted (1)

Agilent Technologies, R&D, Santa Clara, CA (1) - e-MSion Inc., R&D, Corvallis, OR (2) - e-MSion Inc., Manufacturing, Corvallis, OR (3)

Keywords: In-source, Protein, Activation, Mobility, ECD

Introduction:

Tandem mass spectrometry is accepted as a powerful analytical technique and when used with electron capture dissociation (ECD) makes it well suited for protein identification. In-source ion activation can be used to facilitate collision induced unfolding (CIU) of proteins and when coupled to IM-MS offers information about ion energetics and structures [1]. Combining the above technologies may provide top-down protein analysis with improved sequence coverage.

Methods:

An Agilent 6560 IMQTOF instrument was modified to include ion optic elements at the exit of the ion transfer capillary to improve in-source ion activation prior to ion mobility analysis. The instrument was also equipped with a prototype e-MSion ECD cell mounted at the exit of the quadrupole mass filter. Proteins were prepared under native and denatured conditions and data were analyzed using IM-MS browser, CIU suite programs, ProSight, and LcMSspectator.

Results:

Native ESI conditions for carbonic anhydrase and BSA show low charge state precursor ions ranging from +8 to +11 and +15 to +19 respectively. These native low charge state ions have folded compact structures shown by their measured small CCS values, but they can be unfolded by using in-source ion activation. These proteins under denatured ESI conditions provide higher precursor ion charge states, +12 to +38 and +22 to +58 respectively, with correspondingly elongated ion structures and larger measured CCS values. The ECD cell provided nearly complete sequence coverage of denatured proteins as large as carbonic anhydrase with preservation of post-translational modifications. Sequence coverage results will be presented for the above proteins under native and denatured ionization conditions, coupled with CIU to facilitate more extensive fragmentation, and combined with ECD technology. Experimental data from larger proteins like monoclonal antibodies will also be analyzed and presented.

Conclusions:

Electron based ion fragmentation methods, such as ECD, produce extensive ion fragmentation for readily exposed regions of proteins. The fragmentation efficiency for a protein can be enhanced by either using denatured proteins or by unfolding native proteins in gas phase prior to ECD fragmentation. This study focuses on the use of CIU to improve ECD fragmentation efficiency and relates the degree of unfolding and ECD efficiency to protein structure in the gas phase.

Novel Aspect:

In-source ion activation coupled with IM-MS and ECD ion fragmentation for greatly improved sequence coverage and native protein structural analyses.

Andreas Thomas (1) - Mario Thevis (1)

German Sport University Cologne, Biochemistry, Cologne (1)

Keywords: Ion mobility, high resolution MS, insulin, dried blood spots

Introduction:

Analyzing peptides such as insulin from dried blood spots DBS represents an urgent task in various fields of analytical chemistry (e.g. doping controls, forensic- or clinical chemistry) due to simplified sampling, transfer and storage. Coupling liquid chromatography, ion mobility separation with high resolution mass spectrometry enables the sensitive detection of insulin and its synthetic analogues from DBS at physiologically relevant levels.

Methods:

The blood spots (20 μ L) were extracted from pretreated DMPK cards, immunopurified with magnetic beads and anti-insulin antibodies, separated by reversed-phase liquid chromatography (one-pump-trapping) and detected by high resolution mass spectrometry (time-of-flight) including an ion-mobility separation (T-wave IMS). The method was fully validated considering qualitative result interpretation.

Results:

The evaluation of the diagnostic ion traces were performed under consideration of the respective retention times, accurate masses and specific drift times for each of the target peptides. With this strategy, validation of the method yielded specific and sensitive (< 0.5 ng/mL) results for human insulin and all relevant synthetic analogues. Recoveries range at approximately 30 % with precise (CV<25%) and linear results within the working range of the method (0.5 to 10 ng/mL). The proof-of-principle was shown by further analyzing DBS samples from healthy volunteers at non-fasting level (endogenous insulin detected only) and one diabetic volunteer (Type I). Here the rapid acting synthetic insulin Novolog was clearly detected. Generally, in this study was shown that additional separation by ion mobility combined with the accurate mass enhances the results significantly.

Conclusions

Analyzing insulins from urine or blood samples represents an established approach in doping controls [1]. The present study described now a fit-for-purpose method to analyze insulin from DBS cards. The application of DBS sampling becomes more and more interesting in various analytical fields. Here, the combination of immunoextraction, chromatography and high resolution MS with ion mobility separation offers the required sensitivity (sub ng/mL level).

Novel Aspect:

To best of our knowledge the study shows the first assay to determine insulin and its analogues from dried blood spots in physiologically relevant levels with LC-MS.

Keywords:

IM, lipid, isomer, resolution, traveling-wave

Introduction: (400/400 characters)

Lipids represent a diverse group of biomolecules that have an essential role in structural, storage and signaling processes in living systems. Class separation is readily achieved using chromatographic and MS based identification techniques; however, the analysis remains challenging due to the chemical structure diversity and isobaric nature of lipids. The addition of ion mobility (IM) to lipidomic workflows enhances separation and improves isomer resolution.

Methods: (383/400 characters)

Data were collected on a hybrid quadrupole cyclic IM orthogonal acceleration time-of-flight (Q-cIM-oaToF) instrument. Ion mobility separation is achieved using a multi-pass travelling-wave cIM separator, where increasing the number of passes around the device allows of the increase in both mobility resolution and ion residence time. MS and CID fragmentation data were obtained on precursor IM separated lipids followed by ToF mass measurement.

Results: (845/900 characters)

Unsaturated free fatty acid (FA) standards, differing in chain length and number of cis/trans configurations, were chosen to determine the degree of IM separation required to separate lipid isomers. FAs represent the simplest class of lipid components, yet they exist in the structure of each lipid categories. In all direct infusion cIM-MS measurements, FAs with cis-double bond orientations, introduced as two component mixtures, were found to be more compact than those with trans-orientations. Moreover, the cis- and trans-orientations for the monounsaturated FAs were distinguishable. A different number of cycles through the cIM separator, thereby increasing the effective path length/resolution, were required to achieve a similar degree of IM separation for mono-unsaturated FAs of differing chain length. Unsaturated FAs with two or more double bonds, separated by two mid-chain carbons, could not be distinguished. The separation of other lipid classes by cIM is currently under study.

Conclusions (399/400 characters)

A Q-cIM-oaToF geometry has been characterized and successfully applied to the IM separation of isomeric, mono-unsaturated FAs. The required IM resolution was found to be a function of chain length. Shorter, structurally more rigid and compact FAs were discriminated at reduced resolution, as could longer chain mono-unsaturated FAs as a

result of partial chain back-folding. Following IM separation, isomeric lipids were successfully CID fragmented and identified.

Novel Aspect: (108/150 characters)

High resolution ion mobility separation of cis/trans lipid isomers using a using a multi-pass travelling-wave cIM separator.

Keywords: [Proteomics, FAIMS, Ion Mobility, Quantitation, and FTMS]

Introduction:

Limitations in separation peak capacity and dynamic range restrict identifications in single shot proteomics experiments to ~ 5,000 protein groups. Pre-fractionation can skirt these issues; however, it comes at the cost of increased labor and number of samples for MS. Here we demonstrate that High Field Asymmetric Waveform Ion Mobility Spectrometry (FAIMS) coupled with an Orbitrap MS can allow near whole proteome sequencing without the need for pre-fractionation.

Methods:

Proteins were extracted from a human cells (K562) and digested with trypsin. Peptides were loaded onto a nanoflow capillary column (30cm 1.7um BEH C18), ionized, and further separated with a cylindrical electrode FAIMS device prior to injection into an Orbitrap Lumos. The FAIMS system operated with a 3MHz bi-sinusoidal waveform (5000V peak to peak), electrode temperature of 100C, and CVs between -35 and -110V dc. Protein identifications were filtered to 1% FDR.

Results:

We describe a compact, cylindrical, helium free, rapid CV stepping, FAIMS source that easily interfaces between the ES emitter and the MS inlet. This device induces an aerodynamic Coanda effect that entrains and diverts ions away from the inner electrode surface, yielding a high ion transmission efficiency (>50%). 20 ms transit times were obtained by minimizing the ion separation gap and electrode length (2.5mm to 1.5mm and 24mm to 15mm, respectively).

Performance test for single 90 minute analyses with and without FAIMS yielded 6,312 and 5,267 proteins, respectively. Triplicate FAIMS analysis of the same sample with 3 separate CV values (-40V, -60V, -80V) yielded 87,527 unique peptides and 7,427 proteins. To obtain similar performance without FAIMS offline high pH reversed phase chromatography (3 fractions total) had to be performed (95,745 unique peptides and 7,433 proteins). We conclude that FAIMS can accomplish gas-phase separations that offer comparable proteomic depth to conventional two-dimensional approaches.

Conclusions

Beyond these results we present a detailed characterization the z , m/z , mass and sample purity dependence of FAIMS. We compare quantitative (LFQ) reproducibility and identification overlap with and without FAIMS. Lastly we explore the possibility of analyzing with human proteome in a single-shot analysis where we identified 8,023 proteins with intra-analysis CV switching across 4 CVs (-45V, -60V, -75V, and -90V) during a single 5 hour experiment.

Novel Aspect:

A novel FAIMS device enabling gas-phase fractionation as a viable alternative for rapid and deep proteomic analysis.

Keywords: High resolution ion mobility, SLIM, peptides

Introduction: Probing Peptide Conformational Rearrangements with High Resolution SLIM Traveling Wave Ion Mobility-MS.

Multiply charged peptide ions in the gas phase can adopt distinct conformations, trapped in local energy minima [1]. The relative stability of these conformations provides insight into the types of secondary structures adopted by peptide ions and the mechanisms of their conformational rearrangements, such as proline cis/trans isomerization and intramolecular proton transfer. High resolution ion mobility (IM) separations are useful for probing peptide gas phase secondary structures, as they can potentially resolve multiple kinetically trapped conformers of peptides with low activation barriers for rearrangement. In this study we have employed high resolution SLIM traveling wave (TW) IM separations to study kinetically trapped peptide conformations. We investigated the impact of various IM parameters on peptide structural rearrangements during storage and separations in a SLIM IM-MS platform

Methods: Probing Peptide Conformational Rearrangements with High Resolution SLIM Traveling Wave Ion Mobility-MS.

Preliminary experiments were performed using 1 meter and 13 meter Serpentine Ultra-long Path with Extended Routing (SUPER) SLIM platforms [2,3]. The SLIM utilized 6-5 (6 RF strips interspersed with 5 TW segmented arrays) or similar 4-3 electrode arrangements. Samples were introduced via a nano-electrospray ion source and trapped in the funnel trap (IFT) prior to introduction to the SLIM IM module. Afterwards ions were refocused in the rear ion funnel and passed through a segmented quadrupole to the Agilent TOF instrument. IM separations in Nitrogen and Helium were performed in the 2.5 to 4 Torr pressure range. Simion simulations of ion trajectories through a SLIM IM module were performed with Statistical Diffusion Simulation (SDS) Model.

Results: Probing Peptide Conformational Rearrangements with High Resolution SLIM Traveling Wave Ion Mobility-MS.

We tracked the evolution of the kinetically trapped conformations of Substance P (M+3H)³⁺ [1] and other peptide standards as a function of IM parameters, such as the TW electric field as well as source conditions, such as RF ion funnel amplitudes. We estimated the extent of collisional heating in the SLIM platform by monitoring ion losses and fragmentation during storage and separation of selected peptide standards. Velocity distributions of peptides during SLIM IM separations have been modeled with Simion simulations. In preliminary experiments we successfully detected multiple kinetically trapped conformations of multiply charged peptide standards, including Substance P (M+3H)³⁺, Bradykinin (M+3H)³⁺ and Melittin (M+5H)⁵⁺, using both 1 meter and longer path SLIM separations. Impact of average electric field and guard bias voltage on modelled velocity distributions of Substance P (M+3H)³⁺ correlates with the distribution of the peptide conformations in local and global energy minima in the IM experiments. Collisional cross sections of the peptides under a select range of IM parameters are in close agreement with the values experimentally determined in drift tube ion mobility [4]. We detected no ion losses for Leucine Enkephalin with over 100 meter SLIM separations as well as during storage in the SLIM platform. In future experiments we plan to use different peptide ions as well as peptide noncovalent complexes to investigate separations and possible ion activation with the use of on SLIM trapping and in other novel SLIM modules. We will

compare IM experiments with molecular modeling to probe the mechanisms of peptide rearrangement during IM separations.

Conclusions: Probing Peptide Conformational Rearrangements with High Resolution SLIM Traveling Wave Ion Mobility-MS.

SLIM TW IM enables high resolution separations of kinetically trapped conformations whose cross sections are in close agreement with the values determined by drift tube ion mobility. It also enables separation and storage of peptides with minimized dissociation. Collisional heating the SLIM platform can be controlled using certain SLIM IM parameters, enabling studies of peptide structural dynamics and the relative stability of secondary structures during IM separations.

Novel Aspect: Probing Peptide Conformational Rearrangements with High Resolution SLIM Traveling Wave Ion Mobility-MS.

High resolution SLIM TW IM separations of kinetically trapped peptide conformations and the characterization of collisional heating during storage and separation in SLIM.

378 - DIFFERENTIATION OF PANAX GINSENG, PANAX QUINQUEFOLIUS, AND GINSENG PRODUCTS BY USING DIFFERENTIAL ION MOBILITY SPECTROMETRY COUPLED WITH TANDEM MASS SPECTROMETRY

Ri WU (1) - Tak Wah Dominic Chan (2)

Faculty of Science, The Chinese University of Hong Kong, Department of Chemistry, N. T. (1) - Faculty of Science, The Chinese University of Hong Kong, Department of Chemistry, N.T. (2)

Differentiation of Panax ginseng, Panax quinquefolius, and Ginseng Products by Using Differential Ion Mobility Spectrometry Coupled with Tandem Mass Spectrometry

Keywords: Differential Ion Mobility Spectrometry, Tandem Mass Spectrometry, Ginseng, Collision-Induced Dissociation, Electron-Induced Dissociation

Introduction:

Ginseng are highly treasured medicinal herb in traditional Chinese medicines. However, authentication of the origins of the ginseng products is not an easy task [1]. An DMS-MS/MS based method is established for the differentiation of Panax ginseng (Oriental ginseng) and Panax quinquefolius (American ginseng).

Methods:

This method is based on the separation of ginsenosides present in the ginseng extracts using Differential Ion Mobility Spectrometry (DMS), followed by data dependent acquisition with Tandem Mass Spectrometry. Collision-induced dissociation (CID) and electron-induced dissociation (EID) were applied to generate diagnostic fragment ions for the differentiation of structural isomers [2, 3].

Results:

The presence of ginsenoside Rf and pseudoginsenoside F11 in the Oriental and American ginsengs was selected as the criteria of differentiation. A good separation of isomeric ginsenosides was achieved in the Differential Ion Mobility Spectrometry using aliphatic alcohols as polar gas-phase modifiers. Data Dependent Acquisition results of DMS coupled with Collision-Induced Dissociation Mass Spectrometry was highly efficient compared with LC-MS/MS. Continuous ion separation in DMS chamber enabled the utilization of other dissociation methods that required longer acquisition time, such as EID. In comparison with collision-induced dissociation (CID), EID provides more structural informative ions and eliminates glycosyl group migration of Rg1 and Rf.

Conclusions:

The spatial separation of isomeric ginsenosides in DMS and the generation of structural diagnostic ions for isomer differentiation by EID could eliminate ambiguities in differentiating ginseng and ginseng products. This study demonstrates a fast and effective method for differentiation of Oriental ginseng and American ginseng; and for characterization of commercial ginseng products.

Novel Aspect:

High performance DMS-MS/MS method for differentiation and characterization of ginseng and ginseng products.

995 - ULTRA-HIGH THROUGHPUT SCREENING FOR ENGINEERED SYNTHETIC BIOLOGY LIBRARIES BASED ON SAMPLE CHIPS COMBINED WITH DESI MSIMAGING

Cunyu Yan (1) - Eva Garcia-Ruiz (1) - Mark Dunston (1) - Emrys Jones (2) - Aurore Lejeune-Dodge (3) - Emily Kempa (1) - Yizhi Cai (4) - Sabine Flitsch (4) - Perdita Barran (4)

Manchester Institute of Biotechnology, University of Manchester, Manchester (1) - Waters Corp., Waters, Wilmslow (2) - Labcyte Europe, Labcyte Europe, Staffordshire (3) - Manchester Institute of Manchester, University of Manchester, Manchester (4)

Keywords: DESI, mass spectrometry, ion mobility, high throughput, synthetic biology

Introduction:

The screening of variant libraries is an important yet costly and time consuming step in full Design-Build-Test-Learn pipelines [1] central to many current synthetic biology strategies. By employing liquid handling robotic platforms for automated sample-chip preparation, our new HTP strategy can generate visualized imaging data on the scale of 12 sample/min with only nL quantities needed for each sample.

Methods:

MS imaging was performed by using a DESI 2D Omni Spray Ion Source combined with SynaptG2 Si HDMS mass spectrometer [2]. Sample chips were prepared using an Echo 550 liquid handling robotics system and cell strain supernatants transferred onto glass slides covered with a nylon membrane. The maximum capacity of each sample chip was 1536 samples/plate. The DESI imaging pixel size was set as 100µm X 100µm, with a scan rate of 15ms/spectrum. The acquired data were processed with HD imaging software.

Results:

(i) Ambient and direct sampling conditions dramatically reduce liquid handling of samples; (ii) target compound titer measurements are label-free, and can thus be applied to different production pathways for the screening of intermediates and final products from synthetic biological libraries; (iii) the robotic sample chip preparation and low volumes required allow time course tracking and real time monitoring; (iv) the HTP sensitivity can reach µM level (e.g. in the case of pinocembrin flavonoid screening), which is far lower than the normal titres, and demonstrates the potential to apply this approach to other engineered pathways; (v) higher sensitivity is available when triple quadrupole mass spectrometry is applied; (vi) visualized MS imaging measurement provides highly accessible data for upstream Learning and subsequent re-Design-Build.

Conclusions

Our super-high throughput strategy, based on large capacity sample chips combined with MS imaging technology, makes medium and large scale directed evolution synthetic biology library screening possible over reasonable time scales. The superfast measurement data generated can provide sufficient data to allow the application of machine learning to model and debug malfunctioning synthetic biology pathways.

Novel Aspect:

The super-high throughput MS screening method combines the automated production of sample chips and MS imaging that presents a powerful new capability for the screening of large synthetic biology libraries.

328 - STRUCTURAL INSIGHTS INTO POTENTIALLY TOXIC CONFORMATIONS OF B-AMYLOID (1-42) OLIGOMERS

Rene Zangl (1) - Janosch Martin (1) - Tobias Lieblein (1) - Nina Morgner (1)

Goethe University, Institute of Physical and Theoretical Chemistry, Frankfurt (1)

Keywords: Alzheimer's disease, Beta-Amyloid (1-42), Native-MS, LILBID-MS, ESI-IM-MS

Introduction:

β -Amyloid (1-42) (A β 42), the protein involved in Alzheimer's disease (AD) has been demonstrated to generate β -sheet forming oligomers leading to fibrils and plaques. Whereas fibrils have long been suspected to cause neurodegenerative disorders, recent studies suggest misfolded oligomers as the origin of neurotoxic effects in AD. Hence the early oligomerization stage stands in focus of inhibitor development to suppress the formation of toxic oligomers.[1]

Methods:

Additionally to laser induced liquid bead ion desorption mass spectrometry (LILBID-MS), which gives an insight in the early aggregation kinetics of A β 42 in absence and in presence of aggregation inhibitors, electrospray ionization mass spectrometry coupled with ion mobility (ESI-IM-MS) is used to reveal the inhibitor's structural influences on A β 42.[2]

Results:

Whereas LILBID-MS allows to observe the aggregation kinetics and demonstrates the effect of well-known and novel aggregation inhibitors at the oligomeric level ESI-IM-MS provides a detailed look on several inhibitor binding events. Distinct m/z signals reveal the presence of several gas-phase conformations in their arrival time distribution (ATD) of the same oligomer order. Due to inhibitor interactions, the corresponding inhibitor bound states differ in their collision cross sections (Ω), as well in their gas-phase stabilities. Those indicate structural rearrangements which thereby affect distinct aggregation pathways differing in their kinetic behavior.

Conclusions

The investigation of inhibitors by ESI-IM-MS provides an insight into binding behavior of A β 42 at the oligomeric level. A closer look at inhibitor bound states reveals differences due to conformational changes which potentially lead to non-toxic oligomeric states. Estimating aggregation kinetics of A β 42 in absence and in presence of inhibitors by LILBID-MS additionally to the findings by ESI-IM-MS reveals the structural influence on the aggregation behavior.

Novel Aspect:

The combination of LILBID and ESI-IM-MS provides promising results in understanding the aggregation of self-assembling peptides and their prevention by inhibitors.

802 - DETAILED LOOK IN SARA FRACTIONATION: SATURATES, NOT ONLY SATURATED COMPOUNDS!

Zahra Farmani (1) - Wolfgang Schrader (2)

Mass Spectrometry dept., Max-Planck-Institut für Kohlenforschung, Mülheim a.d. Ruhr (1) - Mass Spectrometry dept., Max-Planck-Institut für Kohlenforschung, Mülheim (2)

Keywords: SARA, Saturates, HRMS, direct analysis

Introduction: (348 characters without spaces)

Saturates, Aromatic, Resins and Asphaltenes (SARA) fractionation is a decade old fractionation method of crude oils. Saturates, referring to their chemically descriptive name, are known to contain only aliphatic compounds. To date, there are very few saturates centered studies of which all were performed using GC techniques. Therefore, their direct MS analysis were neglected and never studied in detail.

Methods: (347 characters without spaces)

SARA fractionation was performed on different crude oils using a modified IP-143 method.[1] Saturates were dissolved in Toluene: Methanol (1:1) to the final concentration of 250 ppm. Results of the direct injection HRMS analysis by ESI-(+)-FTMS for all of the samples were compared. In order to get further comparable information, all of the samples were further analyzed using HRGC-EI-MS on a GC-Orbitrap MS.

Results: (772 characters without spaces)

Direct injection HRMS was successfully performed for all of the samples. Comparison of direct injection analysis shows that saturates of different oils, poses different chemical characteristics including their heteroatom containing classes and the length of their aliphatic chains. Results of the HRMS analyses are contradicting the common knowledge about the characteristics of saturates. In this regards, the compounds found in this fraction do not necessarily only contain aliphatic chains and saturated rings, but also many olefinic chains and unsaturated rings. More than 15000 different elemental compositions could be calculated from the data, showing a much wider variety of compounds than expected from a saturate fraction. The GC-MS measurement results show presence of volatile and aliphatic compounds that are obviously only a part of the saturates fraction, which are detectable using GC technique.

Conclusions (290 characters without spaces)

Results of the HRMS analysis prove that the characteristics of saturates fraction differ from the contemporary knowledge consisting of only aliphatic compounds. This is because SARA fractionation is solubility, polarity and adsorption based separation method which cannot give a clear separation and results overlaps between fractions.

Novel Aspect: (138 characters without spaces)

Saturates fraction contains not only GC detectable aliphatic compounds, but many olefinic and aromatic compounds which can be analyzed by direct injection HRMS.

490 - DIRECT INLET PROBE - HIGH RESOLUTION TIME-OF-FLIGHT MASS SPECTROMETRY FOR THE DESCRIPTION OF HIGH BOILING PETROLEUM FRACTIONS

Uwe Käfer (1) - Mohammad Saraji (2) - Jürgen Wendt (3) - Thomas Wilharm (4) - Ralf Zimmermann (5) - Thomas Gröger (1)

Helmholtz Center Munich, CMA, Munich (1) - Photonion, R&D, Schwerin (2) - LECO Europe, European application center, Berlin (3) - ASG, Analytik Service Gesellschaft, Neusäss (4) - University of Rostock, Department for analytical chemistry, Rostock (5)

Keywords: Bitumen, crude oil, direct inlet probe, high resolution mass spectrometry, ionization

Introduction:

High boiling petroleum fractions remain challenging to analyze on a molecular level due to their complexity and physical properties, which make them unsuitable for chromatographic techniques. Therefore, High resolution mass spectrometry has become a key technique for the analysis of these complex materials.

In this study, we used a direct inlet probe (DIP) coupled to High resolution time of flight mass spectrometry for detailed chemical characterization.

Methods:

Crude oil vacuum residues and bitumen were analyzed with a multi-reflection-tof mass spectrometer (LECO Pegasus HRT) equipped with a direct inlet probe. To volatilize the sample components, a temperature gradient from 50°C to 400°C was applied. Beside electron impact ionization (EI), two soft ionization techniques, namely single photon ionization (SPI) and chemical ionization (CI) were utilized on the same system.

Results:

DIP-HRMS allowed the introduction of petroleum residue samples directly into the ion source, where the temperature was linearly increased via a temperature program. Substances could be separated according to volatility and classified into chemical groups by high resolution mass spectrometry. The decreased pressure in the ion source reduces the effective boiling point, which enabled the destruction-free vaporization of high boiling substances. With the time resolved high resolution mass spectra, elemental compositions could be assigned, and homologues series of typical petro-chemical compound classes could be identified. Moreover, several bitumen samples of different origin and varying physical properties could be discriminated on a molecular level. Preliminary results showed that CI and SPI can be advantageous as complementary ionization techniques to EI because of a reduced fragmentation tendency and different selectivities.

Conclusions:

Summarized, DIP-HRMS showed to be a powerful technique for the detailed description of complex, high boiling matrices. The combination of thermal separation and exact mass information enabled identification of characteristic molecular structures. Moreover, it was possible to use the chemical fingerprint to discriminate between vacuum residues which were derived from different crude oils and refineries.

Novel Aspect:

We present a new approach for in-depth analysis of high boiling samples based on the combination of thermal analysis in vacuum and high resolution mass spectrometry

52 - EVALUATION OF DEGRADATION DEGREE OF LUBRICATING OIL BY THERMAL DESORPTION AND PYROLYSIS COMBINED WITH DART-MS (TDP/DART-MS)

CHIKAKO TAKEI (1) - YUKIKO OTAKE (1) - KENICHI YOSHIKAWA (1)

BioChromato, Application support, Fujisawa (1)

Keywords: Lubricating oils, evaluation of degradation degree, TDP/DART-MS

Introduction:(367 /400 characters)

Lubricating oils are composed of a base oil and various additives. Generally, since complicated pre-treatment is necessary prior to analysis, this extending the time and increases the effort required to obtain the final results. Thus, analysis without pre-treatment would be desirable for research and development. Therefore, the purpose of this work is to directly and rapidly evaluate the degradation degree of lubricating oil.

Methods: (397 /400 characters)

Automobile lubricating oil, virgin and after 1000 or 5000 km driving were used. Thermal desorption and pyrolysis(TDP) combined with DART-MS was composed of Q-TOF mass spec equipped with DART ion source and ionRocket TDP device. The samples were used to ~1uL and put into the sample pot. TDP temperature condition was room temperature to 600 °C, a rate of 100 °C/min. To structurally and compositionally characterize samples, Kendrick Mass Defect(KMD) analysis was used.

Results: (886 /900 characters)

The mass spectra were detected for the thermal desorption and pyrolysis products of all samples. In the mass spectra detected at 300 °C, additives such as a phenol-type antioxidant, an amine-type antioxidant, and a salicylic acid-type detergent dispersant were detected in all the samples. There was no significant difference in the ratio of additive compounds at 0 and after 1000 km of driving, but after 5000 km driving, the concentrations of the salicylic acid-type detergent and phenolic antioxidant were remarkably decreased. In the mass spectra recorded at 450 °C the base oil dominated the spectrum at 0 km, while after 1000 km of driving, glycol compounds were also detected, which increased in concentration after 5000 km of driving. Additionally, using KMD plots it differences among the samples were clearly observed. By setting the Kendrick Mass unit based on the mass of the repeating structure, compounds with common repeat units aligned in the horizontal direction on the KMD plot, whereas compounds with different structures shifted.

Conclusions: (288 /400 characters)

TDP/DART-MS enables the detection of additives and base oil in lubricating oils by gradient heating without pre-treatment and can used to evaluate the degradation extent of lubricating oils quickly and easily by monitoring the amount of antioxidants as a degradation marker. Moreover, a combination of TDP/DART-MS and KMD analyses enabled clear recognition of slightly differences in the base oils between the virgin and degraded samples. Thus, the method described herein can be used for the evaluation of the degree of degradation of lubricating oils.

Novel Aspect: (87 /150 characters)

A combination of TDP/DART-MS and KMD analysis is useful for evaluation of degradation degree of lubricating oils.

704 - EVIDENCE OF ISLAND AND ARCHIPELAGO STRUCTURES IN DISTILLABLE AND TRULY NON-DISTILLABLE FRACTIONS OF VACUUM RESIDUES

Diana Catalina Palacio Lozano (1) - Alexander Guzman Monsalve (2) - Enrique Mejía Ospino (3) - Mark P. Barrow (1)

University of Warwick, Chemistry, Coventry (1) - Ecopetrol, Instituto Colombiano del Petróleo, Piedecuesta (2) - Universidad Industrial de Santander, /Chemistry, Bucaramanga (3)

Keywords: island, asphaltenes, archipelago, non-distillable, vacuum residues, dissociation

Introduction:

Vacuum residues (VR) can be separated by molecular distillation into distillable fractions and a truly non-distillable fraction with boiling points above 687 °C. In this work, infrared multiphoton dissociation (IRMPD) was coupled to Fourier transform ion cyclotron mass spectrometry (FTICR MS) and used to determine the aromatic cores of compounds found within the vacuum residues, as a function of boiling point.

Methods:

Molecular distillate fractions from two VRs were analysed, with boiling points of: 540-603 °C, 603-645 °C, 645-687 °C and, finally, 687+°C (non-distillable), all in atmospheric equivalent temperature (AET). MS/MS spectra were acquired using atmospheric pressure photoionization (APPI) coupled to a 12 T Bruker solarix FTICR MS (Bruker Daltonik GmbH, Bremen, Germany) and IRMPD (25 W CO₂ laser).

Results:

Precursor ions were externally accumulated for a period of 0.5- 2 s prior to being transferred to the ion cyclotron resonance cell. It was found that the number of peaks per dalton detected increases exponentially as the boiling point of the fraction increases. A depletion of the relative intensity of polycyclic aromatic hydrocarbons and low heteroatomic-containing species was also observed as the boiling point increased, as expected using Boduszynski's model.[1]Species with up to four heteroatoms can be found in the non-distillable sample. The class distribution of the fragments indicates that up to two heteroatoms can be part of the aromatic core of the VR species, indicating that some heteroatoms can be present in the alkyl chains. MS/MS results also indicate that structural motifs comprise mainly island type structures for the distillable samples. In contrast, structures with two or more fused aromatic rings connected with alkyl chains (archipelago) are the main constituents of the non-distillable fractions of VRs.

Conclusions

Evidence of island and archipelago motifs were found in VR constituents. According with the number of double bond equivalents (DBE) of the fragments, structures of a vacuum residue can have aromatic cores with up to 8 fused benzene rings and up to two heteroatoms. Archipelago structures are concentrated at the heavy ends fractions of crude oils, in particular in the truly non-distillable fractions.

Novel Aspect:

Use of MS/MS to predict the size of the aromatic core and observation that distillable fractions contain mainly island structures.

1152 - THE COMPOSITIONAL AND STRUCTURAL CONTINUUM OF PETROLEUM REVEALED BY FT-ICR MASS SPECTROMETRY

Ryan P Rodgers (1) - Martha L. Chacón-Patiño (1) - Steven M. Rowland (1) - Sydney F. Niles (2) - Donald F. Smith (1) - Greg T. Blakney (1) - Yuri E. Corilo (1) - Amy M. McKenna (1) - Alan G. Marshall (1) - Christopher L. Hendrickson (1)

National High Magnetic Field Laboratory, Florida State University, Tallahassee, FL (1) - Department of Chemistry and Biochemistry, Florida State University, Tallahassee, FL (2)

Keywords: FT-ICR, Petroleum, Petroleomics, Asphaltene, Complex Mixture

Introduction:

Over the past 20 years, advances in modern ultra-high resolution mass spectrometry have forever changed the expectations of petroleum analyses. Facilitated by advances in ionization methods (that enable molecular-level analysis irrespective of initial or final boiling point), ultra-high resolution Fourier Transform Ion Cyclotron Resonance mass spectrometry (FT-ICR MS) routinely resolves and identifies tens-of-thousands of species in individual petroleum samples.

Methods:

Petroleum samples were analyzed by FT-ICR mass spectrometry (operating at 9.4 and 21T) by atmospheric pressure photo-ionization (APPI) and/or (+/-) electrospray ionization (ESI) at concentrations between 100 -300 µg/mL. Data was acquired and processed with Predator and Petro-Org software platforms.

Results:

High field FT-ICR MS has been used to revisit, and ultimately support a decades old theory of the composition of petroleum (the Boduszynski Continuum) and expose the compositional constraints (in class, type, and carbon number) imposed by boiling point. Such compositional information facilitates the accurate boiling point prediction of individual elemental compositions based on mass measurement alone, and is now poised to push forward to the molecular-level modeling of heavy ends (Petroleomics). The structural continuum is completed through the infrared multi-photon dissociation of mass isolated segments, and reveals both island (single aromatic core) and archipelago (multi-aromatic core) molecules. Thus, the current results strongly suggest that the decades-old Boduszynski model, which was largely ignored, is in fact correct, and the Yen-Mullins structural model, which is now largely accepted, is in fact, incorrect. Work supported by NSF Division of Materials Research through DMR-11-57490, State of Florida, Florida State University, and the Future Fuels Institute.

Conclusions:

The current clarity on the compositional and structural continua of petroleum is heavily dependent on chromatography. Thus, current and future prospects in the on-line and off-line analysis of petroleum samples will be discussed. Work supported by NSF Division of Materials Research through DMR-11-57490, State of Florida, Florida State University, and the Future Fuels Institute.

Novel Aspect:

Ultra-high resolution FT-ICR MS analysis of petroleum has revealed a compositional and structural continuum of species that changes predictably as a function of boiling point.

95 - CHARACTERIZATION OF ASPHALTENES PRECIPITATED AT DIFFERENT SOLVENT POWER CONDITIONS USING MAGNETIC RESONANCE MASS SPECTROMETRY (MRMS)

Matthias Witt (1) - Markus Godejohann (2) - Sven Oltmanns (3) - Estrella Rogel (4)

Bruker Daltonik GmbH, MRMS Solutions, Bremen (1) - Bruker BioSpin GmbH, Hyphenation AIC, Rheinstetten (2) - Bruker Optik GmbH, Applications, Bremen (3) - Chevron, Downstream Technology and Services Department, Downstream Technology and Services Department (4)

Characterization of asphaltenes precipitated at different solvent power conditions using Magnetic Resonance Mass Spectrometry (MRMS)

Keywords: Asphaltene, Petroleomics, Complex Mixture

Introduction:

Asphaltene precipitation is affected by factors such as heptane to crude oil ratio (HCOR). This means that for the same crude oil, a different set of molecules would precipitate forming a distinct asphaltene depending on these factors. It is expected that molecules more prone to precipitate are going to be those with the higher aromaticity, higher molecular weight and/or higher polar nature.¹⁻² Effect of solvent power on asphaltene properties HCOR is presented.

Methods:

Asphaltenes were separated from a medium crude oil (API of 30.4). Different HCOR were used to induce precipitation. Asphaltenes were analyzed by MRMS. Samples were analyzed using APPI and LDI in positive ion mode with resolving power of 1.300.000 at m/z 400. Analysis of data including calculation of molecular formulas and relative abundances of compound classes was performed using PetroOrg 10.0 (Florida State University).

Results:

Using LDI it was observed that HC classes as well as classes containing one heteroatom became less abundant as the heptane to crude oil ratio increases (decrease of solvent power). The opposite happened for most classes containing two or more heteroatoms. Similar results were found when positive APPI was used. Based on weighted relative abundances, DBE distributions for the samples were shifted to larger DBEs with higher solvent ratios (lower solvent power) using APPI. In contrast, molecular size distribution did not show a clear tendency. Calculations indicated that while differences in average DBE can be as large as 6 units between different HCOR, the maximum difference in molecular size is around 1.5 carbon atoms. These tendencies were also observed for individual classes for the class HC using LDI. The appearance of molecules with larger DBEs as the solvent power of the solvent decreases leads to an increase in the aromaticity. These results were in agreement with elemental analysis as well as IF-IR and ¹H-NMR results.

Conclusions:

Composition of the asphaltenes changes dramatically depending on the solvent power of HCOR. Decreases in solvent power produce asphaltenes that are more aromatic. Asphaltenes become enriched in molecules with larger DBEs and with more heteroatoms per molecule. No significant changes in molecular size were observed as a function of HCOR. FT-IR and ¹H-NMR measurements confirm the tendencies evaluated by MRMS.

Novel Aspect:

APPI and LDI MRMS can be used to study aromaticity and class distribution of precipitated asphaltenes at different solvent power.

956 - DETAILED MOLECULAR CHARACTERIZATION OF THE UPGRADING PROCESS OF PYROLYSIS OIL BY ULTRAHIGH RESOLUTION MASS SPECTROMETRY

Yun Xu (1) - Zhengwen Cao (2) - Ferdi Schüth (2) - Wolfgang Schrader (1)

Max-Planck Institut für Kohlenforschung, Mass Spectrometry, Mülheim an der Ruhr (1) - Max-Planck Institut für Kohlenforschung, Heterogeneous Catalysis, Mülheim an der Ruhr (2)

Keywords: Ultrahigh-resolution mass spectrometry, pyrolysis oil; biofuel upgrading

Introduction:

Pyrolysis oil from biomass is a potential alternative substitution for fossil fuel. A significant drawback of pyrolysis oil is that high acidity, instability and oxygen content limits its usage as transport fuel. Much work has been done to improve the quality of pyrolysis oil. One effective way is hydrotreating approach which helps to remove oxygen and store hydrogen as well to produce petro-like fuel.

Methods:

Organosolv lignin was used for pyrolysis with the condition of argon atmosphere, 600 °C at the rate of 80 °C min⁻¹. Detailed mass spectrometric measurements of the reactions after hydrotreating were carried out using a prototype-Orbitrap Elite equipped with an APCI source.

Results:

Detailed ultrahigh resolution mass spectrometric analysis shows to be an excellent method to understand the detailed conversion reaction of biomass into a fuel. Here, the detailed molecular transformation can be observed at different steps of the reaction. These steps involve the pyrolysis of lignin into a first product, which then is catalytically transformed into a biofuel under hydrogen atmosphere. The results show that depending on the amount of hydrogen present during the hydrotreating process, different types of reaction products can be observed with varying degree of aromaticity. At the end, the hydrotreating products are composed of mainly hydrocarbon species and some minor oxygen-containing compounds, containing up to only four oxygens per molecule. The formation of lower DBE compositions coincides with disappearance of higher DBE compositions. And this trend can also be indicated by comparing the calculated median DBE/C values.

Conclusions:

Catalytic hydrotreating from lignin derived pyrolysis oil can be fully observed using ultrahigh resolution mass spectrometry. Detailed observation of the different reaction steps allows better understanding of the conversion process.

Novel Aspect:

The catalytic hydrotreating process of pyrolysis oil upgrading can be observed in detail to allow better understanding of chemical process.

B.06 INSTRUMENTATION AND METHODS - ION ACTIVATION AND DISSOCIATIONS

574 - TANDEM MASS SPECTROMETRY TO ASSIST THE DESIGN OF INFORMATION-CONTAINING SYNTHETIC POLYMERS: AN EFFICIENT APPROACH TO FACILITATE THEIR SEQUENCING AND INCREASE THEIR STORAGE DENSITY

Jean-Arthur Amalian (1) - Gianni Cavallo (2) - Salomé Poyer (1) - Jean-François Lutz (2) - Laurence Charles (1)

Institut de Chimie Radicale, Aix-Marseille Université, Marseille (1) - Chimie Moléculaire de Précision, Institut Charles Sadron, Strasbourg (2)

Keywords: Tandem mass spectrometry; sequencing; sequence-controlled polymers; molecular design; information-containing macromolecules.

Introduction:

MS/MS sequencing was found to be the most efficient methodology to retrieve digital information stored in sequence-defined synthetic polymers [1]. In these macromolecules, two comonomers of different mass are defined as the 0- and 1-bit of the ASCII alphabet and placed at defined location throughout the chain to build binary messages [2]. Since the comonomer structure dictates the dissociation behavior, it can be optimized to achieve best MS/MS readability.

Methods:

Poly(alkoxyamine phosphodiester)s were synthesized using an orthogonal strategy that employs successively phosphoramidite and radical-radical coupling steps [3]. Methanolic solutions of polymers were supplemented with ammonium acetate prior to electrospray ionization in the negative ion mode. High resolution MS and MS² experiments were performed on a Synapt G2 Q-TOF mass spectrometer (Waters, Manchester, UK).

Results:

Sequence-defined poly(phosphodiester)s can store large amounts of information as they can be produced in an automated manner as long monodisperse chains [4]. However, extensive fragmentation of all phosphate bonds in each monomer leads to very busy MS/MS spectra that do not systematically ensure full sequence coverage. To simplify CID data and hence facilitate this sequencing step, a weak alkoxyamine bond was introduced between all monomers: as expected in such poly(alkoxyamine phosphodiester)s, fragmentations specifically occurred at C–ON bonds, making all phosphate groups MS/MS silent [5]. Additional structural optimizations included tailoring the distance between phosphate moieties in order to promote their simultaneous deprotonation, which allowed production of fragments which charge state increases with their polymerization degree. Finally, storage density of these chains was further increased by introducing two instead of one coding moieties in each monomer without modifying their optimized dissociation behavior [6].

Conclusions:

In contrast to biomolecules which structure is set by biology, sequence-defined synthetic polymers can be specifically designed to control their CID behavior and ensure full sequence coverage. So simplified dissociation rules can then be easily implemented in the recently-introduced MS-DECODER software [7], allowing efficient MS/MS data analysis and message decoding in the millisecond scale.

Novel Aspect:

MS/MS assisted design of sequence-controlled synthetic polymers to improve readability of molecularly encoded information and increase their storage density.

943 - FACILE ELECTRON CAPTURE DISSOCIATION ON Q-TOFS AND ORBITRAPs FOR TOP- AND MIDDLE-DOWN PROTEOMICS AT CHROMATOGRAPHIC TIME SCALES

Joseph Beckman (1) - Valery Voinov (1)

e-MSion, Inc, Oregon State University, Corvallis (1)

Keywords: ECD, native, de novo, sequencing

Introduction:

Characterizing proteins and their post-translational modifications remain a major challenge for mass spectrometry. Electron capture dissociation (ECD) produces clean spectra of entire proteins while also preserving PTMs but remains impractical because of the technical difficulties of confining low-energy electrons. We have developed an efficient ECD technology that can be retrofitted into most common mass spectrometers.

Methods:

The electromagnetostatic ECD cell is 30 mm long and consists of two magnets, an electron-emitting hot filament and 6 electrostatic lenses. The magnets provide a magnetic field that forces electrons emitted from the filament to be in the flight path of protein ions. The ECD cell is positioned between the mass resolving quad and the mass analyzers in either Orbitraps or in Q-ToF.

Results:

We have developed an ECD cell that can be installed in one hour and does not affect ion transmission [1]. The cell was first optimized to maximize fragmentation of substance P. These same parameters worked well for fragmenting proteins up to 30 kDa. Sequence coverage exceeds 90% for carbonic anhydrase (29 kDa). In addition to producing c and z fragments, a substantial number of d and w sidechain fragments were present in the same spectrum that could distinguish many isobaric leucines from isoleucines. Labile post-translational modifications are retained. For example, all eight phosphoserines in alpha-casein (23 kDa) were retained with 87% sequence coverage. With superoxide dismutase, copper and zinc cofactors remained bound to c and z ions containing their respective binding sites. Deuterium labeling of ubiquitin enabled top-down hydrogen/deuterium exchange with rates consistent with prior NMR results. Sequence coverage of 80-95% for proteins like ubiquitin and alpha-synuclein (14 kDa) was obtained during UHPLC separations from peaks lasting 1-3 seconds.

Conclusions:

The ECD cell is easily adapted into both Orbitrap and Q-ToF instruments without reducing their sensitivity or transmission. Fragmentation produces clean spectra that allows nearly complete characterization of proteoforms with preservation of labile PTMs. The presence of numerous d and w ions enhances the success of de novo sequencing by allowing many leucine/isoleucine or lysine/glutamine pairs to be easily distinguished. The ECD cell can help map disulfides in bottom up approaches [2].

Novel Aspect:

High sequence coverage of proteins up to at least 30 kDa can be produced at chromatographic speeds by retrofitting the ECD into current mass spectrometers.

Keywords: Polyoxometalate; Tandem mass spectrometry; Dissociation mechanism; DFT calculation

Introduction

Polyoxometalates (POMs) are discrete anionic metal-oxygen clusters which exhibit a great diversity of applications in catalysis, medicine, etc. [1] The fragmentation mechanism of discrete polyanions as well as its protonated/organic ammonium/alkali metal adduct ions are well understood by the contribution of a few scientists [2-4], in contrast, the solvated polyanions (in particular H₂O as a solvent) chemistry is scarcely investigated. This sort of research can allow us to shed light on the mechanism of the inverse process of nucleation reaction in a solution, which attracts the most attention of synthetic chemists of POMs. Herein, we report our preliminary result regarding the water-solvated polyanions by taking the Lindqvist-type [W₆O₁₉]²⁻ as an example to probe the dissociation chemistry of the water-solvated [W₆O₁₉]²⁻ in comparison to the bare [W₆O₁₉]²⁻ in order to explicitly define the role of water in the dissociation chemistry of polyanions by tandem mass spectrometry combined with density functional theory (DFT) calculation. Tandem mass spectrometry experiments of [W₆O₁₉]²⁻ and [W₆O₁₉-H₂O]²⁻ were performed on Agilent 6520 Q-TOF mass spectrometer with N₂ as the collision gas. The MS/MS results show that these two ions went through completely different dissociation pathways, where the former produces [W₃O₁₀]²⁻ and [W₄O₁₃]²⁻ fragments whilst the later generates predominately the mono-nuclear fragment [HWO₄]⁻. This result prompts us to search further about the reaction pathways for these two precursor ions by DFT calculation. The DFT results show that the reaction may proceed via two distinctive pathways: "water-free" and "water-assisted". The water-free pathway starts with the cleavage of W-Ob bond of [W₆O₁₉]²⁻ without transition state. Water-free process is calculated to be endothermic by about 39.1 kcal mol⁻¹. However, initially, in the water-assisted process, explicit water coordinates with POM by the intermolecular hydrogen bond, which reduces the energy for about 12 kcal mol⁻¹. Then the cleavage of W-Ob bond in the water-assisted pathway is found to be endothermic by about 30.1 kcal mol⁻¹. Next, in the water-free process, the cleavage of W-O bond is favorable thermodynamically, forming [WO₄]²⁻ anion and intermediate W₅O₁₅. However, for the water-assisted pathway, the water addition proceeds with an 8.2 kcal mol⁻¹ energy barrier at a transition state TS1. All calculated bond parameters (Fig. 1) and IRC calculation results indicate that this is a synchronous process, that is, the addition of H₂O accompanied by a H-transfer to form intermediate [HWO₄-W₅O₁₅OH]²⁻. Next the formation of [HWO₄]⁻ and [W₅O₁₅OH]⁻ proceeds without an energy barrier and is calculated to be exothermic by about 80.1 kcal mol⁻¹. The calculation is on the way to find out the lowest-energy routes to reach the final products, respectively.

Fig. 1. The dissociation mechanism of Lindqvist type POM [W₆O₁₉]²⁻ (Energy in kcal mol⁻¹)

Method

Tandem mass spectrometry combined with density functional theory (DFT) calculation.

Results

Tandem mass spectrometry experiments of [W₆O₁₉]²⁻ and [W₆O₁₉-H₂O]²⁻ were performed on Agilent 6520 Q-TOF mass spectrometer with N₂ as the collision gas. The MS/MS results show that these two ions went through

completely different dissociation pathways, where the former produces [W3O10]2- and [W4O13]2- fragments whilst the later generates predominately the mono-nuclear fragment [HWO4]-. This result prompts us to search further about the reaction pathways for these two precursor ions by DFT calculation. The DFT results show that the reaction may proceed via two distinctive pathways: "water-free" and "water-assisted". The water-free and water-assisted pathway all start with the cleavage of W-Ob bond of [W6O19]2- (1) without transition state. Water-free process is calculated to be endothermic by about 39.1 kcal mol-1. Similarly, the water-assisted pathway is found to be endothermic by about 30.1 kcal mol-1. Next, in the water-free process, the cleavage of W-O bond is favorable thermodynamically, forming [WO4]2- anion and intermediate W5O15. However, for the water-assisted pathway, the water addition proceeds with an 8.2 kcal mol-1 energy barrier at a transition state TS1. All calculated bond parameters (Fig. 1) and IRC calculation results indicate that this is a synchronous process, that is, the addition of H2O accompanied by a H-transfer to form intermediate [HWO4-W5O15OH]2-. Next the formation of [HWO4]- and [W5O15OH]- proceeds without an energy barrier and is calculated to be exothermic by about 80.1 kcal mol-1. The calculation is on the way to find out the lowest-energy routes to reach the final products, respectively.

Conclusions

The Lindqvist-type bare polyanion [W6O19]2- goes through completely different dissociation pathway from its water-solvated counterpart [W6O19·H2O]2-, where [W6O19]2- produces [W3O10]2- and [W4O13]2- fragments whilst [W6O19·H2O]2- generates predominately the mono-nuclear fragment [HWO4]-. The preliminary result of DFT calculation shows that H2O can largely lower the activation energy barrier of the initial steps of fragmentation.

Novel Aspect:

This is the first investigation of the bare and the solvated polyanions with the objective to explicitly define the role of water in the dissociation chemistry of POMs.

658 - CONTROLLED CID OF LARGE AROMATIC IONS IN A LQIT

Mickaël Carlos (1) - Hassan Sabbah (1) - Christine Joblin (2)

Institut de Recherche en Astrophysique et Planétologie, Université de Toulouse, CNRS, CNES, TOULOUSE (1) - Institut de Recherche en Astrophysique et Planétologie, Université de Toulouse, CNRS, CNES,, TOULOUSE (2)

Keywords: linear ion trap, PAH, collisional dissociation, Ion dynamics, astrochemistry

Introduction:

The AROMA (Astrochemistry Research of Organics with Molecular Analysis) setup [1] has been designed to analyse the organic molecular content of cosmic dust analogues, as part of the NANOCOSMOS ERC project. In this work, we test the capabilities of AROMA to study the energetics of molecular ion fragmentation using a Collision Induced Dissociation (CID) scheme. A motivation is to discriminate structural isomers.

Methods:

AROMA is a hybrid setup, composed of a laser desorption/ionization source, coupled with a Linear Quadrupole Ion Trap (LQIT) and an orthogonal Time Of Flight (oTOF). Controlled CID experiments are performed in the LQIT under various conditions of colliding gas pressure and Dipolar Excitation (DE) conditions. Ion dynamics simulations using the Simion software are performed and combined with a Monte Carlo kinetics program.

Results:

We present results on the CID of the pyrene cation $C_{16}H_{10}^+$ colliding with Ar gas. We explored the influence of the DE parameters (amplitude, frequency, duration of the DE). This includes the two different modes of excitation (on and off resonance). With these parameters we can tune the collisional heating rate, reaching different regimes in the competition between heating and cooling by dissociation. This competition governs the breakdown curve (loss of the parent cation) and impacts the H over 2H branching ratio.

Using Simion, we performed simulations of the ion motion taking into account collisional cooling by He during transfer to the LQIT and subsequent dipolar excitation in the LQIT. A hard sphere model was used to describe collisions. We obtained the distributions of the energies at the centre of mass (ECM) and of the time between collisions. Both distributions are used as inputs in our Monte Carlo model. Comparison between simulations and experiments allows us to constrain the efficiency of kinetic to internal energy conversion.

Conclusions

We have set a protocol to quantify fragmentation in the lowest energy channels. This can be used to discriminate structural isomers in complex mixtures such as cosmic dust analogues or extraterrestrial materials. In particular we have been able to reevaluate the assignment of pyrene as the carrier of $m/z=202.08$ in the Murchison meteorite [1]. In the future, we will demonstrate how our heating scheme can also be applied to more strongly bonded systems such as C_{60}^+ .

Novel Aspect:

Our combined experimental and simulation approach allows us to better control dissociation at threshold for large aromatic ions submitted to collisions with Ar in a LQIT.

Investigation of Hemicryptophane Host-Guest Binding Energies Using Advanced Tandem Mass Spectrometry

Keywords (maximum 5 keywords defining the topics of the abstract)

Host-Guest Chemistry; cryptophanes; blackbody infrared radiative dissociation; collision induced dissociation; MassKinetics

Introduction: (Limit of 400 characters)

In advancing host-guest (H-G) chemistry, considerable effort is spent to synthesize host molecules with specific properties including selectivity and adjustable affinity. An important step in the process is the characterization of binding strengths of the H-G complexes. Here, we present a mass spectrometry based multimodal approach to obtain bond dissociation energies (BDEs) of two hemicryptophane cages with three biologically-relevant guest molecules.

Methods: (Limit of 400 characters)

Two model hemicryptophane cages have been selected as the host molecules and their binding properties towards three biologically important guests: choline (C), acetylcholine (AC) and betaine (B) have been studied in the gas phase. Quantitative comparison of the binding dissociation energies of different H-G pairs was achieved using a combination of BIRD and high-pressure CID mass spectrometric techniques with Rice–Ramsperger–Kassel–Marcus (RRKM) modeling.

Results: (Limit 900 characters)

Obtained BDE values fall within a rather narrow range for all host-guest complexes. Among the informative trends and differences extracted from the data, we note that complexes of cage 1 exhibit higher BDE's, and thus are all more stable than those of cage 2. This trend establishes that the linkers (naphthyl for cage 1 and phenyl for cage 2) play important roles in determining the strength of the H-G complexes. Another interesting comparison is the relative stability ranking between various guests for a given host cage. Notably, for both cages 1 and 2, the order of stability of H-G complexes is as follows: choline > acetylcholine > betaine. DFT calculations were performed to gain information concerning possible binding modes and relative stabilities of different non-covalent H-G interactions. The tren and the CTV of the hemicryptophane adopted an approximately C3 symmetry. The arrangement of the phenyl or naphthyl linkers for the six H-G complexes gives compact structures that allow the insertion of the ammonium moiety of the guest inside the cage.

Conclusions (Limit of 400 characters)

The multimodal approach described here, using the BIRD technique in combination with high pressure-CID breakdown curves and RRKM modeling, is useful not only for estimation of bond dissociation energies, but also for accurate surveying of the influence of different functional groups on H-G binding properties. Utilization of this approach can provide a wealth of information pertinent to chemists who seek to design new H-G systems with well-honed properties.

Novel Aspect: (Limit of 150 characters)

Two hemicryptophane host molecules are assessed for their binding properties towards three biologically important guests in the gas phase.

319 - ULTRAVIOLET PHOTODISSOCIATION OF PEPTIDES AND PROTEINS, GENERATED BY ELECTROSPRAY AND MATRIX-ASSISTED LASER DESORPTION/IONIZATION, ON THE SAME Q-EXACTIVE MASS SPECTROMETER

Marialaura Dilillo (1) - Erik de Graaf (1) - Avinash Yadav (1) - Mikhail Belov (2) - Liam McDonnell (1)

Fondazione Pisana per la Scienza - ONLUS, Proteomics Laboratory, San Giuliano Terme (1) - Spectrograph LLC, Spectrograph LLC, Kennewick (2)

Keywords: UVPD, MALDI – UVPD, EP-MALDI – Orbitrap, Top-Down proteomics

Introduction:

Recent literature reports demonstrate that ultraviolet photodissociation can provide extensive sequence coverage for ESI generated protein ions. UVPD has a much lower charge state dependence than ETD and CID, thus the singly charged protein ions produced by MALDI may exhibit equal propensity to fragment. Here we compare UVPD of MALDI and ESI generated ions using a Q-Exactive equipped with a EP-MALDI/ESI dual source and UVPD.

Methods:

All experiments were performed using a Q-Exactive Plus (Thermo Scientific, Bremen) equipped with a ESI/EP-MALDI dual ion source (Spectrograph LLC, Kennewick WA, USA). UVPD was performed using a 193 nm ArF laser (Excistar XS 500, Coherent, Santa Clara CA, USA) aligned coaxially with the HCD cell.

ESI was performed using 10 μ M standard protein solutions infused at 5 μ L/min. MALDI samples were prepared using the dried droplet method (CHCA matrix, 1000:1 molar excess).

Results:

UVPD of MALDI generated ions was benchmarked against MALDI-ISD and ESI-UVPD performed on the same accurate mass, high resolution mass spectrometer.

ESI was first used with peptide and protein standards to optimize laser trigger timing, number of laser pulses and laser pulse energy. UVPD of ESI generated ions using the Q-Exactive Plus performed identically to those previously reported using hybrid instruments.

The optimized parameters were used for UVPD of MALDI generated ions, specifically the small peptide bradykinin and the small protein thymosin β 4 (monoisotopic masses 1059.57 and 5205.63, respectively). The UVPD fragments were compared at different laser pulse energies, and with those obtained from HCD and ISD.

Conclusions

The results demonstrate that MALDI UVPD outperformed MALDI HCD for all laser pulse energies. While MALDI ISD also provided extensive sequence coverage, its lack of precursor ion selection limits its application to isolated proteins whereas MALDI UVPD can be used on proteins from complex mixtures.

Novel Aspect: UVPD performed on intact protein ions generated by EP-MALDI on a modified Q Exactive Plus, demonstrating its ability to further improve MS/MS capabilities for MALDI generated ions.

1192 - UNDERSTANDING FRAGMENTATION OF COMPLEX IONS USING SURFACE-INDUCED DISSOCIATION EXPERIMENTS

Julia Laskin (1)

Purdue University, Dept. of Chemistry, West Lafayette, IN 47907 (1)

Keywords: surface-induced dissociation, threshold energy, activation entropy, peptide, metal cluster

Introduction:

Surface-induced dissociation (SID) is a powerful tool both for analytical applications and for studies of gas-phase fragmentation of complex ions. We have developed experimental approaches for studying the energetics, dynamics, and kinetics of large ion dissociation using SID, which in combination with comprehensive modeling enable mechanistic understanding of complex ion fragmentation difficult to obtain using other experimental techniques.

Methods:

Experiments were performed on a specially designed Fourier transform ion cyclotron resonance mass spectrometer (FT-ICR) configured for time- and collision energy-resolved SID experiments. The experimental results were modeled using RRKM and the analytical form of the internal energy deposition function that adequately describes energy transfer in collisions.

Results:

SID experiments were combined with resonant ejection of selected fragment ions. The approach was first examined using well-characterized peptide systems and subsequently used to explore the kinetics of the gas-phase fragmentation of ligated metal clusters. When combined with RRKM modeling, these experiments facilitate detailed understanding of the competition between different fragmentation pathways.

Conclusions

SID experiments highlight an important role of entropy in dissociation of complex ions. Resonant ejection experiments identify different populations of stable structures and inform on the kinetics of the competing fragmentation reactions.

Novel Aspect:

SID provided unique insights into the energetics of complex ion fragmentation.

466 - GAS PHASE REACTIONS OF INDOCYANINE GREEN USING FEMTOSECOND-LASER-PULSE INDUCED PHOTODISSOCIATION AND COLLISION-INDUCED DISSOCIATION

Elena Mitrofanov (1) - Tassilo Muskat (1) - Jürgen Grotemeyer (1)

Institute of Physical Chemistry, University of Kiel, Kiel (1)

Keywords: Photodissociation, Indocyanine Green, collision-induced dissociation, NIR

Introduction:

The dye Indocyanine Green (ICG) is widely used for medical purposes and as a fluorescent dye [1]. Investigations on the fluorescence of ICG showed very short fluorescence lifetimes [2] which leads to the requirement of femtosecond laser pulses for photodissociation experiments. The results will be compared to collision-induced dissociation processes to investigate stability and reactions of ICG.

Methods:

The mass spectra have been recorded on an Apex III FT-ICR mass spectrometer (7.05 T) (Bruker Daltonik, Germany) using different fragmentation techniques. The ionization was performed via Electrospray Ionization from different solvent mixtures. For the fragmentation reactions, collision gas (Argon) or a femtosecond laser system (Quantronix, USA) with 790 nm and 150 fs pulse duration were used.

Results:

Depending on the solvent mixture, the sodiated or the protonated ions and their clusters were observed in the mass spectra. Collision-induced dissociation (CID) and photodissociation (PD) were applied to the different ions. The photodissociation process at a wavelength of 790 nm resulted in several intense fragments for the sodium adduct and less intense fragments for the protonated molecule. Most fragments arise from the dissociation of a linkage between two identical aromatic systems. Beside these cleavages, only the bisodiated ICG shows the elimination of some small neutral fragments. In contrast to the PD spectra the CID-spectra showed poor fragmentation for the protonated molecule and no fragmentation for the sodium adduct.

Conclusions:

The poor fragmentation in the CID process leads to the conclusion that the collision energy does not exceed the required energy that is reached by multiphoton absorption of the femtosecond laser pulses. The comparison of the fragments from the protonated and the sodiated molecules gives a hint for the influence of the sodium cation on the molecular stability. [3]

Novel Aspect:

Photodissociation reactions of ICG and its clusters in the gas phase using femtosecond laser irradiation.

620 - LOST IN PHASE SPACE: FRAGMENTATION ENERGETICS IN QUADRUPOLE ION TRAPS

Thomas Neugebauer (1) - Thomas Drewello (1)

Friedrich-Alexander-University Erlangen-Nuremberg, Chair of Physical Chemistry I, Erlangen (1)

Keywords: CID Fragmentation energetics, Quadrupole ion trap, Phase-space ellipses

Introduction:

Quadrupole ion traps play a central role in the investigation of ion-fragmentation processes due to their capability to conduct MSⁿ experiments. The motion of ions inside quadrupole ion traps is complex but can be described by Mathieu's equation.[1] Due to the complexity of the consequences of the change in stability parameters the fragmentation has been investigated in the past only by simulation programs. We present a systematical investigation of this process.

Methods:

The analytical solution of Mathieu's equation has been combined with phase-space analysis. Phase-space ellipses have been implemented in calculations over their ellipse angle and explicitly not the quadratic equation, this way avoiding the common treatment of the ellipses as uniformly populated, thus providing a correct treatment of time.

Results:

The phase-shift between the fundamental ion oscillation and the superimposed micromotion creates an elliptical relationship between the position and the velocity of ions at a specific phase of the applied alternating potential. We can show by appropriate application of trigonometry that the angle (the position on the ellipses in phase-space has regarding the coordinate system axes) is related to the variable time and with that, the probability to find an ion on a certain position in phase-space varies.

By the use of these ellipses we provide a straightforward explanation, why and how the amplitudes of ion trajectories can drastically change, resulting in loss of ions, although their m/z value is above the Low-mass cut-off (LMCO) and to which extent this is expected.[2] By the use of the center-of-mass collision energy, E_{com} , we define effective temperatures and further give information about the likelihood of ions enduring successive excitation that can result in consecutive fragmentation.[3]

Conclusions:

We explain how the variables are connected to each other in the complex fragmentation process and provide clues regarding the origin of certain observations as being caused by instrumental or molecular properties. Further general trends are given and it is also discussed how a change in LMCO settings might help achieving the desired information.

Novel Aspect:

Consequences of the change in stability parameters during fragmentation are presented with special emphasis on the likelihood for successive fragmentation events.

509 - COLLISION INDUCED DISSOCIATION OF HYDROGEN DEFICIENT RADICAL IONS ON THE OMNITRAP PLATFORM

Dimitrios Papanastasiou (1) - Roman Zubarev (2)

Fasmatech Science & Technology, Patriarchou Gregoriou, Agia Paraskevi, Athens (1) - Karolinska Institutet, Department of Medical Biochemistry and Biophysics, Stockholm (2)

Keywords: top-down, ion activation, linear ion trap

Introduction:

The omnitrapp platform is a novel linear ion trap sustaining a diverse ion activation network including collision-induced and electron directed dissociation of ions. A series of experiments involving collision induced dissociation of radical ions formed by meta-ionization of poly-protonated species using >10eV electrons are performed and new informative transitions in the fragmentation patterns are reported for insulin chain B and ubiquitin ions.

Methods:

Precursor ions selected in the quadrupole of a QExactive+ are transferred into the omnitrapp platform. Electron meta-ionization of protonated ions is performed by varying electron energy, adjusting irradiation time and the frequency of the trapping waveform to maximize radical ion abundance. CID MS³ experiments of EI-produced hydrogen-deficient radicals are compared to their protonated counterparts in the same charge state.

Results:

Electron meta-ionization of insulin chain B ions is performed and subsequent CID of the radical ions reveals the formation of three complementary c, z fragment pairs near tyrosine residues. A mechanism is proposed to explain the dissociation pathway involving meta-ionization at or near the tyrosine residue followed by the rapid phenolic proton migration towards a basic site, e.g. N-terminus, forming a protonated group, with a neutral radical remaining at the tyrosine residue and initiating N-Cα backbone cleavage. Electron meta-ionization of 7+ ubiquitin ions produced 8+(.) hydrogen deficient species. Comparison of CID MS/MS data of the 8+ protonated ions with the hydrogen deficient radicals at the same charge state reveal significant differences, especially by the presence and position of a, x and c, z fragmentation patterns, as well as significant similarities in the relative abundances of b, y fragments.

Conclusions

The unique versatility of the ion activation network available in the omnitrapp platform is demonstrated using MS³ CID experiments of meta-ionized species. Enhanced sequence information is obtained in CID experiments of the radical ions compared to even electron species at the same charge state. Cleavage position, fragment type and abundance are analyzed in great detail revealing the hitherto unreported fragmentation processes.

Novel Aspect:

Novel ion activation tools for the orbitrap mass analyzer and expanded versatility of the omnitrapp platform for top-down mass spectrometry.

293 - TANDEM TOF MASS SPECTROMETRY OF BIOMOLECULES: FROM DUAL STAGE TO CURVED FIELD AND PARABOLIC ANALYZERS AS SECOND STAGE

Ernst Pittenauer (1) - Guenter Allmaier (1)

TU Wien, TU Wien/Institute of Chemical Technologies and Analytics, Vienna (1)

Keywords: MALDI, tandem TOF instrumentation, high-energy CID, charge-remote fragmentation

Introduction:

By the end of the millennium high-energy CID were moved from FAB/LSIMS tandem sector to MALDI tandem TOF devices. Surprisingly, this generation of instruments exhibits extremely different instrumental features (lasers, collision energies, reflectrons and flight path lengths). In order to demonstrate similarities/differences among high-energy CID spectral data from peptides, lipids and oligosaccharides it is of great interest for future applications [1-4].

Methods:

MALDI high-energy CID spectra of selected peptides, triacylglycerols, glycerophospholipids and oligosaccharides were acquired on an AB Sciex 4700/4800 (ELAB=1 keV), a Bruker DaltonicsultrafleXtreme (ELAB=8 keV), a Shimadzu Axima TOF2 (ELAB=20 keV), a Shimadzu MALDI 7090 (ELAB=20 keV) and a JEOL SpiralTOF/TOF instrument(ELAB=20 keV). MALDI matrices used included α -cyano-4-hydroxy cinnamic acid (only peptides) or 2,4,6-trihydroxy acetophenone.

Results:

Whereas tandem TOF instruments fitted with a limited energy acceptance dual stage reflectron (AB Sciex, Bruker) are typically operated with a rather low collision energy (1-8 keV), the ones with a wide energy acceptance curved field or offset parabolicelectron (Shimadzu, Jeol) allow a collision energy of 20 keV. Protonated peptide molecules only exhibit side chain charge-remote fragmentations (d-, v-, w-ions) at 20 keV collisions allowing distinction between isomeric leucine and isoleucine. Triacylglycerols and glycerophospholipids show - depending on the type of precursor ion (protonated, sodiated) - diagnostic charge-remote fragmentation of the alkyl chains best seen at 20 keV collisions. For sodiated triacylglycerols a clear differentiation between sn1-/sn3- versus sn2-substituents could be made, hardly seen at 1-8 keV collisions. In contrast, sodiated oligosaccharides do not seem to require such high collision energies as there is virtually no difference in the fragmentation pattern in the CID spectra taken at 1, 8 or 20 keV.

Conclusions:

Only instruments fitted with wide energy acceptance reflectrons (curved field and offset paraboloid reflectron) yield true high-energy CID spectra of biomolecules with typical product ions in high abundance (peptide side-chain fragmentation, lipid charge-remote fragmentation). Still a major issue for the observation of unwanted PSD ions in most tandem TOF instruments is a long flight path (~4 m) obscuring CID ions due to their lower intensity (a factor of 10-20).

Novel Aspect:

For the first time different designs of MALDI tandem TOF devices fitted with high-energy CID cells are compared for their usefulness in structural elucidation of biomolecules.

114 - JUGGLING FRAGILE VAN DER WAALS COMPLEXES IN AN ION TRAP FOR MULTIPLEXED INFRARED PHOTODISSOCIATION

Larry Tesler (1) - Matthew Bell (1) - Taylor Harmon (1) - Laura Bailey (1) - Nicolas Polfer (1)

University of Florida, University of Florida/Chemistry, Gainesville (1)

Juggling fragile van der Waals complexes in an ion trap for multiplexed infrared photodissociation

Keywords: infrared photodissociation, cryogenic trap, multiplexing, spectroscopy, metabolites

Introduction:

Cryogenic infrared spectra can in principle serve as a gold standard for molecular identification in MS [1]. However, a key failing of action spectroscopy remains its extremely low duty cycle, where only one analyte is probed at one wavelength step at one time. Here, we discuss the first mass-selective cryogenic trap [2], which allows the IR spectra of multiple analytes to be probed in parallel, given the predictable mass increase/decrease of tagging spectroscopy [3].

Methods:

A custom cryogenic 2D linear ion trap (cryoLIT) is composed of rectilinear electrodes equipped with slits in the left/right rf electrodes for radial ejection. Temperature control is enabled via a helium cycle cryostat, cartridge heaters, and temperature sensors. A gas pulse of He (and 5% N₂) allows ion cooling and tagging. Ions are mass manipulated using an auxiliary dipolar waveform on the left/right rf electrodes that is resonant with the secular frequency.

Results:

When cooling the cryoLIT to cryogenic temperatures, ions exit the trap at lower rf amplitudes in the mass instability scan, which is due to a shrinking of the trap. The magnitude of this shift is related to the expansion coefficient of the material, 0.33% for 17-PH steel and 0.65% for OFHC copper.

Two types of tagged ions will be considered here: 1) solvent-tagged ions (H₂O and CH₃CN) from the electrospray source, or 2) van der Waals N₂-tagged ions generated in the cryogenic trap. Given their extremely low binding energies, the parameters for generating and manipulating N₂-tagged ions are critical. Still, with optimized trap temperature (24K), pumpdown delays, and isolation waveforms a background-free mass isolation of N₂-tagged ions is feasible. High-quality IR spectra of small analytes (tryptophan, MDMA, Leu-enkephalin, etc.) can be recorded in this way and are very comparable to literature cryogenic IR spectra [4]. Current efforts focus on neon tagging, which may be the optimal tag in terms of mass increase (+20) and minimal IR spectral distortion.

Conclusions:

The mass-selective cryoLIT is capable of measuring high-resolution IR spectra of multiple analytes in a multiplexed fashion at reasonable speeds (< 30 min), and at relevant concentrations (nM). This sets the stage for applying cryogenic IR spectroscopy as a bioanalytical tool for small molecule identification (e.g. metabolites). Two-trap designs can further improve speed by decoupling the pumpdown delay (100 ms) from mass manipulation and analysis (100 ms).

Novel Aspect:

First mass-selective cryogenic 2D ion trap where extremely fragile van der Waals-tagged ions can be mass isolated for background-free infrared photodissociation.

1235 - TUNING MASS SPECTROMETRIC PROTEOMICS EXPERIMENTS: COLLISION ENERGY DEPENDENCE OF MASCOT SCORE

Agnes Revesz (1) - Tibor Andras Rokob (2) - Dany Jeanne Dit Fouque (3) - Lilla Turiak (1) - Antony Memboeuf (3) - Karoly Vekey (1) - Laszlo Drahos (1)

Research Centre for Natural Sciences, Hungarian Academy of Sciences, MS Proteomics Research Group, Budapest, Hungary (1) - Research Centre for Natural Sciences, Hungarian Academy of Sciences, Theoretical Chemistry Research Group, Budapest, Hungary (2) - Université de Bretagne Occidentale, UMR CNRS 6521, CEMCA, Brest, France (3)

Keywords: proteomics, peptide fragmentation, collision energy, optimization, Mascot score

Introduction:

Recently, MS-based proteomics has become a powerful tool in protein identification and characterization. In the bottom-up approach, the choice of collision energy of the peptide MS/MS experiment significantly affects the performance of the method. High-level objectives, e.g., highest identification score, have not been explored in this respect. The present work maps the energy dependence of this proteomics variable and determines the optimal collision energy.

Methods:

Tryptic digests of complex standards (HeLa, E. Coli) were subject to nano-HPLC-MS/MS experiments at 21 different collision energies on a Bruker Maxis II ETD QTOF instrument. Spectra were matched against the SwissProt database using the Mascot search engine. Further analysis, including comparison of LC-MS/MS runs and fitting of the Mascot score vs. collision energy curves, were performed with an in-house developed software using Mascot output files as inputs.

Results:

A cluster analysis of Mascot score vs. energy curves revealed two types of energy dependent behavior (unimodal and bimodal) in about 50–50% of the investigated peptides. For bimodal peptides, number and summed intensity of b fragment ions show maxima around the first score maximum. y ions are less sensitive to collision energy but more intense and numerous near the second score maximum. The optimal collision energy, obtained as the peak positions from one or two fitted Gaussians, follow linear trends with respect to m/z, but the three groups have different m/z dependence. The presence of mobile proton decreases the optimum significantly (1–5 eV), but other factors also seem important indicated by the large residual variance even of the separate linear fits for peptides with mobile and partially mobile protons. Where 2 maxima exist, their difference is surprisingly m/z independent and it is ~17 eV on average for both +2 and +3 peptides.

Conclusions:

An unprecedented bimodal behavior of the score vs. energy curves, linked to the different behavior of y- and b-type ions, was identified for about half of the peptides. For these, the average score increases by ~15% upon energy optimization. On the other hand, for unimodal peptides, the original default collision energy seemed quite good, only a slight increase of ~4% could be achieved. The optimal energy has linear m/z dependence with marked effect of proton mobility.

Novel Aspect:

This is the first study to address collision energy dependence of a peptide identification score and to quantify the role of less abundant b-ions in peptide identification [1].

Mitsuo Takayama (1)

Yokohama City University, Graduate School of Nanobioscience, Yokohama (1)

Keywords: Radical-Driven Dissociation, MALDI-ISD, Hydrogen-Excess/Deficient Peptides, Mechanism

Introduction: (Limit of 400 characters)

Radical-driven dissociation (RDD) using ultraviolet, electron transfer, high-energy collision and redox matrix provides us practical information for structure elucidation of organic chemicals, peptides and proteins. Using MALDI MS with redox matrix here we report detailed mechanisms of the formation of hydrogen-excess/deficient radical peptides, $[M+H]^{\cdot}$ and $[M-H]^{\cdot}$, and specific RDD reactions.

Methods: (Limit of 400 characters)

MALDI-ISD experiments were performed with a TOF MS AXIMA-CFR (Shimadzu, Kyoto, Japan). Redox matrices used were 2,5-dihydroxybenzoic acid (2,5-DHB) and 5-amino-1-naphthol (5,1-ANL) for H-donation and 5-nitrosalicylic acid (5-NSA) and 4-nitro-1-naphthol (4,1-NNL) for H-abstraction [2]. The analytes used were synthetic peptides RGV and EGV having Arg at N-terminus (RGVKVDYGPAMAFAPADLAAEF, RGV) and C-terminal side (EGVKVDYGPAMAFAPADLAARF, EGV).

Results: (Limit 900 characters)

ISD spectrum of RGV with H-donating matrix 5,1-ANL merely gave $[c+2H]^+$ ions originated from cleavage at N-Ca bond [1], while the use of 2,5-DHB resulted in $[c+2H]^+$ and $[a]^+$ ions and some $[b]^+$ and $[d]^+$ ions. The ISD spectrum of EGV with 5,1-ANL showed preferential $[z+2H]^+$ ions and minor $[y+2H]^+$ and $[c+2H]^+$ ions, while the spectrum with 2,5-DHB gave preference $[y+2H]^+$ ions and minor $[z+2H]^+$, $[x]^+$ and $[c+2H]^+$ ions. The use of 5,1-ANL resulted in only H-excess radical peptide ions $[M+2H]^{\cdot}$ having the radical (unpaired electron) located on carbonyl carbon of the backbone, and the radical ions $[M+2H]^{\cdot}$ can lead to $[c+2H]^+$ ion and radical intermediate ion $[z+H]^{\cdot}$, although the intermediate never be observed in ISD spectra. On the other hand, the use of H-abstracting matrix 4,1-NNL resulted in preferential $[a]^+$ ions and some $[b]^+$ and $[d]^+$ ions for RGV and preferential $[y]^+$ ion for EGV.

Conclusions (Limit of 400 characters)

The use of naphthalene skeletal redox matrices 5,1-ANL and 4,1-NNL gave simple and very useful information for sequencing peptides and proteins in the MALDI-ISD experiments [2]. The observable fragment ions such as $[c+2H]^+$, $[z+2H]^+$, $[y+2H]^+$, $[a]^+$, $[x]^+$ and $[y]^+$ ions were exactly controlled by the sites of radical (unpaired electron) and Arg residue, and the RDD reactions obeyed simple and successive radical-initiative process.

Novel Aspect: (Limit of 150 characters)

It was indicated that $[a]^+$ and $[ym+2H]^+$ ions were originated from beta-carbon-centered radical ions $[M-H+H]^{\cdot}$ and radical intermediates $[zm+1+H]^{\cdot}$, respectively.

32 - COMPREHENSIVE GLYCOMICS STUDY BY NANOLC-EED-MS/MS

Yang Tang (1) - Juan Wei (1) - Catherine Costello (1) - Cheng Lin (1)

Boston University, 670 Albany St Rm 504, Boston (1)

Comprehensive Glycomics Study by nanoLC-EED-MS/MS

Yang Tang^{1,2}, Juan Wei², Catherine E. Costello^{1,2}, Cheng Lin²

¹Department of Chemistry, Boston University, Boston, MA; ²Department of Biochemistry and Center for Biomedical Mass Spectrometry, Boston University School of Medicine, Boston, MA USA

Keywords: Glycomics, PGC-LC, EED-MS/MS

Introduction:

Comprehensive structural elucidation of glycan mixtures is challenging. Here, glycans are reduced and permethylated or labeled with a reducing-end fixed charge to increase sensitivity, avoid gas-phase structural rearrangement and facilitate spectral interpretation. A PGC column was used to maximize isomer separation [1]. EED was utilized due to its ability to generate informative MS/MS spectra to allow accurate determination of both the topology and linkages.

Methods:

Glycan standards, LNT, LNnT, LNFP I, II, III, V and VI, were either reduced and permethylated [1], or labeled with a reducing-end fixed charge via reductive amination with 3-aminopyridine followed by methylation using iodomethane in ACN [2]. Separation was carried out on a Waters nanoACQUITY UPLC, with a nanoPGC column held at 50 °C. EED-MS/MS analyses were performed on a Bruker 12-T solariX FTICR MS with the cathode bias set between 16 V and 18 V [3-4].

Results:

PGC-LC can often achieve better isomer resolution than RPLC. For example, reduced and permethylated linkage isomers, LNFP II and III, are barely separated by RPLC, yet they are baseline resolved by PGC. Meanwhile, glycans with a reducing-end fixed charge are not retained by RPLC, but form sharp peaks in PGC.

EED can generate more informative spectra than CID or HCD. Here, for glycans with a reducing-end fixed charge, EED produced complete series of Z-, Y- and 1,5X-ions, forming triplets with characteristic spacing that could be easily recognized to facilitate accurate determinations of the glycan topology. Additional radical-driven dissociation pathways were also identified, generating linkage-specific cross-ring, secondary or internal fragments throughout the glycan backbone. The presence and location of the branching site(s) and the linkage configuration at HexNAc residues could also be determined based on characteristic fragmentation patterns occurring only at those sites.

Conclusions:

Isomer resolution was achieved on PGC-LC for glycans in two different derivatized forms. EED of permethylated glycans and glycans with a reducing-end fixed charge produced rich structural information with unique spectral

features for reliable determination of the glycan sequence, branching pattern and linkage configurations. Online PGC-LC-EED-MS/MS should become a powerful method for comprehensive glycome characterization.

Novel Aspect:

Separation and detailed structural characterization of isomeric glycan mixtures are achieved in a single LC-EED-MS/MS analysis.

101 - ESI(-)MS/MS OF 2-OXOCARBOXYLATE HYDRAZONES: CARBOXYL GROUP PARTICIPATION IN TWO FRAGMENTATION PATHWAYS

Robert L. White (1) - Ben W. Firth (1) - Luc M. LeBlanc (1) - J. Stuart Grossert (1)

Dalhousie University, Chemistry, Halifax (1)

Keywords: ESI(-)MS/MS, hydrazone derivatives, fragmentation mechanism, decarboxylative elimination, computations

Introduction:

Analysis of aldehydes and ketones has been achieved by formation of hydrazone derivatives and negative-ion electrospray tandem mass spectrometry [ESI(-)MS/MS] [1,2]. Upon collision induced dissociation (CID), major product ions were formed by losses of NO and NO₂ [3]. In our current ESI(-)MS/MS studies on hydrazones of 2-oxo carboxylic acids, fragmentations are directed by the carboxylate group.

Methods:

Mass spectra were obtained using ESI(-)MS/MS with MeOH solvent. A triple quadrupole spectrometer gave both product- and precursor-ion spectra, while an ion trap spectrometer gave complementary product-ion spectra. Quantum mechanical computations of gas-phase ions were done using Gaussian 09 software at the MP2/6-311++G(2d,p)//B3LYP6-31++G(2d,p) level of theory.

Results:

Phenyl, 4-nitrophenyl and 2,4-dinitrophenylhydrazone derivatives of glyoxylic and phenylglyoxylic acid were prepared. Upon CID, the deprotonated glyoxylate and phenylglyoxylate hydrazones primarily yielded anilide ions; decarboxylation was a minor process for the glyoxylate derivatives. The major pathway was consistent with decarboxylative elimination [4], in which an anilide ion, a nitrile and CO₂ are formed by N–N and C–C bond cleavage. Barriers of less than 100 kJ/mol were determined by computations and breakdown curves showed the influence of nitro and phenyl substituents on the energetics of decarboxylation. ESI of samples in acetonitrile gave reduced abundance of the minor decarboxylated product ion. The minor pathway was attributed to solvent-assisted ionization on nitrogen, rearrangement to Ar-N=N-CH₂CO₂⁻ (barrier = 130 kJ/mol) and lastly decarboxylation (negligible barrier).

Conclusions:

The fragmentation behavior of the 2-oxo carboxylate hydrazones resulted from reactions of the carboxyl group. The major fragmentation pathway proceeded by decarboxylative elimination, whereas the minor pathway observed for the glyoxylate hydrazones involved ionization on nitrogen, rearrangement and subsequent decarboxylation.

Novel Aspect:

Different pathways of deprotonated hydrazone derivatives highlight the challenges of predicting the fragmentation behavior of multifunctional ions.

Keywords: binding affinity, dissociation, LILBID, native mass spectrometry, ion source

Introduction:

LILBID is an ion desorption method for native mass spectrometry in which droplets of aqueous solution are irradiated with pulsed IR laser light, leading to explosive expansion of the droplets and release of sample molecules as ions. LILBID-MS is primarily used to assess the stoichiometry of noncovalent biomolecular complexes. Here we outline a new method to quantitatively determine binding affinities with LILBID-MS and present preliminary results from this method.

Methods:

In LILBID, harsher or softer laser energy transfer leads to different amounts of dissociation of noncovalently bound biomolecular complexes. In this new method, the sample is measured while purposely varying the energy transfer from the desorption laser to the droplet in the LILBID ion source. The amount of dissociation in the resulting spectra is then plotted against a measure of energy input, resulting in a dissociation curve analogous to a melting curve.

Results:

The amount of energy transferred to the sample during desorption can be changed by varying instrument parameters such as laser power and droplet position within the laser beam. However the relationship between these parameters and the amount of energy transferred to the sample is not straightforward. We monitor energy input using the shape of the droplet's explosive expansion. Certain parameters of the shape of this expansion are closely correlated with both energy input and spectral results and can be used as robust measures of laser energy transfer. During a binding affinity measurement, one of the instrumental parameters for energy transfer is purposely varied as droplets are emitted. For each droplet, an explosion image and a mass spectrum are recorded. The shapes of the explosive expansions are analyzed, and the amounts of dissociation in the spectra are calculated and plotted against the corresponding laser energy transfer, which we derive from the explosion shape. The resulting curve is a plot of dissociation with increasing energy input.

Conclusions:

Dissociation curves for different short dsDNA reflect the binding strengths of the samples, demonstrating that this method allows conclusions about the binding strength of biomolecules in solution. Since data for each dissociation plot can be collected within minutes and with a fraction of the sample necessary for a titration or a melting curve with LILBID, this method represents an attractive alternative to titration-based binding affinity experiments.

Novel Aspect:

This method constitutes a new way to perform fast top-down analysis of binding affinities of biomolecular complexes.

1315 - STRUCTURAL CHARACTERIZATION OF COMPLEX LIPIDS BY OZONE-INDUCED DISSOCIATION AND ULTRAVIOLET PHOTODISSOCIATION ON HIGH-RESOLUTION MASS SPECTROMETERS

Angela Criscuolo (1) - David L. Marshall (2) - Martin Zeller (1) - Berwyck L. J. Poad (2) - Jan-Peter Hauschild (1) - Todd W. Mitchell (3) - Gavin E. Reid (4) - Stephen J. Blanksby (2)

Thermo Fisher Scientific (Bremen) GmbH, Life Science Mass Spectrometry, Bremen, Germany (1) - Queensland University of Technology, Central Analytical Research Facility, Institute for Future Environments, Brisbane, Australia (2) - University of Wollongong, School of Medicine, Illawarra Health and Medical Research Institute, Wollongong, Australia (3) - The University of Melbourne, School of Chemistry, Department of Biochemistry and Molecular Biology, Parkville, Australia (4)

Keywords: Lipidomics, ultraviolet photon dissociation, ozonolysis, double-bond position

Introduction:

Lipids play different physiological roles as sources of stored metabolic energy or structural matrices in biological membranes. Alterations to the lipidome have been associated with the onset and progression of numerous diseases such as cancer, diabetes and cardiovascular diseases. Detailed structural characterization of lipids in complex extracts is thus desirable, including the determination of: (1) lipid class; (2) number of carbons and double bonds; (3) relative position of acyl chains; and (4) location and stereochemistry of double-bonds.

Current tandem mass spectrometry approaches identify lipid class, total carbons and double bonds, but not further information. In this study, we investigate the utility of new ion activation techniques, specifically, ozone-induced dissociation (OzID) and ultraviolet photodissociation (UVPD) for more comprehensive lipid structure elucidations.

Methods:

Lipids were extracted from human blood plasma [1] and analyzed using both shotgun and LC-MS approaches. For the latter, lipids were separated using a Thermo Scientific™ Accucore™ C30 column (2.1 x 150 mm, 2.6 μm) and a Thermo Scientific™ UltiMate 3000™ UHPLC system operated at 50°C, and a flow rate of 325 μL/min. ESI-MS analysis was performed in positive ion mode on a modified Q Exactive HF mass spectrometer with ozone (approximately 11% O₃ in oxygen O₂) replacing nitrogen as the HCD collision gas. Photodissociation was implemented on a Thermo Scientific™ Orbitrap Fusion™ Lumos™ Tribrid™ MS equipped with a 213 nm UVPD laser.

Results:

Preliminary experiments were performed incorporating OzID on a Thermo Scientific™ Q Exactive™ HF MS to identify the position of acyl chain position and double-bonds in phospholipids and triacylglycerols. By combining HCD activation with OzID on selected [M + Na]⁺ lipid ions on the Thermo Scientific™ Q Exactive™ HF MS, the relative position of acyl chains on the glycerol backbone could be determined without compromising in scan time. In a shotgun phospholipidome analysis of plasma it was possible to cover the mass range from m/z 650 to 950 in only 14 minutes. Importantly, a single phospholipid HCD/OzID spectrum provides information about the phospholipid class, the number of carbons and double bonds and their sn-position, therefore highlighting the presence of isomeric lipids.

Additionally, reaction of selected lipid ions with ozone inside the mass spectrometer can produce two characteristic product ions: an aldehyde and a Criegee ion. These ions are diagnostic for the double bond position and can be obtained by OzID increasing the HCD cell fill time and decreasing the collision energy. With this technique, double bond position of the analyzed lipids can be readily obtained. We found the triacylglycerol and phospholipid fractions within plasma samples to be rich in monounsaturated fatty acids containing a double bond in either the n-7 or n-9 position. OzID experiments were compared with lipid fragmentation by UVPD on an Orbitrap Fusion Lumos MS equipped with a 213 nm laser. Experiments conducted by Williams et al. [2] and Ryan et al. [3] report this new tool as a promising technique to complete structural elucidation of lipid structures.

For Research Use Only.

Conclusions

In our study we compared ozonolysis and ultraviolet photon-dissociation for comprehensive lipid structure elucidations. Insaturation in cholesterol ester, phospholipids and triacylglycerols can be identified with both techniques due to the generation of structural diagnostic product ions: the aldehyde and a Criegee ion for the Ozonolysis and a pair of ions formed by the cleaving in specific site of the double bond upon photon uptake. Linoleic acid (18:2n-6, n-9) was observed as the major polyunsaturated fatty acid in the lipidome with both techniques.

Novel Aspect:

Successful implementation of OzID and UVPD as complementary techniques for comprehensive global lipid structure elucidation and resolving isomeric lipids.

915 - A VERSATILE INTEGRATED AMBIENT IONIZATION SOURCE (IAMIS) PLATFORM AND ITS APPLICATIONS

Yu Bai (1) - Wanpeng Ai (1) - Shuting Xu (1) - Huwei Liu (1)

Peking University, College of Chemistry, Beijing (1)

Keywords: ambient ionization, hybrid ionization mode, complex sample, sensitive detection

Introduction:

Ambient mass spectrometry (AMS) has become more and more attractive because of its simple sample pretreatment process, the ability to operate in the open air, and capability to probe the surface of samples of any size and shape. The development of AMS opens a new insight for realizing high-throughput, nondestructive, in situ sample analysis from complicate sample[1-3].

The pursuit of high-throughput sample analysis from complex matrix makes the development of multiple ionization techniques with the complementary specialties on demand. Compared with single ambient ionization, combined or hybrid ambient ion source have been attempted to achieve complementary and high-throughput analysis, the reduction of sample complexity, and allowing the simultaneous detection of a broader range of analytes.

Methods:

A versatile integrated ambient ionization source (iAmIS) platform was proposed in this work, based on the ideas of integrating multiple functions, enhancing the efficiency of current ionization techniques, extending the application and decreasing the cost of the instrument. The design of the iAmIS platform combines 5 different ionization mode. All individual and combined ionization mode can be easily realized by modulating parameters.

Results:

AMS and their combination with other fast sample pretreatment approaches (for example, SPE and SPME etc) and the coupling with different instrument have been developed in our lab [2-4]. By using this iAmIS platform, coconut essential oil and perfume sample has been successfully analyzed. On the other hand, together with the immunalrecognition, DESI mode and signal amplification strategy, ultrasensitive detection of proteins in attomolar or zeptomolar were realized.

Conclusions

A versatile integrated ambient ionization source (iAmIS) platform was developed. Complex sample can be analyzed by using this platform, while the sensitive detection of protein at attomolar level can be realized using DESI-MS mode.

Novel Aspect:

A versatile integrated ambient ionization source (iAmIS) platform was developed for diverse applications.

Keywords: Desorption electrospray ionization-high resolution mass spectrometry, sampling substrates, new psychoactive substances, screening method

Introduction:

New psychoactive substances (NPS) are a large group of drugs of abuse: being considered as a major threat to public health, the development of rapid methods for their determination is in great demand. DESI-MS enables the in situ analysis of specimens in their native ambient state with minimal sample pretreatment [1,2]. In this context, the role of new materials as sampling substrates is of paramount importance to increase the instrumental response of the analytes.

Methods:

Different sampling substrates, i.e. commercial PTFE, poly(lactic acid) (PLA)- and silica-based films were synthesized and tested for the DESI-HRMS analysis of NPS (synthetic cannabinoids, synthetic cathinones, ketamine) in saliva. Oral fluid samples from volunteers outside clubs and during roadside patrol control on drivers were collected. A Micro Extraction by Packed Sorbent (MEPS)-DESI-HRMS method was optimized and validated for NPS determination.

Results:

The first phase of the study was devoted to the optimization of the DESI parameters affecting the ionization yield and the ion recovery in terms of: i) spray composition; ii) spray flow; iii) acquisition mode; iv) geometrical parameters. With the aim of achieving high sensitivity, different sampling substrates, i.e. unfunctionalized PLA, carbon/PLA-based films and a silica-based coating were synthesized and tested. Both unfunctionalized PLA and the silica-based coating proved to be the best choice for NPS detection. A full factorial design followed by the multi-criteria method of desirability functions was applied for the optimization of the MEPS extraction in terms of both loading and eluting cycles. The method was validated obtaining detection limits in the $\mu\text{g}/\text{kg}$ level, good linearity, precision and accuracy. Finally, the method was applied for NPS determination in saliva samples: achieving results in agreement with those obtained by a MEPS-GC-MS method used for confirmatory purposes.

Conclusions:

The synthesized support materials showed enhanced performances in improving the DESI-HRMS responses of the investigated compounds. Both the MEPS-DESI-HRMS and MEPS-GC-MS methods represent suitable tools for NPS analysis in oral fluids, combining screening and confirmatory purposes. In particular, the DESI-HRMS method allowed high throughput analyses characterized by both high sensitivity and selectivity, very short analysis times and low costs.

Novel Aspect:

Pivotal role of new supporting materials in enhancing the MS responses of the investigated compounds, thus allowing their rapid detection at trace levels in complex matrices

1181 - MATRIX EFFECTS IN LOW TEMPERATURE PLASMA IONIZATION (LTPI) MASS SPECTROMETRY

Andreas Kiontke (1) - Birte Scholz (2) - Walther Honscha (2) - Claudia Birkemeyer (1)

n/a, University Leipzig, Institute of Analytical Chemistry, Leipzig, Germany (1) - n/a, University Leipzig, Institute of Pharmacology, Pharmacy and Toxicology, Leipzig, Germany (2)

Keywords: low-temperature plasma ionization, ambient mass spectrometry, matrix effects

Introduction:

In recent years, various ionization techniques for mass spectrometry (MS) have been published that allow fast and simple analysis of samples under ambient conditions. Plasma-based methods in particular aroused the interest of many researchers because they offer great potential for use in mobile analytical devices. However, systematic investigations of signal response with this technique, such as the influence of the matrix on signal intensity, are still rare.

Methods:

In a first approach, six anilines each in nine different solvents were spotted on a paper target and analyzed by low temperature plasma ionization (LTPI) MS under optimized conditions [1]. In a second approach, 1 μ L of a 1 mM chlorpyrifos solution, a common pesticide, was analyzed from peels of different fruits, vegetables and mushrooms. The samples were analyzed using a plasma source coupled to a Bruker 3000+ ion trap.

Results:

Our results show that the impact of compound characteristics strongly outperforms the influence of simple sample matrices such as different organic solvents and water, with the trend that volatile solvents tend to decrease the signal responsiveness of the analytes. However, several specific solvent-analyte interactions occurred, which have to be considered in targeted applications of this method.

When choosing a single compound to assess matrix effects, the pesticide chlorpyrifos was detected on all tested different fruits, vegetables and mushrooms. However, we found a strong influence of the matrix on the signal response. For example, citrus fruits showed a particularly strong signal suppression.

Conclusions:

For the influence of the solvents, with the exception of water, most solvents seemed to be almost equally well suited for mass spectrometry with LTPI. However, a better signal intensity of the analyte with higher boiling solvents was achieved indicating that a high boiling matrix may be optimal with this ionization technique. In contrast, when investigating the influence of biological matrices such as peels of different fruits, vegetables and fungi, the response of chlorpyrifos was particularly decreased when analysis was done from the waxy surfaces of citrus fruits. To find the reasons for this behavior is an ongoing project in our lab.

Novel Aspect:

We present new insights on matrix effects in low temperature plasma ionization for mass spectrometry.

1023 - APPLICATION OF LDTD/TQMS-HRMS METHODS FOR QUANTIFICATION OF PSYCHOACTIVE COMPOUNDS IN TISSUE MICROSAMPLES.

Adam Borik (1) - Andrea Vojs Stanova (1) - Katerina Grabicova (1) - Tomas Randak (1) - Roman Grabic (1)

University of South Bohemia in Ceske Budejovice, Faculty of Fisheries and Protection of Waters/Laboratory of Environmental Chemistry and Biochemistry, Vodnany (1)

Keywords: LDTD, psychoactive compounds, microsamples, brain, juvenile fish

Introduction

Psychoactive pharmaceuticals exhibit continuously increased consumption trends[1]. Although a concentration reached only residual levels a negative effect on aquatic organism have been observed[2].

Laser diode thermal desorption (LDTD) is direct sample introduction technique without previous analyte separation. The new analytical method with this instrumentation have been developed for psychoactive compound analysis in tissue microsamples.

Methods:

The method has been evaluated for low (LDTD-QqQ) and high-resolution (LDTD-HRPS) mass spectrometer then compared with previously developed method employed liquid chromatography (LC-HRPS). The exclusion of separation technique brings some benefits such as dramatic reduction of analysis time requirement and exclusion of sample filtration as pre-treatment step which can be beneficial specially when total sample amount is limited.

Results:

The LDTD parameters were carefully evaluated to achieve sufficient number of data points, the highest and the most stable response.

Linearity of calibration curve (0.1-50 ng·g⁻¹) were confirmed for all mass spectrometers and compounds by R² coefficient (no lower than 0.9950).

Developed method was validated to brain tissue samples fortified at four concentration levels. For example, average recovery obtained for citalopram at concentration of 5 ng·g⁻¹ was 102±4 % (LDTD-HRPS) and 136±9 % (LDTD-QqQ), respectively. Similar results were obtained for tramadol in a case of QqQ.

Conclusions:

Validated method was used for analysis of brain tissue samples of juvenile fish exposed to psychoactive compounds at environmentally relevant concentrations. Preliminary obtained correspond with results from LC-HRPS and show potential of LDTD-QqQ and LDTD-HRPS method for analysis of complex biological samples in very short run time.

1257 - IMPROVEMENT OF NANO-ELECTROSPRAY AND DESORPTION NANO-ELECTROSPRAY SIGNAL BY REGULATION OF PRESSURE IN AN INLET OF TRIPLE QUADRUPOLE MASS SPECTROMETER

Lucie Borovcová (1) - Petr Fryčák (1) - Dominik Mosler (1) - Štěpán Dostál (2) - Vladimír Havlíček (3) - Karel Lemr (1)

Palacký University, Department of Analytical Chemistry, Olomouc, Czech Republic (1) - Palacký University, Department of Analytical Chemistry, Olomouc, Czech Republic (2) - ASCR, Institute of Microbiology, Prague, Czech Republic (3)

Keywords: mass spectrometry, nano-electrospray ionization, desorption nano-electrospray

Introduction:

Both nano-electrospray (nanoESI) and desorption nano-electrospray (nanoDESI) [1,2] use a narrow spray tip and consume small amount of samples. We modified a commercial ion source to switch between both ionization modes easily by the change of direction of a spray but sensitivity of nanoDESI was not sufficient.

To improve ion signal intensity we have tested regulation of pressure drop between an atmospheric and evacuated region of a mass spectrometer.

Methods:

Experiments were carried out using a Xevo TQD triple quadrupole mass spectrometer (Waters, Manchester, UK). The commercial inlet was replaced by a custom-made inlet with a sample cone and a heated capillary allowing for the pressure regulation. Nano-electrospray tips ($2 \pm 1 \mu\text{m}$ I.D., PicoTips, New Objective, Woburn, USA) were used for nanoESI as well as nanoDESI. Compounds in the wide mass range (m/z from 111 to 1922) were ionized to test the performance of ion sources.

Results:

Mass spectra were acquired for different values of pressure drop between an atmospheric and evacuated region and absolute as well as relative ion signal intensities were compared. Repeatability of the intensities was also evaluated. The relative intensities of ions of analytes were not influenced significantly but absolute signal was changed by pressure regulation in the whole studied mass range. Using nanoESI in positive ion mode, absolute ion signal of oxidized ultramark 443 (m/z 459) and ultramark 1621 (m/z 1222) increased 5 times for pressure drop 0.4 bar. For nanoDESI and the same pressure drop, signal of ion at m/z 459 and m/z 1222 was enhanced 7 and 9 times, respectively. Similar behavior was also observed in negative ion mode, e.g. for benzoic acid, sorbic acid or acetylsalicylic acid. Relative standard deviations of signal intensities did not change significantly for different values of pressure drop.

Conclusions:

New design of the mass spectrometer inlet allowed to increase yield of ions. For nanoDESI some ions were not detected without the pressure regulation. The pressure drop between 0.4-0.7 bar was suitable for the whole studied m/z range. The source modification needed an additional rough pump but sensitivity was improved dramatically. The effect can be influenced by a pumping system of a mass spectrometer as the pressure in an evacuated region depends on its capacity.

Novel Aspect:

New design of an ion source of a triple quadrupole mass spectrometer allowing pressure drop regulation to increase ion signal intensity.

1032 - BREATH ANALYSIS WITH SECONDARY IONIZATION HIGH-RESOLUTION MASS SPECTROMETRY (SESI-HRMS) IN THE CLINICAL ENVIRONMENT WITH A FOCUS ON DISEASE SPECIFIC BIOMARKERS IN CHILDREN WITH CYSTIC FIBROSIS

Tobias Bruderer (1) - Naemi Haas-Baumann (1) - Ronja Weber (1) - Astghik Baghdasaryan (2) - Srdjan Johnny Micic (1) - Simona Mueller (3) - Florian Singer (1) - Renato Zenobi (3) - Alexander Moeller (1)

University Children's Hospital Zurich, Division of Respiratory Medicine, Zurich (1) - Joint Medical Center Arabkir, Division of Allergology, Yerevan (2) - ETH Zurich, Departement of Chemistry and Applied Bioscience, Zurich (3)

Keywords: high-resolution mass spectrometry, ambient mass spectrometry, clinics, children, cystic fibrosis

Introduction: (Limit of 400 characters without spaces)

This is the first study to assess real-time "breath-prints" of children with SESI-HRMS (1, 2, 3) in the clinical environment. In the context of cystic fibrosis (CF), major contributors to morbidity are early and often subclinical pulmonary infection and pronounced neutrophilic inflammation. Early detection of disease and disease associated complications is crucial for implementing timely therapeutic measures to reduce disease burden and improve prognosis.

Methods: (Limit of 400 characters without spaces)

A novel SESI ion source was used with highly inert surfaces. We present data of 41 children (23 CF and 17 healthy controls, HC), 4 - 16 years old, from an ongoing cross-sectional study. Carefully pre-processed MS data was used for biomarker detection and classification. Mann-Whitney U tests together with q-values were applied to isolate m/z values. Subsequent variable reduction through principal component analysis was used to perform binary logistic regression.

Results: (Limit 900 characters without spaces)

Breath analysis with SESI-MS in the clinical environment requires careful control of temperatures, gas flows, contaminations (e.g. fatty acids from skin), cleaning procedures (e.g. cluster formation) and polarity switching. CF and HC had comparable BMI (17.7 ± 3.0 vs. 16.9 ± 2.3 , $p = 0.17$) and FEV1 (z-scores -0.45 ± 1.18 vs. -0.27 ± 1.13 , $p = 0.37$). Four children were *Pseudomonas aeruginosa* positive. We were able to isolate 43 m/z peaks with elevated intensity signals in CF vs. HC below an FDR control level of $q = 0.15$. Classification was applied to the first three principal components and resulted in significant outcomes (CF vs. HC) with an average accuracy of 81.3 % and a Cohen's Kappa value of 0.61. We could annotate the detected m/z peaks with molecular formulae and identify several homologues series of compounds. Structure elucidation is on-going based on comparison of fragment spectra with reference compounds for unequivocal confirmation of the involved molecular markers.

Conclusions (Limit of 400 characters without spaces)

Non-invasive breath analysis with SESI-HRMS identifies CF specific compounds in children. This will allow further phenotyping of CF lung disease, with the potential for early detection of airway infection.

Novel Aspect: (Limit of 150 characters without spaces)

This is the first study to assess real-time "breath-prints" of children with SESI-MS in the clinical environment. We could identify CF specific volatile compounds in children.

1103 - ONE SIZE DOES NOT FIT ALL: DART AND COMPLEMENTARY AMBIENT IONIZATION METHODS

Robert Cody (1)

JEOL USA, Inc., Mass Spectrometry, Peabody, MA (1)

Keywords: ambient, ionization, DART, paper spray, flame

Introduction:

Each of the ambient ion sources has specific strengths and weaknesses. No one method is universal. The application of several ambient ionization sources (DART, paper spray, inlet ionization and thermal ionization) to widely varying analytical problems will be presented from the perspective of the analytical chemist where no two sample types are the same.

Methods:

Samples were analyzed using a high-resolution time-of-flight mass spectrometer with an exposed atmospheric pressure interface. A Direct Analysis in Real Time (DART) ion source was coupled with a thermal ionization and pyrolysis device. Ambient ionization included a prototype paper spray source, a butane torch, and inlet ionization with 3-nitrobenzonitrile matrix.

Results:

A surprising application is the use of DART analysis for trace quantitation of D₂O in water. DART ionization with the thermal desorption source was applied to material analysis such as forensic identification of automotive paint chips and failure analysis, yet direct analysis of natural rubber gave better results than thermal desorption. The latter observation supports the hypothesis that the DART mechanism involves more than just thermal desorption. Other applications could not be analyzed by DART. Thermal ionization was used to detect trace iodide in milk. Inlet ionization was found to be the best method for rapid quantitation of polyphenols in tea infusions, while paper spray was the best method for copolymer analysis and detection of anthocyanins in berry extracts.

Conclusions

Although the DART mechanism involves ionization of atmospheric water, DART can still be used for trace D₂O quantitation. Temperature-programmed thermal desorption/DART is useful for material analysis, but it is not always the best approach. The DART mechanism may involve more than simple thermal desorption. While paper spray and inlet ionization produce similar ion types and similar mass spectra, their applications can be complementary.

Novel Aspect:

Contrasting different ambient ionization methods for unusual applications and observing some mechanistic clues

144 - ENHANCED COUPLING OF ACOUSTIC LEVITATION SAIL MASS SPECTROMETRY FOR DIRECT IONIZATION AND REACTION MONITORING

Elizabeth A. Crawford (1) - Demian Dietrich (1) - Cemal Esen (2) - Dietrich A. Volmer (3)

Saarland University, Institute of Bioanalytical Chemistry, Saarbruecken (1) - Ruhr-University Bochum, Department of Mechanical Engineering,, Bochum (2) - Humboldt University Berlin, Department of Chemistry, Berlin (3)

Keywords: Containerless reactions, ambient mass spectrometry, acoustic levitation, reaction miniaturization and acceleration

Introduction:

Acoustic (ultrasonic) levitation has emerged as the most practical method of object levitation. In our previous work using DART-MS [1], the heated gas beam of the DART ionization source could not penetrate the acoustic field of the levitator. In this work, solvent-assisted inlet ionization (SAIL), namely ambient ionization occurring directly in the heated inlet of the mass spectrometer, permitted collection and ionization of samples in a single step.

Methods:

Solvent-assisted inlet ionization (SAIL) was coupled to an ion trap mass spectrometer. Online ionization of microdroplet reactions suspended under ambient conditions in an acoustic levitator was achieved directly at the inlet of the mass spectrometer. Fused silica capillary (ID 100 μm x OD 360 μm) dimensions employed in SAIL were critical for optimal ionization and external resistive heating of the capillary inlet enhanced analyte signal intensities.

Results:

Solvent-assisted inlet ionization (SAIL) greatly improved the direct sampling capabilities for the coupling of liquid samples suspended in an acoustic levitator with online mass spectrometric detection. The fused silica tubing employed in SAIL proved optimal for directly extracting droplets from the levitator, simultaneously acting as the sample transfer tube and ionization source. Positioning of the fused silica capillary within the inlet also played a key role and the optimized ionization conditions were achieved by placing the ionizing end of the SAIL capillary less than a millimeter into the inlet of the mass spectrometer. A derivatization reaction of cholest-4-en-3-one with Gerard's Reagent T consisting of a 6 μL total reaction volume was compared with bulk (600 μL) reactions. Reactions carried out in the reduced reaction volume (in stillo) were approx. 10-fold faster. It was shown that external heating of the inlet of the mass spectrometer provided a 10-fold increase in signal intensity.

Conclusions:

Miniaturizing the reaction scheme to the microliter scale reduced the materials needed to carry out the reaction. Performing reactions in an acoustic field allowed all of the materials to react without interferences from container walls, therefore also enhancing reaction miniaturization. Coupling the micro-reactions with SAIL-MS enabled online real time mass spectrometric monitoring.

Novel Aspect:

Coupling of acoustically levitated droplets (in stillo) with SAIL mass spectrometry enabled enhanced online containerless micro-reaction monitoring.

602 - DIRECT INFUSION RESONANCE-ENHANCED MULTIPHOTON IONIZATION MASS SPECTROMETRY OF LIQUID SAMPLES UNDER VACUUM CONDITIONS

Hendryk Czech (1) - Claudia Kruth (1) - Martin Sklorz (1) - Johannes Passig (1) - Sven Ehlert (2) - Achille Capiello (3) - Ralf Zimmermann (1)

University of Rostock, Chair of Analytical Chemistry, Rostock (1) - Photonion GmbH, Research & Development, Schwerin (2) - University of Urbino, LC-MS Laboratory, Urbino (3)

Keywords: mass spectrometry, photoionization, atmospheric pressure, petroleum, PAH

Introduction:

The generation of ions with ambient ionization techniques are affected by the sample matrix leading to concurrent ion yields of molecular ions, quasi-molecular ions formed by adducts and fragments. In this study, we present direct-infusion resonance-enhanced multi-photon ionization (DI-REMPI) at 266 nm combined with a direct liquid interface [1] for soft and matrix-independent analysis of aromatics in complex oil samples.

Methods:

The instrumental setup basically consists of a nano-flow UPLC for sample injection, a quadrupole mass spectrometer [2] and an Nd:YAG laser. A polycyclic aromatic hydrocarbon (PAH) solution, five diluted crude oils and four diesel samples were injected by a manual injection valve of 20 nl in a continuous solvent flow (400 nl/min) of acetonitrile. Only the tip of the capillary is heated to 280°C and ends 1 mm in front of the repeller inside the ion source.

Results:

The total eluent enters the ion source where it becomes promptly nebulized followed by desolvation, which is supported by the heater enclosing the repeller. REMPI under vacuum conditions and moderate laser intensities refers to a soft, selective and sensitive ionization technique for PAHs [3], so molecular ions of six PAHs were detected from the standard solution with good linear relation between intensity and concentration. Moreover, the addition of 1, 3, 10 and 30% toluene to one crude oil did not affect the mass spectrum except its molecular ion.

In the next step, crude oils were analyzed and compared to REMPI mass spectra of evolved gases released from a thermal balance [4]. Due to the total transport of sample into the ion source by DI-REMPI, the m/z range is extended that compounds which decompose in the thermal balance can still be detected. However, homologue series of odd m/z between 200 and 300 dominated the mass spectra of the crude oils which are assigned to ionization fragments of species with high molecular weight and low ionization energies.

Conclusions

DI-REMPI with direct liquid interface enables to enhance the m/z range of analytes by introducing the entire sample into the ion source while maintaining all advantages of REMPI under vacuum conditions, including no influence of matrix, selectivity for aromatics and the generation of molecular ions. Therefore, DI-REMPI is an alternative ionization technique for liquid chromatography or direct mass spectrometry.

Novel Aspect:

DI-REMPI is a novel soft ionization technique for liquid chromatography or direct mass spectrometry to investigate aromatics in liquid samples without matrix effects.

Keywords: acoustic loading; mass spectrometry; high-throughput screening;

Introduction:

Mass spectrometry (MS) is a widely utilized label-free technology capable of measuring a broad range of analytes but lacks the throughput to support large HTS campaigns. Current commercial ESI MS-based systems using solid-phase extraction (SPE) are capable of running medium-sized screens. We have implemented a platform utilizing acoustics to load samples into a time-of-flight mass spectrometer capable of analysing more than 100,000 samples per day.

Methods:

An acoustic transducer emits sound waves into a sample in a 384-well plate located on a moving XY-stage. High voltage is applied to a charging cone above the well, inducing charge separation in the sample. The acoustic wave ejects a mist of droplets which are drawn through a heated transfer interface into the MS, during transit droplets dry and an ion beam is generated. The extracted ion peak for substrate and product from each well are used to calculate enzyme activity.

Results:

AMI-MS was used to build an enzyme assay to identify inhibitors from the AZ compound collection. Having established the kinetic parameters for this enzyme target, validation sets were tested to understand the variability within the assay. Once the robust nature of both the assay and this new MS technology were proven to meet the requirements of a high throughput screen the assay was moved into production. In total over 2 million samples were tested using a single automated AMI-MS platform over a 5 week period. Typical throughput of 100,000 samples per day were achieved. From the collection, 6745 compounds were identified in the first round of screening as actives - a hit rate of 0.3%. From this population of compounds, 4872 were followed up in concentration response format to confirm the activity, ~75% were confirmed as actives. The AMI-MS platform was further utilised during triaging of compounds to identify false positive samples which were likely to be contaminated with zinc.

Conclusions

AMI-MS proved a robust technology capable of screening a large compound collection (>2 million samples) and identifying chemical equity capable of inhibiting the enzyme target. Typically, this single instrument was capable of processing samples at a rate of 100,000 data points per day. The final hit rate in this assay was ~0.3%, of these the majority confirmed as active in follow up testing (75%).

Novel Aspect:

This is the first demonstration of AMI-MS technology successfully supporting a full collection screen against a pharmaceutically relevant target.

1040 - ION CHEMISTRY FUNDAMENTALS OF SECONDARY ELECTROSPRAY IONIZATION MASS SPECTROMETRY (SESI-MS) FOR VOC ANALYSES

Kseniya Dryahina (1)

J. Heyrovský Institute of Physical Chemistry, Department of Chemistry of Ions in Gaseous Phase, Prague (1)

Keywords: SESI-MS, VOC, chemical ionization, ion-molecular reactions, SIFT-MS

Introduction:

SESI-MS is a highly sensitive technique for the analyses of trace gaseous analytes in air and breath. It has been previously applied to several metabolomic studies, including lung infection in a murine model and identification of volatile metabolites with molecular weights up to 1000 Da in human breath. However, a major weakness of this method is a lack of accurate quantification of gaseous analytes, which hinders its application in the biological and medical areas.

Methods:

The physical and chemical processes, which lead to gas-phase ionization of VOC in electrospray and influence of transfer line on the ion composition, are studied. Sequences of ion-molecular reactions involved in the formation of product ions are described and the chemical kinetics is assessed for equilibrium and non-equilibrium situations. Chemical kinetics modeling is exploited combining analytical and numerical methods based on experimental data.

Results:

Chemical kinetics of hydrate ion formation is described as a function of temperature and partial pressure of water vapor in the gas present in the ionization chamber. The influence of transfer from the atmospheric pressure ionization region to the vacuum of the mass spectrometer via heated capillary on the ion composition is characterized. Representative mass spectral data are shown combining the SESI-MS and the selected ion flow tube mass spectrometry, SIFT-MS, experiments. Factors influencing the quantitative sensitivity of SESI-MS are summarized.

Conclusions:

The step-by-step understanding of chemical and physical processes affecting the composition of ions on their journey from the ESI droplets, via the atmospheric pressure gas containing traces of analyte, through the ion transfer line into the low pressure regions of the mass spectrometer will lead into robust methods of quantification of VOCs from the SESI-MS data.

Novel Aspect:

Description of sequence of processes involved in the formation of product ions in SESI will lead into a practical method of absolute quantification of trace gaseous analytes.

345 - SPIDERMASS A NOVEL TOOL TO TACKLE IN-VIVO MASS SPECTROMETRY

Philippe Saudemont (1) - Emmanuel Bouchaert (2) - Quentin Pascal (2) - Michael Ziskind (3) - Dominique Tierny (2) - Michel Salzet (1) - Isabelle Fournier (1)

PRISM Inserm U1192, University of Lille, Lille (1) - Oncovet Clinical Research, University of Lille, Lille (2) - CNRS UMR 8523 PhLAM, University of Lille, Lille (3)

Keywords: in-vivo, real-time, Laser, diagnostic, surgery

Introduction:

Over the past 20 years, Mass Spectrometry has been translating progressively from analyzing extracts to raw surfaces. This went with the developments of technologies operating under ambient conditions all grouped within the field of Ambient Ionization Mass Spectrometry (AIMS) [1]. AIMS enable the analysis of raw material without sample preparation but are not suited for in-vivo analysis and at least not with minimal invasiveness. We have developed a novel system for in-vivo MS analysis and in-man use.

Methods:

SpiderMass [2] is composed of an OPO laser system tuned to 2.94 μm to access the most intense absorption band of water molecules. The laser irradiation promotes the excitation of water present within the tissues leading to a phase explosion. The plume of desorbed material is transferred to the MS instrument by aspiration through a tubing of several meters length connected to the MS instrument through a dedicated interface which replaces the conventional source.

Results:

We have studied and optimized the performances of our instrument for different applications. In particular, we have developed a fibered laser terminated by a handpiece allowing free scanning of all surface types. At the laser energy requested for ion production, this system is of low invasiveness only leaving a temporary white trace, which disappears within minutes after the experiment, at the surface of scan tissues. We have then assessed the system for different applications. In oncology, we demonstrate that SpiderMass molecular signatures have the requested specificity and sensitivity for classification purposes of cancer types and grades as exemplified with sarcoma. Further experiments performed in-vivo on model mice developing breast cancer and then intraoperatively at the veterinary surgery room confirm the performances of SpiderMass for cancer research. But SpiderMass reveals also to be well suited for fast diagnostic from FFPE tissues at the pathologist bench, bacteria typing or dermatology with real-time in-man DMPK.

Conclusions

The novel developed SpiderMass system with its fibered laser demonstrates to be an easy and robust tool for MS analysis in-vivo with a minimal invasiveness. This system opens the door to many applications in various fields including clinics for surgeons and pathologists. The capacities of the system to operate in both positive and negative ion modes and the possible analysis of proteins makes it as well as very interesting tool for biological research.

Novel Aspect:

Novel system enabling in-vivo MS analysis

Keywords: Surgery navigation, Cancer, Molecular resonance, EESI

Introduction:

Quantum Molecular Resonance (QMR) technology was recently developed as a surgical tool for tissue dissection [1]. In QMR a well-defined spectrum of high-frequency electromagnetic field is produced to selectively break molecular bonds without inducing a significant rise in local temperature. In general purposes QMR was designed for the surgery. Here we demonstrate QMR technology in combination with MS as a novel Surgery Navigation technique. We show that this technique allows on-line ambient molecular analysis of biological tissues with high chemical sensitivity.

Methods:

The quantum molecular resonance generator was used as a desorption probe for breast cancer tissues chemical scanning. The probe was coupled with air jet pump which delivered desorbed molecules into the home-made EESI source coupled with qTOF mass spectrometer (Maxis, Bruker Daltonics, Germany). Tissue samples were obtained in the Research Center for Obstetrics, Gynecology and Perinatology and stored under 193 K until measurements. All data were processed with PCA and OPLS-DA methods to determine the most significant differences between tissues.

Results:

The method utilized in the study allowed obtaining highly intensive, stable and reproducible signal from tissues in both positive and negative ion modes. Molecular composition differences in real time were shown for different cancer tissues. Multivariate analysis was used to classify the mass spectrometric data. Score plots from OPLS-DA revealed good clusterization of data points with accordance to tissue source. Real-time feedback to the surgeon about margin status in patients with breast cancer was shown. High accuracy tumor boundary detection is also presented.

Conclusions:

A novel on-line ambient platform for biological tissue analysis is introduced

Novel Aspect:

Molecular Surgery Navigation system based on the combination of mass spectrometry with molecular resonance probe desorption was developed.

1281 - STUDY ON THE IONIZATION MECHANISM OF POLYMERS UNDER CLUSTER ION IRRADIATION

Makiko Fujii (1) - Jiro Matsuo (2)

Yokohama National University, Graduate School of Environment and Information Sciences, Yokohama, Japan (1) -
Kyoto University, Quantum Science and Engineering Center, Kyoto, Japan (2)

Keywords: ionization, cluster ion beam, polymer, SIMS

Introduction:

Secondary Ion Mass Spectrometry (SIMS) has been widely used for the analysis of semiconductors and electronic devices in past decades. Recently, the development of novel ion beam, cluster ion beam, enabled us to detect large organic molecule in SIMS analysis. However, the sensitivity of molecular ion derived from large organic molecules are still insufficient for high-resolution imaging mass spectrometry with SIMS.

Methods:

To increase the sensitivity of organic molecules in SIMS, some alkali metals and organic acids were added to the sample. This is because molecular ions are generally detected as alkali metal-adducted molecular ion or proton-adducted molecular ions. Therefore, by adding alkali metal ion or proton, the molecular ion yields can be thought to be enhanced.

Results:

The model polymer samples used in this study were Polyethylene Glycol (PEG) of average molecular weight of 1000, 2000 and 3000. Lithium, Sodium, Potassium and Cesium were added to PEG sample to investigate the molecular ion yield enhancement by cationization agent. Citric acid and some other organic acids were added to investigate the molecular ion yield enhancement by protonation agent. The concentration of each additive was optimized in the preliminary study. The ion beam used in this study was Argon gas cluster ion beam (Ar-GCIB) of acceleration energy of 10 keV originally developed in Kyoto University. The ion dose density was around 1×10^{12} ions/cm² in each measurement. The molecular ion yield of PEG1000, 2000 and 3000 were calculated and compared each other in order to discuss the degree of the molecular ion yield enhancement depends on the molecular weight.

Conclusions:

The molecular ion yield enhancement could be confirmed in all additives in the comparison with without additive sample. In addition, the degree of the molecular ion yield enhancement depended on the chemical structure of targeted organic molecule besides molecular weight.

Novel Aspect:

The molecular ion yield with cationization or protonation agents was investigated. It will help understanding the ionization mechanism under ion beam irradiation.

979 - A COMPARISON BETWEEN DIATHERMIC KNIFE AND CO₂-LASER COUPLED TO REIMS-TOF FOR INSTANTANEOUS TISSUE CLASSIFICATION

Michele Genangeli (1) - Ron M.A. Heeren (1) - Tiffany Porta (1)

M4I, Maastricht University, Maastricht (1)

Keywords: , CO₂-Laser, MSI, DESI, REIMS, TOF

Introduction: (Limit of 400 characters)

Lately, numerous studies have shown the benefit of coupling rapid evaporative ionization mass spectrometry (REIMS) to a diathermic knife for rapid tissue sampling and characterization. In addition, Co₂ laser can also be used for the same purpose but in a less invasive manner. Herein, we assess the opportunities and limitations of the laser and diathermic knife coupled with REIMS based on quality of data generated and invasiveness of both sampling techniques.

Methods: (Limit of 400 characters)

Fresh tissue (i.e. muscle, liver, bone, bone marrow, cartilage, skin, fat) from different animals were analysed using the two sampling tools. Generated vapors were directly analyzed by a REIMS-TOF system, and tissue/species-specific molecular profiles were recorded. These profiles were integrated in a database and multivariate statistical analysis was employed to build a classification/prediction model which would function as real-time recognition software.

Results: (Limit 900 characters)

It was possible to generate tissue vapors rich in lipids with both sampling tools. Each tissue-specific mass spectrum (= molecular fingerprint) can be recorded within 3 seconds after ablation and cauterization. The laser system allows controlling penetration power and wave type, which results in cleaner spectra with better overall signal, higher S/N ratio and higher reproducibility when compared to the diathermic knife. A statistical model employing principal component analysis and linear discriminant analysis (PCA-LDA) was built based on the characterization of different molecular profiles such as tissue type and animal species. When using one or the other technique on the same tissues, similar molecular profiles are displayed, which demonstrates the possibility to build a common database from both sampling tools.

After analysis, samples were frozen and cut into 10 µm sections. Further investigations via DESI-TOF imaging were conducted to the different lipids composition and distribution in the tissues around the burnt area.

Conclusions (Limit of 400 characters)

Combining REIMS with different sampling interface has shown promises for several applications such as food analysis. We demonstrate laser-REIMS to produce clean cut and more reproducible signal, and the possibility to sample a wider variety of samples including hard tissues, which is not possible with the diathermic knife. The possibility to build a common database for both tools renders REIMS more versatile and extends its field of possible applications.

Novel Aspect: (Limit of 150 characters)

Novel versatile and robust applications of REIMS technology with the possibility to build a common database between sampling techniques for instant sample recognition.

928 - MULTI-SCHEME CHEMICAL IONIZATION INLET FOR ATMOSPHERIC PRESSURE MASS SPECTROMETRY APPLICATIONS

Matti P. Rissanen (1) - Jyri Mikkilä (2) - Jani Hakala (2)

University of Helsinki, University of Helsinki, Helsinki (1) - Karsa Ltd, Karsa Ltd, Helsinki (2)

Keywords: Atmospheric pressure chemical ionization, Multiple reagents

Introduction

Atmospheric Pressure Chemical Ionization (APCI) is a sensitive and selective method to ionize the sample for mass spectrometric analysis. Different ionization chemistries ionize different compounds, and using several ionization schemes will give a comprehensive view on the composition of the sample, without losing the selectivity of the chemical ionization method.

Methods

We introduce a multi-scheme chemical ionization inlet (MION) capable of combining multiple ionization schemes in one instrument. The MION consists one or more ion sources, from which the reagent ions are mixed in the sample without contaminating the sample with the neutral reagents. The ion sources can also be turned off to measure the naturally occurring ambient ions. The MION can also be equipped with a filter desorber/calibrator unit allowing the analysis of filter samples and liquid microinjections.

Results

We studied the performance of the MION with two reagent ions, nitrate (NO_3^-) and bromide (Br^-). The MION is capable of switching between the ionization schemes within seconds, and turning the ionization sources off and switching into the ambient ion mode is as fast. The neutral reagents are prevented from mixing with the sample, leaving the sample as unperturbed as possible.

We determined the sensitivity of the MION with gaseous sulfuric acid in NO_3^- mode. Sulfuric acid represents the compounds that get ionized at (or close to) the collisional limit. The sensitivity of the MION was found to be on par with the current state of the art NO_3^- -chemical ionization inlet at the low ppq/s level [1].

We also explored the alpha pinene ozonolysis. The reaction results in, among others, a multitude of compounds having a formula $\text{C}_{10}\text{H}_x\text{O}_y$, where the amount of oxygen (y) varies over a wide range [2]. The Br^- chemistry is selective towards the less oxidized ($y = 2 - 10$) species, including the hydroperoxyl radical, whereas the NO_3^- chemistry is towards the more oxidized species ($y = 4 - 11$).

Conclusions

Our new MION inlet greatly expands the possibilities what can be done in the field of APCI-mass spectrometry with one mass spectrometer. The fast switching and superb sensitivity allows for as many ionization schemes as the user finds practical, without losing much of the time resolution.

Novel Aspect

We have produced a new atmospheric pressure chemical ionization inlet, MION, capable of switching from one ionization scheme to another within seconds.

588 - OBSERVABLE CHARGE STATES IN NATIVE MS: DIFFERENCES BETWEEN ESI AND LILBID

Jan Hoffmann (1) - Kudratullah Karimi (1) - Nina Morgner (1)

University, Goethe University Frankfurt / Institute of Physical and Theoretical Chemistry, Frankfurt (1)

Keywords: native MS, observable charge states, nESI, LILBID

Introduction:

Many applications used in mass spectrometers are highly charge state dependent processes. This includes CID (collision induced dissociation), CIU (collision induced unfolding) as well as IM-MS (ion mobility MS). Different ionization methods result in different detectable charge state distributions. Depending on the application highly and lowly charged species both have their advantages and disadvantages respectively.

Methods:

In LILBID[1] droplets of the analyt solution are transferred into vacuum and irradiated by IR laser pulses. This leads to an explosive expansion of the droplet and thus release of analyte ions into gas phase. The ions are collected using an ion funnel and transferred into a modified qToF[2] (QTOF I; MS Vision) mass spectrometer. Different mechanisms of dissociation (laser power and collision cell) can be combined. For comparison a commercially available nanoESI-MS instrument (Synapt G2s; Waters) was used.

Results:

To investigate the observable charge state distributions samples of both native and chemically modified[3,4] lysozyme were analyzed. Modifying lysosome was achieved by acetylation (alternatively: by propylation) of amino groups by varying excess of acetic (propionic) anhydride at basic pH value. According to the protein's isoelectric point a change in charge distribution could be observed either with varying pH or with different degree of acetylation in either ion mode. Typically the actively ionizing nanoESI results in highly charged species which is in contrast to the non-actively ionizing / desorbing LILBID ion source where mostly lowly charged species are detected. In addition, with increasing hydrophobicity due to increasing modifications signal intensity issues also occurred.

Conclusions:

When analyzing the average per-species charge states a decrease depending on the degree of modification could be observed as expected. Both ion sources behave very similar in this respect. Interestingly the actual decrease in charge state is significantly lower than expected indicating more complex underlying mechanisms.

Novel Aspect:

LILBID coupled to a qToF enabled the investigation of small modifications to biomolecules used here to study the observable charge states of different ion sources.

1176 - PERFORMANCE ENHANCEMENT USING HE BUFFER GAS IN A SMALL-SCALE LIT FOR IN-THE-FILED MASS SPECTROMETRY

Aurika JANULYTE (1) - Yves ZEREGA (2) - Jacques ANDRE (2)

Aix-Marseille University, Laboratoire PIIM, Marseille (1) - Aix-Marseille University, Laboratoire MADIREL, Marseille (2)

Keywords: Instrumentation; in-the-field and miniature MS; LIT; Ion/buffer gas collision

Introduction:

A LIT, composed of hyperbolic electrodes and disk endcaps, operates a Single Ion Monitoring mode consisting in a series of injection, cooling, isolation and ejection steps, realized by means of only DC switched voltages, to simplify conception and guarantee stability [1,2].

The collisional process of ions with buffer gas is simulated with the aim of improving mass analysis performances depending on: peak width, analysis duration and relative number of ions involved.

Methods:

The design of the electrodes, then ion trajectories have been computed using CPO software [3]. An additional subroutine has been implemented for modeling ion/buffer gas colliding as follows: random drawing according to Poisson law to define collision times (event-driven simulation); modifying ion velocity according to elastic collision law with random uniform scattering angle after collision.

Results:

Collisional process does not induce a significant modification of ion state (distributions in positions and velocities) due to short duration-time of trap filling with ions at injection, with He pressures less than 10^{-3} torr.

For cooling stage, the trap is operated in RF only mode. The collisional process improves the relative number of confined ions. The cooling duration-time, to reach equilibrium ion state, has been estimated at 4.5 ms, involving almost 70 collisions, with He pressure equal to 10^{-3} torr. At equilibrium ion state, the distributions tend to Gaussian distributions, except for the distribution of axial ion positions.

For ion isolation stage, the trap is operated close to the apex. In these conditions, the cooling process induces fast-ion loss. A set of values has been found: 150 μ s for isolation step time-duration and 50% of injected ions involved in the mass spectra, with mass separation of 1u and He pressure equal to 10^{-3} torr.

Conclusions

To reduce ion loss observed during isolation step, the He buffer gas pressure could be reduced, however the duration of cooling time will be increased by the same factor. Dividing by two the pressure, the number of confined ions during isolation step has been found up to 70% and the duration of the sequence is about 10 ms.

Mass separation could be improved by a specific ramp to move the trap operating point from the center toward the apex of the stability diagram.

Novel Aspect:

Same performances have been obtained with a small-scale LIT than with a mass filter with larger length for in-the-field application.

399 - CHARACTERIZATION OF COLD ELECTRON IONIZATION FOR PORTABLE MASS SPECTROMETERS

Seung Yong Kim (1) - Wanseop Jeong (2) - Bongyoon Yi (2) - Jae Yeong Eo (1) - Byeongwon Kang (3) - Hyun Sik Kim (1) - Mo Yang (1)

Korea Basic Science Institute, Mass Spectrometry & Advanced Instrumentation, Cheongju (1) - Korea Basic Science Institute/Mass Spectrometry & Advanced Instrumentation, Chungbuk National University/Department of Physics, Cheongju (2) - Chungbuk National University, Department of Physics, Cheongju (3)

Keywords: Cold Electron Ionization Source, Microchannel Plate, UV LED, Portable Mass Spectrometer

Introduction

Cold electron ionization (CEI) has been developed using a microchannel plate (MCP) electron multiplier initiated by UV photons from light-emitting diode (LED) [1]. Pulsed mode CEI consumed only 5 μW in average and can be controlled in nanosecond scales and is expected to replace the hot cathode electron ionization in portable mass spectrometers with the advantages such as low power consumption, low temperature, and precise control of pulse width and electron density.

Methods

A microchannel plate is used to generate the secondary electrons by illumination of an UV photons generated by various LEDs (240, 260, 280, and 300 nm wavelength) and then sequential current amplification of the electrons was performed with various combinations of electron multipliers such as microchannel plates and channeltrons. A high voltage power supply has delivered up to 2400 V. The emitted electron beam current signal is picked up by an impedance-matched anode.

Results

The property of the electron beam pulse emitted from the MCP illuminated by photon pulse from an UV LED was studied. With UV LED operated with 10 V input in 3 ns, extremely short electron beam pulse was generated which can be used as an ionization pulse in TOF MS. The measured electron beam current was more than $\sim 10^7$ electrons within 2 ns. Zubarev et al. has reported 10^7 - 10^8 electrons were generated by an incident nuclear fission fragments from ^{252}Cf and recorded mass spectra of various samples with a time-of-flight mass spectrometer (TOF MS) [2]. Similar ions were observed with CEI as previously reported in electron-avalanche-desorption (EAD) ionization MS. EAD ionization required sufficient electrons to desorb and ionize the molecules and record the mass spectra. For the portable TOF MS, the duration of the electron beam pulse from CEI can be precisely controlled in nanosecond scales and also provide the sufficient current, so that CEI generated enough electrons to be applicable to the portable TOF MS as well as ion trap MS.

Conclusions

Cold electron ionization provided more than $\sim 10^7$ electrons within 2 ns. CEI provided high enough current to ionize the gas analyte in ion trap and TOF MS. In addition, 2 nanosecond cold electron beam pulse had been demonstrated to be an extremely short pulse for portable TOF MS. This CEIS is expected to be applicable for the portable MS with low power consumption and precise control of pulse width and electron density.

Novel Aspect

Extremely short and high current cold electron beam pulse was generated by operating a UV-LED and electron multipliers and applied for the portable ion trap and TOF MS.

343 - A UNIQUE APPROACH TO CHARGING IONS FOR LCMS

Charles Jolliffe (1) - Lisa Cousins (1) - Reza Javahery (1) - Anna Kornilova (1) - Heather Gamble (1) - Mehrnaz Sarrafzadeh (1)

Perkinelmer Inc., RND, Woodbridge (1)

Keywords: ESI, APCI, MS/MS, LCMS

Introduction:

This paper discusses a novel approach to charging ions at atmospheric pressure, suitable for both polar and nonpolar compounds, as well as extracting ions from opposite polarity droplets. Typically ESI is used with the majority of polar compounds and APCI with less polar. Here we discuss a single approach capable of producing an optimum signal for the full range of analyte polarity and to extract ions of opposite polarity.

Methods:

Experiments were performed using a QSight 210 triple quadrupole mass spectrometer with a modified ion source probe that permits adjustable regions of turbulence and laminarization at the exit of the ion formation region. Analytes including myoglobin, reserpine and chlordane were studied. MRM sensitivity was taken at a 500ul/m, as a function of droplet charging. The same single probe physical position and sample tube position was maintained.

Results:

Results are reported for a prototype ion source probe that embodies the characteristics of a turbulence and ion entrainment as well as the ability to optimally charge droplets, including the selection of an ion polarity opposite to the droplet polarity. Single probe S/N at high flow is compared with typical individual APCI and ESI probe results, using compounds which respond to both ESI and APCI, as well to those which respond predominantly to ESI or APCI. For example, although conventionally myoglobin is ESI favourable, reserpine is responsive to both ESI and APCI, and chlordane is APCI favourable, the new probe demonstrates suitable performance for all types. Single probe MRM data was taken of the opposite polarity of the charged droplets for all of the chosen analytes. For example, it was observed that the reserpine droplets can have a variable negative charge while still observing positive reserpine ions. A graph of the reserpine sensitivity vs voltage difference between the probe nebulizer tip and desolvation region illustrates this phenomenon.

Conclusions

The data from the MRM of the chosen analytes show that single probe sensitivity with optimized droplet charging is at least comparable to the individual APCI or ESI probes.

In addition, the single probe shows that significant MRM sensitivity is possible for APCI favourable compound chlordane using oppositely charged droplets. The effect of oppositely charged droplets upon chemical interferences is unexplored at this juncture.

Novel Aspect:

A single atmospheric pressure ion probe produces comparable sensitivity to individual ESI and APCI probes as well as producing ions from oppositely charged droplets.

222 - GRAPHENE LAYER SUBSTRATE ASSISTED LASER DESORPTION AT ATMOSPHERIC PRESSURE FOR HIGH SPATIAL RESOLUTION MASS SPECTROMETRY IMAGING

Jae Young Kim (1) - Sun Young Lee (1) - Hee Jin Lim (1) - Ji-Won Park (2) - Dong-Kwon Lim (3) - Dae Won Moon (1)

Daegu Gyeongbuk Institute of Science and Technology (DGIST), Department of New Biology, Daegu (1) - Chungnam National University, Graduate School of Analytical Science and Technology (GRAST), Daejeon (2) - Korea University, KU-KIST Graduate School of Converging Science and Technology, Seoul (3)

Graphene Layer Substrate Assisted Laser Desorption at Atmospheric Pressure for High Spatial Resolution Mass Spectrometry Imaging

Keywords: Ambient MS imaging, graphene layer, laser desorption, small molecule analysis, micro-meter spatial resolution

Introduction:

We are demonstrating a new method that can facilitate the laser desorption process without gold nanoparticle treatment step. The use of graphene layer substrate is excellent platform to induce the desorption process using 532 nm-continuous wave (CW) laser. By using this method, high spatial resolution atmospheric pressure mass spectrometry (AP-MS) imaging of humid tissues can be obtained.

Methods:

We used the previously developed AP-nanoPALDI MS system with a change in laser source [1]. One of the most widely used lasers, a 532nm CW laser, was used as the desorption source. A graphene layer substrate was prepared by transferring commercial CVD graphene on Cu foil to slide glass. The specimen was placed on graphene layer substrate and positioned on the scanning stage for MS imaging.

Results:

Many previous studies reported using graphene layer as a substrate for absorbing laser energy have shown that the laser source was located above the specimen and the laser light first met the specimen rather than the graphene layer [2-4]. Thus, in order for the graphene layer to role as a light absorbing layer, the thickness of the specimen had to be thin. In our proposed AP-MS system, since the laser light was focused on the specimen by the objective lens of the inverted type optical microscope, the laser source was placed under the specimen, so that the laser light was irradiated to the graphene layer first and the light energy was converted to heat from graphene layer and transferred to the tissue specimen. Therefore, micrometer-resolution ion images for mouse hippocampal tissue slices were obtained under ambient conditions.

Conclusions:

Compared to the preparation of the nanoparticles treated biological specimen, while the nanoparticle treatment of the specimen was omitted, the process of transferring the graphene layer was added to the slide glass substrate. The graphene layer substrates can be prepared and stored in advance, resulting in a simplified specimen preparation and a great advantage in preparing living tissue faster.

Novel Aspect:

The efficient laser desorption of bio-molecules on the wet-state hippocampal tissue is possible by use of graphene layer substrate.

keywords ; Time-of-Flight, cold electron ionization, portable mass spectrometer, nanosecond electron pulse

Introduction

A time-of-flight mass spectrometer (TOF MS) is widely used due to fast data acquisition, wide mass range and high sensitivity. Since a very short ionization pulse is essential for high mass resolving power, a fast laser pulse is commonly used in a TOF MS. However, the size and power requirements of the laser device limit the miniaturization of a TOF MS. To solve this problem, a tiny cold electron ionization (CEI) source was suggested to generate the short ionization pulse.

Methods

The cold electrons were generated with 3 microchannel plates (MCPs) and one of MCPs was illuminated by UV photons to generate the secondary electrons [1]. They are accelerated to a metal surface where sample molecules are adsorbed. The desorbed ions are analyzed through a 18 cm ion flight tube and recorded with a oscilloscope with 2.5 GHz bandwidth. The electronic circuit for nano second electron pulse was operated with 10 V, 200 mA and 3 nanosecond.

Results

The cold electron trajectory was calculated with SIMION[®] Version 8.1 and analytical Methods: And the calculated trajectory was confirmed with the luminescence of phosphors materials pasted on the sample plate. The cold electron ionization source recently developed in this laboratory has shown a current of up to 9 mA in 2 nanoseconds duration. This indicates the number of electrons up to 3×10^7 that would be enough for recording an usual mass spectrum. The size of cold electron ionization source is less than 2 cm³ and the power consumption is 10 mA with a voltage of 10 V, which means 0.5 nW in average power with a 5 nanosecond per second. With the integrated CEI TOF MS, volatile gas molecules, benzene, toluene and xylene, were injected separately and detected molecular ions with H⁺ and C_nH_{2n-1}⁺ ions as previous reported in EAD (electron-avalanche-desorption) MS [2].

Conclusions

The experimental results of CEI TOF MS using a small cold electron source that generates more than 10⁷ electrons in a few nanoseconds indicate that a portable CEI TOF MS with a suitable high mass resolution can detect the gas molecules. Further instrumental optimization is under development and higher electron currents and improved operating parameters will provide a useful TOF MS applicable in the field.

Novel Aspect

A portable TOF-MS was developed using an extremely short ionization electron beam pulse generated with cold electron ionization method.

Keywords: GC-MS/MS, EI, soft and hard ionization, GC, MS, MS/MS

Introduction: Ionization Sources in Mass Spectrometry

Electron Ionization is one of the most frequently used methods in MS. While being efficient, reproducible, and non-selective, it is still a "hard ionization" method that results in high fragmentation and loss of molecular ions. A dual mode EI (DMEI) source that allows both "soft" and "hard" ionization has been developed and coupled to a GC. Such combination allows both qualitative and quantitative analyses for various volatile and semi-volatile mixtures.

Methods:

Dual ion source was coupled to a modified PerkinElmer QSight220 triple quadrupole MS and a PerkinElmer Clarus 680 GC. Gaseous pure compounds and their mixtures were injected into the capillary column of the GC. Once separated compounds were then carried by the carrier gas (He) into the DMEI source where they were ionized; resulting ions were then analyzed by the MS/MS. System performance (reproducibility, linearity and detection limits) will be presented and discussed.

Results:

Pure hexane, heptane, toluene, ethylbenzene, p-xylene, o-xylene and their mixtures were analyzed using GC-DMEI-MS/MS system. Compounds were successfully separated using GC, and then individually ionized in the DMEI. Depending on the ionization source settings two fragmentation patterns were achieved. One with minimal fragmentation and substantial molecular ion peak ("soft" ionization) and another with extensive fragmentation and almost no molecular ion peak ("hard" ionization). Different electronic settings of the ionization source allowed changing fragmentation patterns and signal intensities. Various tests showed that both modes are valuable and efficient; hence one source (DMEI) can be used for both compound identification (hard ionization) and compound quantification (soft ionization) with no change in the hardware. And since switching between hard/soft modes is almost instantaneous, both modes can be used during one sample analysis.

Conclusions

It was shown that dual mode electron ionization source can be used to perform soft and hard ionization of volatile compounds with no changes in the hardware. And while these are preliminary results and further investigations are still required, current system performance is promising and its future development is justified.

Novel Aspect:

Introduction of an EI source that can be used in "traditional" and "soft" ionization modes. Use of GC-DMEI-MS/MS system for analysis of gaseous analytes and their mixture

828 - ION SOURCE MULTIPLEXING ON A SINGLE MASS SPECTROMETER

Yury Kostyukevich (1) - Alexander Zhrebker (1) - Eugene Nikolaev (1)

Skoltech, Skoltech, Moscow (1)

Keywords: Ion source, ESI, APPI, Isotopic exchange, Proteins, Orbitrap.

Introduction:

The high variety of species that need to be investigated by a mass spectrometry determined the development and use of different ion sources. For example, ESI is one of the most suitable ion sources for investigation of peptides, proteins or natural organic substances, hormones can be investigated using APCI and APPI etc. With the introduction of the ion funnel, that can effectively gather ions, it became possible to develop a multiple inlet systems in which ions from different sources are transported into the fore vacuum region through different inlet capillaries. Here we present the simple approach for the combination of different ion sources on a single mass spectrometer and simultaneous performing different gas phase reactions without any interference between them [1-3].

Methods:

All experiments were performed on an orbitrap QExactive mass spectrometer (Thermo) with installed ion funnel and fore vacuum MALDI (Spectrograph). The front panel with the MALDI translational stage was replaced with specially developed plate with several inlet capillaries. For the experiment with multiple ion sources copper tubes were connected to inlet capillaries. Valves enabled switching channels on and off. For experiments with thermal dissociation stainless steel tubes were connected to inlet capillaries. One of the tubes was wrapped in a special heat resistant cable with a nichrome conductor in the magnesium oxide and steel braid. This cable allowed heating of the extended capillary to 600 °C. To perform H/D exchange a droplet of D₂O was placed below the capillary inlet.

Results:

By using separate inlet capillaries and relatively long transfer tubes with valves we have succeeded in combining 4 different ion sources: APPI, radioactive ion source, native ESI and regular ESI. Switching between channels takes less than 1s and no interference between channels was observed. We were able to observe simultaneously native tetramers of streptavidin, unfolded ubiquitin, crude oil and residue organic present in air. The developed source was used for internal calibration of humic substances by infusing clusters of phosphorus acid through another channel. Using the independence of different channels it is possible to develop a system in which ions (produced by the same or different ion sources) would be subjected to the ion-molecular reactions, such as thermal fragmentation or H/D exchange in such a way that through one channel always pass a non-modified parent ions.

We have developed a novel concept of MS-SWATH in which parent ions are observed simultaneously with the fragment ions in the same mass spectrum. Peptides of Cytochrome C digest were separated by liquid chromatography, ionized by ESI and delivered to mass spectrometer through 2 different capillaries one of which was heated to induce thermal dissociation. Another channel remains cold. By regulating flow in channels it is possible to regulate intensities of parent and fragment ions which are present in spectrum simultaneously.

Instead of thermal dissociation other gas phase reactions can be performed in different channels independently. We demonstrated this for the gas phase H/D exchange reaction. Using multiplexed ion source it is possible to rapidly switch between the channel in which H/D reaction takes place and the reference channel. It was found that channels do not affect each other.

Conclusions

We have developed a novel approach to the combination of different ion sources on a single mass spectrometer. By using separate inlet capillaries and relatively long transfer tubes with valves we have succeeded in combining 4

different ion sources: APPI, radioactive ion source, native ESI and regular ESI. Switching between channels takes less than 1s and no interference between channels was observed. Such different objects as crude oil and streptavidin tetramers can be infused and recorded simultaneously. The possibility to transport ions through a 1.5 long tube makes it possible to assemble different ion sources on different working places that would not interfere with each other.

Use of our approach considerably expands the capability of gas phase chemistry to the investigation of structure of unknown sample. Indeed, ions produced from the same ion source, possibly, preselected by Filtered Asymmetric Ion Mobility Spectrometry (FAIMS), could be split into different transfer tubes in which different gas phase reactions occur. One of the channels may be remained as reference. We have demonstrated such idea for thermal dissociation and gas phase H/D exchange reactions. Using valves it is possible to rapidly switch between different channels and it was proved that channels do not affect one another. Comparison of mass spectra recorded when different channels are open, will provide structural and chemical information about unknown species.

Novel Aspect:

A multiplexed ion source allowing simultaneous combination of various ion sources and performing gas phase reactions was developed.

752 - IDENTIFICATION OF CHEMICALS IN DIFFERENT OBJECTS BY DIRECT ANALYSIS IN REAL TIME MASS SPECTROMETRY

Ákos Kuki (1) - Borbála Antal (1) - Lajos Nagy (1) - Tibor Nagy (1) - Georgina Zelei (1) - Miklós Zsuga (1) - Sándor Kéki (1)

University of Debrecen, Department of Applied Chemistry, Debrecen (1)

Keywords: direct analysis in real time mass spectrometry (DART-MS), semi-quantitative analysis, textile articles, healthcare products, polyurethane

Introduction:

The manufacture of textile, healthcare and polyurethane (PU) products employs a diverse range of processes using a large number of chemicals. Residues of these substances may remain in the products. The investigation of chemicals in these clothing and hygiene and PU articles (e.g. socks, shirts, sanitary articles, sterile gauze bandages, sponges, foam toys) is important since they can get into direct contact with the human skin.

Methods:

Measurements were performed with a MicroTOF-Q type Qq-TOF MS instrument (Bruker Daltonics, Bremen, Germany) equipped with a DART SVP ion-source (IonSense, Saugus, MA, USA). The solid samples were manually introduced into the DART gas stream without any sample pretreatment. The results were confirmed by GC-MS and HPLC-MS.

Results:

The presence of more than 100 chemicals have been revealed in 50 different commercially available clothing, personal care, healthcare, and PU items [1,2]. The identification was confirmed by DART MS/MS experiments for 42 compounds by combining the MS/MS spectra with findings from the literature and databases of spectra. In the clothing and healthcare items the most notable hazardous substances were nonylphenol ethoxylates (NPEs), phthalic acid esters, amines released by azo dyes, quinoline derivatives, tributyl phosphate, tris(2,4-di-tert-butylphenyl) phosphite, erucamide. Residues of catalysts, stabilizers, antioxidants, flame retardants, plasticizers, chain extenders, chain terminators, polyols, solvents, degradation products and contaminants, a few of them presumably toxic, were detected and identified in the PU items. Automated data acquisition and processing method and an efficient semi-quantitative DART-MS analysis were developed for the recognition, and quantitation of NPE residues, respectively.

Conclusions:

The large number and diversity of the detected compounds proves unambiguously the effectiveness of DART-MS and DART-MS/MS for the rapid identification of compounds in clothing, personal care, healthcare, and PU items without any sample preparation. Our experiments might have drawn attention to the presence of many harmful substances on the surface of commonly used products that can come into direct contact with human skin, or even blood.

Novel Aspect:

Our work has explored a new application field of the DART-MS technique. A semi-quantitative DART-MS analysis was developed to determine the concentration of NPE.

Keywords: Trace explosives detection, mass spectrometry, high-throughput, TNT, TATP

Introduction:

The threats of terrorism using explosives have been a serious problem around the world [1]. In this study, we developed two types of mass spectrometry-based explosive trace detectors (ETDs), namely, a high-throughput ETD which detects explosive particles using non-contact sampling, and a compact ETD which detects explosive particles and their vapor by one sampling unit.

Methods:

Based on the prototype of high-throughput ETD [2, 3], the non-contact sampling system was improved using a fluid dynamic simulation for stable high sampling efficiency. A mass spectrometer which operated as a sensor in that ETD was downsized, leading to the downsizing of overall system. As the other type of ETD, we combined such mass spectrometer with both a vapor introduction port and swab sampling function.

Results:

The newly developed high-throughput ETD has an ID card insertion port where several air nozzles are located. The position of such nozzles were decided based on the fluid dynamic simulation. An air jet from the nozzles efficiently dislodge explosive particles from the ID card and explosive molecules are then detected by mass spectrometry. We confirmed that the high-throughput ETD detected one of representative explosive molecule, TNT within 3 sec after the insertion of the ID card and its sensitivity was ng level. This throughput enables that ETD to operate as a security gate inspecting all people passing the gate. The compact ETD with a weight of around 60 kg has a function of continuous monitoring of surrounding gas and swab sampling. Experimental results suggested that the compact ETD detected vapor of TATP, which is popular improvised explosive device, at a concentration of below 0.1 ppm and TNT particle at ng level. The compact ETD can be interspersed in several locations to increase the security level in a wide area.

Conclusions:

High-throughput ETD and compact ETD were developed based on the same mass spectrometer. Use of those ETD as a security gate and an area monitoring system is considered to increase the security level in a wide area of the city.

Novel Aspect:

Based on the mass spectrometer as a core technology, changes in a sampling system resulted into two types of ETD used for several purposes.

38 - DIRECT DETECTION OF SMALL N-ALKANES AT SUB-PPBV LEVEL IN BREATH AIR BY PHOTOELECTRON INDUCED O₂⁺ CATION CHEMICAL IONIZATION MASS SPECTROMETRY AT KPA PRESSURE

Yan Wang (1) - Lei Hua (1) - Haiyang Li (1)

Dalian Institute of Chemical Physics, Chinese Academy of Sciences, CAS Key Laboratory of Separation Sciences for Analytical Chemistry, Dalian (1)

Direct Detection of Small N-alkanes at Sub-ppbv Level in Breath Air by Photoelectron Induced O₂⁺ Cation Chemical Ionization Mass Spectrometry at kPa Pressure

Keywords: small n-alkanes, high-pressure photoionization induced O₂⁺ cation chemical ionization, kPa pressure, direct detection, time-of-flight mass spectrometry

Introduction:

Alkanes are important target analytes in the fields of petrochemical industry, environmental detection, as well as being a significant product in human metabolic processes.[1] However, online and real-time measurement of saturated hydrocarbons, especially small n-alkanes, using direct mass spectrometry, remains a great challenge due to their low basicity and fewer ionizable functional groups.

Methods:

A high-pressure photoionization induced O₂⁺ cation chemical ionization (HPPI-OCI) source was developed and coupled with a time-of-flight mass spectrometer. An efficient online pretreatment system was developed for eliminating the interference of humidity and carbonyl compounds. High-intensity O₂⁺ reactant ion could be generated by photoelectron ionization for efficient ionization of n-alkanes.[2]

Results:

The HPPI-OCI mass spectrum pattern of C₃-C₆ n-alkanes differed a lot at different ion source pressure. The quasi-molecular ions [M-H]⁺ were gradually dominating and the fragmentation of n-alkanes by O₂⁺-CI was depressed while the ion source pressure was elevated from 88 to 1080 Pa, with more than three orders of magnitude improvement in signal intensity. This was attributed to collisional deactivation effect, by which [M-H]⁺ tend to be more stable other than fragmentation, as the excess energy in the quasi-molecule ions could be more efficiently quenched at higher pressures. The achieved LODs (S/N=3) were down to 0.07-0.14 ppbv for C₃-C₆ n-alkanes in one minute. The HPPI-OCI TOFMS was successfully used in the analysis of exhaled small n-alkanes of healthy smokers and nonsmokers as well as the concentration variation of exhaled small n-alkanes after alcohol consumption.

Conclusions:

This work not only provides new insights for controlling the chemical ionization process by adjusting the ion source pressures but also prompts an innovative and high-performance direct MS technique for small n-alkanes analysis. It is likely that the HPPI-OCI MS will be a powerful tool in various research fields such as on-site environmental analysis and high-throughput medical diagnostics.

Novel Aspect:

Small n-alkanes can be soft ionized with O₂⁺ cation at kPa pressure and direct detected at sub-ppbv level.

866 - EXPLOSIVES DETECTION WITH A MOBILE THERMAL DESORPTION DIRECT ANALYSIS IN REAL TIME MASS SPECTROMETRY SYSTEM (TD- DART-MS)

Frederick Li (1) - Brittany Laramée (1) - Paul Liang (1) - Brian Musselman (1)

IonSense, Inc., Chemistry, Saugus (1)

Keywords: DART-MS, Thermal Desorption, Explosives Detection, Swipe Sampling, Mobile MS System

Introduction (400 Characters without spaces)

A thermal desorber is configured to a DART-MS system on a mobile platform to permit the detection of explosives from swipe sampling. The mobility aspect of this configuration can permit mass spectrometry based detection of explosives in the field. This work presents the capability of the system and serves as a means of determining the readiness level of the system as an explosive trace detector.

Methods(400 Characters without spaces)

A thermal desorption unit is coupled to a DART equipped single quadrupole mass spectrometer, which is configured to a mobile cart. Standards of explosives were deposited onto PTFE-coated fiber glass swipes for analysis. A design of experiment was employed to evaluate conditions that affect detection and sensitivity. Limit of detection was determined for each explosive.

Results (900 Characters without spaces)

Explosives were deposited directly onto PTFE-coated fiberglass swipes and analyzed using the thermal desorber operated at three temperatures: 100°C, 200°C and 300°C. Preliminary results showed the response was at the highest at 200°C for more than half of the explosives. Desorption is near instantaneous for all 10 explosives, typically requiring 5 seconds after insertion of the swipe. Complete desorption of the explosive from the swipe can be achieved in 6-12 seconds, which is dependent on the vapor pressure of the explosive and quantity on the swipe. Thermal desorber temperature, the DART grid voltage and flow rate of the pump used for DART had a significant effect on sensitivity. Sensitivities between 5 ng and 50 ng for both organic explosives such as TNT, RDX, HMTD and TATP and inorganic explosives such as potassium perchlorate were consistently achieved.

Conclusions (400 Characters without spaces)

Detection of all explosives was consistently achieved at levels between 5 ng and 50 ng. TD-DART-MS provides a means for rapid detection of explosives from swipe sampling. The mobility aspect of this system is attractive for field detection of explosives. Future work will include determining the sensitivity of additional explosives such as smokeless powder, C-4 and homemade explosives (HMEs).

Novel Aspect (150 Characters without spaces)

TD-DART-MS on a mobile platform can enable field detection of a wide range of explosives from swipe sampling.

1352 - USING AUTOMATED LOW VOLUME PIPETTING TO ENABLE HIGH THROUGHPUT DART-MS DETECTION OF DRUGS DIRECTLY FROM BIOLOGICAL MATRICES

FREDERICK LI (1) - Paul Liang (1) - Brittany Laramée (1) - Brian Musselman (1)

IonSense, Inc., Chemistry, SAUGUS, United States (1)

Keywords: DART-MS, Drugs of abuse, Automation, High-throughput Experimentation, Toxicology

Introduction:

Direct Analysis in Real Time Mass Spectrometry (DART-MS) is a technique capable of directly analyzing biological samples without sample preparation. Utilizing a 384 format nanoliter pipettor to spot nanoliter droplets on a wire mesh, matrix effects can be reduced up to a factor of 100 times, thus enhancing analyte detection. The 384 sample mesh can then be analyzed with DART-MS at the rate of one sample per second, achieving complete analysis in less than 10 minutes.

Methods:

Urine was spiked with various drugs and internal standard (IS) and serially diluted to simulate real-world urine samples submitted for drug tests. Nanoliter droplets of the spiked urine were spotted on a mesh screen using a 384 nanoliter pipettor. A DART ion-source with a high throughput (HT) module was interfaced to a quadrupole mass spectrometer to enable rapid analysis of the mesh screen samples.

Results:

Various sample deposition volumes, 50 – 1000 nL, and sample concentrations, 50 ng mL⁻¹ – 1000 ng mL⁻¹, were evaluated to determine the level of matrix effect reduction as well as the lowest droplet volume that provided sufficient response for detection. A constant final amount of material was deposited using different size droplets of varying concentration; Preliminary results showed that the low droplet volume provided comparable signal intensity and a significant reduction of matrix effects. A five-point calibration curve was constructed using 200 nL droplets, and quantification with IS correction showed that the data was reproducible, with a RSD% less than 1%. The drug concentrations were accurately quantified between 50 – 1000 ng mL⁻¹ within a 10% error.

Conclusions

Using nanoliter volume quantities of sample reduced the matrix interference and enabled direct analysis of the samples with DART-MS without any prior sample pre-treatment. The high throughput DART-MS configuration can enable the analysis of 384 samples in approximately 7 minutes and is capable of providing accurate and reproducible quantitation. Future work will include a wider drug panel and different biological matrices.

Novel Aspect:

Nanoliter volumes can reduce the matrix effects of biological samples, therefore enabling rapid analysis of biological samples using DART-MS without sample manipulation.

1066 - PREDICTING AGENTS THAT “SUPERCHARGE”

Rachel Ogorzalek Loo (1) - Reid O'Brien Johnson (2) - Michael Nshanian (2) - Joseph Loo (2)

UCLA, DOE Laboratory for Genomics & Proteomics, Los Angeles (1) - UCLA, Chemistry & Biochemistry, Los Angeles (2)

Keywords: supercharging, electrospray ionization mechanism,

Introduction:

Supercharging is the ability to increase analytes' average charge state by supplementing electrospray solvents with a low volatility compound. The supercharging methodology is useful for MS and MS/MS, but the mechanism(s) responsible for increasing charge are contentious. We describe a “supercharging” mechanism that applies to native and denaturing solutions and demonstrate its utility to predict agents that sub- and supercharge.

Methods:

ESI mass spectra were acquired on hybrid quadrupole time-of-flight (QTOF; Waters Synapt G2-Si), ESI-TOF (Agilent), and 15-Tesla Fourier transform-ion cyclotron resonance (FT-ICR; Bruker solarix) spectrometers. NanoESI sources used borosilicate glass capillaries with metal coatings (Proxeon Biosystems) operated at low analyte flow (< 50 nL/min). Final protein concentrations for ESI-MS (non-denaturing) were ~ 5 μ M in 20 mM ammonium acetate, pH 6.8.

Results:

Multiple mechanisms have been proposed to explain how low-volatility additives increase charge in ESI, but they typically explain only subsets of experimental conditions or analytes; e.g., surface tensions exceeding those of CH₃CN or CH₃OH were credited with some additives' abilities to increase protein charge from denaturing solutions, while increases delivered by the same compounds from near-native solutions were attributed to protein denaturation, driven by the additives' increasing concentration within the evaporating droplet. The former proposal was subsequently countered by evaporation rate arguments addressing surface tension changes in evolving droplets, while the latter proposal was countered by many experimental observations.

Many factors impact charge state distributions (CSDs), but we think they can be unified into a single mechanism, applicable to a broad range of molecules from both denaturing and non-denaturing solutions. A correct mechanism will predict how new reagents affect charging in ESI.

Conclusions:

The hypothesis that supercharging and sub-charging molecules have specific Bronsted acidity and basicity properties (ideally neutral molecules that are both very weak bases and very weak acids compared to H₂O), was tested by examining how adding related compounds of known pK_a/pK_b (pyrazole, 1-nitropyrazole, 3-nitropyrazole, pyrrole, 1-ethyl pyrrole, 2-methyl pyrrole, and others) to ESI solvents altered CSDs. Analyte charging shifted in accordance with predictions.

Novel Aspect: (Limit of 150 characters without spaces)

Supercharging and sub-charging additives for positive ion mode can be predicted based on the solution phase basicities of low-volatility compounds.

93 - DIRECT MASS SPECTROMETRY ANALYSIS USING IN-CAPILLARY IONIC LIQUIDS-BASED DISPERSIVE LIQUID-LIQUID MICROEXTRACTION AND SONIC-SPRAY IONIZATION

Qiang Ma (1)

Chinese Academy of Inspection and Quarantine, Chinese Academy of Inspection and Quarantine, Beijing (1)

Direct Mass Spectrometry Analysis Using In-Capillary Ionic Liquids-Based Dispersive Liquid-Liquid Microextraction and Sonic-Spray Ionization

Keywords: In-Capillary Ionic Liquids-Based Dispersive Liquid-Liquid Microextraction; Orbitrap Mass Spectrometry; Sonic-Spray Ionization; Direct Mass Spectrometry Analysis

Introduction: (Limit of 400 characters)

Public concern on the environmental and human impact of chemical approaches has encouraged analytical chemists to introduce safer and cleaner alternatives. Ionic liquids (ILs) are showing increasingly promising perspectives as green solvents in a diversity of fields. The unique physicochemical properties make ILs favorable alternative media to replace organic solvents for extraction, separation and detection techniques. In this study, a novel ILs-based dispersive liquid-liquid microextraction (DLLME) method coupled with sonic-spray ionization (SSI) has been developed for direct mass spectrometry analysis of environmental water samples. An in-situ formed dicationic IL was introduced to not only act as an effective extraction medium, but also create a positively charged complex with target analytes, allowing a significant increase in sensitivity.

Methods: (Limit of 400 characters)

A disposable borosilicate glass capillary (1.5 mm o.d., 0.86 mm i.d., 8 cm length) with a pulled tip (5 μm i.d.) was prepared using a P-1000 micropipette puller (Warner Instrument, Hamden, CT, USA). Four liquid plugs were sequentially injected into the capillary from the open end: 2 μL of aqueous $\text{Li}[\text{NTf}_2]$ solution at 30 μM , 20 μL of environmental water sample, 2 μL of aqueous $[\text{C}_4(\text{MIM})_2]\text{Br}_2$ solution at 20 μM , and 10 μL of dichloromethane. An in-capillary liquid-liquid microextraction was facilitated by the simple action of tilting the capillary up and down. The dichloromethane phase migrated to the tip end of the capillary due to higher density. The process does not need high voltage and was performed at ambient temperature.

Results: (Limit 900 characters)

Perfluorinated compounds (PFCs), an exemplary class of chemical substances of very high concern for regulatory control due to their persistent, bioaccumulative and toxic properties, were selected for method development and validation. The environmental water plug was sandwiched between the two miscible, hydrophilic IL plugs of $\text{Li}[\text{NTf}_2]$ and $[\text{C}_4(\text{MIM})_2]\text{Br}_2$. Within the combined aqueous phase, $\text{Li}[\text{NTf}_2]$ acted as an ion-exchange reagent and underwent an in situ metathesis reaction with $[\text{C}_4(\text{MIM})_2]\text{Br}_2$ to form a new hydrophobic IL of $([\text{C}_4(\text{MIM})_2][\text{NTf}_2]_2)$. The exchange process generated a cloudy, homogeneous solution with fine microdroplets of the resulting extractant phase which greatly increased the contact surface area of the IL extraction solvent resulting in enhanced extraction efficiencies for perfluorooctanoic acid (PFOA) and perfluorooctanesulfonic acid (PFOS). After hand swing, the 10 μL dichloromethane liquid slug migrated to the tip end of capillary, extracting the hydrophobic compounds. The Venturi effect occurs when the high-velocity nebulizing gas flows through the capillary tip, causing a reduction in fluid pressure and self-pumping effect. The signal profile proved to be stable monitored by means of base peak chromatogram (BPC) and extracted ion chromatogram (EIC). The dichloromethane phase gives a clear mass spectrum with only two characteristic ions for m/z 719.1 (combination of $[\text{C}_2^{++}\text{PFOS-}]^+$) and m/z 500.1 (combination of $[\text{C}_2^{++}\text{Tf}_2\text{N-}]^+$). This method detect the positively charged adduct which composed of dications and analyte anions. Especially when determining the concentration of PFCs which can hardly undergo fragmentation under negative MS/MS mode. The adduct lost either a proton or a methyl imidazolium group of dications, resulting in a singly

charged fragment for detection. Quantitative analysis was performed with internal standard calibration curve method, and the limits of detection (LODs) and limits of quantitation (LOQs) were 0.03 and 0.15 ng/mL for PFOS, and 0.05 and 0.21ng/mL for PFOA.

Figure 1 a) The schematic diagram of direct in-situ microextraction and sonic-spray ionization analysis of water samples; b) MS/MS spectra recorded for 10 μ L water solution containing 10 ng/mL PFOS; c) Quantitative analysis of PFOS and PFOA spiked water solution (0.5-100ng/mL) with ¹³C₄-PFOS and ¹³C₄-PFOA (20 ng/mL) as IS compounds.

Novel Aspect: (Limit of 150 characters)

An ILs-based dispersive liquid-liquid microextraction (DLLME) method coupled with sonic-spray ionization (SSI) has been developed for direct mass spectrometry analysis.

Substrate Modification for the Analysis of Highly Volatile Chemical Warfare Agents by Paper Spray Mass Spectrometry

Phillip M Mach, Elizabeth S Dhummakupt, Paul S Demond, Daniel O Carmany, Michael W Busch, Trenton M Tovar, Ann M Ploskonka, Jared B DeCoste, Trevor Glaros

Keywords: Paper spray, chemical warfare agents, volatility, metal-organic framework, derivitization

Introduction:

Paper spray mass spectrometry (PS-MS) has been shown successfully analyze chemical warfare agent (CWA) simulants [1,2]. However, transitioning to actual G-series CWAs (i.e. sarin, soman) for analysis via PS-MS proves challenging due to volatility differences between the simulants and actual CWAs. In order to address this challenge, methods to fix these chemistries utilizing 2-[[dimethylamino)methyl]phenol (2-DMAMP) and metal-organic frameworks (MOFs) to extend their analytical lifetime were explored.

Methods:

Two separate methods of modification were utilized: 1) MOFs were weighed out in 1:1 ratio with cornstarch and dissolved in 5 mL of water. An aliquot was spotted onto cut glass fiber filters and allowed to dry. 2) Two microliters of a 2-DMAMP solution in methanol were spotted onto paper and allowed to dry. For each method, quantities of CWAs were applied in solution or vaporized to the treated substrates. Time courses and calibration curves were subsequently carried out.

Results:

Attempts to analyze G-series CWAs on paper substrates were not successful, as the agents volatilize off the paper in less than five minutes. Analysis on glass substrates only extends the analytical lifetime for up to 15 minutes. The addition of the MOFs HKUST-1 and UiO-66 to the glass substrate was found to extend the analytical lifetime of GB, GD, and GF for up to at least 60 minutes.

Paper substrates treated with 2-DMAMP were spotted with either GB or GF and analyzed over time. The G-DMAMP complexes formed were persistent out to 96 hours (the last time point tested). Additionally, calibration curves of the two G-DMAMP complexes were generated, and the limit of detection (LOD) for GB-DMAMP was 0.941 ng/mL and GF-DMAMP was 5.14 ng/mL.

Conclusions:

Substrate modifications have proven useful to (1) prolong the analytical lifetime of highly volatile native G agents and (2) complex with the G agents to reduce their volatility. The MOF approach allowed for a four-fold extension in time, while preserving the ability to analyze the native molecule. The 2-DMAMP allowed for long term capture through derivitization. Sub-1 ng/mL limits of detection were achieved with G-DMAMP complexes, and the complexes remained stable for up to 96 hours.

Novel Aspect:

First on-substrate modification and reaction of highly volatile chemical warfare agents.

Keywords: Mass Spectrometry, Lipidomics, REIMS, Cells

Introduction

Lipidomics analysis of living cells is still a difficult task, mainly because of the low abundance lipids that demand the use of time-consuming lipid extraction Methods: In the present study we report the application of LA-REIMS directly in the cell culture, in ambient environment.

Methods

LA-REIMS was performed in CHO-S cell culture liquid aliquots using the OPO (optical parametric oscillator) laser, which was connected through a REIMS source interface to a Waters G2-XS Q-ToF. The advantage of the OPO laser in contrast to others is the ability to vary the wavelength in the mid- and far-infrared region, which allows selective excitation of different functional groups.

Results

LA-REIMS connected to a Q-ToF and operated in full scan mode was able to detect most of the lipids related to CHO-S cell line, as reported in the literature [1,2], with good sensitivity.

The culture medium was used as control sample in order to distinguish the peaks coming from the cells. CHO-S cell pellets were also tested for comparison purposes. Different laser settings were tested for optimization, and the best signal was obtained with a mid-range laser power and 2900 nm wavelength.

The background “noise” was consistently low, allowing detection of low abundant lipids.

The majority of the m/z values detected in the cell culture and the cell pellet but not in the control sample were matched to putative lipids of all classes using accurate mass annotation and statistical analysis showed clear differences between the control and the sample.

Conclusions

The results of this study indicate that LA-REIMS can be used for fast and high-throughput lipidomics analysis in cell cultures without requiring any sample preparation. It is a fast and user-friendly method that is applicable in both the industry and academia for cell analysis at different levels of development.

Novel Aspect

LA-REIMS can be used for fast and high-throughput analysis of living cells as a biological snapshot of cell cultures in their native state.

273 - OPTICAL CHARACTERISTICS OF MATRIX MATERIALS FOR MATRIX-ASSISTED LASER DESORPTION/IONIZATION

Noritaka Masaki (1) - Shigetoshi Okazaki (1)

Department of Medical Spectroscopy, Hamamatsu University School of Medicine, Hamamatsu (1)

Keywords: matrix-assisted laser desorption/ionization, photo-dissociation, photosensitization, excited triplet state

Introduction:

Finding new matrix materials for matrix-assisted laser desorption/ionization (MALDI) is an analytical demand for biological study to analyze wider variety of molecular species and to improve ion yield. Matrix materials have been opted conventionally based on acid–base neutralization mechanism [1]. In the present study, we aimed to characterize matrix materials from optical aspects.

Methods:

Absorption spectra of matrix materials dissolved in MeOH or sprayed on quartz slide were measured with U-3500 spectrometer (Hitachi). Photo-dissociation of matrix materials was evaluated with time course of absorption spectra of matrix solutions after various irradiation periods of Nd:YAG laser. Photosensitization effect of matrix materials was detected as 1270 nm emission from singlet oxygen [2].

Results:

α -Cyano-4-hydroxycinnamic acid, sinapic acid, 2,5-Dihydroxybenzoic acid, 2,5Dihydroxyacetophenone, NorHarmane, 4-Nitroaniline, 2',4',6'-Trihydroxyacetophenone monohydrate, 9-Aminoacridine, and 1,5-Diaminonaphthalene were analyzed as typical matrices. Absorption profile obtained in a film state was more suited for wavelength at 337 nm or 355 nm than in a solution state. Absorption profile after irradiation of 355 nm Nd:YAG laser showed decrease of peaks characteristic to matrix materials reflecting photo-dissociation. As the photo-dissociation was reduced by bubbling with nitrogen gas, it dues to dissolved oxygen. In addition, photosensitized singlet oxygen was detected as 1270 nm emission from most of typical matrix materials against 355 nm Nd:YAG laser irradiation. These suggest that the laser excited matrix materials to a triplet state through intersystem crossing.

Conclusions

Photo-dissociation and/or photosensitization effect were found in all the typical matrix materials used in this study. Both photo-dissociation and photosensitization are related to production of singlet oxygen by 355 nm Nd:YAG laser irradiation. Therefore, matrix material for MALDI can be characterized as excitation to triplet state by MALDI laser or photosensitization ability.

Novel Aspect:

Excitation to a triplet state with 355 nm laser was revealed as a common optical characteristic to matrix materials for MALDI.

1250 - TOWARD HIGH THROUGHPUT SCREENING OF CELL-MATERIAL RESPONSE USING LIQUID EXTRACTION SURFACE ANALYSIS-MASS SPECTROMETRY (LESA-MS)

Joris Meurs (1) - Josephine Bunch (2) - Morgan Alexander (1) - David Barrett (1) - Dong-Hyun Kim (1)

Advanced Materials & Healthcare Technologies Division, University of Nottingham, Nottingham, United Kingdom (1)
- National Centre for Excellence in Mass Spectrometry Imaging, National Physical Laboratory, Teddington, United Kingdom (2)

Keywords: Cell-material response, high-throughput screening, in situ trypsin digestion, protein analysis, LESA-MS

Introduction:

Pluripotent stem cells are a valuable source for cell production. Biomaterials have been discovered that assist in pluripotency maintenance, but the response mechanism is not well understood. Pre-adsorption of proteins is crucial in this process [1]. LESA-MS has shown potential to be used for analysis of adsorbed proteins [2]. Here, we describe the development of a high throughput LESA-MS strategy to analyze strongly attached proteins in a complex matrix.

Methods:

Essential 8™ medium (E8) was incubated for 1 hour onto the Droplet Microarray which has shown to allow robust automatic surface extraction [3]. Removal of interfering compounds was optimized using ammonium formate solutions and a 10-minute washing. Next, optimization of in situ trypsin digestion was done using organic-aqueous systems and MS-compatible detergents which have shown to enhance in-solution digestion [4]. Tryptic digests were then analyzed by LESA-MS.

Results:

Surface washing was optimized by varying the NH₄HCOO concentration. To determine the washing efficiency and reproducibility, the total sodium intensity was calculated using an in-house MATLAB script. One washing round significantly reduced the amount of sodium independent of the NH₄HCOO concentration. More washing rounds as well as the NH₄HCOO concentration were not found to have a significant effect on the washing efficiency. The most reproducible washing was obtained using deionized water. Performing trypsin digestion with a mixed organic-aqueous system (DMF/50 mM NH₄HCO₃ (30:70 v/v) increased the number of identified peptides as well as the MASCOT scores for BSA compared with trypsin digestion using an ammonium bicarbonate solution solely. Addition of a MS-compatible detergent seems to interfere with in situ digestion or MS analysis due to insufficient removal of the breakdown products.

Conclusions:

We showed that with discrete sample areas the extraction repeatability and detection limits of LESA-MS for peptides can be improved. Further, using an optimized washing protocol inorganic salts present in E8 could effectively be removed prior to in situ digestion enhancing the peptide signal. In addition, the use of organic-aqueous trypsin solution significantly enhances the in situ digestion efficiency and protein identification.

Novel Aspect:

This work is the first to show a strategy directing towards high throughput analysis of surface-adsorbed proteins for media- and cell-derived proteins.

1053 - EXTENDING THE POLARITY RANGE FOR DIRECT SPME-MS ANALYSES BY USING NOVEL CAPILLARY DBDI AND APPI SOURCES

Mario Francesco Mirabelli (1) - Anna K Huba (1) - Renato Zenobi (1)

ETH Zurich, D-CHAB, Zurich (1)

Keywords: SPME-MS, DBDI, APPI, reactivity, electrodes

Introduction:

Although direct interfaces of solid-phase microextraction (SPME) with mass spectrometry (MS) are rapidly spreading and proved themselves as a fast and convenient way to analyze complex sample matrices, some limitations still need to be addressed: the limited range of compound polarity achieved by most ambient ionization sources, the sometimes severe matrix effects, and the lack of proper sample introduction strategies for a simple and fast analytical workflow

Methods:

The capillary atmospheric pressure photoionization (cAPPI) and dielectric barrier discharge ionization (DBDI) sources used in this study were built in-house, in a capillary format directly connected to the MS using a leak-tight connection. For both sources, dopants were used to enhance ionization efficiency. In addition, the ionization efficiency for nonpolar compounds was increased for DBDI by using customized electrode geometry (spring- and ring-shaped)

Results:

Most ambient ionization sources used for direct SPME-MS analyses are mainly sensitive towards polar compounds. Capillary DBDI and APPI allowed to efficiently ionize nonpolar compounds (e.g., PAHs), introduced into the sources by thermally desorbing SPME fibers. In most cases, more polar compounds could be ionized efficiently as well. The results show a sensitivity in the pg/mL concentration range, even in the presence of relatively complex sample matrices like lake water or food samples. The analytical workflow was completely automated with a commercial PAL RTC autosampler (CTC Analytics), with a throughput of 1 sample every 1.5 minutes. For cAPPI, best results were obtained with chlorobenzene, fluorobenzene and acetone as dopants. For DBDI, the use of dopants affected the ionization mechanism, resulting in the preferential formation of radical versus protonated cations. The energy involved in the ionization processes was quantified by using substituted benzylamines thermometer ions

Conclusions

The proposed approach allowed to quantify polar and nonpolar compounds from relatively complex matrices within minutes. The range of compound polarity accessible to SPME-MS direct analyses was broadened. The selectivity of the ionization process could be tuned by using different dopants. In addition, specific DBD electrode configurations allowed to extend or contract the plasma generated inside the source, promoting chemical reactions inside the plasma

Novel Aspect:

Nonchromatographic analysis of complex samples by efficient capillary plasma- and photoionization sources. Reactivity tuned by dopants and custom electrode configuration

194 - COMBINED INFRARED AND ULTRAVIOLET LASER ABLATION ELECTROSPRAY IONIZATION MASS SPECTROMETRY

Kermit Murray (1) - Remi Lawal (2) - Fabrizio Donnarumma (2)

Louisiana State University, Department of Chemistry, Baton Rouge (1) - Louisiana State University, Chemistry, Baton Rouge (2)

Keywords: Laser, ablation, electrospray, infrared, ultraviolet

Introduction:

We are using combined mid-infrared and deep-ultraviolet two-laser ablation coupled with electrospray ionization for ambient mass spectrometry of biomolecules in tissue. The goal is to increase nanoparticle production and improve sensitivity by using the UV laser to disrupt the tissue structure followed by IR ablation and ionization.

Methods:

In this work, we are using a 193 nm ArF excimer laser to disrupt the tissue prior to irradiating with a 3000 nm IR optical parametric oscillator. Both lasers are focused onto the same target spot and separated in time by an adjustable delay. A nanospray needle is directed at the inlet on-axis of a modified quadrupole time-of-flight mass spectrometer.

Results:

The two-laser ablation system has been constructed and initial studies carried out for optimization of the system with peptide and protein standards. The lasers are mounted on an aluminum breadboard adjacent to the ion source and are focused onto the target with a single calcium fluoride lens for each beam. The dual-laser configuration can be operated either with the UV firing first to disrupt the covalent bonding in the tissue or with the IR firing first to heat the tissue. Initial studies with 193 nm laser ablation electrospray ionization demonstrate that the deep-UV is a much softer ionization method than might be anticipated and can produce ions from peptides and proteins without a matrix and with little fragmentation. Based on this interesting new result, initial experiments are aimed at improving the efficiency of the deep-UV ablation using IR laser pre-heating.

Conclusions:

We have demonstrated that deep-UV and IR ablation coupled with electrospray ionization is a promising soft ionization method for large molecules with applications to tissue imaging. Continuing experiments are aimed at optimizing the UV and IR laser pulse energies and time delay to improve the sensitivity as well as improving the UV laser focus to improve spatial resolution.

Novel Aspect:

Combined mid-infrared and deep-ultraviolet laser ablation on the same spot for laser ablation electrospray ionization imaging.

1146 - RAPID QUALITATIVE ANALYSIS OF TWO FLAVONOIDS, RUTIN AND SILYBIN, IN MEDICAL PILLS BY DIRECT ANALYSIS IN REAL TIME MASS SPECTROMETRY (DART-MS) COMBINED WITH IN SITU DERIVATIZATION

Lajos Nagy (1) - Tibor Nagy (1) - Ákos Kuki (1) - Miklós Zsuga (1) - Sándor Kéki (1)

University of Debrecen, Department of Applied Chemistry, Debrecen (1)

Keywords: direct analysis in real time mass spectrometry (DART-MS), silylation, in situ derivatization, flavonoid derivatives, silybin, rutin

Introduction:

Flavonoids belong to the family of benzo-pyrone having a wide range of biological and pharmacological effects, including anti-allergic, anti-inflammatory, antioxidant, anti-cancer activities. The conventionally used mass spectrometric and chromatographic methods are quite time consuming and labor intensive. In contrast, direct analysis in real time mass spectrometry (DART-MS), enable the examination of solid samples without sample preparation.

Methods:

Measurements were performed with a MicroTOF-Q type Qq-TOF MS instrument (Bruker Daltonics, Bremen, Germany) equipped with a DART SVP ion-source (IonSense, Saugus, MA, USA). Derivatization of the standard samples was carried out on DART sampling rods by adding 2 μ L of the silylation reagent to the standard powder. These samples were manually inserted into the helium gas stream.

Results:

Direct analysis in real time mass spectrometry (DART-MS) with in situ silylation was used for the rapid analysis of the flavonoids (silybin, rutin) [1]. Three commercially available silylation reagents were applied. The flavonoids were detected with various degrees of silylation, and the formation of dimers was also observed. HMDS/TMCS/pyridine was the best choice for the DART-MS analysis of silybin, and BSA/TMCS/TMSI was the most effective for the detection of rutin. The effects of the DART source temperature on desorption, ionization, in-source fragmentation, dimer formation, and hydrolysis of the trimethylsilyl groups were also studied. In addition, the collision-induced dissociation (CID) properties of the derivatized silybin and rutin were explored. With our in situ silylation method, the derivatized bioactive compounds in intact medical pills could also be detected by DART-MS.

Conclusions:

Our experiments showed that in situ silylation enables the use of DART-MS for the analysis of compounds that have low volatilities and/or are thermally unstable, such as silybin and rutin. Three silylating reagents were tested, and significant differences were found in their efficiencies of silylation. HMDS/TMCS/pyridine was the best choice for the DART-MS analysis of silybin, whereas BSA/TMCS/TMSI was the most effective for the detection of rutin.

Novel Aspect:

Our work has explored a new application field of the DART-MS technique. A method was developed for the rapid analysis of silybin and rutin by DART-MS using in situ silylation.

348 - DEVELOPMENT OF THE FEEDBACK CONTROL SYSTEM FOR THE ADVANCED TAPPING MODE SCANNING PROBE ELECTROSPRAY IONIZATION (T-SPESI)

Yoichi Otsuka (1) - Bui Kamihoriuchi (1) - Aya Takeuchi (1) - Futoshi Iwata (2) - Takuya Matsumoto (1)

Osaka University, Department of chemistry, Toyonaka (1) - Shizuoka University, Department of engineering, Hamamatsu (2)

Keywords: ambient sampling ionization, feedback control, scanning probe, multimodal imaging, capillary

Introduction:

Ambient sampling and ionization (ASI) technique has been attracted attention due to its capability of rapid chemical analysis and/or chemical imaging. We have developed the technique named as tapping-mode scanning probe electrospray ionization (t-SPESI) [1-4], in which the unique fusion of the key techniques used in atomic force microscopy (AFM) and mass spectrometry (MS) is achieved, to realize ASI with a single capillary probe.

Methods:

For the advanced SPESI, we developed the feedback control system. The optical lever method is based on the technology used in AFM. The laser light is irradiated to the capillary probe and the displacement of the reflected light is detected with the photodiode to obtain the oscillation amplitude of the probe. The position of Z-stage is controlled to maintain the oscillation amplitude during ASI with proportional-integral-derivative (PID) algorithm.

Results:

The optical lever method developed in this study enables us to measure the oscillation amplitude of capillary probe. The analog to digital converter, field programmable gate array, real-time OS and PC are controlled by the homemade software coded in LabVIEW. We confirmed the oscillation amplitude is proportional to the input voltage to the piezo actuator which is attached to the capillary probe for the stable oscillation at resonant frequency. The feedback control system maintains the oscillation amplitude at the desired set point by adjusting the Z position of sample during the ASI by t-SPESI. This system can be utilized not only to stabilize the probe scanning on the sample surface with micro asperity but also to measure the surface roughness. The measurements of the mass spectra and the output signal to the z-stage is executed simultaneously. The ion images and the topographic image are reconstructed.

Conclusions:

The information of the probe oscillation is utilized to improve the reproducibility of ASI with SPESI. We demonstrated the simultaneous visualization of the chemical distribution and the surface shape. This simple optical technique is expected to provide the mechanical properties of the nano-litter-volume liquid bridge containing extracted molecules from the sample.

Novel Aspect:

The stability improvement of ASI and the multimodal imaging are realized by the optical lever method with t-SPESI.

1360 - DEVELOPMENT OF A MULTIMODAL IMAGING PLATFORM BASED ON PHOTOINDUCED THERMAL DESORPTION AND ANALYSIS BY ATMOSPHERIC PRESSURE CHEMICAL IONIZATION MASS SPECTROMETRY

Matthias Lorenz (1) - Mario Viani (2) - Aleksander Labuda (2) - Stephen Jesse (1) - Roger Proksch (2) - Olga Ovchinnikova (1)

Oak Ridge National Laboratory, Center for Nanophase Materials Sciences, Oak Ridge, United States (1) - Oxford Instruments, Asylum Research, Santa Barbara, United States (2)

Development of a Multimodal Imaging Platform based on Photoinduced Thermal Desorption and Analysis by Atmospheric Pressure Chemical Ionization Mass Spectrometry

Matthias Lorenz,^{1,2} Mario Viani,³ Aleksander Labuda,³ Stephen Jesse,² Roger Proksch,³ Olga S. Ovchinnikova²

¹University of Tennessee, Knoxville; ²Oak Ridge National Laboratory; ³Oxford Instruments

The key to advancing materials is to understand and control their structure and chemistry. Thorough chemical characterization can be challenging since many existing techniques analyze only a few properties of the specimen, thereby requiring multiple measurement platforms to acquire the necessary information. The multimodal combination of atomic force microscopy (AFM) and mass spectrometry (MS) transcends existing analytical capabilities for nanometer scale spatially resolved correlation of the chemical and physical properties of a sample surface. We recently introduced the utilization of a photoinduced cantilever heating technology developed by Oxford Instruments for the localized thermal desorption and analysis and presented a closed cell design for sampling on an Oxford Instruments Cypher ES microscope to interface with a Thermo Orbitrap Velos Pro mass spectrometer using inline atmospheric pressure chemical ionization (APCI). The photoinduced cantilever heating technology works with standard AFM probes that are compatible with advanced AFM modes for the nanomechanical and electromechanical characterization of samples. We previously demonstrated below 500 nm spatial resolution for the spot-sampling by thermal desorption from thin layers and the chemical analysis of small organic molecules in full scan MS mode.

We demonstrate the application of multiple and advanced AFM measurement modes such as AMFM nanomechanical characterization on a single AFM cantilever, combined with photoinduced thermal desorption and analysis by mass spectrometry to link chemical composition with material functionality. We show the chemical analysis by mass spectrometry of gas phase species evolving from polymeric material in contact with a heated AFM probe, spatially resolved with nanometer resolution, and identify small organic molecules and characteristic fragments and pyrolysis products from the polymer. We present results from systematic studies of factors limiting the efficiency of transport and ionization of material evolving from the sample surface, with the objective to enhance the achievable spatial resolution and compound coverage of the multimodal imaging platform. Parameters studied include the timing of the photothermal cantilever heating and analysis by mass spectrometry, transport conditions for the gaseous material from the closed desorption cell to the mass spectrometer, and the operating conditions of the inline ionization stage. Computational fluid dynamics (CFD) simulations were used to study the uptake and transport of material. Experimental studies on prototype cell models prepared by additive manufacturing provide support for the modeling data.

439 - A NOVEL MODULAR AND VERSATILE TOF PLATFORM COMBINABLE WITH VARIOUS ION SOURCES

Alfons Jordan (1) - Felix Piel (2) - Stefan Feil (1) - Eugen Hartungen (1) - Gernot Hanel (1) - Jens Herbig (1) - Klaus Winkler (1) - Rene Gutmann (1) - Lukas Märk (1) - Philipp Sulzer (1)

Ionicon Analytik GmbH, n.a, Innsbruck (1) - Ionicon Analytik GmbH, University of Innsbruck, Institute for Ion Physics and Applied Physics, Innsbruck (2)

A novel modular and versatile TOF platform combinable with various ion sources
B. Instrumentation and Methods (Ambient and new ionization methods)

Keywords: TOF, TOF-MS, mass spectrometry, APi, PTR-MS

Introduction

Time-Of-Flight (TOF) mass spectrometers are state-of-the-art analyzers not only in Proton-Transfer-Reaction – Mass Spectrometry (PTR-MS) [1], but many other fields. Depending on the application the TOF instruments range from bulky high-resolution to compact low-resolution models. Here we present a novel modular TOF design, which can be adjusted in dimensions and mass resolution and used in combination with various ion sources.

Methods

The newly developed TOF recipient consists of an orthogonal injection "base unit" equipped with an ion mirror and microchannel plate detector. The flight path of ions can be extended by installing one or two recipient extension modules, respectively. An ion funnel and a hexapole ion guide can be integrated for ion focusing, either in combination or separately. We tested the setup with a PTR source and a novel Atmospheric Pressure interface (APi) front-end.

Results

Utilizing a well established PTR ion source [2] we evaluated the performance of the modular TOF platform (0, 1 and 2 flight path extension modules, respectively) in combination with an RF ion funnel and hexapole ion guide, while analyzing a certified gas standard (TO-14A). The mass resolution of the compact base unit without any RF focusing device is above 1500 $m/\Delta m$ and the sensitivity is between 40 (below m/z 100) and more than 100 cps/ppbv (above m/z 100). By the implementation of an ion funnel the sensitivity gets significantly improved, i.e. to more than 500 cps/ppbv. After installation of 2 extension modules, an ion funnel and a hexapole ion guide a mass resolution of $>6000 m/\Delta m$ and sensitivities of >1000 cps/ppbv can be achieved. The latter means that after an integration time of one minute the detection limit of the instrument is below 1 pptv.

Exchanging the PTR source with an APi front-end, consisting of differential pump stages and an additional hexapole ion guide, we are able to investigate ions in the atmosphere over broad m/z range.

Conclusions

The results obtained with the modular TOF platform in combination with a PTR ion source indicate an excellent performance, which surpasses known PTR-TOFMS instruments [3]. The design is highly versatile, so that e.g. using two TOF base units in opposite polarity with APi front-ends, creates a revolutionary APi-TOF instrument for simultaneously detecting positive and negative ions over a broad m/z range.

Novel Aspect

A modular TOF design enables maximum flexibility utilizing extension modules while performing at high mass resolution and sensitivity.

1295 - WHAT DETERMINES THE POSTIONISATION EFFICIENCY IN MALDI-2: A COMBINED SOFT-/HARDWARE-BASED SET-UP TO SEMI-AUTOMATICALLY CHARACTERIZE THE ROLE OF FIVE RELEVANT INPUT PARAMETERS

Alexander Potthoff (1) - Klaus Dreisewerd (1) - Jens Soltwisch (1)

Institute of Hygiene, Uni Münster, Münster, Germany (1)

Keywords: MALDI-2, Post-ionisation, Laser fluence, wavelength

Introduction:

MALDI with laser-induced post-ionization (PI), also named MALDI-2, was recently introduced by us to increase ion yields for numerous classes of lipids, metabolites and carbohydrates [1]. Here we present a semi-automatic protocol to investigate and optimize the efficiency of the PI process in dependence of five relevant input parameters: pulse energies of the two lasers, PI laser wavelength, delay between the laser pulses, and buffer gas pressure in the ion source.

Methods:

All experiments were conducted with a modified Synapt G2-S mass spectrometer (Waters) [1]. A N₂ laser (337 nm) served for desorption/ablation of material and a wavelength-tunable optical parametric oscillator (OPO) laser (relevant range, 220 – 350 nm) for PI. 2,5-Dihydroxybenzoic acid (DHB) and a mixture of polar phospholipids were investigated as matrix/analyte system. Samples were prepared by spraying the prepared mixture onto a glass slide.

Results:

At the core of our study stands a newly developed setup that combines hardware components and LabVIEW VI-based software for control and read-out of all relevant input parameters. In this way, during a MALDI imaging run on a homogenous sample, up to four (out of the overall five studied) input parameters were systematically varied and mass spectra recorded simultaneously. For example, by use of motor-driven laser energy attenuators (neutral gradient filters) and solenoid gas valves, laser fluences and buffer gas pressure in the ion source were precisely adjusted in predefined steps. The complex obtained MS data set including total ion counts and abundances of molecular ion signals of matrix, analytes and fragments in dependence of the respective input parameters was used to identify optimal MALDI-2 conditions for the tested DHB/lipid system. As will also be discussed in our poster, the so collected multidimensional data cube provides valuable insight into the mechanisms underlying the MALDI and MALDI-2 processes [2].

Conclusions:

Our new software/hardware setup allowed for (rapid) characterisation of the MALDI-2 process in dependence of all relevant input parameters. Our approach could not only support further optimization of MALDI-2 for different matrix systems for lipids, but also allow for a screening of new analytes (e.g., peptides and proteins) which under current conditions show no significant PI. Furthermore the approach is a valuable tool to study the MALDI and PI processes.

Novel Aspect:

Combined hard-/software setup for optimization and characterization of the MALDI-2 process in dependence of five input parameters and preliminary data for a DHB/lipid system.

Björn Raupers (1) - Jürgen Grotemeyer (1)

Institute of Physical Chemistry, University of Kiel, Kiel (1)

Keywords: LTP, ICR MS, Terpenes, Cluster, Atmospheric conditions

Introduction:

Previous studies [1;2] have shown signs of terpenes forming large clusters in low temperature plasma (LTP) ion mobility spectrometry hyphenations. In this work we present further studies of terpene systems using a Bruker fourier transform ion cyclotron resonance mass spectrometer (FT-ICR-MS).

Methods:

Mass analysis were performed on a 7.05 T FT-ICR system, provided by Bruker Daltonik. A LTP torch built according to the design of Nørgaard et al. [3] with slight variations was used as an ion source. Plasma gas and sample gas were Argon (99.999 %) by Air Liquid Deutschland GmbH. As a test substances a great variety of diterpenes and sesquiterpenes were used. All purchased from Sigma Aldrich (Taufkirchen).

Results:

Mass spectra of LTP FT-ICR hyphenations mostly show a great variety of ions. Predominantly Dehydrated species, oxides and fragments can be detected. Furthermore clusters of all these can be found. Depending on the analyte species clusters can reach a size of up to eight times the molecule. All mass spectra indicate only ions formed via Penning ionization induced by excited Argon molecules. As a result the most intense signal belongs to the $[M-H]^+$ molecule. To get further information about the oxidation process also the presence of water in the sample was analyzed. Depending on the amount of water the cluster size and the oxidation rate varies. Also the presence of atmospheric Oxygen and Nitrogen was investigated.

Conclusions:

Measurements show that the main ionization product are the $[M-H]^+$ as well as $[M-2H-H]^+$. It is most likely that the corresponding mechanism is a radical reactions followed by a dissociation into a cation and one electron. This is also underlined by the formation of dehydrated species and C_xH_y losses. The cluster formation is highly dependent on structure of the analyte molecule.

Novel Aspect:

Investigation of the clustering and fragmentation patterns of LTP ionization products under atmospheric conditions via FT-ICR-MS.

341 - DEVELOPMENT AND APPLICATION OF A NOVEL PLASMA ION SOURCE WITH GC-MS/MS

Mehrnaz Sarrafzadeh (1) - Reza Javahery (1) - Chuck Jolliffe (1)

PerkinElmer, R&D, Woodbridge (1)

Keywords: Tandem quadrupole mass spectrometry, Gas chromatography, Glow discharge plasma

Introduction:

Developing an ion source for GC-MS/MS system capable of generating enhanced signal for molecular ions is very important for the analysis of unknown compounds. Traditional GC-MS with EI source often results in extensive fragmentation and the sample identification is mainly through a library search. Although library identification is a valuable tool, the reliability of the results cannot be ensured in many cases due to the absence of molecular ions.

Methods:

All experiments were performed with a plasma ionization source integrated to a modified Qsight™ 220 triple quadrupole mass spectrometer equipped with a Clarus 680 GC. Several commercially available classes of compounds such as hydrocarbons, pesticides and terpenes were injected into the GC, which then were introduced to the plasma source by a heated transfer line, ionized and subsequently transmitted into the triple quad mass analyzer and detected.

Results:

Our results indicated that the plasma source could efficiently ionize a wide range of compounds with a significant sensitivity enhancement of the precursor ions through soft ionization. The plasma source results in a very clean full mass spectrum with minimal fragments dominated by the precursor ions. This is in contrast to results of standard GC-EI systems in which the spectrum is dominated by fragments, while the precursor ion is absent or low in abundance. This allows for accurate identification of unknown compounds as well as direct quantitation by selection of precursor ions. Additionally, acquired fragmentation at various collision energies in MS/MS revealed very similar fragmentation patterns as those of electron ionization, which offers an opportunity for library identification.

Conclusions

Plasma source is a very simple, inexpensive and robust ion source which requires very low maintenance. GC-MS/MS with the plasma source offers improved performance and wider application over the conventional GC-MS or GC-MS/MS systems with the EI source by efficiently enhancing the sensitivity of GC-MS/MS analyses, with the unique advantage of producing high yield of intact molecular ions without extensive fragmentation due to the softer ionization.

Novel Aspect:

Development of a low-cost and efficient plasma ionization source for a GC-MS/MS system which enhances molecular ions yield

285 - A NOVEL VOLTAGE-ASSISTED PAPER SPRAY-APPI-HRMS METHOD FOR THE SCREENING AND QUANTIFICATION OF SEMI-VOLATILE FLUORINATED COMPOUNDS

Raquel Seró Llor (1) - Juan Francisco Ayala Cabrera (1) - Francisco Javier Santos Vicente (1) - Encarnación Moyano Morcillo (1)

University of Barcelona, Chemical Engineering and Analytical Chemistry, Barcelona (1)

Keywords: ambient mass spectrometry, paper spray, non-polar solvents, photoionization, semi-volatile fluorinated compounds

Introduction:

Paper spray (PS) mass spectrometry is a fast ionization technique widely used for the detection of polar compounds mainly based in ESI ionization mechanisms. To improve the ionization of non-polar or low polar compounds, the traditional PS technique has been modified for the direct analysis of semi-volatile fluorinated pollutants by ambient-HRMS [1] in negative ionization mode using atmospheric pressure photoionization (APPI) [2].

Methods:

Standards and samples were loaded into chromatography paper triangles and were placed in front of a Q-Orbitrap with the APPI-UV lamp set orthogonally between the sharp tip and the MS inlet. Toluene/cyclohexane was used for the extraction/transport of analytes to the paper tip and for dopant-assisted APPI. By applying 1.5 kV, a spray was generated to desorb the non-polar analytes to be further photoionized in gas phase using negative ionization mode for HRMS analysis.

Results:

Several working parameters, including dopant, solvent mixture, spray voltage and paper and APPI-UV lamp positions, which may affect the ionization, extraction and transport efficiency of the analytes, were carefully optimized for the analysis of the two most challenging families of fluorinated compounds by PS, zero-voltage PS-APPI and voltage-assisted PS-APPI. Under PS-HRMS and zero-voltage PS-APPI-HRMS conditions, most analytes were not or poorly ionized, while using voltage-assisted PS-APPI-HRMS, useful $[M-H]^-$ and/or $[M+O_2]^-$ ions were detected. High resolution MS/MS experiments were also performed for further confirmatory purposes. Thus, major improvements in terms of sensitivity were obtained by using voltage-assisted PS-APPI ionization and method quality parameters demonstrated good repeatability, reproducibility and linearity with negligible matrix effects for the analysis of waterproof liquid matrices. Besides, internal standard method allowed the quantification of these families of compounds at $\mu\text{g mL}^{-1}$ levels.

Conclusions:

The use of APPI as an alternative ionization for PS-based techniques allowed the screening and quantification of non-polar and/or low polar compounds by PS. The voltage-assisted PS-APPI-HRMS method was applied for the detection of semi-volatile fluorinated compounds in real samples without any sample manipulation at $\mu\text{g mL}^{-1}$ levels demonstrating its potential as a fast and useful technique for quality control laboratories.

Novel Aspect:

To the best of our knowledge, this is the first time that PS is successfully combined with APPI for the determination of semi-volatile fluorinated compounds.

582 - ADVANCES IN SELECTED ION FLOW-DRIFT TUBE MASS SPECTROMETRY, SIFDT-MS, FOR AMBIENT QUANTIFICATION OF TRACE VOLATILE COMPOUNDS IN AIR.

Patrik Španěl (1) - Anatolii Spesyvyi (1) - David Smith (1) - Kristýna Sovová (1)

Czech Academy of Sciences, J. Heyrovský Institute of Physical Chemistry, Praha (1)

Keywords: SIFT-MS, SIFDT-MS, VOCs, quantification, chemical ionization

Introduction:

The Selected Ion Flow-Drift Tube Mass Spectrometry, SIFDT-MS, technique represents an important development of the Selected Ion Flow Tube Mass Spectrometry, SIFT-MS, technique building on its strengths (rapid switching between reagent ions and near thermal ion chemistry) and removing some of its weaknesses (lower sensitivity in comparison with proton transfer reaction, PTR, MS). It has a range of applications in biological, medical and environmental fields.

Methods:

The selected reagent ions (either H_3O^+ , NO^+ or O_2^+) for selective chemical ionization of volatile compounds present in the air matrix are created in an external ion source and injected into the flow-drift tube reactor with well-defined reaction time and reagent ion-analyte molecule interaction energy, E_r . The absolute concentrations of the analytes can thus be accurately quantified using the chemical kinetics principles.

Results:

Accuracy of quantification is shown to be determined by the accuracy of the reaction time measurement and by the uncertainties in the values of the ion-molecule reaction rate constants. The reactions of H_3O^+ , NO^+ and O_2^+ ions have thus been studied with a range of compounds, including ketones, terpenes, isoprene isoflurane, sevoflurane and acetonitrile in order to reveal their dependencies on ion-molecule interaction energies, E_r , whilst also gaining insight into their mechanisms. The rate constants, k , for the reactions of H_3O^+ proceeding via exothermic proton transfer are seen to reduce by about one third over the E_r range from 0.05 eV up to 0.5 eV, in agreement with the collisional theory. The NO^+ /ketones reactions often proceed via the formation of excited $(NO+M)^*$ adduct ions that partially fragment, and k reduce with E_r sometimes more dramatically. The k for the O_2^+ charge transfer reactions are observed to be greater than their calculated k_c implying that long distance electron transfer occurs.

Conclusions

Whilst several advantages of SIFDT-MS over the established SIFT-MS are becoming apparent (including better sensitivity, improved accuracy and feasibility of design of portable instrument), it is very important to assess the potential complications due to increased E_r , including fragmentation and changes of k . This technique thus has a potential for accurate analyses in matrices such as environmental air, food flavours or exhaled breath.

Novel Aspect:

New experimental data are presented and interpreted on the kinetics of ion-molecule reactions allowing a new approach to soft chemical ionization of trace compounds in air.

625 - A TRIPLE REAGENT ION SOURCE FOR TRACE VOCs QUANTIFICATION BY SELECTED ION FLOW-DRIFT TUBE MASS SPECTROMETRY

Anatolii Spesyvyi (1) - Patrik Španěl (1)

J. Heyrovský Institute of Physical Chemistry of the CAS, v. v. i., Department of Chemistry of Ions in Gaseous Phase, Prague (1)

Keywords: SCI-MS, SIFDT-MS, VOCs, quantification, chemical ionization

Introduction

Selected Ion Flow-Drift Tube Mass Spectrometry, SIFDT-MS, was developed to quantify volatile organic compounds in air. The original instrument had two quadrupole mass filters: to select the reagent ions from the microwave discharge into the drift tube reactor and to analyze the product ions. To increase the sensitivity, the first quadrupole and the microwave discharge were replaced by a triple source creating the reagent ions by sequences of ion-molecule reactions.

Methods

The SIFDT-MS apparatus and the basic principles of the technique were previously described [1, 2]. For the present work a newly designed ion source was constructed consisting of three hollow cathode discharges arranged parallel to the drift tube axis. Different gas (water vapor, NO or O₂) is used in each discharge creating reagent ions H₃O⁺, NO⁺ or O₂⁺ rapidly switchable by drift lens voltages.

Results

It was demonstrated that the ion source allows simultaneous use of three different gases to produce reagent ions of interest that can be selected by applying optimized sets of DC electric potentials to drift lenses. Increase in the analytical sensitivity is described that was achieved by greater reagent ion intensity increased several times due to the absence of the orifice between the ion source and the drift tube, which are now pumped by a common vacuum line and have similar pressures of about 2 mbar. Ion-molecule reactions in the drift tube are governed by the voltage applied across the drift tube. It is shown how the relative electric field strength E/N affects the reaction time, the ion interaction energy and the diffusion losses. Illustrative results include enhanced product ion fragmentation [3] and suppression of unwanted reactions, for example formation of hydrated ions.

Conclusions

The presented enhancement of SIFDT-MS makes this technique more sensitive and allows construction of robust and small instruments. It thus represents a viable addition to the family of soft chemical ionization mass spectrometric techniques such as SIFT-MS and PTR-MS that are becoming widely used in the area of real time quantification of the VOCs in the medical, food and environmental fields.

Novel Aspect

Three reagent ions H₃O⁺, NO⁺ or O₂⁺ are produced in the triple ion source simultaneously and can be selected instantly at greater intensities than possible using a mass filter.

1068 - DIRECT COUPLING OF MAGNETIC-PARTICLE-BASED SAMPLE PREPARATION STRATEGIES TO MASS SPECTROMETRY VIA MICROFLUIDIC OPEN INTERFACE

Marcos Tascon (1) - Varoon Singh (1) - Mohammad Huq (2) - Janusz Pawliszyn (1)

University of Waterloo, Chemistry, Waterloo (1) - University of Waterloo, Chemistry, Waterloo (2)

Keywords: Dispersive droplet extraction, Fast analysis, Magnetic particles, Microfluidic Open Interface, SPME-MS

Introduction:

Magnetic micro- and nanoparticles are an emerging technology in the field of solid-phase extractions.[1] However, current analysis strategies are limited to off-line desorption where just a fraction of the solution is detected. Hence we developed a new design of the microfluidic open interface (MOI) which acts as an interface for the direct coupling of the magnetic-particles-based sample preparation to mass spectrometry resulting in increased sensitivity while reducing the time of analysis and sample size.[2]

Methods: (Limit of 400 characters without spaces)

Dispersive extractions of six model small molecules from droplets of PBS and urine using C18 magnetic nanoparticles in droplets for 30 s were performed. On the other side, IMAC magnetic microparticles were dispersed in droplets of β -casein digests and in-droplet β -casein trypsin digestions for extraction of phosphopeptides. In both approaches, the nanoparticles were collected by applying a magnetic field followed by direct desorption via MOI and MS detection.

Results:

The methodology developed for the direct coupling of magnetic particles to MS via MOI was evaluated using nano and microparticles. The desorption consisted in the generation of an isolated droplet (\approx five μ L) that wets the particles, these are held by the magnetic field applied by a 3D-printed holder. Then, the enriched droplet is rapidly drained to the ESI source where the compounds are ionized. The dispersive extraction using nanoparticles from droplets (20-40 μ L) was completed after 10 seconds. Limits of quantitation in the range 1-5 ng/mL were achieved in PBS and urine for all the compounds with an overall analysis time below 2 min. On the other hand, IMAC microparticles allowed efficient phosphopeptide extraction in less than 5 minutes from protein digests and in-droplet digest as a screening tool. Because of the high sensitivity achieved in both cases, the amount of particles used was within 30-100 μ g per sample, which is about ten times less than conventional exhaustive extraction Methods:

Conclusions

A technology to efficiently couple magnetic-particle-based extractions to MS has been developed. The combination of fast desorption kinetics, low desorption volume, and no further dilutions made MOI-MS a rapid and very sensitive strategy. To proof the concept, droplet extractions using about 50 μ g of particles were tested for small and medium-size molecules. The results demonstrated good sensitivity using the minimum amount of sample and particles in a short analysis time.

Novel Aspect

A novel interface to directly and efficiently couple magnetic-particle based extractions to MS via a microfluidic open interface was developed for fast and rapid analysis.

908 - AIRBORNE LASER-SPARK ION SOURCE FOR DIRECT MICROFLUIDIC COUPLING

Sebastian van Wasen (1) - Andreas Bierstedt (2) - Jens Riedel (2) - Dietrich Volmer (1)

Humboldt-Universität zu Berlin, Department of Chemistry, Berlin (1) - Federal Institute for Materials Research and Testing, BAM, Berlin (2)

Keywords: ambient mass spectrometry, laser-induced plasma, DPSS laser, high repetition rate

Introduction:

The development and improvement of new ionization techniques for mass spectrometry often requires dedicated, specific sampling approaches. Recently, a novel ionization scheme for ambient MS has been introduced based on a quasi-continuous laser-induced plasma, which was ignited directly before the MS inlet. This setup combines the general advantages of ambient ionization, provides electro neutrality, sufficient duty cycle and a ubiquitous plasma medium. [1, 2]

Methods:

A high repetition rate DPSS laser (Conqueror 3-LAMBDA, Nd:YVO₄, 1 - 500 kHz, average output power: 12 W at 50 kHz, Compact Laser Solutions GmbH, Germany) and the corresponding optomechanical system were installed on an optical breadboard above the inlet of a LCQ DecaXP ion trap mass spectrometer. The quasi-continuous airborne plasma was ignited inside the sprayed sample in front of the inlet via focused laser irradiation.

Results:

The introduction of liquid samples into laser-induced plasmas requires higher plasma power during solvent evaporation as compared to gaseous samples. This increased demand was approached via a two-fold strategy: Firstly, an alternative, more powerful, laser plasma driven by the fundamental instead of the second harmonic wavelength was implemented, which provided a 10-fold increase of signal intensity, while maintaining the same reagent ion pattern as the previous plasma. Protonated water clusters [(H₂O)_nH]⁺, NH₄⁺ as well as charge transfer promoting ion O₂⁺, dominated the reagent ion mass spectrum. Secondly, a miniaturized nebulizer was used to minimize the size of the plasma quenching solvent droplets. The result of these improvements was a new and very stable ion source for direct microfluidic coupling. A variety of samples demonstrated the performance of the ion source.

Conclusions:

A laser-driven plasma was shown to be a powerful ion source for gaseous and solid samples. For the first time, liquid samples were examined using the novel source. In addition to demonstrating an improved strategy for igniting the laser plasma, this contribution also covers the miniaturization of the spray source for enhanced ionization, while minimizing sample consumption via a microfluidic spray systems.

Novel Aspect:

The first laser plasma ionization spectrum was recorded for liquid sample

Development and the application of a 96 high throughput solid phase microextraction (SPME) transmission mode (TM) system for direct analysis in real time (DART) mass spectrometry (MS)

Tijana Vasiljevic, German Augusto Gomez Rios and Janusz Pawliszyn

University of Waterloo

Keywords: High throughput; Ambient mass spectrometry (AMS); Direct analysis in real time (DART); Solid phase microextraction (SPME); Drugs

Introduction

Development of a high throughput system capable of delivering the two “Rs” (rapidity and reliability) is one of the most sought-after research fields in the area of ambient ionization mass spectrometry (AIMS). In this research, we have taken the single SPME-TM mesh and transformed it into a 12 mesh format for rapid high throughput detection/quantification of opioids in biomatrices using direct analysis in real time mass spectrometry (MS).

Methods

SPME-TM meshes were manufactured to a 12 mesh format using pre-made photochemically milled stainless steel substrates, which were etched and adequately coated with C18 particles. Urine and plasma samples were spiked with a set of opioids, followed by a 10 minute extraction step and desorption at 450 °C of DART source with tandem MS analysis. A set of 96 samples was extracted, analyzed and interpreted in less than 1.5 hours.

Results

The SPME-TM 12 mesh strip were created utilizing a careful fabrication protocol with respect to etching and coating process, while their performance was maximized using a robust holder made at University of Waterloo (UW) capable of analyzing all 12 meshes at the same time. Positive preliminary assessment of mesh performance (i.e. coating stability, extraction efficiency) led us to apply the meshes for a high throughput quantification of selected opioids in urine and plasma. Experimental procedure was optimized with respect to extraction time, DART source temperature (TEM), rail speed and pH of samples ultimately resulting in low limits of quantification (LOQ) (i.e. 0.5 ng mL⁻¹ fentanyl for PBS and urine and 1 ng mL⁻¹ for plasma), acceptable accuracy (73.4-109.5 %) and repeatability (1.6-11.3%). Indeed, these results take a firm step toward establishing DART SPME-TM as potential tool for detection of varying substances in scenarios where high throughput is required.

Conclusions

Novel Aspect

First reported use of a high throughput SPME 96 system for opioid detection using DART/MS

682 - SINGLE-USE POLY(ETHERETHERKETONE) SOLID-PHASE MICROEXTRACTION-TRANSMISSION MODE DEVICES FOR RAPID SCREENING AND QUANTITATION OF DRUGS OF ABUSE IN ORAL FLUID AND URINE VIA DIRECT ANALYSIS IN REAL-TIME

University of Waterloo, Chemistry, Waterloo (1)

Single-Use Poly(etheretherketone) Solid-Phase Microextraction-Transmission Mode Devices for Rapid Screening and Quantitation of Drugs of Abuse in Oral Fluid and Urine via Direct Analysis in Real-Time Tandem Mass Spectrometry

Vasiljevic, Tijana, German Augusto Gomez-Rios, Janusz Pawliszyn

University of Waterloo

Keywords: Direct-analysis in real time (DART), Solid phase microextraction (SPME), Polyetheretherketone (PEEK), Drugs, Quantification

Introduction

Rapid detection of prohibited substances in biologicals is important in forensic science. Herein, we report on results obtained for detection and quantification of drugs of abuse in urine and oral fluid (OF) by using biocompatible single use plastic SPME-TM meshes made of polyetheretherketone (PEEK) coupled to direct analysis in real time mass spectrometry (DART-MS).

Methods

PEEK meshes were coated with hydrophilic lipophilic (HLB) particles. The biofluids were spiked with a mix of drugs and internal standards. The meshes were used for extraction of selected drugs in 700 μL of urine and 300 μL of OF. Extraction time was kept at 1 minute, followed by wash in water and drying. Meshes were placed onto a homemade holder and desorbed between the DART source and the MS on a linear rail. Analysis was carried out using a triple quadrupole MS with MRM mode.

Results

The goal behind development of the plastic meshes was to be create a tool which could potentially be used for on-site in vivo analysis. Indeed, the plastic meshes provided us good results for quantification of 13 different drugs in urine and OF, with linearity ranging from 0.5-200 ng/mL and R² values > 0.99. Validation points were tested at 4 different levels and provided acceptable accuracy in the range of 75- 127 %. Also, the LOQs obtained for the analytes were below the limits imposed by substance abuse and mental health services administration (SAMSHA). In addition, OF samples were collected from a volunteer for detection of caffeine levels prior to and after coffee consumption. The results obtained at different time points were in accordance with caffeine half-life for healthy adults. In addition, we looked at impact of material on heat transfer in DART. Such findings highlight the fact that ambient ionization techniques such as DART are very useful tools in providing law enforcement with much needed reliable and rapid data.

Conclusions

Results obtained indicate great potential of SPME-TM DART for use in many scenarios where rapid, reliable and quality data is required in a timely fashion. Utilization of alternate materials such as PEEK opens up a great prospect for use in situations where in vivo detection of prohibited substances may be required, in addition to having great prospect for use with portable MS instrumentation.

778 - IMPROVEMENTS IN SMALL MOLECULE DETECTION VIA MALDI-MS USING BINARY MIXTURES OF NOVEL IONLESS MATRICES

Jerrit Weissflog (1) - Aleš Svatoš (1)

Max-Planck-Institute for Chemical Ecology, Research Group Mass Spectrometry/Proteomics, Jena (1)

Keywords: MALDI-MS, ionless matrices, binary matrices, small molecule detection

Introduction:

Matrix-assisted laser desorption/ionisation mass spectrometry (MALDI-MS) is mainly used for the analyses of larger molecules ($m/z > 1000$) due to interfering mass signals below $m/z 600$ generated by conventional matrices. So called ionless matrices like graphene [1] and the recently introduced DPN[2] do not generate matrix signals and therefore allow detection of small molecules. This study aims to improve their sensitivity by applying mixtures of such matrices.

Methods:

Several established matrix compounds like 1,8-di(piperidinyl)-naphthalene[DPN], 9-aminoacridine[3] and 2-naphthylsulfonic acid[4] were mixed in distinct ratios and their ionization potential was assessed via MALDI-ToF-MS using a variety of analytes e.g. fatty acids and amino acids. Additionally, in several experiments graphene, as well as strong acids or bases were applied together with these matrices to test their influence on the ionization performance.

Results:

When the ionless matrices are used in binary mixtures, a clear increase in signal intensity can be observed. The ionizing properties of these blends are higher than those of the single matrices. Graphene for example was able to improve the performance of DPN in negative ion mode especially for hydrophobic analytes like fatty acids while the spectra remained free of any signals besides the ones from the analytes. Furthermore, the required energy per laser pulse for optimal signal intensity is reduced when graphene is applied alongside DPN.

Conclusions:

The mechanism of ionization in MALDI is a complex interplay between absorption and distribution of laser energy, proton transfer between analyte and matrix, and separation of ion pairs in the gas phase. By employing mixtures of matrices, a possible existing shortcoming of a single matrix in one of these aspects can be mitigated if the other matrix surpasses the first in this particular property.

Novel Aspect:

A substantial improvement of sensitivity for the detection of small molecules via MALDI-MS using mixtures of ionless MALDI-matrices as well as graphene.

1220 - MATRIX-ASSISTED-IONIZATION-IN-VACUUM COUPLED TO HIGH-RESOLUTION FOURIER TRANSFORM MASS SPECTROMETRY (MAI-FTMS) IN CHARACTERIZING LIPIDS IN COOKING OIL AND BACTERIA

Rohanna Liyanage (1) - Jennifer Gidden (1) - Jackson Lay, Jr. (2) - Charles Wilkins (2)

University of Arkansas, Statewide Mass Spectrometry Facility, Fayetteville, United States (1) - University of Arkansas, Chemistry and Biochemistry, Fayetteville, United States (2)

Keywords: MAI, Ionization, Matrix, Lipids, Bacteria

Introduction

MAI seems to be a reliable alternative to ESI and MALDI for some applications. Solvent free and laser free aspects of MAI appeal to most mass spectrometrists[1,2]. The primary disadvantage of MAI is rapid evaporation/consumption of the matrix in the vacuum during analysis. There are relatively few literature reports of measuring lipids by MAI-FTMS. Here we show the use of MAI-FTMS lipid profiles in differentiating a variety of cooking oils and bacteria.

Methods

Samples were prepared by dissolving in matrix solutions. MAI analysis was done by FTMS immediately after drying the sample solutions in either positive or negative ion mode. The FT-ICR mass spectrometer is a 9.4 T Apex FT-ICR mass spectrometer (Bruker, Bremen, Germany). After air drying and loading, the plate voltage was set at 300 V. The acquisition size was at least 512 K points for high signal abundance. Twenty acquisitions were averaged to obtain a mass spectrum.

Results

3-nitrobenzotrile (3-NBN) solubilized in acetonitrile was used as a matrix. Quality MAI-FTMS spectra from TAGs in cooking oil result when prepared with high concentrations of matrix dissolved in pure acetonitrile. Phospholipids from the bacteria only required dilute matrix. Generally, increasing the amount of water in the matrix allowed high quality phospholipid spectra with increases in the lifetime of matrix in vacuum. MS/MS fragmentation yields all important peaks in MAI-FTMS. TAG profiles obtained for all the cooking oils, peanut, soy, sunflower, coconut, cocoa butter, canola, and vegetable, are identical to those obtained with MALDI. MAI had more reproducible intensity variation, allowing statistical determination of small compositional differences[3]. Although most of the MALDI-observed phosphatidylethanolamines (PE) lipids from *E. coli* are adducts of sodium or potassium, MAI primarily produces protonated

Conclusion

The newly-developed MAI-ionization technique is a rapid and simple method for characterization of polar and non-polar lipids in complex mixtures[1,2]. This technique is complementary to ESI and MALDI mass spectrometry methods and combines some of the best features of both.

Novel Aspect

Application of MAI-FTMS in characterizing polar and non-polar lipids in complex samples

219 - 3D-PRINTED LOW-TEMPERATURE PLASMA (3D-LTP) PROBE FOR IMAGING AND IN VIVO STUDIES

Sandra Martínez-Jarquín (1) - Abigail Moreno-Pedraza (1) - Héctor Guillén-Alonso (1) - Humberto Herrera-Ubaldo (2) - Ignacio Rosas-Román (1) - Cesaré Ovando-Vázquez (3) - Stefan de Folter (2) - Robert Winkler (1)

CINVESTAV Unidad Irapuato, Biotechnology and Biochemistry, Irapuato (1) - CINVESTAV UGA, LANGEBIO, Irapuato (2) - IPICYT, CNS, San Luis Potosi (3)

Keywords: low-temperature plasma, 3D-printing, ambient imaging, in vivo studies, real-time monitoring

Introduction

A wide range of organic molecules from solid, liquid and gaseous samples can be detected with low-temperature plasma (LTP) ionization mass spectrometry (MS) under ambient conditions [1]. LTP probes are relatively easy to build, but there is no commercial system available. Thus, we designed an LTP probe from 3D-printed and standard parts and tested its analytical performance on chemical and biological samples.

Methods

We constructed an LTP probe from standard and 3D-printed components and tested the suitability of the 3D-LTP probe for MS by measuring reference standards and complex samples[2]. For automated sampling and imaging, we built a robot based on RepRap technology. We investigated the biocompatibility of LTP-MS by monitoring the nicotine content in tobacco leaves for 10 days and subsequently evaluating the tissue damages with a microscope.

Results

The 3D-LTP probe was functional and coupled to a standard MS analyzer. The 3D files were published under a Creative Commons (non-commercial) Public License.

Compounds of different volatility and polarity and with a molecular weight up to ~500 Da could be detected from simple and complex matrices. The diameter of the plasma beam was about 200 μm . The technical resolution of the sampling robot was 12.5 μm . Therefore, ambient mass imaging of eukaryotic tissues with cellular resolution is possible when combined with laser desorption (LD).

We subjected tobacco plants with modulated nicotine biosynthesis to daily measurements for 11 days. The LTP-MS measurements resembled the expected time course which indicated correct monitoring of the biosynthesis. Staining and microscopic evaluation only showed minor tissue damage and no systemic effect was observed. This evidence demonstrated the high potential of LTP-MS for in vivo biosynthesis studies[3].

Conclusions

The 3D-LTP probe can be easily built from 3D-printed and commercially available parts. The plasma jet diameter is sufficient for imaging macroscopic samples. Short-time exposure of plant surfaces to LTP only resulted in negligible (microscopic) lesions, thus demonstrating the value of LTP-MS for in vivo measurements. Our license model promotes the free exchange and innovation of LTP probe designs.

Novel Aspect

The Creative Commons (non-commercial) license of the 3D-LTP probe permits the rapid building of custom low-temperature plasma probes.

68 - IDENTIFICATION OF MEDULLOBLASTOMA SUBGROUPS ON INTRASURGICAL TIMESCALES WITH PICOSECOND INFRARED LASER DESORPTION MASS SPECTROMETRY

Michael Woolman (1) - claudia Kuzan-Fischer (2) - Isabelle Ferry (2) - Taira Kiyota (3) - Betty Luu (2) - Megan Wu (2) - David Munoz (4) - Sunit Das (2) - Ahmed Aman (3) - Michael Taylor (2) - James Rutka (2) - Howard Ginsberg (4) - Arash Zarrine-Afsar (5)

University of Toronto, Department of Medical Biophysics, Toronto (1) - Hospital for Sick Children, University of Toronto, Toronto (2) - Ontario Institute for Cancer Research, University of Toronto, Toronto (3) - St Michael's Hospital, University of Toronto, Toronto (4) - University Health Network, University of Toronto, Toronto (5)

Keywords: Medulloblastoma, picosecond infrared laser, mass spectrometry, molecular pathology, real time analysis

Introduction: Medulloblastoma (MB) is the most common brain tumor in children that is comprised of four different subgroups (WNT, SHH, Group 3, Group 4) each with distinct prognostic characteristics [1-3]. While risk stratification of MB patients based on molecular features may offer the prospect of personalized therapies, the long analysis times of conventional classification methods prevents subgroup-specific adjustments of the extent or the aggressiveness of the resection.

Methods: We investigated the potential of rapid tumor small molecule profiling with Picosecond Infrared Laser desorption Mass Spectrometry (PIRL-MS) [4,5] as a new method of medulloblastoma subgroup classification. A local tissue bank comprising 113 ex vivo medulloblastoma tumors was subjected to 10-second PIRL-MS data collection, and Principal Component Analysis with Linear Discriminant Analysis (PCA-LDA).

Results: A model for MB subgroups was built based on the laser extracted lipid profiles of 72 independent tumors, comprised of 190, 10-second PIRL-MS data points. Forty one de-identified unknown tumors were subjected to 10-second PIRL-MS sampling and real time PCA-LDA analysis using the model above where the resultant 124 sampling events, after the application of a 95% PCA-LDA prediction probability threshold, yielded a 99% correct classification rate, and only one misclassified data point. This was accompanied with 28 sampling events that were not classifiable into any known MB subgroups. We thus used an extended MB signature library that was comprised of 278 sampling events to better capture the intrinsic biological heterogeneity of MB, through which we were able to correctly reclassify 21 out of the said previously unclassifiable sampling events with no misclassification. Detailed post ablation histopathological analysis of MB samples suggests that intratumoral heterogeneity at the site of laser ablation can explain the apparent misclassification.

Conclusions : Our observations suggest that rapid tumor small molecule content profiling with PIRL-MS is effective in medulloblastoma subgroup classification with only 10 seconds of sampling, an analysis time thus opening up the possibility of subgroup specific treatment of medulloblastoma beginning in the operating room during a surgical procedure.

Novel Aspect: Rapid intraoperative identification of Medulloblastoma subgroups in 10 seconds based on lipid profiling with Picosecond InfraRed Laser Mass Spectrometry is now possible.

1186 - BREATHMETABOLOMICSUSING SECONDARY ELECTROSPRAY IONIZATION (SESI) - HIGH RESOLUTION MASS SPECTROMETRY

Renato Zenobi (1)

ETH Zurich, HCI E 329 - CH-8093 ZÄrich, Switzerland (1)

Keywords: exhaled breath analysis • ambient ionization • secondary electrospray ionization mass spectrometry

Introduction:

On-line breath analysis is a powerful approach to obtain insights into the metabolism of a person. With ambient ionization methods, this can be achieved rapidly and completely non-invasively, opening up interesting possibilities to diagnosediseases via exhaledbreath, to discerniurnalchangesin the metabolism, and to monitordrug use (or drugabuse) by analyzing thechemicalcomposition of exhaledbreath.

Methods:

Besides SESI-MS there are other methods in use for breath analysis, notably selected ion flow tube-mass spectrometry (SIFT-MS) and proton transfer reaction-mass spectrometry (PTR-MS). These will be compared in terms of analytical performance (mass resolution, upper mass limit, detectionlimit, softness of ionization, etc.) and the coverage of biomarkers (polarity, volatility, molecularweight, etc.).

Results:

SESI-MSaffordssub-pptlimits of detection, and analysis of compounds with molecularweights up to 1000 Da. Ifcoupled to a high-resolutioninstrument, SESI-MS offersexcellentcoverage of the breathmetabolome and deepinsightinto the metabolic state of a person.Moreover, the high resolutionallowsdetailedcharacterization of compoundsthat can be usedasbiomarkers [1]. Thiskeynotelecturewillpresentseveral examples in medicaldiagnosis, including the detection of novelbiomarkers for respiratorydiseases suchasobstructivesleep apnea (OSA) [2],chronicobstructive pulmonarydisease (COPD) [3], pulmonaryfibrosis, and asthma.Monitoring of drugcompliance and pharmacokinetics [4] via real-time SESI-MS willalso be shown.

Conclusions:

A variety of biomarkers that describe diseases have been detected in exhaled breath and identified via SESI-MS, often aided by chromatography,of exhaled breath condensate and comparison against commercially available or synthetic reference compounds.

Novel Aspect:

Noninvasive monitoring of the detailed chemical composition of exhaled breath via SESI-HRMS.

Keywords: imaging mass spectrometry, instrumentation, high spatial resolution

Introduction:

Measurement methods of spatial distribution of molecules at cellular-scale are required in many fields. Recently, scanning type imaging mass spectrometry with matrix-assisted laser desorption/ionization is intensively used for biomolecular analysis. However, the spatial resolution of scanning MALDI-IMS is limited to about 10 - 100 μm and inadequate for cellular-scale observation. Therefore, we are developing a stigmatic MALDI imaging mass spectrometer to achieve spatial resolution of sub-micron.[1]

Methods:

The experimental apparatus for stigmatic imaging consists of a MALDI ion source with focusing ion optics, TOF mass spectrometer and a time and position sensitive ion detector. Sample molecules ionized by laser irradiation are extracted and accelerated by extraction electrode. Ion distributions at the sample plate are magnified and projected with the ion optical lens system onto the detector.

Results:

For a stigmatic MALDI imaging, laser irradiation spot is focused to several hundreds micro-meter diameter with accurate uniformity. This diameter is several times larger than ordinary MALDI, so laser power is required about ten times larger than ordinary one. And for uniform laser irradiation, we develop a laser beam homogenizer system consists of a dynamic rotating diffuser to eliminate laser speckle and a square core optical fiber to form flat-top square profile. We used this system with a high power UV (355 nm) pulse laser (NL202, Ekspla, Lithuania) and evaluated imaging performance by observation of test samples. We observed grid pattern formed by test samples of crystal violet dye covered with fine metal mesh. We verified imaging quality by this experiment and then observed more practical samples of eye tissue of mouse and amoeba cells.

Conclusions:

We developed new stigmatic imaging mass spectrometer with a uniform laser beam system. Our evaluation experiments verified that this apparatus achieved high spatial resolution of 1 micro-meter with a field of view of 500 x 500 micro-meter within observation time of several minutes. This spatial resolution and measurement speed was drastically improved from conventional scanning type imaging mass spectrometers. We also show applications of this apparatus to actual biological samples.

Novel Aspect:

We developed optics of stigmatic MALDI imaging mass spectrometer and observed high spatial resolution image.

715 - DEVELOPING MS IMAGING IN THE CONTEXT OF CHEMICAL ECOLOGY - LASER ABLATION ELECTROSPRAY IONIZATION ON THREE-DIMENSIONAL SAMPLES

Benjamin Bartels (1) - Dirk Hölscher (2) - Purva Kulkarni (3) - Aleš Svatoš (1)

Research Group Mass Spectrometry/Proteomics, Max Planck Institute for Chemical Ecology, Jena (1) - Ökologische Agrarwissenschaften (OPATS), Universität Kassel, Witzenhausen (2) - Terrestrial Ecology, Netherlands Institute of Ecology (NIOO-KNAW), Wageningen (3)

Keywords: Mass spectrometry imaging, LAESI, profilometry, multimodal, application

Introduction:

Laser ablation electrospray ionization (LAESI) is an ionization method applicable for mass spectrometry imaging (MSI) on biological samples [1]. Making use of indigenous water, LAESI is not dependent on externally applied matrices, reducing the sample preparation component of any experiment considerably. By integrating a profilometer, sample topography becomes measurable and employable during laser ablation, allowing access to ecologically relevant samples.

Methods:

Various parts of *Gossypium hirsutum* plants were used as a model system to evaluate a custom build LAESI source for MSI [2]. Before conducting MSI experiments, the surface topography was measured and subsequently applied to guide the laser ablation process during the actual MS experiment. Sample preparation was unnecessary, except trimming the sample to fit a microscopy slide. Mass spectra were acquired in positive and negative ion mode on a Synapt HDMS (Waters).

Results:

During MSI experiments performed on different ROIs of leaves and stems with our custom-build LAESI source, profilometry was successfully applied to guide the laser ablation. As a result, laser ablation marks were of equal diameter, reproducible and independent of sample surface topography. Specialized metabolites with known insect deterring properties [3], such as gossypol and heliocide isoforms were localized in specialized glands distributed all over *G. hirsutum* plants. By exploiting the measured height profiles, the diameter of laser ablation marks was controllable between 30 μm and $\sim 150 \mu\text{m}$ in a reproducible manner. Based on experiments on *G. hirsutum*, ecologically relevant interactions between various other plant species and microbial interaction partners were investigated.

Conclusions:

Our custom-build LAESI source allows for the inclusion of a profilometry step in MSI experiments. The described setup is able to deal with challenges posed by ecologically relevant samples of delicate plant-microbial interactions.

Novel Aspect:

Analysis of various plant surfaces and plant-microbe interactions without the need for sample preparation or sectioning.

1009 - IMPROVED SENSITIVITY AND SPEED OF ACQUISITION USING QUADRUPOLE BASED MASS SPECTROMETER FOR DESI-MSI

Emmanuelle Claude (1) - Praveen Harapanahalli (2) - Emrys Jones (3)

Waters Corporation, Scientific Operations, Wilmslow (1) - Waters Corporation, Software, Wilmslow (2) - Waters Corporation, Research, Wilmslow (3)

Improved sensitivity and speed of acquisition using quadrupole based mass spectrometer for DESI-MSI

Emmanuelle Claude, Praveen Harapanahalli, Emrys Jones

Introduction: (Limit of 400 characters)

DESI-MSI is typically known for the mapping of small molecules directly from tissue sections. DESI MSI has been proven to be successful when used on Time-Of-Flight (TOF) based mass spectrometers in particular for untargeted analysis or mass spectral fingerprinting. Tandem quadrupole mass spectrometers are renowned for their sensitivity and specificity for targeted application using Single Ion Monitoring (SIR) or Multi Reaction Monitoring (MRM) modes of acquisition.

Methods: (Limit of 400 characters)

Experiments were performed on a Xevo TQ-XS (Waters) in SIR or MRM modes of acquisition and a Xevo Q-ToF G2-XS (Waters) in MS or MS/MS modes of acquisition. A 2D DESI stage (Prosolia) DESI was used with spray conditions set 2 μ L/min, 95:5 MeOH:water and a nebulising gas pressure of 5 bar. DESI imaging datasets were subsequently processed and visualised using in-house software tools and High Definition Imaging (HDI) software.

Results: (Limit 900 characters)

To evaluate the level of sensitivity, dilution series of several drug compounds including Propanolol and Bromofenac were spotted on tissue sections from 0.25ng up to 1 μ g. On the TQ system, MRM mode of acquisition was set with a first transition for the drug and second transition for an endogenous lipid. On the oa-TOF system, MS and MS/MS modes of acquisition were used. The limit of detection for Propanolol using the TOF system was 2.5 ng on tissue whereas it was 0.25ng for the DESI TQ. The limit of detection for Bromofenac using the TOF system was 50 ng on tissue in MS and whereas it was 0.25ng on tissue for the DESI TQ. A similar improvement in level detection of drugs was observed from dosed tissue section using the DESI TQ allowing mapping drugs in tissue at therapeutic levels which is not straightforward using TOF mass spectrometer for MSI.

With the improved sensitivity, it was possible to increase the speed of analysis using stage rate from 1 to 30 scans/s or the number of MRM, resulting in a decreased dwell time for each pixel.

Conclusions (Limit of 400 characters)

DESI mounted on TQ mass spectrometer has clearly demonstrated some advantages in an imaging setting such as increased sensitivity allowing drug compounds to be mapped at therapeutic level from dosed tissue sections.

Novel aspects: (Limit of 150 characters)

Mapping of drug compounds at therapeutic level using highly sensitive and selective DESI mounted on triple quadrupole mass spectrometer.

1288 - PATERNÒ-BÜCHI PHOTO-DERIVATIZATION PROTOCOL FOR MALDI-MS IMAGING OF CARBON-CARBON DOUBLE BOND POSITIONAL ISOMERS OF PHOSPHO- AND GLYCOLIPIDS IN BIOLOGICAL TISSUES

Antonín Bednařík (1) - Stefan Bölsker (2) - Jens Soltwisch (2) - Klaus Dreisewerd (2)

University of Münster, Institute for Hygiene - Biomedical Mass Spectrometry, Münster, Germany (1) - University of Münster, Institute for Hygiene, Biomedical Mass Spectrometry, Münster, Germany (2)

Keywords: Paternò-Büchi reaction, Benzaldehyde, MALDI-MS imaging, Double bond positional isomers, MALDI-2

Introduction: Current MALDI-MS imaging (MALDI-MSI) techniques visualize the global distribution of phospho- and glycolipids in tissue sections, but are generally blind to the physiologically relevant carbon-carbon double bond (C=C) position. Here we present a fully MALDI-(2)-MSI compatible “on-tissue” Paternò-Büchi (PB) photo-derivatization protocol that enables mapping the distribution of C=C positional isomers of numerous phospho- and glycolipids in mouse brain.

Methods: Benzaldehyde (BA; mmonoisotopic 106.04 Da) vapor was introduced into a reaction chamber and condensed on the sample (sections of murine brain) at ~6 °C. PB reaction was triggered for 1-2 min by use of a 254 nm-UV lamp. Subsequently, BA was allowed to evaporate at ambient temperature. After coating with matrix, samples were analyzed at 25 µm pixel size with a Q Exactive plus Orbitrap that was equipped with a dual MALDI/ESI injector and a postionization laser for MALDI-2 [1,2].

Results: Making use of our combined PB-MALDI-2 approach, numerous phospho- and glycolipids produced clear [M+BA+H]⁺ ion signals in the positive ion mode. Overall PB photo-derivatization yields were in the 5–30% range (depending on lipid class). Low-energy CID of the protonated PB products generated clear MS/MS spectra and characteristic ion pairs exhibiting a mass difference of 74.05 Da. These unambiguously revealed the C=C positions for numerous singly and poly-unsaturated phospho- and glycosphingolipids in mouse cerebellum. Several C=C positional isomers of phosphatidylcholine and, for the first time, phosphatidylserine species were found to be expressed with highly differential levels in the white and gray matter areas of cerebellum. In contrast, C=C isomers of galactosylceramides were found with equal distributions in the myelin-rich white matter. Importantly, at the applied lateral resolution of 25 µm, no tissue damage or analyte delocalization, which could be associated with our PB protocol, was observed.

Conclusions: Our PB-MALDI-2-MS/MS protocol provides a valuable glimpse into phospholipid organization complexity in tissues with currently unknown biological background. Compared to the also just introduced ozon-based derivatization protocol (OzID) for differentiation of C=C positional isomers [3], our approach has the advantage to widen the class of amenable lipids; moreover, use of any standard MALDI-MSI instrument (also without postionization module) is possible.

Novel Aspect: Paternò-Büchi reaction-based protocol to visualize the distribution of C=C positional isomers of phospho- and glycolipids by MALDI-MS imaging at high lateral resolution

Keywords: targeted and untargeted AP-MALDI imaging

Introduction:

The interest of scientist for MALDI imaging is growing since the last decade and latest developments has led to a significant impact in the pharmaceutical and cosmetics field, but also in materials research. MALDI imaging is now enabled on high resolution Orbitrap instruments by means of Atmospheric Pressure MALDI sources available on the market.

Methods:

An AP-MALDI UHR ion source (Masstech Inc.) is coupled to a LTQ/Orbitrap Elite high resolution mass spectrometer (Thermo Scientific) was used for the development of targeted and untargeted imaging Mass Spectrometry experiments. Samples were coated with matrices using a HTX-TM sprayer.

Results:

Several modes of operation of the AP-MALDI Orbitrap setup are presented based on samples from various types and sizes for the detection of targeted and untargeted molecules. The instrument allows for both large and small scale imaging (using Pixel map or Constant speed raster modes).

The information extracted from each image pixel may be adjusted to either untargeted (full scan HRMS) or targeted (MS/MS or MSⁿ). These various experiments may performed simultaneously in both analyzers in each location of the sample.

Conclusions:

We show the characteristics and applications of a Masstech AP-MALDI UHR ion source to enable targeted and untargeted MALDI imaging capabilities down to 10 micron lateral resolution, when associated to a LTQ/Orbitrap mass spectrometer. This system allows to rapidly switch from the MALDI configuration to LCMS configuration.

Novel Aspect:

Easily interchangeable AP-MALDI (Masstech UHR ion source) for targeted and untargeted MALDI HR-MS or -MSⁿ imaging capabilities down to 10 micron lateral resolution.

Jörg Hanrieder (1)

University of Gothenburg, Department of Neuroscience and Physiology, Gothenburg (1)

Keywords: MALDI imaging mass spectrometry, hyperspectral chemical imaging, electrooptic fluorescent probes, Alzheimer's disease, plaque polymorphism

Introduction: Amyloidogenic aggregation of beta-amyloid peptides into senile deposits is the major pathological hallmark of Alzheimer's disease (AD). While the exact mechanisms of AD pathogenesis are not fully understood, plaque pathology has been identified as critical, driving AD pathogenesis. Delineating plaque pathology in situ is however challenging and calls for novel, multimodal chemical imaging tools such as imaging mass spectrometry ¹ in combination with other biochemical imaging techniques^{2,3}.

Methods: A hyperspectral chemical imaging paradigm is presented, implementing multimodal MALDI imaging MS of peptides and lipids ³ along with chemical imaging using electrooptic fluorescent probes that recognize structural characteristics of A β aggregation dynamics⁴. The method was employed for probing A β plaque polymorphism in human AD brain as well as in transgenic AD mouse models⁵.

Results: The results allowed to identify various A β and lipid species associated with AD pathogenesis. Here, the data on in human and mouse tissue show both a significant increase of A β 1-40 in senile, neurotoxic plaques as compared to plaques of diffuse, pre-amyloid morphology, where no A β 1-40 was observed both in human AD as well as in control patients that exhibit amyloid pathology but no cognitive decline. Additional data in mice show that this increase in A β 1-40 was associated with plaque maturation over time, where both senile plaques and cerebrovascular deposits at 18 months contained higher A β 1-40/1-42 levels than at 12 months. A proportionally higher A β 1-42 content appears therefore to be characteristic for pre-mature deposits suggesting diffuse plaques to be precursors of senile plaques and that maturation into senile plaques is associated with AD pathogenesis. These data show for the first time what A β and lipid profiles are associated with differences in plaque morphology in progressing A β pathology.

Conclusions:

Taken together, the here presented hyperspectral chemical imaging paradigm of individual, chemically and structurally delineated A β deposits provides insight in the chemical aspects underlying plaque polymorphism observed in Alzheimer's disease pathology that is not facilitated by other biochemical techniques. The results show that it is possible to attribute structural features of plaques to A β profiles and highlight the role of different A β isoforms and associated neuronal lipids in formation of distinct biochemical conformation of A β aggregates.

Novel Aspect:

The data highlight the potential of implanting different MALDI imaging modes with other chemical imaging tools for comprehensively probing molecular disease pathology.

M4I, The Maastricht MultiModal Molecular Imaging institute, Maastricht University, Universiteitssingel, 50, 6229 ER Maastricht, The Netherlands (1)

Keywords: Imaging MS, MALDI, SIMS, Clinical diagnostics, Isomers

Introduction:

A comprehensive understanding of molecular patterns of health and disease is needed to pave the way for personalized medicine and tissue regeneration [1]. The best way to capture disease complexity is to chart and connect multilevel molecular information within a tissue, using mass spectrometry. Charting this territory with molecular maps from cells and tissue has become reality through the clinical implementation of imaging mass spectrometry [2]

Methods:

High resolution FTMS technologies (FTICR-MS and Orbitrap MS) combined with smart ion chemistry, stable isotope labeling approaches, ambient ionization, new data acquisition approaches and funnel based MALDI ion sources allows us to address some of the open challenges that still exist in the field of imaging MS. In concert with high throughput MALDI-TOF imaging technologies truly translation clinical studies have become reality.

Results:

We pushed the limit of spatial resolution, molecular resolution and maybe more importantly, structural resolution forward in imaging MS. A novel elevated pressure MALDI imaging ion source is employed to reveal local biochemistry at high throughput. In addition, we have employed OzID in combination with MALDI-MSI to reveal the distinctive regulatory role of lipid isomeric forms in a variety of diseases. These methods are employed for the generation of molecular atlases from cells and tissue and complemented with high throughput "omics" approaches. Multimodal approaches enable the study of clinical samples at a variety of molecular and spatial scales. The combination with tools from structural biology makes it possible to perform mass spectrometric experiments at length scales from cells to patients.

Conclusions

We have demonstrated how new MS based chemical microscopes target biomedical tissue analysis in various diseases as well as other chemically complex surfaces. In concert they elucidate the way in which local environments can influence molecular signaling pathways on various scales. The integration of this pathway information in a surgical setting is imminent, but innovations that push the boundaries of the technology and its application are still needed.

Novel Aspect:

Imaging MS reveals new structural detail in tissue analysis

1249 - HEAT-ASSISTED LASER ABLATION ELECTROSPRAY IONIZATION (HA-LAESI) FOR MS IMAGING OF ANIMAL TISSUE

Juha-Pekka Hieta (1) - Riikka-Marjaana Räsänen (1) - Jaakko Kopra (1) - Heikki Räikkönen (1) - Risto Kostainen (1) - Tiina Kauppila (1)

University of Helsinki, Faculty of Pharmacy, Helsinki, Finland (1)

Keywords: HA-LAESI, LAESI, imaging, tissue, laser

Introduction:

Heat-assisted laser ablation electrospray ionization (HA-LAESI) [1] and laser ablation electrospray ionization (LAESI) [2] are ambient MS techniques for the sensitive analysis of compounds with low molecular weight (<1000) from water-rich samples. Previously, HA-LAESI has been showed to be more efficient in ionizing nonpolar and neutral compounds than LAESI, and thus HA-LAESI is expected to show complementary data in the imaging of animal tissue.

Methods:

Imaging measurements were carried out using a Bruker micrOTOF MS. In HA-LAESI measurements, tissue was ablated using an OPOTEK IR Opolette 2940 laser, and a heated capillary extension was used to add heat to electrospray which was emitted with a typical 100 µm I.D. stainless steel needle. The tissue sections were cooled to -4 °C using a Peltier element and they were rastered inside a N₂ filled box. Waters Xevo QTOF with a ACQUITY UPLC was used for compound identification.

Results:

Previously, a simple technique for improving the focus of OPO IR lasers has been demonstrated by solely increasing the laser beam travel distance [3]. The new focusing technique was combined with HA-LAESI to show heat maps of tissue sections with <50 µm pixel size. The HA-LAESI imaging technique was applied to several types of whole tissues, such as mouse brain, heart and kidney. Some of the detected analytes were identified using Waters' UPLC/MS system. E.g. from mouse brain tissue, HA-LAESI showed spectra covered with high intensity phospholipid, cholesterol, ceramide, and cerebroside signals.

Conclusions

HA-LAESI was found to be a suitable technique for high resolution imaging of animal tissues, and it showed to be more efficient in ionizing nonpolar compounds than LAESI.

Novel Aspect:

High resolution HA-LAESI imaging of animal tissues

Keywords: SIMS, Imaging, MS/MS, Orbitrap

Introduction:

SIMS offers the possibility to acquire chemical information from submicron regions. This capability has been especially intriguing for researchers with life science applications. The vision to image molecules has been driving instrumental development. While new ion sources expanded the usability, SIMS analysers lacked the required mass resolution, mass accuracy and MS/MS capabilities.

Methods:

To specifically address the requirements in the life science field a powerful new Hybrid SIMS instrument [1] was developed in a research project by IONTOF and Thermo Fisher ScientificTM, in close cooperation with the National Centre of Excellence in Mass Spectrometry Imaging, GlaxoSmithKline, and the University of Nottingham, following Prof Ian S Gilmore's original idea.

Results:

In this contribution we will demonstrate the possibilities of the new instrumental design, which combines an OrbitrapTM-based Thermo ScientificTM Q ExactiveTM HF mass analyser with a high-end ToF-SIMS system from IONTOF GmbH. First application data of high resolution SIMS spectrometry, MS/MS analyses, high resolution imaging of tissues and depth profiles of biological samples will be presented. Especially the power of combining the two mass analysers on a single instrument – time-of-flight analyser for fast images with highest spatial resolution and orbital trapping analyser for highest mass resolution and mass accuracy – will be highlighted. Results also cover single beam depth profiles through porcine skin samples, which allow for a clear skin layer elucidation following different molecular ion signals.

Conclusions:

The new Hybrid SIMS instrument combines for the first time highest mass resolution (> 240,000) and highest mass accuracy (< 1 ppm) and full MS/MS capabilities with high resolution cluster SIMS imaging, making SIMS an even more viable technique for the analysis of life science samples.

Novel Aspect:

The combination of the imaging capabilities of a TOF analyser with the unique performance of the OrbitrapTM provides a new level of SIMS information.

Keywords: Targeted MS imaging, multiple reaction monitoring, neutral loss scanning, precursor ion scanning, drug discovery

Introduction:

Drug discovery aims at finding suitable drug candidates that are being metabolized and distributed to the target site, bind to the biological receptors, and block or stimulate a metabolic reaction.[1] Mass spectrometry imaging has established itself as a powerful tool to provide spatial information on drugs and metabolites but suffers from low sensitivity and irreproducibility due to background ions from biological sample matrix.[2]

Methods:

Our work reports a novel targeted MS imaging approach using desorption electrospray ionization (DESI) combined with multiple reaction monitoring (MRM), neutral loss (NL), precursor ion (PREC), and product ion (PROD) scans for the analysis of drugs and lipids in pre-clinical studies. MRM uses a precursor ion-product ion transition to provide the selectivity required to separate isobaric species based on different product ions.

Results:

For this purpose, a set of experiments is executed on a pre-clinical drug study in which multiple dog liver tissues were analyzed using DESI prior to PROD, NL, and MRM modes to target, map and identify two potential drug candidates. The accumulation of the drugs correlated with histological lesions (already annotated by the pathologist) indicates severe fibrosis which resulted in stopping these compounds from further development. In addition, we further assessed the potential of MRM, NL, and PREC imaging modes by monitoring several endogenous lipid species in consecutive tissue sections, to complement the investigation of the toxic effect. The improved selectivity and sensitivity of this technology was investigated by the comparison of NL and PREC scanning modes with the MRM mode of low abundant lipid species in rat brain.

Conclusions:

Our approach opens doors for the pharmaceutical industry to target and image drugs and metabolites with high selectivity without the need for expensive high mass resolution imaging technologies. The use of a triple quadrupole MS not only offers higher selectivity and sensitivity but also allows to explore a (semi) quantitative strategy due to its high dynamic range.

Novel Aspect:

The selective capability of a triple quadrupole is now combined with mass spectrometry imaging for the first time by using targeted NL, PREC, and MRM imaging.

Keywords: data acquisition, digitizer, digital signal processing, pattern noise reduction, baseline drift

Introduction

Accurate pulse detection is vital in data acquisition systems for mass spectrometry but problems such as component aging and temperature variations typically reduce the accuracy of the detection and may generate misleading results. Drift in baseline level and pattern noise from interleaved analog-to-digital converters (ADCs) may result in missed pulses or incorrect detection of false pulses.

Methods

Data acquisition modules from Teledyne SP Devices utilize on-board real-time signal processing to remove baseline drift and reduce ADC pattern noise. The Digital Baseline Stabilizer (DBS) operate in the background and perform highly accurate baseline adjustment to a user-defined target value. ADC pattern noise reduction is achieved by continuous background calibration that corrects for gain, offset and time skew mismatch errors.

Results

Baseline adjustment and pattern noise reduction results in significantly improved detection accuracy. Continuous background correction allows the user-controlled trigger level to be valid over time without any need for manual calibration procedures. Baseline drift and pattern noise can be significant sources of noise – the latter with mismatch errors ranging up to a hundred ADC codes [1]. DBS reduces the pattern noise to a level corresponding to 22 bits resolution.

Conclusions

High-precision pulse detection requires estimation and correction of imperfections and mismatch errors in analog electronic components. Baseline drift in data acquisition for mass spectrometry can lead to misleading pulse characteristics and peak values as they are determined against an incorrect baseline level and ADC pattern noise can further significantly contribute to false readings.

Novel Aspect

DBS shows how expertise in signal processing, hardware knowledge, and application know-how is combined to create an optimized system solution.

Keywords: ambient ionization, ambient imaging, 3D printing, low temperature plasma, instrumentation

Introduction

Ambient ionization has revolutionized mass spectrometry, because samples can be analyzed under atmospheric condition without prior preparation, including imaging [1]. Technologies such as 3D printing help to easily share, implement and reproduce ambient ionization probes [2]. Inspired by this technology, we decided to generate an automated sampling platform based on RepRap systems for high throughput analyses and imaging to further enhance the utility of AIMS.

Methods

RepRap technology was used for the ambient sampling platform. The system was designed in our laboratory and built by MakerMex (Gto. Mexico). Additional accessories to adjust ionization sources and optical tools were designed using Blender and printed using a MM1 Beta RepRap printer with acrylonitrilebutadiene styrene (ABS) polymer. For system control and data analysis, the software rmsiGUI was built based on the free statistics software R using: shiny package.

Results

We developed a complete kit for an ambient sampling platform, consisting of -robot -software -adapters. The sampling platform can incorporate new tools/accessories depending on the applications. The system can be used for imaging and high throughput analyses. The theoretical resolution of our platform is 12.5 μm . However, the natural diffusion of the compounds generates a practical resolution of 200 μm . We used a PlasmaChip (NovionX, Germany) to automate sample analyses and for ambient imaging we used a 3D-plasma probe alone or in combination with laser desorption (LD). The rmsiGUI software has tabs for different functions, generates a G-code to control the robot movements, creates mzML files for mass spectrometry imaging, uploads a photo from a sample and marks a region of interest (ROI). Data can be analyzed by multiple statistical tools to identify metabolic markers.

Conclusions

We demonstrated the functionality of an open, modular ambient sampling platform for automated sampling and mass imaging. The rmsiGUI is able to perform a complete analysis from MSI data. The design of the sampling robot and the rmsiGUI software are freely available for non-commercial uses.

Novel Aspect

We present an open platform for analysis under ambient conditions based on RepRap technology which enables the user to design new features based on his specific needs.

1374 - UNAMBIGUOUS PRECURSOR MASS ASSIGNMENT ENABLES ACCURATE AND SENSITIVE PEPTIDE IDENTIFICATION OF DATA-INDEPENDENT ACQUISITION MASS SPECTROMETRY DATA

Dong-Gi Mun (1) - Sang-Won Lee (1)

Korea University, Korea University, Seoul, Korea, Republic Of (1)

Keywords: Data-independent acquisition, multiplexed MS/MS spectra, precursor mass, multi-stage database search

Introduction:

Data-independent acquisition (DIA) approach has emerged as a promising strategy for robust and large-scale quantitation with the development of advanced mass spectrometer and data analysis tool [1]. However, accurate and sensitive interpretation of highly complex multiplexed MS/MS spectra acquired through DIA experiment still remains a challenge.

Methods:

Novel DIA data analysis strategy are presented utilizing unambiguously determined precursor mass. Accurate monoisotopic masses of multiple precursor ions corresponding to multiplexed MS/MS spectra were determined through mPE-MMR (multiplexed post-experimental monoisotopic mass refinement) procedure which was previously developed and applied for interpretation of multiplexed MS/MS spectra from DDA data [1].

Results:

MS/MS data with determined precursor mass through mPE-MMR were searched against spectral library using in-house built spectral library search tool (The first stage search) under precursor mass and retention time tolerance. MS/MS data without peptide identification were searched against customized protein database using MS-GF+ search engine (The second stage search) [2]. The remained uninterpreted MS/MS data after the first and second stage search process were subjected to MODplus search engine [3] specified for unrestricted modification detection. Up to 60,000 peptides were identified from 3hr gradient DIA experiments. Comparing to conventional DIA data analysis approach which does not consider precursor mass during database search, our strategy utilizing precursor mass effectively increase accuracy and sensitivity in peptide identification.

Conclusions

Interpreting multiplexed MS/MS spectra of DIA data were interpreted with assigned precursor mass through mPE-MMR and multi-stage database search. It provided increased sensitivity and accuracy in peptide identification.

Novel Aspect

Previously developed DIA data analysis tools considered elution time and fragment ions are considered for targeted extraction or spectral library search. There are few methods providing intuitive accuracy determinant parameter of identified peptides such as mass measurement accuracy.

356 - INFRARED LASER ABLATION MICROSAMPLING COUPLED WITH MALDI IMAGING

Kermit Murray (1) - Fabrizio Donnarumma (1) - Kelin Wang (1) - Touradj Solouki (2) - Michael Pettit (2)

Louisiana State University, Department of Chemistry, Baton Rouge (1) - Baylor University, Department of Chemistry, Waco (2)

Keywords: MALDI, Imaging, Laser, Ablation

Introduction:

Matrix-assisted laser desorption/ionization (MALDI) mass spectrometry imaging (MSI) is a powerful method for determining the location of biomolecules in tissue; however, protein identification and quantification remains challenging. The goal of this project is to develop an imaging workflow that combines MALDI imaging with laser ablation microsampling for liquid chromatography tandem mass spectrometry.

Methods:

In the combined workflow, MALDI imaging is used to identify regions of interest (ROI) from intact proteins. The ROI are sampled using infrared laser ablation and the captured material is analyzed by LC-MS/MS using data independent acquisition to identify and quantify the proteins. The data are cross-correlated to identify the localized proteins in the MALDI images.

Results:

Development of the combined approach is aimed at creating an automated system for ablation and capture and using it in a coupled workflow of MALDI imaging and LC MS/MS analysis. The infrared laser ablation and capture system uses a mid-infrared optical parametric oscillator laser with a custom reflective objective that has a large working distance and good numerical aperture. We have developed custom positioning software that allows MALDI MSI heat maps to be overlaid on camera images to co-register ROI ablation with the IR laser. Tissue sections are mounted on conductive microscope slides and either consecutive sections or MALDI analyzed sections can be used. Laser ablated proteins are digested with magnetic capture beads and the peptides released for analysis with a Waters nanoAcquity UPLC system coupled to a Synapt G2-HDMS.

Conclusions

MALDI MSI coupled with region-specific laser ablation sampling for LC MS/MS is a fast and versatile approach for spatially resolved tissue proteomics. We have demonstrated that proteins can be identified from spatially localized regions and are developing new methods for correlating the intact proteins observed in MALDI with the proteins identified by tandem mass spectrometry.

Novel Aspect:

Coupled MALDI imaging with high precision infrared laser ablation capture for LC MS/MS for protein identification and quantification.

1237 - CYCLOBRANCH: AN OPEN TOOL FOR ANNOTATION OF ISOTOPIC FINE STRUCTURES OF NATURAL PRODUCTS

Jiri Novak (1) - Anton Skriba (1) - Jakub Zapal (1) - Marek Kuzma (1) - Vladimir Havlicek (1)

Institute of Microbiology, v.v.i., Czech Academy of Sciences, Prague 4, Czech Republic (1)

Keywords: dereplication, natural products, isotopic fine structure, metabolomics, software

Introduction

CycloBranch(<http://ms.biomed.cas.cz/cyclobranch/>) is an open tool for de novo sequencing of non-ribosomal peptides and for dereplication of natural products from MALDI-MS, LC-MS, MSI (mass spectrometry imaging) and MS/MS datasets [1, 2]. Recently, a fusion of MSI data (imzML) with histology images was also reported [3]. Here, we present how CycloBranch can be used for more reliable dereplication of natural products benefiting from isotopic fine structure [4].

Methods

The high-resolution mass spectra of standard bacterial siderophores [5] were collected on 12T Solarix FTICR mass spectrometer (Bruker Daltonics, Billerica, USA) equipped with ESI source in positive ion mode. The results were verified by nuclear magnetic resonance (NMR) spectroscopy by ^1H NMR, ^1H - ^{13}C HSQC, ^1H - ^{15}N HSQC, ^1H - ^{13}C HMBC, TOCSY and J-resolved experiments (AVANCE III 700 MHz, Bruker Biospin GmbH, Rheinstetten, Germany).

Results

The fine isotope patterns of pyoverdines D/E - whose structures differ by (de)amidation only - were recorded with 840,000 @ m/z 1334 resolution in a conventional mass spectrum. If the minimum relative intensity threshold was 0.5%, the tool annotated 11 out of 12 theoretical peaks of pyoverdine D (m/z 1334.6) and 8 out of 9 peaks of pyoverdine E (m/z 1333.6). The fragmentation mass spectrum was collected with 550,000 @ m/z 1334 resolution. The complete m/z scale including the sequence-specific b-ion series was generated by CycloBranch in silico. The tool correctly annotated 201 out of 221 experimental peaks exceeding 0.5% relative intensity. Sixteen other peaks with intensities below 2.4% were correctly unannotated artefacts, and 4 remaining peaks with intensities below 1.6% were unknown. We observed 19 peaks with relative intensities 0.5-7.5% (without isotopologs) specific to pyoverdine E and only one peak m/z 601.24 (3%) unique to pyoverdine D. The remaining peaks corresponded to fragment ions of both pyoverdines.

Conclusions

The fine isotope feature of our open-source software called CycloBranch was reported on a showcase example of bacterial siderophores pyoverdines D/E whose masses differed by 1 Da. The quantitative results were confirmed by NMR analyses. Acknowledgement: Ministry of Education, Youth and Sports of the Czech Republic (NPU LO1509) and Czech Science Foundation (16-20229S).

Novel Aspect

A free software utilizing the benefits of isotopic fine structure for dereplication of natural products from MALDI-MS, LC-MS, MSI, and MS/MS datasets.

Keywords: FTMS, MALDI/DESI, imaging, transient, software

Introduction:

High mass resolution FTMS MALDI and DESI imaging techniques are widely employed for analyzing biological tissues, plants, and oils. Real-life sample complexity, tiny quantities of analytes, and long experimental times require increased sensitivity, resolution, and throughput. Here, we describe innovations in FTMS transient acquisition and processing algorithms and their integration into big data analysis workflows for leveraging FTMS imaging applications.

Methods:

MALDI and DESI imaging data were acquired with commercial ICR and Orbitrap FTMS instruments. Mass spectra and transients were recorded in parallel using original instrument manufacturer and in-house developed data acquisition hardware and software. Data post-processing was performed using custom software tools and algorithms, including absorption mode FT (aFT) and least-squares fitting (LSF), using multicore and graphic card processing capabilities.

Results:

We evaluated the key benefits resulting from the use of a novel big data processing workflow. Disabling on-the-fly FTMS data processing (including FT, peak picking, and recording data on a drive) reduced the total time of measurements up to 2-fold per image. Additionally, the scan rate was further increased via an optimized use of overhead times and application of aFT (allows approx. half the transient time compared to magnitude mode processing) or LSF for targeted imaging. The LSF demonstrated superior performance to magnitude and aFT in terms of required minimum transient length. LSF processing, being implemented on graphic cards, reduced data processing times to practically-useful acceptable levels. Increases in sensitivity and identification confidence were achieved by transient or full-profile mass spectra summation over a region of interest and summation across multiple experiments, e.g. 3D MALDI/DESI. Mass accuracy was improved using an internal pixel-by-pixel non-linear mass re-calibration based on binomial averaging.

Conclusions

Increasing the rate at which FTMS transients are generated, while storing them for post-processing and re-analysis, appears attractive for higher-throughput MALDI/DESI imaging applications. The aFT and LSF methods allow the use of shorter transients, without compromised accuracy in identification of molecules (e.g., lipids). Increased sensitivity enhances the confidence and the number of lipids identified and quantified per MALDI/DESI imaging experiment.

Novel Aspect:

Advanced algorithms of time-domain signal (transient) acquisition and post-processing, and big-data analysis boost FTMS performance for MALDI/DESI imaging applications.

1340 - ELECTROSPRAY IONIZATION/ATMOSPHERIC PRESSURE INTERFACES:
COMPREHENSIVE SIMULATION OF GAS FLOW, SPACE CHARGE AND ELECTRIC FIELDS

Philipp Krahl (1) - Laurent Bernier (1) - Stephan Rauschenbach (2) - Julius Reiss (1)

Technical University Berlin, ISTA, Berlin, Germany (1) - University of Oxford, Dept. of Chemistry, Oxford, United Kingdom (2)

Keywords: ESI, simulation, gas flow, space charge, ion funnel

Introduction:

In electrospray ionization (ESI) ions are often transferred through a narrow capillary from ambient to a lower pressure stage, where complex ion optics like ion funnels are used to form the ion beam. The particle transport is governed by electric forces, space charge and by the gas flow. Their interplay determines the behavior and in particular the efficiency of the source. However, most simulations include only some of these effects, often neglecting the gas dynamics.

Methods:

We simulate the gas flow of the capillary and the first pumping stage including an ion funnel. The resulting flow fields are used to simulate the ion transport by a self-written software. It allows to treat the space charge effects and collimation by the rf- and dc-fields of the ion funnel by first principles and to quantify the different effects. It also reveals the conditions the ions experience, like temperature, pressure and electric fields, during transfer.

Results:

We find a strong influence of the gas flow on the ion transmission. High transmission rates recently observed can be reproduced by the simulation and understood, with numerical results comparing quantitatively to the experiment. The key factor to obtain high transmission in a transfer capillary is transport in a laminar flow. High transmission is further obtained for low net currents (low space charge repulsion) and good pre-collimation of an electrospray before entering the transfer capillary, as for instance achieved by recently presented funnel inlets. But also under ideal laminar conditions, space charge effects determine the maximal current transmitted through the capillary. Time resolved simulations with many individual particles allow an in-depth description especially in the ion funnel. When designing an ESI sources all the different aspects need to be taken into account.

Conclusions:

Gas flows in the high pressure part of an ESI interface are important for ion transport and deserve higher attention due to their large potential for optimizing ion sources. Space charge effects become important for high currents and can partly be mitigated by an improved extraction and collimation at the inlet by the gas flows. Better understanding of the interplay of space charge and gas flow is the key to high current and high transmission ion sources.

Novel Aspect:

A comprehensive simulation of the transfer capillary and the first stage with an ion funnel reveals detailed insight into important aspects of the ion transport.

891 - PULSED COLD PLASMA FOR POST-IONIZATION IN MALDI-MS IMAGING

Jens Soltwisch (1) - Ulrich Röhling (2) - Klaus Dreisewerd (3)

University of Münster, Institute for Hygiene, Münster (1) - University of Münster, Institute for Medical Physics and Biophysics, Münster (2) - University of Münster, Institute for Hygiene, Münster (3)

Keywords: Plasma-Postionization, MALDI-MSI, Enhanced sensitivity

Introduction:

In MALDI, only a minor fraction of desorbed molecules is concomitantly ionized and, therefore, available for mass spectrometric analysis. To mitigate this inherent shortcoming, we here present a new strategy that utilizes a gas discharge for post ionization (PI) inside an intermediate pressure ion source. The RF-driven dielectric barrier discharge (DBD) is pulsed and timed to directly interact with the MALDI plume, leading to effective PI of matrix and analyte.

Methods:

The DBD unit was integrated into the sample holder assembly of a SpectroGlyph dual funnel MALDI/ESI ion source, coupled to an Orbitrap MS. Consisting of an insulated antenna and a metal counter electrode, the DBD produces a spatially confined plasma right above the surface of the MALDI sample. Custom-made electronics were used to drive and trigger the discharge. MALDI-DBD-MS imaging experiments were performed with different matrices and in both polarities.

Results:

In the first part of the presentation, concept and considerations for the design of the plasma region and RF-electronics for pulsed DBD-PI inside the intermediate pressure ion source will be described. This is followed by results from fundamental studies on the influence of relevant input parameters like DBD pulse duration, peak-to-peak voltage, delay between laser and DBD pulses, and the effect of gas pressure and its composition on the plasma. Careful optimization of laser and plasma parameters resulted in PI of phospho- and glycolipids with low degree of fragmentation. Under these optimized conditions, the DBD-MALDI mass spectra largely resemble those as produced by laser-induced PI in a MALDI-2 setting [1,2], i.e., a boost of protonated/deprotonated lipids and further metabolites is obtained. First DBD-MALDI imaging results obtained with mouse brain sections will be presented.

Conclusions:

Pulsed DBD-PI holds great potential for increasing the sensitivity of MALDI-MSI in intermediate pressure ion sources at low costs. Synchronized to laser-generated material ejection, short bursts of DBD, suitably tailored in length and intensity, lead to a strong post ionization of matrix molecules and subsequent charge transfer reactions to neutral analytes within the evolving MALDI-plume.

Novel Aspect:

A low-cost pulsed dielectric barrier discharge assembly for effective post ionization of lipids in an elevated pressure MALDI MS ion source

J. Soltwisch et al., *Science*, 348, 211-214 (2015)

205 - VALIDATION STUDIES OF PHOSHOPEPTIDE ENRICHMENT PROCEDURES USING TiO₂-ATTACHED MEMBRANE FUNNEL-BASED SPRAY IONIZATION FOR IMAGING MASS SPECTROMETRY

Hung Y.-L. Winnie (1) - T.-W. Dominic Chan (1)

The Chinese University of Hong Kong, Chemistry Department, The Chinese University of Hong Kong, Hong Kong (1)

Keywords: Imaging mass spectrometry, protein digestion, phosphopeptides, titanium dioxide, selective enrichment

Introduction:

Imaging Mass Spectrometry (IMS) displays the distribution of different chemicals across a surface [1]. In this work, the analytical performance of an automated membrane funnel-based spray ion source was validated for phosphopeptides selective imaging mass spectrometry. Array of TiO₂-attached membrane funnels was fabricated for in situ clean-up and enrichment of phosphopeptides to alleviate matrix suppression effect in the ionization process(es) [2].

Methods:

In-solution bovine beta-casein digest mixed with two phosphopeptide standards with different loadings were analyzed using funnel spray ionization mass spectrometry. In-funnel digestion of bovine beta-casein with different loadings was also performed. To evaluate the attainable spatial resolution of the IMS based on funnel spray ionization, "flower" figures were inkjet-printed onto Parafilm® membrane and images with different inter-funnel distances were obtained.

Results:

The digestion derived phosphopeptides and the phosphopeptide standards were detected with good reproducibility. The analytical method exhibited reasonable linearity over a concentration range of 2.5 to 10 pmol for phosphoprotein loadings and 0.5 to 4.5 pmol for phosphopeptides loadings, demonstrating the feasibility TiO₂-attached membrane funnels in removing interfering non-phosphorylated peptides then selectively enriching phosphopeptides from complex protein digest samples. A mono-phosphorylated peptide was added as internal standard to the in-funnel digests before mass spectrometry analysis. This could reduce the experimental influence and improve the linearity of the analytical method. The best attainable spatial resolution for the IMS experiment was 200 microns and there was no detectable cross-contamination. Attempts to further reduce the inter-funnel distance using the current funnel fabrication method were hampered by the deformation of the membrane surface.

Conclusions:

Phosphopeptides from protein digest were selectively detected with satisfactory detection limit, reproducibility and linearity using our developed workflow. IMS experiment with reasonable spatial resolution was demonstrated on this ion source. It is believed that this in situ single-pixel sample pretreatment method is a promising technique for the image studies of phosphoproteins of biological tissues.

Novel Aspect:

An array of funnels could be used to pixelize a tissue surface for in situ single-pixel protein digestion and selective enrichment of phosphopeptides.

1011 - PHASE-CONSTRAINED SPECTRUM DECONVOLUTION– REAL TIME SUPER-RESOLUTION PROCESSING OF FTMS DATA

Konstantin Aizikov (1) - Dmitry Grinfeld (1) - Arne Kreuzmann (1) - Daniel Mourad (1) - Eugen Damoc (1) - Tabiwang N. Arrey (1) - Oliver Lange (1) - Alexander Makarov (1)

ThermoFisher Scientific, LSMS, Bremen (1)

Keywords: FTMS, Orbitrap, super-resolution, high-throughput, TMT

Introduction:

The Phase-Constrained Spectrum Deconvolution Method (Φ SDM) [1] is a novel signal analysis approach which enables qualitatively faster FTMS scan rates while preserving the levels of mass resolution and accuracy. This presentation discusses real-time Φ SDM processing of complex experimental spectra that provide the increased depth of analyte coverage.

Methods:

The MS experiments were conducted on the research grade Q Exactive™ family of Orbitrap™ mass spectrometers. The LC separation was done on EASY-Spray™ PepMap™ RSLC C18 column using UltiMate™ 3000 NCS system. Intact proteins were infused directly. An auxiliary computer equipped with four Titan X Nvidia™ GPU cards was used for the full mass range Φ SDM calculations. Spectral windows comprising the TMT labels were processed directly on the instrument's computer.

Results:

Back to back LCMS runs of 11-plex TMT labeled HeLa digests demonstrated that the Φ SDM facilitates a significant increase in the spectral acquisition rate on a research grade Q Exactive HF which results in 1.74x more MS/MS scans and allowed the 1.55x PSM increase. The numbers of quantified peptides and proteins is boosted by factors of 1.47 and 1.32, respectively. The Q Exactive HF-X data shows the 2.39x MS/MS scan rates and 1.99x PSM's. The peptide and protein quantification improvement was demonstrated as 1.82x and 1.62x, correspondingly.

Real-time Φ SDM processing of intact protein spectra isotopically resolves the entire charge state envelope of Ubiquitin (8.6 kDa) with MS scan rate in excess of 30 Hz, with the reported deconvolved nominal mass accuracy of \sim 1ppm. For the carbonic anhydrase (29 kDa), the baseline isotopic resolution of the charge state envelope is achievable at scan rates of \sim 7.5 Hz, with the reported nominal mass accuracy of \sim 2ppm.

Conclusions

Φ SDM has been used for real-time LC experiments. Its ability to provide the super-FT resolution allowed higher MS/MS rates and, consequently, boosted up the identification and quantification. Protein isotopic envelopes were completely resolved with Φ SDM even at high repetition rates, which allowed reliable charge state identification and accurate reporting of the nominal mass.

Novel Aspect:

Φ SDM, a new FTMS algorithm, was for the first time implemented for real-time data processing. Quantitation improvement and superior mass resolution are demonstrated.

25 - TAMI SOFTWARE FOR THE PROVISION OF ELEMENTAL FORMULA FROM YOUR SINGLE QUADRUPOLE GC-MS OR LC-MS DATA

Aviv Amirav (1) - Alexander Fialkov (1) - Tal Alon (1)

Tel Aviv University, School of Chemistry, Tel Aviv (1)

TAMI Software for the Provision of Elemental Formula from your Single Quadrupole GC-MS or LC-MS Data

Aviv Amirav, Alexander Fialkov and Tal Alon

School of Chemistry, Tel Aviv University, Tel Aviv 69978, Israel,
Email: amirav@tau.ac.il

Introduction

In order to significantly improve sample identification by GC-MS we developed the Tal-Aviv Molecule Identifier (TAMI) software. TAMI inverts the molecular ion isotopomeric pattern into elemental formulae and automatically confirms or rejects NIST library identification for improved confidence in the identification. When NIST identification fails, TAMI provides the sample compound elemental formula from standard centroid data files.

Method

When the quadrupole MS scans in profile mode, TAMI improves the mass accuracy (typically <50 ppm) and combined with isotope distribution analysis it usually provides the correct elemental formula as number one in its hit list.

The TAMI software was extensively explored with Agilent 5975/5977 GC-MS, Aviv Analytical 5977-SMB GC-MS with Cold EI that provides enhanced molecular ions, Thermo ISQ Chromeleon and Advion CMS LC-MS data files with the following main benefits:

Preliminary data

- A) Automatic linking with the library. TAMI automatically confirms or rejects the NIST library identification via independent isotope abundance analysis.
- B) Independent provision of elemental formula from standard centroid data files. In case of rejection of the library identification such as when the compound is not in the library, TAMI independently provides a list of elemental formulae with declining order of matching to the experimental data.
- C) Simple to use. The linking of TAMI with the NIST library is automated while the provision of elemental formula requires only one mouse click.
- D) Improved mass accuracy. When the quadrupole MS scans in profile mode TAMI improves the quadrupole mass accuracy via the use of special weighted average algorithm and mass calibration with PFTBA to be typically better than 50 ppm.
- E) Special compatibility with Thermo Chromeleon Data Files. The Thermo ISQ in combination with Chromeleon software provides <50 ppm mass accuracy using the TAMI PFTBA based mass tune function with standard centroid data files.

Novel Aspect

Software for the provision of elemental formula from unit resolution quadrupole GC-MS or LC-MS based on isotope abundance analysis and improved mass accuracy

Keywords Elemental formula from quadrupole MS

611 - THE DATABASE FOR CROSS-PLATFORM MINING BIOMARKERS IN THE BRAIN TUMOR TISSUE

Moscow Institute of Physics and Technology, Laboratory of Ionic and Molecular Physics, Dolgoprudny (1) - Burdenko Scientific Research Neurosurgery Institute, Burdenko Scientific Research Neurosurgery Institute, Moscow (2) - Skolkovo institute of science and technology, Skolkovo institute of science and technology, Skolkovo (3)

Keywords: mass-spectrometry, database, biomarkers, brain tumors, high and low resolution

Introduction:

One of the most challenging problems when using highly specialized mass spectrometry instruments and ionization techniques is both the unification of the raw data obtained and the interpretation of the final result of their processing. So, we present here an approach using database for comparing the high and low resolution spectra obtained by various ionization methods on different mass spectrometers and intended for identification of different tumor types.

Methods:

Tumor tissues were dissected during neurosurgery. The spectra were measured by: a) needle electrospray ionization [1] on ICR-based HR mass spectrometer LTQ FT Ultra; b) direct spray of lipids extracted from tissue by Folch method on Thermo LTQ-Orbitrap XL and Bruker Esquire 3000 plus. The high and the resolution was 56,000 and 1,000 at 800 Th, respectively. Information about ionization method, instrument type, tumor type, etc. was stored in NoSQL database.

Results:

A database of over 300 samples of different tumor tissues and surrounding tissues from over 250 patients was collected in the study. All of the samples were provided by the Burdenko Neurosurgical Institute. Collected spectra were filtered and stored in column-oriented database MonetDB. User interface allows for visualisation, comparison, transformation (PCA, ICA etc.) of the spectra. The integration with R/Bioconductor makes whole spectra of statistical analysis and machine learning techniques readily available from API as well as from user interface. To demonstrate the infrastructure performance 9 classifiers were trained on 20 astrocytoma and 9 unmodified brain samples with different settings. Comparative analysis of the results obtained from spray-from-tissue ionization experiments and extracts analysis shows that both methods demonstrate similar series of peaks. All major peaks are found in both types of spectra. Peaks in low resolution usually are larger when normalized to TIC.

Conclusions

Vast majority of selected features distinguishing the tumor tissue from the adjacent tissue was found in both high- and low-resolution spectra. We have created mapping schema, which allows using classifier trained to separate tumor samples from non-tumor brain samples on high-resolution spectra with data from low-resolution spectra with a minor decrease in accuracy.

Acknowledgements: Supported by the RSF (16-15-10431).

Novel Aspect:

Our cross-platform approach is a huge step to the unification of the data obtained at various types of mass spectrometry platforms, in particular, for LC-MS.

MICHAEL CAUCHI (1)

UNIVERSITY OF LIMERICK, MATHEMATICS & STATISTICS, LIMERICK (1)

Combining GC-MS with Machine Learning for Non-Invasive Cancer and Disease Diagnostics
Dr Michael Cauchi, University of Limerick, Ireland.

Keywords: Metabolomics; GC-MS; Machine learning; Biomarker discovery; Medical diagnostics

Introduction:

The use of machine learning in biomedical applications has grown. Gold standard techniques are invasive, costly and time-consuming. A non-invasive approach measures the volatile analytes present in patients' urine or faeces via gas chromatography mass spectrometry (GC-MS) in conjunction with optimised machine learning models that can distinguish between ill and healthy patients. Bladder cancer [1] and Crohn's disease [2] are presented.

Methods:

Patients diagnosed with bladder cancer or Crohn's disease were recruited and donated urine or faecal samples respectively. Samples were processed and passed through a GC-MS instrument. Each sample generated a data matrix from which the total ion count (TIC) chromatogram was attained. Normalisation was followed by peak alignment via correlation optimized warping (COW). The data were subjected to machine learning algorithms for diagnosis and biomarker discovery.

Results:

The three machine learning algorithms employed were partial least squares discriminant analysis (PLS-DA), support vector machines (SVMs) and random forests (RFs). The models were optimized via a bootstrapping process in order to ensure confidence in the results. The bladder cancer data (from urine) consisted of three control groups (no disease, infection and urological disease) and three cancer grade groups. Of great interest was to see if urological diseases could be distinguished from the cancer grades: 77%, 79% and 74% overall accuracies were attained for PLS-DA, SVMs and RFs respectively. The other control group comparisons attained higher accuracies (i.e. >85%). The Crohn's disease data (from faeces) also produced a very good overall accuracy of 85%. Interrogation of the optimal PLS-DA models for the bladder cancer and Crohn's disease suggested significant retention time peaks which led to the identification of possible markers.

Conclusions:

The application of GC-MS in conjunction with machine learning techniques offers a highly feasible, non-invasive procedure for cancer and disease diagnosis. In the case of bladder cancer there was an improvement on the gold standard technique of urine cytology. In the case of Crohn's disease, results compared favourably with the gold standard technique of colonoscopy.

Novel Aspect:

Combining GC-MS with machine learning offers a non-invasive approach to cancer and disease diagnostics. Applications to other diseases/instruments are highly feasible.

1296 - TISANE DENOISING ALGORITHM FOR LARGE DENSE SPECTRA

Lionel Chiron (1) - Marc-André Delsuc (2)

Casc4de, Data analysis, Strasbourg, France (1) - IGBMC, Université de Strasbourg, Strasbourg, France (2)

Keywords:

Denoising, large datasets, Proteomics

Introduction:

In Fourier Spectroscopies noise can critically hamper data analysis. In particular, for FTICR datasets characterized by a large number of points and in some cases, by a large density of lines, removing the noise is a non trivial task. Some denoising methods were devised (Chiron et al. (2014)) (Fabrice Bray and Rolando (2017)) able to cope with the size problem but for a large number of lines.

Methods

We present here a fast, parallelizable algorithm TiSane which is able to tackle the denoising problem for both a large datasets and a large density of lines. This is done by performing the denoising by part, dividing the spectrum in small chunks on which the Sane algorithm is applied. The resulting denoised chunks are then reassembled to produce the whole denoised spectrum.

Results

Recently, the invention of the ultra high resolution - harmonized FT-ICR cells (Nikolaev et al. (2011)) led to FTICR datasets containing millions of points. Here we show the processing of a proteomic dataset obtained with such a cell, with $R \geq 500k$ at $m/z=400$, 4194304 points, with an estimated total number of peaks of about 15000. For Sane, with a computer having a RAM memory of 30Gb, the rank for this dataset cannot exceed 500. It is about 30 times under the value needed for the theoretical correct denoising with this method. Here TiSane got around the memory limitation by running with the following parameters: 4000 intervals, an adaptive rank and 15 processing cores. The processing took 40 seconds. Finally we observe that TiSane's robust clean up gives access to the small isotopic patterns.

Conclusions

The processing with TiSane is quite fast considering the size of the dataset. It benefits from a double acceleration in comparison with the Sane algorithm by using both a divide and conquer approach and parallelization. Apart large and dense line data the algorithm can be applied to small datasets with the advantage of its speed.

Novel Aspect

TiSane can be also useful for Proteomics where denoising is crucial for peptides identification with automatic search engine like MASCOT.

1210 - LEVERAGING NEW ALGORITHMS FOR BETTER MS SPECTRA

Marc-André Delsuc (1)

IGBMC, 1 rue Laurent Fries, BP 10142, 67404 Illkirch, France (1)

Keywords: Big-Data, Data Analysis, Isotopic Deconvolution, Pattern Matching, Compressed Sensing

Introduction

Complex analysis of large volumes of data is not unusual in MS analysis. However, signal processing approaches of the raw data in order to extract by the best of the acquisition data, has been only partly explored. In the recent years, in particular thanks to advances in mathematics, new approaches related to Compressed Sensing or to Machine Learning, allow to the development of improved sensibility and results, or even to explore new acquisition procedures.

Methods

As an example of such optimisation, the natural sparsity of MS data can be exploited through the minimization of the ℓ_1 or ℓ_2 norms. Proximal algorithms can be then developed which rapidly converge without the need to compute a (costly) gradient. Discrete pattern dictionaries and pattern matching algorithms will be presented for the analysis of isotopic patterns, and fast rank reduction operation as a method to reduce the noise, or even complement missing values.

Results

The basis of the approach will be presented on resolution enhancement of Orbitrap experiments, obtained by a fast optimization of a sparsity score function, using proximal operators. These approaches being fast enough to allow a near-real time analysis.

The same approach is then applied to FT-ICR data-sets, in particular to the 2D FT-ICR method[1]. Here, sparsity is combined to random projections to remove unwanted noise[2], enhance resolution, and missing point reconstruction[3].

Finally, we present recent work where isotopic patterns in complex are recognized in overlapped spectra, without the need of separated peaks. The use of the average model[4] allows to build a fast approximation of the patterns, and a search in the Fourier space allows to considerably speed-up the analysis and reduce the memory burden[5]. Promising results are already obtained with this method on peptide mixtures with several charge states intermixed, or with large proteins for which precise determination of the monoisotopic value is obtained.

Conclusions

The methods presented here rely on the analysis of the raw data, as obtained before any further processing. They have to be inserted before the usual data analysis pipeline. This displaces the chemist habits but is certainly worth the burden. This research is from a joint action with the CASC4DE spin-off company. This company works on data analysis in the biosciences, and is chosen to develop the data analysis pipeline of the EU_FT-ICR_MS European infrastructure.

Novel Aspect

New mathematics in data processing can bring you unexpected results.

26 - ONE SMALL STEP FOR INFLUENZA –NEW MASS-BASED BIOINFORMATICS AND PHYLOGENETICS APPROACH REVEALS INSIGHTS INTO THE EVOLUTION OF THE VIRUS

Kevin Downard (1) - Elma Akand (1)

University of New South Wales, Medicine, Sydney (1)

One Small Step for Influenza –New Mass-Based Bioinformatics and Phylogenetics Approach Reveals Insights into the Evolution of the Virus

Keywords: evolution, phylogenetics, influenza, epistasis, mass spectrometry

Introduction: (Limit of 400 characters)

The word “influenza” is Italian for influence since in ancient Rome it was widely believed that epidemics were caused by an unfavorable conjunction of the stars as viewed through Galileo’s telescope. It is now known that epidemics are associated with the generation of escape mutants. We have advanced a novel mass (or number) based phylogenetic approach to study protein mutations and epistasis associated with the evolution of influenza to help improve responses.

Methods: (Limit of 400 characters)

Full length (HA0) non-redundant H3 hemagglutinin sequences from all human H3N2 type A strains across the period from 1968-2008 were downloaded from the GISAID EpiFlu database and digested in silico with trypsin using the FluGest algorithm. Mass trees were constructed from the mass maps using a modified MassTree algorithm [1] that displays mutations along branches of the tree, when visualised with the Figtree algorithm, and calculates their frequency and score.

Results: (Limit 900 characters)

The mass trees were analysed to study mutation trends and identify consecutive or near-consecutive mutations typically associated with positive epistasis. Non-conservative mutations were the focus of the study since these cause the greatest structural and functional change associated with the evolution of the virus. Consecutive or near consecutive mutation pairs were identified along interconnected branches within an average evolutionary distance cut-off. Leading or parent mutations were found to predominate within reported antigenic sites of the protein while subsequent mutations resided exclusively in different antigenic regions, or elsewhere in the protein, providing the virus with a possible immune escape mechanism. The results also enable a “small steps” evolutionary model to be proposed where the most frequent non-conservative mutations exhibited less structural, and thus functional, change [2]. This favours virus survival over mutations that involve more substantive change which could cause or risk its extinction.

Conclusions (Limit of 400 characters)

An innovative mass-based phylogenetic approach provides a reliable and robust method to study the evolution of organisms at the molecular protein level. It adopts a global view to study the interconnectedness of mutations associated with epistasis irrespective of their position in a protein. The ability to display mutations on mass trees and better predict future evolutionary trends should assist in the production of efficacious vaccines ahead of influenza outbreaks.

Novel Aspect: (Limit of 150 characters)

Mass map data, vital for protein identification in proteomics, is herein used in a phylogenetics strategy to better understand and predict evolutionary trends of any organism.

* Equal contribution

Life scientists working with big data such as genomics, proteomics and metabolomics are beginning to experience numerous difficulties of handling, processing and moving information that has not been experienced before. These intensive computational tasks cannot be tackled by regular laptops and workstations. The high demand for more resources and increased flexibility has even turned the well-known shared high-performance computing unresponsive.

Cloud computing together with microservices architecture offer a compelling alternative to these old models, with the possibility to instantiate and configure on-demand resources such as virtual computers, networks, and storage, together with operating systems and isolated software tools.

We have developed an architecture which uses components for data analysis encapsulated as microservices connected into operating computational workflows. This solution provides users with complete, ready-to-run, reproducible and scalable data analysis environment that can be easily deployed on desktop computers as well as public and private clouds, without requiring special IT skills from the user.

We showcase the capability of this architecture using four demonstrators: in the first demonstrator we reproduce a large metabolomics data analysis and show how it can be effortlessly scaled up on cloud computing resources with little efficiency loss. In this case, 1092 computationally intensive tasks were performed in less than four hours which otherwise could have taken days to finish on a workstation. In the second demonstrator we provide new mass-spectrometry data from multiple sclerosis patients, and present for the first time, to the best of our knowledge, a complete start-to-end analysis of untargeted mass-spectrometry and identified novel biomarkers. The last two demonstrators describe NMR workflow and fluxomics workflows, emphasizing that microservice architecture is domain-agnostic.

The four demonstrators show the versatility, applicability and scalability of our method in metabolomics; however, the methodology can be applied to all scientific disciplines, paving the way towards for large-scale integrative science.

1267 - VALIDATION DATA PROCESSING BY ADVERSE 2.0 FREE SOFTWARE PACKAGE:
ASSESSMENT OF THE ANALYTICAL REQUIREMENTS OF A GC-MS METHOD FOR THE DETERMINATION OF 16 PAHS IN
SMOKED FISH

Arianna Piersanti (1) - Tamara Tavoloni (1) - Luca Scrucca (2) - Roberta Galarini (3)

Keywords: method validation, data processing, PAHs, smoked fish

Introduction

Polycyclic aromatic hydrocarbons (PAHs) are a wide group of carcinogenic environmental contaminants. Official methods are not set for food monitoring plans, therefore in-house developed procedures need to be validated to assess their compliance with the strict performance characteristics required by Regulation 836/2011 (1).

Methods

A new developed GC-MS procedure for the determination of 16-EU-PAHs in smoked fish was validated (2). The study was performed at three spiking levels (0.9, 3 and 7.0 µg/kg) in four different days for a total of 41 experiments. The data were processed with the in-house-developed package ADVERSE 2.0 (Analytical methods Validation Results Speedy Elaboration) for the R statistical environment (3).

Results

In the European Union maximum levels are fixed in food for both, the sum of four marker PAHs, (benzo(a)pyrene, benzo(a)anthracene, benzo(b)fluoranthene and chrysene) and for benzo(a)pyrene alone (4). Linearity, precision, recovery, LOD and LOQ of a new method for the determination of PAHs in smoked fish were estimated using ADVERSE, a free software package developed by analytical chemists and statisticians. Measurement uncertainty was also calculated applying a top-down approach. The results were comparable with those obtained with the traditional spreadsheets, confirming that the method was fit for purpose (1,2). However, using ADVERSE, the Validation Report is produced in few seconds, overcoming tedious calculations and possible mistakes, especially when a large number of analytes is included in the method scope.

Conclusions

Thanks to the use of automated statistical tools to handle validation data, analytical chemists engaged in the official control can go back to their original job focusing the efforts to improve analytical protocols instead of studying possible approaches to uncertainty estimation or statistics methodologies to demonstrate the performances of their Methods:

Novel Aspect

ADVERSE package allows a true feedback cycle going back and forward from method optimization to validation.

610 - VALIDATION OF ANALYTICAL METHODS FOR THE DETERMINATION OF RESIDUES IN FOOD: THE STUMBLING BLOCK OF DATA PROCESSING

Roberta Galarini (1)

Istituto Zooprofilattico Sperimentale dell'Umbria e delle Marche, Center for Method Development and Validation, Perugia (1)

Keywords: method validation, data processing, residues, food control

Introduction

Starting from the late 90s, the ISO accreditation standard along with the EU rules required a great effort to validate methods and to process the relevant data in order to demonstrate the fitness for purpose of internal developed procedures. Today, this aspect is even more critical because, thanks to MS detectors, multiclass methods including dozens of analytes are currently applied.

Methods

The free software package called ADVerSE (Analytical methods Validation Results Speedy Elaboration) has been developed in R environment [1]. ADVerSE produces the Validation Report processing the validation data put into a predefined Excel file. In the same file the legal requirements fixed for each coupling analyte/matrix (maximum permitted levels) are inserted, too.

Results

The first part of Validation Report (.doc) generated by the ADVerSE package includes the descriptive statistics of results, i.e. mean recovery and precision at each validation level for each analyte. Linearity (linear regression) is assessed applying Mendel and lack-of-fit tests. In the second part, the precision is studied as a function of concentration; limits of detection and quantification are estimated using the results obtained at the lowest concentration of the validation study. With regards to the assessment of compliance with legal limits, the measurement uncertainty is estimated applying the top-down approach [2]. Finally, according to the specific requirements stated by Commission Decision 2002/657/EC (veterinary drug residues in food), the limit of decision ($CC\alpha$) and detection capability ($CC\beta$) are calculated both for banned and permitted substances [3].

Conclusions

The created Report allowed the overcoming of the long data processing saving time and minimizing calculation mistakes. The few seconds required for its generation favor an immediate evaluation of method performance characteristics helping the analyst to eventually improve her/his analytical procedure or the experimental design adopted for the validation study.

Novel Aspect

This is the first package able to produce a Validation Report usable in the various legislative contexts of the official control of residues in food.

University of Warwick, MAS CDT, Coventry (1) - University of Warwick, Department of Chemistry, Coventry (2) - Universitat Pompeu Fabra, Department of Economics and Business, Barcelona (3) - University of Warwick, Department of Statistics, Coventry (4)

Keywords: FTICR, GC, complex mixtures, data analysis, algorithm

Do not add here the title

Introduction:

The coupling of gas chromatography (GC) to a Fourier transform ion cyclotron mass spectrometer (FTICRMS) affords additional information about complex mixtures. Co-eluted components can be resolved due to the ultrahigh resolving power, also allowing extracted ion chromatograms (EICs) to be used for the observation of isomers. There is a current need for data analysis tools for processing these datasets, aiding data analysis, and extraction of key information.

Methods:

A petroleum-related sample was analyzed using GC coupled with FTICR MS. An algorithm was used for pre-processing of the data. Peaks were filtered with respect to m/z and retention time (RT) and an averaged list was generated prior to compositional assignments using the petroleomics software, Composer. The algorithm was subsequently used to incorporate the assignments into the processed data, generating a series of interactive plots.

Results:

The typical workflow for this type of data is based upon manually merging data over a range of retention times, extraction of a peak list, performing the compositional assignments, visualizing the results, and repeating for each retention time range. An environmental sample from the oil sands region of Alberta, Canada, was used as a testbed for a new algorithm, which was developed using the open source R language, coupled with the array of tools offered by the Tidyverse and Shiny packages. The algorithm was used to process the dataset, monitor peaks with respect to m/z and retention time, filter peaks of inconsistent m/z , and generate an averaged peak list of all the EICs detected. The data was then visualized according to heteroatom class, carbon number, double bond equivalents (DBE), and retention time. The algorithm also affords the abilities to screen for isomeric contributions and to follow homologous series and compound classes, instead of individual components, as a function of time.

Conclusions

Using a new algorithm, a time-consuming workflow has been replaced with one taking only a few minutes. It has become possible to follow both individual components and compound classes as a function of retention time, without the necessity for averaging multiple time windows and the accompanying loss of information. The algorithm is not only suitable for application to GC data, but also data produced using other separation techniques.

Novel Aspect:

New algorithm developed in R to process and visualize complex mixture data, acquired using hyphenated ultrahigh resolution mass spectrometry.

Keywords: Application Programming Interface, Library Generation

Introduction:

The desire to extract mass spectrometry data from commercial systems is becoming increasingly popular. Customers of such systems wish to use data in bespoke applications and incorporate data into existing repositories. An Application Programming Interface (API) is proposed that allows access to raw and processed mass spectrometry data contained within the instrument platform. An external application using the API to create a library of compounds is discussed.

Methods:

A representational state transfer (REST) API uses HTTP requests to move, change, create and delete data. Data acquired on an ion-mobility enabled instrument for a selection of 500 natural products were processed in the UNIFI mass spectrometry data system. An application, written using the UNIFI API, was employed to automatically interrogate the processed data, then to aggregate the reduced outcomes, to produce a library of compounds.

Results:

Manual analysis and collation of mass spectrometry data to create a library of compound information is a laborious task that is prone to error. An application, external to the UNIFI mass spectrometry data system, has been written that accesses data through the UNIFI API and automatically extracts processed data to produce compound library content. The library content produced by the application is rich in content and can optionally consist of retention times, multiple adducts, together with their individual collisional cross section measurements, and fragment ion m/z values which have been generated using an *in silico* structure fragmentation tool and matched to measured high energy ions. All quantities derived can be averaged over multiple replicate injections. The application transforms a manual process, which often takes weeks or even months, and is open to transcription errors, into an automated process that can be performed error-free in a matter of hours.

Conclusions

The UNIFI Application Programming Interface allows direct access to raw and processed data within UNIFI. A compound library generation application has been presented which accesses data through the UNIFI API and then uses the data to derive accurate library content. A library of commercially natural product compounds has been created and contains information on multiple adducts, collisional cross sections and fragment ions.

Novel Aspect:

Direct access to mass spectrometry data for use with third party applications. Automatic production of mass spectral library content through the analysis of processed data.

Andrea Luterova (1) - Tomas Furst (1) - Miroslav Strnad (1) - Jiri Gruz (1)

Palacky University, LGR, Olomouc (1)

Keywords: LC-MS, metabolomic analysis

Introduction:

Metabolomic analysis allows to systematically identify and quantify metabolites from a biological sample. Non-targeted analysis which refers to the analysis of all metabolites is typically performed by liquid chromatography-mass spectrometry (LC-MS). The resulting 3D-chromatogram contains thousands of features that need to be properly analysed and processed. This can only be achieved by automated computational approaches.

Methods:

MATLAB, a multi-paradigm numerical computing environment (MathWorks, Inc.).

Results:

A software for automated data evaluation was developed in our laboratory by using Matlab programming language. Besides basic chromatogram alignment, various postprocesses were designed and developed. One of them is grouping of so called "friendly ions" that consist of isotopic, adduct and fragment ions (originating from a single metabolite). Another postprocessing approach is the mass correction which is based on known background ions or identified metabolites. This allows lockmass-like correction with no measured lockmass data. The third postprocessing method is an algorithm for automated molecular peak identification. This approach is based on identification of typical fragments and adducts under defined experimental conditions. As it relies on correct determination of friendly ions, its effectivity is also affected by retention time stability and separation effectivity.

Conclusions:

The developed algorithms can help to process high density metabolomic data with improved accuracy and effectivity.

Novel Aspect:

The described algorithms take advantage of the access to raw MS data which greatly improves their effectivity when compared to current Methods:

880 - A STRATEGY TO ANALYZE THE SPECTRAL DATASETS OF UNKNOWN COMPOUNDS USING MASS SPECTRAL SIMILARITY NETWORK

Eisuke Hayakawa (1)

Okinawa Institute of Science and Technology, Okinawa Institute of Science and Technology, Okinawa (1)

Keywords: Informatics, Metabolomics, Natural Product, Fragmentation, Structure Analysis

Introduction:

In mass spectrometry-based small compound analysis, fragment spectra have been widely used to deduce the structures of analyte compounds. In recent years, approaches such as reference spectrum library searching and structure database-assisted spectrum matching have been used in many applications. However, systematic and high-throughput structure annotation for large scale spectral datasets is still quite difficult to accomplish.

Methods:

Mass spectral similarity network, also called as MS/MS spectral similarity network or molecular networking, is a method to assess and visualize the similarities of fragment spectra of structurally related compounds. Since similarities of fragment spectra can be correlated to the structural similarities of the corresponding compounds, this network is a useful tool to detect structural similarity of analyte compounds.

Results:

We have developed a data analysis framework employing mass spectral similarity network to organize, classify, (sub)structurally annotate and visualize the complex fragment spectral dataset of unknown compounds. Reference fragment spectra is acquired from public spectral library such as MassBank and used to create "reference" spectral similarity network. Further, in-silico fragment spectra are generated by applying fragmentation models to the subsets of chemical structure database to create "in-silico" mass spectral similarity networks. These spectral similarity networks are further divided into user-defined classes such as chemical classes, substructures, source types. The multi-layer representation of spectral similarity networks effectively visualizes and categorizes the spectra of unknown compounds in samples. Further, network informatics and cheminformatics methods are applied to the network structure to extract and assign the structural information, providing the structural information of the unknown compounds.

Conclusions:

This versatile method can be applied to mass spectral datasets containing a wide range of small molecules. We demonstrate the application of this method using case studies.

Novel Aspect:

A novel mass spectral similarity-based method to detect, classify and annotate the structures of unknown compounds in large-scale datasets of fragment spectra.

A low pulse current measurement circuit for current monitor system at mass spectrometer

ZiXing He, Lihua Zhai, ChaoHui He, QingMin Zhang, Zhiming Li , Xianglong Yuan

Keywords: reverse charging; constant current source; blast pulse; Mass spectrometer

Introduction

A pulse beams at 105 particles per second have been generated by laser Resonant ionization at 10KHz. Beam current is normally measured with the aid of Faraday cup. However, the signal is difficult to be monitored by Faraday cup amplifier, which was developed to monitor the beam current at pA range. Simultaneously, a discriminator is inappropriate, due to the time of death[1] and response rates. Therefore, What has been designed is a low pulse current measurement circuit, which is used for current monitor system at mass spectrometer.

Methods

A low pulse current measurement circuit, applying synchronous charging module and reversed charging constant current source module, was designed for current monitor system at mass spectrometer. This circuit turns the strength of measuring signal into the amplitude of voltage[2]. As a modified charge integration circuit for periodic blast pulse, a reverse charging circuit is designed[3], aiming to discharge integral capacitor for the avoidance of saturation. At the same time, it requires to improve the efficiency of measurement. So, a controllable constant current source model will be designed.

Results

In circuit simulation once the integral capacitor's voltage exceeds given threshold of 12V, the comparator will generate a pulse signal for discharging. Then the integral capacitor's voltage will drop rapidly. At the end of discharging process, the integral capacitor's voltage just drops to -10V. At the same time, the discharged signal is generated by the comparator as a counting signal sent to the counter. In experiments, A modified charge integration circuit for periodic blast pulse is verified by measuring the synchronous pulse signals that are generated by laser ionization. Verification results show that the experiment error is 2%.

Conclusions

By calculations, simulations and experiments, The results show that a charge measurement circuit for periodic blast pulse is very effective. It is also shown that the count rate of periodic blast pulse signals between 103 and 107 periodic blast pulse can be measured by this circuit. At the same time, the circuit is effective in the continuous measurement of the periodic blast pulse signal. Measurement precision of this circuit is mainly affected by the slew rate of operational amplifier and the bypass capacitors of the input signal[4]. So, it is feasible to further improve the accuracy of measurement by perfecting the circuit.

Novel Aspect:

A modified charge integration circuit for periodic blast pulse, a reverse charging circuit is designed and dynamic range of the ion monitor is effectively expanded.

270 - DART IMAGING FOR MOLECULAR ACCUMULATIONS ON THE MUD SURFACE

Yayoi Hongo (1) - Motoshi Sakakura (2) - Teruhisa Shiota (3) - Kazumi Yoshiya (1)

Tokyo Institute of Technology, Earth-Life Science Institute, Tokyo (1) - AMR, Inc., Mass Spec Application development, Tokyo (2) - AMR, Inc., Marketing, Tokyo (3)

Keywords: molecular mapping for non-structured surface, DART mass imaging, geochemical samples, on-surface derivatization

Introduction:

Local accumulation of amino acids and oligopeptides on a surface of mud sediments was visualized using DART imaging. A movable stage and He cone were specialized to the analyses of unstructured samples. The image of surface distribution of the building blocks of biomolecules would help to see the correlation between local geochemical conditions and abiotic amino acid evolutions, suggesting the possible requirements of emergence of life on the primitive earth.

Methods:

DART-OS (IonSense) was mounted on Q-TOF (Xevo QTOF, Waters) and Q-IMS-Q-TOF (Synapt G2, Waters). Activated helium supplied through a narrow hole (0.5 mm) ionized target molecules on a narrow surface, c.a. 2 mm², of the non-structured mud samples collected at Ege-Jigoku in Beppu, Ohita, Japan. The sample stage was moving with a constant speed in 0.2 mm/sec. DART Source temperature was set at 430 °C and derivatization was also examined using DBD-Py-NCS or TFATBDMS.

Results:

Authentic oligoglycines, tetraglycine, glycilalanine, and alanilglycine dipeptides doped on the mud surface were detected with a spatial information. Heated mud dried and altered the wet mud surface locally, so that the position once ionized did not interfere the later ionizations at the next spot. The maximum sample size was limited to 3 cm x 3 cm due to the source configuration. The optimum distance between the sample surface and He cone was kept within 4 mm. The position of the target molecule was reconstructed by the calculation using the constant moving speed of the stage and detection times of ions corresponding to the targets. On-surface chemical derivatizations with DBD-Py-NCS or TFATBDMS worked not only for enhancing the signals but also selecting the specific structures to the amino acids or oligopeptides. Gas-phase ion chromatography in the ion mobility mass spectrometry and MSⁿ also enhanced molecular selectivity to characterize isomeric peptides having different amino acid sequence.

Conclusions:

Unlike SIMS, MALDI, and DESI, DART ionization does not depend on the surface characters, such as electron conductivity or smoothness. DART ionization with the movable sample stage enabled us to visualize the accumulation of amino acids and oligopeptides on the unsmooth and heterogeneous surface of the unstructured mud sediment. On-surface chemical derivatization was assisted by the ionization heat and profitable to detect the signals specific to the targets.

Novel Aspect:

Amino acids and oligopeptide mapping of the heterogeneous surfaces of mud sediments was realized using DART imaging mass spectrometry.

955 - LC-MS1 METHOD FOR PROTEIN IDENTIFICATION AND QUANTITATION WITHOUT USING TANDEM MASS SPECTRA

Mark Ivanov (1) - Irina Tarasova (1) - Elisaveta Solovyeva (1) - Mikhail Gorshkov (1)

V.L. Talrose Institute for Energy Problems of Chemical Physics Russian Academy of Sciences, V.L. Talrose Institute for Energy Problems of Chemical Physics Russian Academy of Sciences, Moscow (1)

Keywords: proteomics, protein identification, LFQ quantitation

Introduction:

A major bottleneck of modern shotgun proteomics is limitation of fragment mass spectra acquisition speed. We present a novel workflow for protein identification based on LC-MS1 analysis with no using of tandem mass-spectra [1]. The proposed method has no drawbacks of accurate mass tags (AMT) or classic peptide-mass fingerprinting approaches.

Methods:

Proposed approach combines prediction of peptide retention times and accurate peptide mass measurements obtained using high resolution mass spectrometers. Dinosaur software [2] is used for peak picking, ELUDE algorithm [3] is used for retention time prediction and Diffacto algorithm [4] is used for quantitation analysis.

Results:

Here we present identification and quantitation efficiency of developed workflow. The MS1-based approach outperforms traditional MS/MS search in both number of identified proteins groups and sequence coverage for the HeLa cell line analyzed on Orbitrap Velos with 25 min LC gradient. We have shown that LC-MS1 based approach does not depend on the length of chromatographic gradient and can potentially replace traditional MS/MS approach in high throughput proteomics applications. Also, we have shown that MS1-based workflow successfully found changes in concentration of all 6 proteins from iPRG2015 data set without any false positives. For the blood plasma samples, the MS1-based approach reported concentration changes in 4 proteins which are known FDA-approved disease markers.

Conclusions:

The ability of using the developed method for short gradients with better efficiency compared with MS/MS can potentially be an interesting feature for the applications requiring high throughput analyses of clinical samples using relatively simple and inexpensive LS-MS setups.

Novel Aspect:

A novel scheme for successful protein identification in complex mixtures using short LC gradients and no peptide fragmentation.

871 - HIGH RESOLUTION TANDEM MASS SPECTROMETRIC ANALYSIS OF NATURAL PRODUCTS

Eun Sun Ji (1) - Kwang Hoe Kim (1) - Gun Wook Park (1) - Jong Shin Yoo (1) - Jin Young Kim (1)

Korea Basic Science Institute, Biomedical Omics Group, Cheongju-si (1)

Keywords: Natural product, High resolution tandem mass spectrometry

Introduction:

Natural products are small molecules produced by organisms, including primary and secondary metabolites, which have complex chemical structures. Recently, advances in mass spectrometry (MS) with high sensitivity and specificity have enabled it to become a major tool in the analysis of natural products. However, the analysis of natural products is still challenge because of an insufficient reference data of tandem mass spectrometry. Therefore, to provide a sufficient reference is necessary for the characterization of various natural products.

Methods:

We selected 1,400 natural products with the diversity of the structure. Then, we analyzed them using three different high resolution mass spectrometer including Orbitrap MS, Triple Time-of-flight (Triple TOF) MS and Quadrupole Time-of-flight (Q-TOF) MS. Tandem mass spectra were acquired at five different collision energies and they were used for the construction of spectral library.

Results:

Currently, the library contains more than 20,000 tandem mass spectra for 1,400 compounds. Comparative analysis of tandem spectral data showed different fragmentation patterns according to the structure of natural products, instrument types and collision energies.

Conclusions :

High resolution tandem mass spectral library of natural products was constructed and used to identify unknown compounds or secondary metabolites in complex sample.

Novel Aspect:

A high resolution tandem mass spectral library for 1,400 compounds using authentic standards and purified compounds has been constructed.

404 - CHARACTERISING THE CATABOLISM OF PEPTIDES USING ION MOBILITY ENABLED HIGH RESOLUTION MASS SPECTROMETRY WITH MASS-METASITE INTEGRATION FOR DATA PROCESSING

Jayne Kirk (1) - Ismeal Zamora (2) - Antoni Riera (3) - Tatiana Radchenko (2) - Anna Escola (3) - Russell Mortishire-Smith (1) - Yun Alelyunas (4) - Mark Wrona (4)

Waters Corporation, Scientific Operations, Wilmslow (1) - Lead Molecular Design, S.L., Pharmacoinformatics group, Sant Cugat Del Valles (2) - Institute for Research in Biomedicine (IRB Barcelona), The Barcelona Institute of Science and Technology, Barcelona (3) - Waters Corporation, Scientific Operations, Milford (4)

Keywords: Mass-MetaSite, WebMetabase, IMS QToF, Biotherapeutics, ADME

Introduction

A growing need exists to characterize and optimize the absorption, distribution, metabolism and excretion (ADME) properties of biotherapeutics. The challenge is that few software packages available to characterise the clearance and metabolic fate of biotherapeutics. Here, we mine ion mobility high resolution mass spectrometric data for the analysis of biotherapeutic drug metabolism using the Mass-MetaSite and WebMetabase software platform for processing.

Methods

The studied peptides are 14-amino acid analogues of the hormone somatostatin. They were incubated in human serum at eleven time points between 0 – 48 hr. Data were collected on an ACQUITY UPLC coupled to an IMS QToF using HDMSE. Data were processed in a prototype version of Mass-MetaSite 5.1.9 able to read data directly from UNIFI 1.9.2 using the built-in Application Programming Interface (API) and also uploaded onto the server based application, WebMetabase 3.2.9.

Results

A number of catabolites for the parent peptides were identified over the time course and could be attributed to hydrolysis of the peptide backbone, with the main catabolites identified attributed to hydrolysis of the non cyclic portion of the peptides. A measure of the ratio of structurally matched to mismatched product ions found by Mass-Metasite provides confidence in catabolite assignment through data acquired by data independent acquisition (DIA). Approximately 99 % of the parent was rapidly (<10 min) turned over generating three key catabolites with minor metabolites, possibly attributed to hydrolysis of cyclic portion of the peptide, formed over the incubation time course. The use of HDMSE showed an improvement in data quality through alignment of precursor and fragment ions in both RT and DT (drift time) thus leading to improved spectral quality and an increase in identified fragment ions over the number of false positives for several peptides.

Conclusions

Mass-MetaSite and WebMetabase were used to characterize metabolic fate of the parent peptides showing that data can be collected routinely, processed and reviewed efficiently across time courses and treatments. A tightly integrated, UPLC HRMS informatics platform with high chromatographic performance, high mass accuracy and fast scanning capabilities afforded by the IMS QToF enabled rapid and confident detection of peptides and any corresponding catabolites.

Novel Aspect:

Informatics and ion mobility HRMS workflow for detecting and reviewing peptide catabolites.

695 - SEMI-QUANTITATIVE LC/ESI/MS ANALYSIS USING PREDICTIVE MODELS OF ESI IONIZATION EFFICIENCIES

Jaanus Liigand (1) - Piia Liigand (1) - Mari Ojakivi (1) - Karl Kaupmees (2) - Anneli Kruve (3)

University of Tartu, Institute of Chemistry, Tartu (1) - University of Tartu, Institute of Chemistry, Tartu (2) - Freie Universität Berlin, Institut für Chemie und Biochemie, Berlin (3)

Keywords: electrospray, ionization efficiency, prediction model, semi-quantitation

Introduction:

As the omics are rocketing we gain insight into the chemical transformations occurring in living beings. The lack of authentic standard substances hinders obtaining deeper quantitative information about these processes. In recent years, artificial intelligence is improving different fields of life. We propose an approach of applying machine learning to overcome the lack of authentic standard substances via predicting the ionization efficiencies (IE).

Methods:

Altogether, ionization efficiencies of 400 compounds were measured in electrospray ionization positive and negative mode in 29 mobile phases (altering the percentage of acetonitrile or methanol and covering a variety of the most used additives) in flow injection. For model development, descriptors from PaDEL and different machine learning approaches (multilinear regression, random forest regression and artificial neural networks) were used.

Results:

For both ionization modes, universal models overall mobile phases were developed. For positive mode regularized random forest regression gave the best model with a residual standard error of 0.54 logIE units and R^2 0.82. For negative mode, multilinear regression gave the best model with a residual standard error of 0.58 logIE units and R^2 0.77.

The coefficients in these models are expected to depend on the instrument. Therefore, we propose using a set of calibrants to transfer ionization efficiency prediction models between instruments. This means analyzing a smaller set of calibration compounds (6) and samples together using the corresponding instrument and mobile phase in one batch. The relative IE values measured in this way can be used to fit a model between the logIE values observed for calibrants and descriptors. As a result, the fitting coefficient for the model are obtained which describe directly the system used to analyze the samples.

Validating this approach with gradient elution resulted in a 3.7-fold mismatch of concentration.

Conclusions

Universal ionization efficiency prediction models help to reduce the need for authentic standards with less than 4 times mismatch in concentration compared to a conventional comparison of peak areas that can result in a mismatch of several orders of magnitude. The approach only requires 2D structures of the compounds and a small set of compounds for system calibration.

Novel Aspect:

Universal ionization efficiency prediction models are developed for positive and negative ESI, allowing semi-quantitative analysis on LC/ESI/MS with high accuracy.

810 - MSIML – AN OPEN-SOURCE PROGRAM FOR THE VISUALISATION AND PIXEL-BY-PIXEL CLASSIFICATION OF MASS SPECTROMETRY IMAGING DATASETS

Lukasz Migas (1) - Emrys Jones (2) - Richard Chapman (3) - Steven Pringle (3) - Perdita Barran (1)

Manchester Institute of Biotechnology, University of Manchester, Manchester (1) - Waters Corporation, Research Department, Wilmslow (2) - Waters Corporation, Research Department, Wilmslow (3)

Keywords: Imaging Mass Spectrometry, machine learning, bioinformatics, DESI, software

Introduction:

Mass spectrometry imaging (MSI) is used to interrogate the contents of biologically relevant samples often directly without sample preparation. The most readily employed methods (i.e. DESI and MALDI) generate vast amounts of data [1], often making the analysis cumbersome and time-consuming. In addition, the resurgence of machine learning and deep-learning methodologies offer an opportunity to mine MSI datasets and provide a need for user-friendly and accessible software solutions.

Methods:

MSIML was developed to enable rapid access to machine learning, clustering and multivariate methods for the analysis of MSI applications. The software suite is written in python and incorporates scikit-learn for machine-learning and neupy for neural-network training. Sections of whole mouse body, kidney and brain were analyzed using DESI on a Xevo G2-XS Q-ToF (Waters, UK) to demonstrate MSIMLs capabilities in the analysis of complex MSI datasets.

Results:

Unsupervised multivariate analysis techniques is shown to greatly improve the interpretation of large MSI datasets, as well as aid differentiation of spectral and anatomical features. MSIML provides easy access to most commonly used methods including (i.e. PCA, NNMF) as well as clustering (i.e. K-means, Birch) and embedding (i.e. Spectral Embedding, t-SNE or HSNE) algorithms. However the main strength of MSIML lies in its ability to interactively label MSI pixels of multiple files, enabling building of complex supervised classification models that can be easily applied to unknown samples [2]. Here, classification models were applied to segregate healthy and tumorous regions in mouse samples and differentiate tissue components. In addition, on-the-fly classification is demonstrated in a high-throughput environment where each mass spectrum is pre-processed and immediately labelled by previously build classification models, providing the user with more information and directions for further analysis.

Conclusions:

Here, we present open-source platform (MSIML), an all-in-one program that can be used for the entire analysis workflow, including loading of single or multiple .imzML or Waters .raw files, pre-processing, spectral analysis, data mining, machine learning and sample classification. MSIML offers easy to operate GUI environment, enabling rapid interrogation of large datasets and providing valuable bioinformatics information.

Novel Aspect:

Combined machine learning classifications and multivariate analysis of known and unknown imaging mass spectrometric datasets can enhance differentiation of complex samples.

Atomicus OOO, Atomicus OOO, Minsk (1) - Atomicus GmbH, Atomicus GmbH, Karlsruhe (2)

Keywords: atom probe tomography, Bayesian approach, automatic peak identification, peak labeling.

Introduction

Atom probe tomography relies on the analysis of mass-spectrometry data [1, 2] and requires preliminary identification of the mass-spectrum peaks. Establishing correct correspondence between the peaks in the spectrum and the particular atomic species is crucial for accurate interpretation of the measured data [3, 4]. Manual peak labeling is a time-consuming procedure and vulnerable to errors [4]. We propose a Bayesian approach suitable for robust automatic peak identification.

Methods

We apply the Bayesian approach, previously developed for search and match analysis of X-ray powder diffraction data [5], to the problem of peak identification in atom probe mass spectra. The optimal peak association can be found as the maximal likelihood estimate of the specimen model for the given experimental mass spectrum. The designed technique is applied to the measured time-of-flight mass-spectrometry data.

Results

The Bayesian approach provides a general framework for derivation of physically grounded methods for peak identification. The initial information about the investigated specimen (e.g. presence or absence of some elements, possible correlations between presence of different ions, etc.) is encoded in prior probabilities for the sample models. The expected inaccuracies of the measurement and peak search are characterized by the likelihood function. Then, based on the measured data, posterior probabilities are calculated for the specimen models. The optimal peak labeling is provided by the most likely model (having the maximal posterior probability). By varying the probability models, one can construct different peak identification algorithms, suitable for different types of measured input data.

For testing, a peak identification algorithm based on a simple model of mutually independent inaccuracies of positions and intensities of the peaks was designed. Applicability and robustness of the algorithm was demonstrated for a number of experimental datasets.

Conclusions

The proposed Bayesian approach is universal and suitable for construction of different peak identification algorithms by taking into account different aspects of the data acquisition process. It is capable of correct analysis of overlapping peaks, of making model- and probabilities-based decisions when the mass-to-charge ratio is the same for different ions, and of taking into account possible global systematic errors (e.g. miscalibration).

Novel Aspect

Instead of "guessing" an automatic analysis algorithm, suitable for superseding manual peak labeling, we demonstrate derivation of such an algorithm from first principles.

885 - DEMYSTIFYING MATCH FACTORS IN LIBRARY SEARCHING

Arun Moorthy (1) - Anthony Kearsley (2) - William Wallace (1)

National Institute of Standards and Technology, Mass Spectrometry Data Center, Gaithersburg (1) - National Institute of Standards and Technology, Applied and Computational Mathematics Division, Gaithersburg (2)

Keywords: Algorithms, Electron Ionization Mass Spectrometry, Hybrid Search, Library Searching

Introduction: (395/400 characters)

Match Factor is a term ubiquitous in mass spectral library-searching. It is a numerical measure of similarity between spectra used to sort a hit-list of potential identifications to a query. But what happens when multiple unique hits have very similar match factors? How do you decide which is correct? Here we detail how match factors used in library searching are computed [1,2], and present a decomposition method to help interpret hit-lists when ambiguities exist.

Methods: (358/400 characters)

An EI spectrum can be represented as a vector where indices are the integral-mass of fragment-ions and values are the corresponding abundances. The masses of all peaks considered in a match factor computation is a set. This set can be decomposed into subsets: (1) matching peaks, (2) query only peaks, (3) library only peaks, (4) zero peaks. The ratio of sums of peaks in each subset can be used to interpret hit-list ambiguities.

Results: (898/900 characters)

Simple and Hybrid match factors are computed as a function of peak intensities from the full set of peaks. This function is referred to as the modified dot product and differs from a standard dot product of two vectors in that the input values are rooted and the function output is squared and then scaled by 999. The difference between simple and hybrid match factors is in defining the subset of matching peaks. In hybrid match factors, this subset includes peaks from both spectra that differ by the molecular mass difference between the two compounds in addition to peaks that share the same mass.

When library spectra give the same match factors to a query, the ratio of sums from each subset of peaks can be used to discriminate hits. For example, a match factor of 800 due to peak intensity variability reducing the sum of matching peaks but with no unmatched peaks is more likely to be the correct identification of the query than the same score generated from a pair with many unmatched peaks in either the query or library spectra. Several example scenarios will be discussed.

Conclusions (352/400 characters)

Mass spectral library search algorithms use computed match factors to sort potential identifications of a query spectrum. When two or more hits have similar match factors, simply choosing the highest match factor may be incorrect. This presentation details a method of further decomposing match factors to assist analysts in this situation. An R implementation of this method is available through correspondence.

Novel Aspect: (138/150 characters)

The decomposition of peaks into subsets is a novel method of analyzing match factors and greatly improves the interpretation of ambiguous library search results.

632 - TOWARDS AUTOMATED REPORTING AND REVIEW OF METABOLIC PATHWAYS FOR LARGE MULTIMODAL MSI STUDIES

Teresa Murta (1) - Alex Dexter (1) - Spencer A. Thomas (1) - Rory T. Steven (1) - Chelsea J. Nikula (1) - Efstathios Elia (1) - Adam J. Taylor (1) - Tingting Fu (1) - Ala Al-Afeef (1) - Bin Yan (1) - Robin Philip (1) - Kenneth N. Robinson (1) - Josephine Bunch (1)

National Physical Laboratory, NiCE-MSI, London (1)

Keywords:

MSI, automated data characterisation, metabolism, cancer

Introduction:

Enormous effort has been made to understand the metabolic hallmarks of cancer [1]. MSI techniques are promising tools to visualise the spatial distribution of the molecules that constitute the metabolic pathways altered in cancer. Identifying and characterising which molecules can be measured is crucial to study their interactions. An automated tool to search the HMDB [2], collect and organise varied information regarding these molecules was implemented.

Methods:

Either the list of detected masses or those identified as drivers of a multivariate analysis or machine learning classification result can be fed to this tool. The input is compared to a list of adducts generated from all molecules present in the database. For each potential assignment, information such as name, metabolic pathways in which it is known to be involved, and tissues in which it has been found, for example, are collected and organised for further exploration.

Results:

This tool outputs lists of potentially measured metabolites or potential drivers of segmentation or classification results, as well as estimates of the metabolic pathway coverage (i.e. percentage of pathway constituents that can be measured), for example. Its outputs can be used to: (1) compare data acquired from the same sample but with different MSI techniques or with the same MSI technique but at different sites; (2) adjust the acquisition protocol to either maximise the number of measured molecules or to focus on a particular set of molecules (e.g.: those expected to be crucial to understand the particularities of metabolic alterations happening in tumours and surrounding tissues); and (3) restrict data post-processing analyses to particular sets of molecules. This tool will be part of an automated data processing pipeline developed to cope with the large amount of data generated by a 5-year multisite, multimodal, and multiscale project focused on improving our understanding of metabolic alterations occurring in various types of cancer.

Conclusions:

This automated MSI data characterisation tool can be useful not only for optimisation of MSI acquisition protocols, but also to understand the usefulness of MSI techniques to investigate biologically relevant questions, in particular, those leading to a better understanding of cancer-specific metabolic alterations.

Novel Aspect:

Automated collection and organisation of metabolic information available in MSI data, highly relevant to study the metabolic fingerprints of cancer using MSI data.

887 - MODPLUS: TOWARDS SEARCHING FOR HUNDREDS OF POST-TRANSNATIONAL MODIFICATIONS IN SHOTGUN PROTEOMICS

Seungjin Na (1) - Jihyung Kim (1) - Eunok Paek (1)

Hanyang University/Dept. of Computer Science, Hanyang University/Dept. of Computer Science, Seoul (1)

Keywords: bioinformatics, post-translational modification; software; tandem mass spectrometry

Introduction:

Computational approaches to PTM identification using tandem mass spectrometry are severely limited when dealing with many types of modifications [1]. MODplus is a practical, unrestrictive modification search tool that works well for complete proteome databases, hundreds of modifications from the Unimod [2], multiple modifications in a peptide, partially tryptic peptides and so forth.

Methods:

Sequence tag approach significantly filters out useless peptides from a database [3], and improved spectral alignment based on aligned multiple tags rapidly identifies top N candidate peptides. The spectral alignment defines regions (called gaps) within a peptide that were not aligned with any tags but possibly contain modifications, and the mass differences defined over the gaps can be interpreted by enumerating modifications in Unimod or user-defined list.

Results:

We assessed the performance of MODplus with Q-Exactive data from human proteome (HEK293 cell lysate, ProteomeXchange: PXD001468) in terms of its search time and the number of identifications with varying the number of modifications. In case of a standard database search tool (MS-GF+ [4]), the search time scaled linearly with the number of input modifications and the number of identifications started to diminish with a dozen modifications. In contrast, MODplus search with ~700 variable modifications required only ~3-fold time than that with three modifications where MODplus search time was similar to that of the standard database search tool. Even as the search space got bigger with the number of modifications, MODplus lost almost no existing identifications (or identifications from a smaller search space) and yielded more identifications. We also demonstrated the utility of MODplus with TMT-labeled, phosphorylation enriched data (Human Skeletal Muscle, ProteomeXchange: PXD001543), which is of great interest in many laboratories.

Conclusions:

A tag-based approach could resolve many computational issues in an unrestrictive modification search. MODplus successfully addressed both scalability and reliability challenges in searching for hundreds of modifications from human proteome datasets such as HEK293 cells and TMT-labeled phosphorylation enrichment. MODplus can be easily integrated with any search strategy or workflow to play its role as a part of a data analysis pipeline.

Novel Aspect:

MODplus dramatically increases the depth of post-translational modification discovery by mass spectrometry-based proteomics.

918 - DEVELOPMENT AND VALIDATION OF SEMI-AUTOMATIC MALDI-HDX SAMPLE PREPARATION AND DATA ANALYSIS TOOLS

Sam MacIntyre (1) - Thomas Nebl (1)

CSIRO, Biomolecular Interactions, Parkville (1)

Keywords: MALDI-TOF, Hydrogen-Deuterium Exchange, Automation, Biomolecular Interactions

Introduction: Use of MALDI-TOF as high-throughput hydrogen-deuterium exchange MS platform

Hydrogen deuterium exchange followed by Mass Spectrometry (HDX-MS) is a biophysical tool capable of probing protein/ligand interactions, conformational changes, and protein dynamics. Despite an increased number of applications, the expansion of the technology has been slowed by its intrinsic technical and analytical complexity (e.g. sequential online pepsin digestion and HPLC separation at pH 2.5, 0°C). Although most HDX-MS studies have been conducted with electrospray ionization (ESI), matrix-assisted laser desorption/ionization-time of flight (MALDI-TOF) mass spectrometry turns out to be a convenient tool for this purpose. MALDI-TOF combines the advantages of high speed of analysis and excellent sensitivity and accuracy of mass measurements with the capability to analyse peptide maps in a single spectral acquisition. With recent advancements in automated sample preparation entire HDX-MS experiments can be executed within one hour [1].

Methods: Development of an R-package for the semi-automated analysis of large MALDI-HDX datasets

We have developed an R-package to help analyse large MALDI-HDX datasets. This software facilitates the assessment of the quality of spectral segments for accurate centroid mass determination of identified peptides. It allows the user to semi-automatically validate, visualize and compare the relative deuterium incorporation of peptide features. The resulting HDX dataset can also be exported a format suitable for subsequent statistical analysis or 3D protein structure mapping using the MEM-HDX package [2].

Results: Development of a MALDI-HDX workflow for the analysis of peptide binding interactions

Coupling MALDI with HDX has been challenging because of undesired back-exchange reactions during sample preparation, spotting and analysis. In this report, we systematically evaluated different methods utilizing MALDI coupled with a commercially available high-throughput nanolitre dispenser capable of highly accurate and precise spotting of 96 samples in less than five minutes. We establish a sample preparation protocol using sub-zero temperatures and non-aqueous matrix solution that minimize back exchange. We applied our newly developed MALDI-HDX data analysis package to demonstrate specific binding of M2 anti-Flag antibody to FLAG or 3xFLAG peptides in a mix of 9 peptide calibration standards.

Conclusions: MALDI-HDX provides accurate linear epitope mapping data

The biophysical characterization of a monoclonal antibody recognizing different linear epitopes establishes the ability of MALDI-HXMS to provide accurate peptide binding data. This approach may be extended to glycopeptide or macro-molecular interactions, provided that peptide mapping is conducted carefully in order to minimize back exchange and confirm sequence coverage.

Novel Aspect: New software package facilitates the systematic analysis of MALDI-HDX data

We present a new R-package to help analyse large MALDI-HDX datasets. We used this software to systematically analyse peptide back exchange rates and other technical challenges associated with the coupling of MALDI and HDX. This has allowed us to establish a protocol utilizing a nanoliter dispensing system for rapid, automated MALDI sample preparation. This step is an essential pre-requisite for future use of MALDI-HDX as a high-throughput platform to study biomolecular interactions.

Daniel Ortiz (1) - Laure Menin (1) - Luc Patiny (1)

EPFL, ISIC/SSMI, Lausanne (1)

Keywords: MS tool, high resolution, protein fragmentation, internal fragments, contaminants, m/z deconvolution, teaching

Introduction (Limit of 400 characters without spaces, currently 220):

Cloud based services are becoming of main importance for many applications like collaborative working, large databases analysis and IoT (Internet of Things). Nevertheless, few scientific implementations are currently available online. For the last 10 years, we are developing core functionalities to allow mass spectra processing directly in the browser [1]. Recently, we compiled various tools to solve usual tasks encountered in MS research laboratories, available on the website <http://ms.cheminfo.org>. Those tools are open-source (MIT licence), don't require any installation and are always up-to-date (just need to reload the web page). In addition to classical tools such as calculation of isotopic distributions and simulation of fragmentation ions, the tool assists the user in finding possible molecular formulas from an experimental high resolution monoisotopic mass, associated with the list of PubChem candidates. Among others, the tool allows to check for the presence of known contaminants or compounds listed in a Google Spreadsheet that can be dynamically created by the user. This tool implements a matching algorithm that compares experimental and theoretical spectra in order to generate interactive reports that can be easily shared between colleagues. These algorithms were successfully used to analyze intricate systems involving for example protein metal complexes [2] or complex ionic liquid cluster deconvolution. <http://ms.cheminfo.org> also contains interactive teaching oriented tools that can be used in MS related lectures.

Methods (Limit of 400 characters without spaces, currently 77):

The libraries are implemented in JavaScript and available on GitHub. The main library can be downloaded on <https://github.com/cheminfo-js/molecular-formula>. The code is thoughtfully tested using jest and each commit is automatically processed in order to check for any broken code. Currently, there are over 150 tests that cover more than 80% of the code. Code syntax is enforced by over 200 eslint rules, that yields to a code easy to read, maintain and release under a MIT license.

Results (Limit of 900 characters without spaces, currently 411):

Several tools available on <http://ms.cheminfo.org> were unified and recently updated. These applications are daily used in our mass spectrometry facility of ISIC (EPFL), for a wide range of applications and projects. Among others:

Core function to generate isotopic pattern distributions. It can be calculated from a molecular formula or a chemical structure (Drawn or imported), with the possibility to select isotope abundances and charges. Based on the customizable FWHM, the system generates the theoretical isotopic distribution that can be compared with experimental data and exported as high quality figures (SVG).

Application to determine possible molecular formulas for a specific monoisotopic mass acquired by high resolution mass spectrometry (HRMS). It is possible to specify the molecular formula range for a single monoisotopic value but also to specify groups of atoms that, when combined, generate multiple combinations that will be matched and compared with experimental data. The system allows as well to specify the ion types (polarity, number of charges, adducts, etc.).

Easycont to track classical contaminants inherent to the sample preparation such as detergents (Tween, SDS, Triton...), polymers (PEG, PPG...), contaminants from containers (phthalates, plasticisers) and solvent interferences. The experimental mass spectrum can be rapidly screened against the updated ms.cheminfo.org database of contaminants. Easycont browses the results ordered by similarity (%) and gives information about each identified contaminant.

Apm2s calculates theoretical fragment ions (a, b, c, x, y, z and internal fragments) from a given protein/peptide sequence with any user defined modification such as post translational modifications, chemical modifications, non-natural amino acids, ligands or metal ions bound to the protein, and matches each individual theoretical isotopic pattern to the experimental mass spectra to provide a list of matches with similarity score. Very recently [2], this exhaustive Apm2s matching tool provided an abundance of data which gave critical insights into cisplatin-ubiquitin binding.

MS/MS fragmentation is a virtual and interactive fragmentation tool. Bonds can be selected from any chemical structure with a mouse click and all fragments and combinations of them are generated and compared to the experimental data.

The new deconvolution tool consider an experimental mass spectrum as a linear combination of spectra simulated from expected molecular formulas and this is achieved using SVD (Single Value Decomposition). This algorithm can deal with molecular formulas that yield to overlapping spectra, e.g. M⁺ and M²⁺⁺. For example it has been used to shed light on the different clusters and their relative intensity in a complicated mixture of ionic liquids.

Conclusions(Limit of 400 characters without spaces, currently 98):

Contrary to beliefs, JavaScript proves to be suitable for creating fast and efficient scientific tools from any Web browser and indeed are competitive with most vendor's applications. Many different analytical tools were gathered on the ms.cheminfo.org website such as isotopic pattern distributions generations, molecular formula finder from monoisotopic mass and several advanced tools to compare the experimental data to the automatically predicted isotopic distributions of thousands species. The applications associated with this automated workflow are endless and can certainly be of extremely valuable help for any user with internet access having complex high-resolution mass spectra data to analyze.

Novel Aspect(Limit of 150 characters without spaces, currently 72) :

Complex problems involving MS measurements can not necessarily always be solved using commercial solutions. In top of that, commercial softwares are often expensive, inflexible, and their installation and upgrade procedures are generally time-consuming. In order to use the versatile ms.cheminfo.org toolbox, the only mandatory application is a web browser already installed on a computer. The free and open source applications of ms.cheminfo.org are in constant development, quickly evolving with the researchers requirements.

Burdenko Scientific Research Neurosurgery Institute, Moscow (2) - Skolkovo institute of science and technology, Skolkovo institute of science and technology, Skolkovo (3)

Keywords: clinical application, neurosurgical support, profiling.

Introduction:

High-resolution mass spectrometers are widely used in research facilities around the globe, but applying mass spectrometry to clinical use requires reproducing the results on the low-resolution instruments. But in practice high- and low-resolution spectra obtained from one sample are not so similar as one could expect. In our work we analyze feature selection approach to determine features that are common for the different resolution spectra.

Methods:

All experiments were performed on Thermo LTQ Orbitrap XL instrument using the direct method of extraction of lipids from brain tumor tissues followed by ESI. Multiple switching between Orbitrap and LTQ analyzers allows obtaining high-resolution spectra as well low-resolution ones almost simultaneously from the one sample.

Results:

Both types of spectra were processed through the identical data analysis pipeline for denoising, aggregation, normalization, peak picking and peak alignment. Two datasets were then aligned to each other and analyzed. The low-resolution spectra contain about one-third of the peaks, detectable in high-resolution spectra; however, all major peaks are found in both types of spectra. Analysis of peaks selected as features to distinguish the tumor tissue from boundary brain tissue demonstrate that vast majority of selected features were preserved in both types of spectra. Moreover, we have created a mapping scheme, which allows us to use a classifier trained to separate tumor samples from non-tumor brain samples on high-resolution spectra with data from low-resolution spectra with a minor decrease in accuracy.

Conclusions:

It was demonstrated that tissue profiling and identification techniques developed on the high-resolution mass-spectrometers could be transferred to low-resolution instruments that are commonly used in routine application.

Novel Aspect:

It is shown that low-resolution spectra preserve distinctive features of brain tumor samples and could be used for sample classification in clinical settings.

870 - INTEGRATION OF HIGH MASS ACCURACY GC-TOFMS RESULTS USING EI AND FI IONIZATION METHODS:

Yoshihisa Ueda (1) - Ayumi Kubo (1) - Kenji Nagatomo (1) - Masaaki Ubukata (1) - Takaya Satoh (1)

JEOL Ltd., MS business unit, Tokyo (1)

Keywords: GC/MS, EI, FI, Time-of-Flight Mass Spectrometer

Introduction:

Electron ionization (EI), which accompanied by extensive fragmentation, is the most popular method used in gas chromatography-time of flight mass spectrometry (GC-TOFMS). The compounds are identified by mass spectral database search. On the other hand, the field ionization (FI) is also available in GC-TOFMS, which can obtain the molecular information from accurate mass. We have developed the software to integrate the GC/EI and GC/FI data obtained from GC-TOFMS.

Methods:

The commercially available vinyl acetate resin was used as a sample for GC/EI and GC/FI analysis. The GC-TOFMS, (AccuTOFTM GCx-plus, JEOL) combined with a pyrolyzer (PY-2020iD, Frontier lab) was used for data acquisition. The thermal decomposition products were injected with split mode (100:1) and separated using GC capillary column DB-5msUI. The EI/FI combination ion source was used for GC/EI and GC/FI measurement.

Results:

The data integration of GC/EI and GC/FI was performed with following steps. (i) The GC peaks were detected from GC/EI and GC/FI data separately. (ii) The mass spectra were extracted for each GC peak. (iii) Database search was performed for extracted GC/EI mass spectra using NIST mass spectral library. (iv) The mass spectra from GC/EI and GC/FI data were linked using retention time information. (v) The accurate mass analyses were performed by using mass of molecular ion shown in GC/FI spectra and the masses of fragmentation ions in GC/EI mass spectrum. The one useful point of the software is the confirmation of database search results with GC/EI mass spectra by molecular information of GC/FI spectra. The other is to support analysis of unmatched compounds by database search. Both elemental compositions of molecular ion and fragment ions, which represent substructure, can be estimated by accurate mass from GC/FI and GC/EI mass spectra, respectively.

Conclusions

We have developed the software to integrate high mass resolution GC/EI and GC/FI data. The functions are tested using GC/EI and GC/FI data obtained by Py GC-TOFMS analyses for vinyl acetate resin. The software is useful to overview the sample chemical information in complicated mixture.

Novel Aspect:

Development of integration software for GC/EI and GC/FI ionization data acquired by high mass resolution time-of-flight mass spectrometer.

777 - BEYOND THE ACQUISITION OF FTMS SPECTRA - DATA INTERPRETATION AND VISUALIZATION OF ACCURATE DATA FROM COMPLEX SAMPLES

Alessandro Vetere (1) - Wolfgang Schrader (1)

Max-Planck-Institut für Kohlenforschung, Departement for Mass Spectrometry, Mülheim an der Ruhr (1)

Keywords: FTMS – data analysis – complex mixtures –visualization - software

Introduction:

The analysis of complex mixtures from energy related mixtures has been pushed forward during the last years by the development of powerful mass spectrometric machinery that is not only capable of producing ultra-high resolving and accurate mass data, but that is also of high sensitivity. Still problematic, is simple and coherent data analysis that allows to gather the relevant bits of data from the enormous variety of numbers acquired during a typical measurement.[1]

Methods:

Vendor software that enables the complete analysis and non-targeted assignment of complex FTMS spectra from crude oil or biofuels, especially in a time-resolved manner, is to date not available. Therefore a mixture of third party software and self-written tools needs to be applied. An essential part during data analysis is adequate grouping and visualization of the results to convey the necessary information.

Results:

The first step in data analysis typically involves the assignment of elemental compositions to each peak within a given spectrum. This step can be aided by the use of Kendrick mass scale[2] and the fact that within crude oil related samples one typically finds broad homologous series of compounds where the repeating units are either CH₂ and/or H₂. A first step in data accessibility involves grouping into so called heteroatom classes which define the amount of heteroatoms per molecule. For visualization and reevaluation of the data, as well as for the comparison of different datasets, several tools have been developed that first transfer the data into heavily structured MS Excel workbooks. From here graphs with varying degrees of detail can be easily created. An additional tool enables a straightforward overview of heteroatom class distributions by plotting the findings into a hexagonal grid.[3]

Most challenging is the handling of time resolved data for which a lab-built database approach was devised.

Conclusions:

Mass spectra of crude oil related samples reach an average peak density of 100-200 signals per mass unit over a range of $100 \leq m/z \leq 1200$. For an aim-leading interpretation of such spectra not only mass resolution and accuracy are of utmost importance, also data interpretation and representation play a vital role. A broad and flexible set of visualization tools helps understanding the composition and the chemistry of such complex samples as crude oils.

Novel Aspect:

New software tools were developed to ease up the data analysis and visualization pathway of complex crude oil samples.

535 - ADVANCED MASS SPECTROMETRY METHODS FOR UNRAVELLING THE MECHANISMS OF ORGANOPHOSPHATE TOXICITY

Huixin Wang (1) - Michael Leeming (2) - Blake Cochran (3) - William Donald (1)

School of Chemistry, UNSW, School of Chemistry, University of New South Wales, Sydney (1) - School of Chemistry, The University of Melbourne, Melbourne (2) - School of Medical Science, University of New South Wales, Sydney (3)

Keywords: Organophosphate; protein-target identification; bottom-up proteomics; stable isotope labelling; metabolomics;

Introduction:

Organophosphates (OPs) are widely used as insecticides. Some of the most toxic organophosphates have been used in warfare causing thousands of fatalities. Acute and chronic exposure to organophosphate insecticides can cause adverse health effects. The mechanism of delayed toxicity is thought to involve off-target inhibition of serine proteases [1], although the precise molecular details remain unclear due to the lack of an analytical method for global detection of proteins that have been covalently modified by organophosphates.

Methods:

A novel mass spectrometry method was developed to identify OP-adducted proteins in a non-targeted fashion. Human plasma was incubated with a mixture of isotope labelled and unlabeled OP pesticides. Proteins were extracted, digested and analyzed by LC-MS/MS to detect "twin ions" of peptides adducted by OPs. The LC-MS/MS data was processed by a blended data analytics software, which can identify the amino acid residue of proteins modified by the labelled OPs [2-4].

Results:

We found that proteins can be modified covalently by OPs by both trans-methylation and phosphorylation. Transmethylation at Glu, Asp, Cys, His and Lys residues are identified as major reactive pathways which have not been reported in the literature to date. Seven protein targets of OPs from human plasma were identified. These amino acid residue target sites were also confirmed by NMR by reacting four commonly used OP insecticides with single amino acids.

Conclusions :

We discovered a new non-selective reaction pathway between OPs and human proteins. This transmethylation reaction may be responsible for the mechanism of delayed toxicity owing to organophosphate exposure. It is anticipated that this information will be useful for revealing the mechanism(s) of organophosphate toxicity.

Novel Aspect:

We report the first non-targeted identification of the proteins that react relatively non-specifically with OPs. This method is more reliable and efficient compared to the traditional pull-down method [5]. Transmethylation is identified as a new reaction pathway in addition to the well-known phosphorylation mechanism for OP-protein interactions.

Keywords: FT-ICR MS, isotope analysis, LCMS, cancer therapeutics, data analysis

Introduction:

The majority of chemotherapy utilizes metal-based compounds to preferentially attack cancer cells. Proteomic investigations of compounds and effects on cellular components is widely sought after to understand the mechanisms of action for potential drugs, but difficult to interpret.^{1,2} To accurately identify and assign these species we present a new method to reveal metallodrug-modified species within complex data sets such as LCMS runs, MS imaging, and 2DMS.³

Methods:

The SNAP Algorithm (V2.0), coded inside Bruker Data Analysis software (V4.0, 4.1, 4.2, and 4.3) was used to peak pick acquired data sets. SNAP-LC and MSi was coded using the internal visual basic environment inside DA to automate peak picking and processing.

All spectra were acquired using a 12T Solarix FT-ICR MS. LC-MS and MS/MS analysis was acquired using an EASY nLC II system coupled to a micro-ESI source, and used a water-CAN separation gradient and 15cm C18 nLC column.

Results:

SNAP-LC analyses each and every scan from large LCMS acquisitions and produces a “metal chromatogram” of the specified metal searched.³ This method was successfully applied to tryptic digest samples containing Pt,² Os,⁴ and Ir metallodrugs. SNAP-LC was then applied to a proteomic investigation of an osmium metallodrug administered to a human ovarian cancer cell line, successfully identifying four modified drug target species within ~10,000 biomolecules observed, automatically and accurately.

SNAP-MSi reveals not only the location of all metal containing species (in a similar fashion to LA-ICP MS) but also the speciation information of the analytes detected, such as free drug identity or metal modified biomolecule, providing detail on drug targets and transformations. SNAP analysis of 2D data sets was of particular interest due to their complex nature and diagonal dependence of isotopes with respect to precursor and data point location.⁵

Conclusions

Accurate analysis of complex data sets is the key to understanding large biological systems, but is hindered by sample complexity and the ability to differentiate species of interest. SNAP-LC, MSi, and 2D analysis allows us to exploit the unusual isotopic patterns of metal chemotherapy agents and accurately identify drug targets in complex samples regardless of prior identity. These techniques are also applicable to such as halogenated species, pesticides, etc.

Novel Aspect:

Exploitation of metal isotope patterns using SNAP analysis reveals cancer drug biomolecule targets and drug transformations in biological samples.

Keywords: MALDI MS, bacterial typing, spectral pattern matching, bootstrapping

Introduction:

Rapid and reliable bacterial typing is an urgent requirement for public safety [1]. Matrix-assisted laser desorption/ionization mass spectrometry (MALDI-MS) is now widely used to analyze bacterial samples [2]. Identification of bacteria at species level can be realized by matching the mass spectra of samples against a library of mass spectra of known bacteria. Nevertheless, identification accuracy should be further improved [3].

Methods:

We propose a new framework for more accurate MALDI-MS based bacterial typing. This framework includes two steps. First, spectral pattern matching is applied to figure out the candidates of identification results, where we introduced two new measures for spectral similarity. Second, the identification results are further assessed by a novel bootstrapping model [4] to provide more reliable characterization.

Results:

The performance of the framework was evaluated with a general dataset containing the mass spectra of 1741 strains of bacteria and another challenging dataset containing 250 strains, including 40 strains in *Bacillus cereus* group that were previously claimed impossible to be resolved by MALDI-MS [5]. Compared to the commonly used cosine correlation [6], our new similarity measures showed better performance. With the help of the bootstrapping assessment, the sensitivity of bacterial identification at the species level increased from 41% to 88% at the same error rate (5%) on the data set containing 1741 strains. Our approach also enabled to resolve the *Bacillus cereus* group.

Conclusions

This framework could provide much more reliable bacterial identification at both the genus and species level with the bootstrapping assessment. The method could promote MALDI-MS based bacterial typing and may further be applied to many other spectroscopy based analytics, e.g., the MS/MS spectral pattern matching in proteomics and metabolomics.

Novel Aspect:

To the best of the authors' knowledge, our method is the first to provide a statistical assessment to MALDI-MS based bacterial typing to improve accuracy and reliability.

98 - DECOY METHODS FOR FALSE DISCOVERY RATE ESTIMATION IN HIGH MASS ACCURACY PEPTIDE SPECTRAL LIBRARY SEARCHES

Zheng Zhang (1) - Meghan Burke (1) - Yuri Mirokhin (1) - Dmitrii Tchekhovskoi (1) - Sanford Markey (1) - Stephen Stein (1)

National Institute of Standards and Technology, Mass Spectrometry Data Center, Gaithersburg (1)

Keywords: peptide mass spectral library, target-decoy approach, PeptideProphet algorithm, false discovery rate, false positive

Introduction: (Limit of 400 characters) (Title calibri 12)

Spectral library searching (SLS) is an attractive alternative to sequence database searching (SDS) for peptide identification due to its speed, sensitivity, and ability to include any selected mass spectra. While decoy methods for SLS have been developed for low mass accuracy spectral library, it is not clear that they are optimal to high mass accuracy spectra. Therefore, we report the development and validation of methods for high mass accuracy decoy libraries.

Methods: (Limit of 400 characters) (Title calibri 12)

Reverse and Random decoy libraries are found to be suitable for high mass accuracy SLS. The first constructs spectra by reversing and the second by randomly replacing all peptide sequences in the library while maintaining the library's amino acid distribution. In both cases, the m/z 's of fragment ions are shifted according to the decoy sequences generated. No alteration to fragment ion intensities, peptide length, or precursor charge state are made.

Results: (Limit of 900 characters) (Title calibri 12)

The utility of Reverse and Random libraries for target-decoy SLS in estimating false positives and FDRs was demonstrated using spectra derived from a recently published synthetic human proteome project.¹ For data sets from two large-scale label-free and iTRAQ experiments, these decoy building methods yielded highly similar score thresholds and spectral identifications at 1% FDR. The results were also found to be equivalent to those of using the decoy-free PeptideProphet algorithm. The Reverse method yields slightly higher thresholds presumably due to its keeping homology matches. However, differences in these methods are rather small. Using these methods for an example FDR estimation, MSPepSearch, which is a NIST-developed search software, led to 18% more identifications at 1% FDR and 23% more at 0.1% FDR when compared with other widely-used SDS engines coupled to post-processing approaches such as Percolator. An application of these methods for FDR estimation for the recently reported 'hybrid' library search² method is also made.

Conclusions: (Limit of 400 characters) (Title calibri 12)

The methods reported here for determining FDR values for high mass accuracy spectra enable results of library searches to be directly integrated with those of more widely used sequence searching Methods: The availability of a reliable means for estimating these FDR values should encourage the use of SLS, which offers advantages in speed and sensitivity. It is shown that SLS can yield more peptide identifications than SDS, especially at the highest levels of confidence.

Novel Aspect: (Limit of 150 characters) (Title calibri 12)

Reverse and Random decoy methods for high mass accuracy SLS permit the merging of SLS and SDS results, increasing assignment of peptides, leading to deeper proteome coverage.

1161 - A NEW BY-PRODUCT ENRICHED IN PHENOLIC COMPOUNDS, EVALUATED BY UHPLC-HRMS, FROM OLIVE MILL WASTEWATER

Giuseppe Avellone (1) - Vita Di Stefano (1) - Maria Eugenia Novara (2) - Rosa Pitonzo (2)

UDS PALERMO, STEBICEF, PALERMO (1) - UDS PALERMO, ATeN Center, PALERMO (2)

Key words: Olive mill wastewater, by- product, UHPLC-HRMS, hydroxytyrosol.

Introduction:Olive mill wastewater (OMW),a by-product obtained during olive oil extraction, represents an important environmental problem for the high toxicity, the resistance to biodegradation and the high volumes processed. Instead of the pollution, OMW is a rich source of bioactive compounds, polyphenols, which could be found up to 98% of the total content of olive fruits.[1]Hydroxytyrosol is the main detected phenolic alcohol [2, 3], widely known due to the natural antioxidant and anti-inflammatory properties[4].

The aim of the present study is to explore and compare the qualitative and quantitative phenolic profile of two OMW treated by two different techniques: freeze-drying and spray-drying.

Methods: Two samples of OMW, Ava and Bava, from two different Sicilian oil mills and generated by three phase continuous systems, were centrifuged, the supernatant was dismissed while the solution was subjected to freeze-drying (FD) and spray drying (SD). The experimental conditions of these techniques were optimized.

The phenolic compounds were extracted by ethyl acetate and, finally, were analyzed by ultra-high-performance liquid chromatography-heated electrospray-high resolution mass spectrometry (UHPLC-HESI-HRMS).

Results:Qualitative and quantitative phenols composition were evaluated by UHPLC-HESI-HRMS. For freeze-drying and spray drying samples were identified and quantified about eleven polyphenols. This new HRMS analyzer allows to characterize in complex mixtures small molecules with confident and rapid monitoring.

The qualitative and quantitative analysis showed an important complexity of this wastes, in which, thanks to the new HRMS analyzer, it was able to determine the high concentration of polyphenols belonging to phenyl acids, phenyl alcohols and secoiridoids derivatives. Hydroxytyrosol is the most important phenolic compounds, extracted in FD and SD samples, and the concentration, up to 18,11 mg/g (in FD OMW). This amount was determined for the first time with this high concentration. Elenolic acid and hydroxy-O-decarboxymethyl-oleuropein aglycone were the second phenolic compounds most represented: 6,57 mg/g in Bava FD and 1,87 mg/g in Bava SD and the second one was 4,48 mg/g in Bava FD and 1,82 mg/g in Bava SD. Freeze-dry was the best method to enrich in phenolic composition the OMW samples especially in hydroxytyrosol.

Conclusions: the possibility of using and recycling bioactive compounds from agroindustrial wastes would reduce pollution caused by the latter, and would also allow to realize pharmaceutical, cosmetic, food and feed products enriched with functional molecules. In this view, new technologies, proposed to treating of OMW, have been used to valorise these wastes as a low-cost starting material as predicted by new bio economy.

The recovered polyphenols obtained by freeze-drying could lead towards better usage of by-products from olive oil production.

Novel aspect: these techniques allow to recycle the OMW, only, through physic treatment without any chemicals extraction or processes. For SD samples was added maltodextrin, widely known as food additive, which necessary to maintain the stability over the time.

Therefore, the agricultural industries could implement the FD or SD systems in order to obtain valuable health-products while containing costs, especially for SD.

832 - USE OF ICP-MS-BASED TECHNIQUES FOR THE CHARACTERIZATION OF NANOMATERIALS USED IN FOOD-RELATED APPLICATIONS

Federica Aureli (1) - Francesca Ferraris (1) - Sara Savini (1) - Andrea Raggi (1) - Francesco Cubadda (1)

Istituto Superiore di Sanità, National Institute of Health, Rome (1)

Keywords: nanoparticles, food additives, nutrient sources, single particle inductively coupled plasma massspectrometry, asymmetric flow field flow fractionation-UV-MALS-ICP-MS

Introduction

Applications of nanotechnologies to agricultural production, food processing, and food contact materials are rapidly developing. Such applications may bring benefits but potential risks have to be assessed and excluded since, if nanoparticles persist as such after gastrointestinal digestion, they may be absorbed in the gut. In the NANO-PERSIST project the transformations and fate of food-relevant nanoparticles during human digestion and in lysosomal conditions are being studied.

Methods

In the project, carried out in collaboration with the EC-JRC, acellular in vitro tests are applied to assess the dissolution/biopersistence of nanomaterials used in the food and nutrition sector and form the basis of the risk assessment strategy for these materials. A multi-method approach is used for the physicochemical characterization of the samples, where the results of MS-based techniques (spICP-MS, AF4-UV-MALS-ICP-MS/MS) are compared with those of centrifugal liquid sedimentation (CLS) and transmission electron microscopy (TEM).

Results

Ten different samples, belonging to four material types (namely synthetic amorphous silica, titanium dioxide, iron oxides/hydroxides, and zinc oxide) were studied. The pristine materials were characterized after dispersion with a standardized protocol. Whereas TEM was essential to study particle morphology, MS-based techniques provided excellent performances for the size characterization of the materials after proper method development. In particular for spICP-MS, the use of μ s dwell times combined with the use of ion-molecule chemistry for resolution of spectral interferences was essential to obtain quantitative data - with fast acquisition times - and with improved (lower) size LODs.

Conclusions

ICP-MS based techniques are the most promising tools for routine characterization and detection of inorganic nanomaterials, also in complex matrices after proper sample preparation. Development of multi-technique approaches and combination of separation and sizing techniques appears to be the way forward for the physicochemical characterization of particulate materials used as food additives and nutrient sources.

Novel Aspect

For the first time a range of materials belonging to four different material types have been characterized with state-of-the-art MS-based techniques and the results compared with TEM and CLS.

670 - HOW TO MANAGE MATRIX EFFECTS FOR ACCURATE NANOPARTICLE SIZING USING SINGLE-PARTICLE ICPTOFMS?

Lyndsey Hendriks (1) - Alexander Gundlach-Graham (1) - Detlef Günther (2)

ETH Zurich, Department of Chemistry and Applied Biosciences, Zurich (1) - ETH Zurich,, Department of Chemistry and Applied Biosciences, Zurich (2)

Keywords: nanoparticles, single-particle ICPMS (sp-ICPMS), time-of-flight MS (TOFMS), food, complex matrices

Introduction:

The use of nanoparticles (NPs) in consumer products is not new. In our kitchen, inorganic NPs can be found as food additives with specific purposes: color or flavor enhancers, preservative agents and texture modifiers. Detection and characterization of NPs in these complex media is necessary to assess risk linked with their use; however, standardized protocols and methods are still lacking for NPs characterization in complex samples.

Methods:

Single-Particle Inductively Coupled Plasma Mass Spectrometry (sp-ICPMS) is used to measure elemental mass of individual NPs and particle number concentrations in complex matrices. To investigate matrix effects on NP measurements, we combined ICPTOFMS (icpTOF, TOFWERK AG, Switzerland), with a dual sample introduction system, in which microdroplets doped with analytes of interest are used for calibration [1].

Results:

Gold NPs were measured in diverse matrices with varying complexity, ranging from ultra-pure water to food samples (fruit juices & milk) and a buffer solution (PBS) used in biological research. In fruit juice, we observed few matrix effects—sizing of Au NPs was identical to that obtained in water. However, with Au NPs dispersed in milk or PBS, we observe an attenuation of NP and microdroplet signal intensities. Because the sensitivities of calibrant droplet and analyte NP are affected in the same way, Au NPs could be sized accurately despite this matrix effect. In contrast, without online microdroplet calibration, Au NP diameters would have been underestimated by 27% or 34% for milk and PBS matrices, respectively.

Conclusions

Microdroplets (calibrant used to determine the instrument sensitivity) are introduced concurrently with the NP-containing sample and experience the same plasma conditions. This online calibration approach can be used to compensate for plasma-related matrix effects. This setup allows for the analysis of large volume samples, rapid switching of NP-containing samples, and calibration of a wide range of NPs.

Novel Aspect:

We demonstrate a successful strategy to detect and accurately size metallic NPs in various real samples with automatic compensation for plasma related matrix effects.

gulzhan.khamitova@unicam.it

Keywords: Espresso Coffee (EC), Particle Size Distribution (PSD).

Introduction

EC extraction depends deeply on ground and roasted coffee particles produced by the grinding and brewing process. To extract tempting aroma and taste in EC, the grinding process is a crucial step. The taste and flavor change in important manner owing to the particle size of ground coffee [1]. This research aims at optimizing the impact of different particle size on aroma and bioactive compounds.

Methods

Quantitative and qualitative analyses were carried out on Arabica and Robusta cultivars. Different particle size average (200 and 400 microns) were used for extraction. Volatiles and bioactive compounds analyses were carried out through GC-MS and HPLC-VWD, respectively. The usual espresso machine settings (9 bars and 92 °C) were kept [2].

Results

EC extraction times, kinetics of extraction and its dependence on water pressure and temperature were controlled during the analysis. Volatile compounds, determined in different particles, were divided into family groups and their characteristics were identified [3]. According to literature [4], particle size influences the amount of extracted bioactive compounds in EC. To study the effect of the particle size, EC samples were processed analyzing caffeine, nicotinic acid and trigonelline. EC extraction were in triplicate for each condition for each particle size. Results confirmed a good extraction efficiency of caffeine, which accounted for 170 mg and 90 mg per cup, on 200 and 400 microns, respectively. Hence, amount of bioactive compounds were increased extracting smaller particle sizes.

Conclusion

EC extraction of different particle sizes were analyzed for their content in bioactive components and volatiles normally found in EC. Extraction optimization will be developed by modifying of extraction variables and further studies will be conducted.

Novel Aspects

The feasibility study of particle size effect on extraction of EC has not been well established yet. Understanding particle size impact on EC will help in setting optimal extraction conditions.

1310 - STUDYING OF PHENOTYPIC AND PHYSIOLOGICAL INFLUENCES OF ABIOTIC STRESSORS (TiO₂ AND EXCESS IRRADIATION) ON TOMATO PLANTS.

Jung Ah Ko (1)

Korea Institute of Toxicology, Future Environment Research Center, Jinju, Korea, Republic Of (1)

Keywords: environmental pollutant, Titanium dioxide (TiO₂), phytotoxicity, climate change, nanoparticle behavior

Introduction

Titanium dioxide (TiO₂) nanoparticles are widely used for skin care, food additives, solar cells, and photocatalysis. However, high demand of TiO₂ raise chance of the releasing into the environment as a pollutant. [1] Since nanoparticles including TiO₂ can arise toxicological effect based on their physicochemical activity, [2-3] studying and expecting the possible influence to the human health is important issue in recently.

Methods

Herein, we studied about influences of TiO₂ when it exposed to tomato plants as a pollutant under excess light condition, for simulating behaviors of TiO₂ under climate change. Plant cultivation was performed in hydroponic system, and phenotypic and physiological analysis were performed to monitor and to suspect any possible influences on the human health.

Results

Accumulation of TiO₂ in leaves were analyzed qualitative and quantitative measurement with STEM, XRD, and ICP-MS. Through the obtained result, we have confirmed clear evidence of TiO₂ presence based on the plant parts, i.e., high accumulation of TiO₂ was detected in leaves and root, while no storage was analyzed in stem.

Other physiological effects on the model plant were exhibited, for example, increased level of oxidative enzyme activity and antioxidant level, color and thickness change of leaves, enhancement on photosynthetic rate, and reproductivity, with respect to the abiotic stressors of TiO₂ and excess irradiation. Presence of TiO₂, especially, lead to increase of the photosynthetic efficiency by improving the activity that related with photosynthesis, such as quantum yield of PSII, electron transport rate, stomatal conductance and so far.

Conclusions

Abiotic stressors of TiO₂ and excess light induced more oxidative stress in comparison with control, and the increased stress expected arisen by direct physical damage as well as enhancement of photosynthetic efficiency. However, we confirmed raised antioxidant level, and higher growth efficiency and fruits production, of which can improve quality of fruit and fruit yield in agricultural field from the tomato plants grown under the stressful environment.

Novel Aspect

This study focused on not only phenotypic influence but also physiological effect of tomato plants to expect possible effect on human health.

Ruud Peters (1) - Anna Undas (1) - Martijn van der Lee (1)

RIKILT Wageningen University & Research, Wageningen, The Netherlands (1)

Key words: nanoparticles, HDC, AF4, ICP-MS, spICP-MS

Introduction:

Nanotechnology is on its way to become a key enabling technology and is expected to stimulate industrial growth, innovation and development in the most diverse fields. Although potential beneficial effects of nanotechnologies are generally well described, still existing uncertainties concerning environment, health and safety aspects need to be addressed to explore the full potential of this new technology. One challenge consists in the development of methods that reliably identify, characterize and quantify nanomaterials, both as substance and in various products and matrices. Mass spectrometry plays an important role here.

Methods:

Recent applications of mass spectrometry for the identification and characterization of nanoparticles have been reviewed.

Results

Mass spectrometry, in the form of inductively coupled plasma mass spectrometry (ICP-MS) has been used in combination with hydrodynamic chromatography (HDC) to determine the presence and concentration of metal and metal oxide nanoparticles. This combination has been used to determine not only the presence of NP in environmental samples and food, but also to study the fate of silica nanoparticles following digestion. MALDI-TOFMS has been used to identify organic nanoparticles but can also be used to identify organic coatings on nanoparticles. In many occasions asymmetric field flow fractionation (AF4) has replaced HDC as the separation method for nanoparticles. To detect and quantify nanoparticles, AF4 is often combined with ICP-MS. AF4-ICP-MS has been used to identify and characterise nanoparticles in environmental samples and in food and personal care products. A relatively new technique is single particle ICP-MS (spICP-MS) which serves as a screening technique for nanoparticles. spICP-MS determines the particle size and the particle number- and mass-based concentration. The attractive feature is that spICP-MS determines a number-based size separation, very much in line with European recommendation for the definition of a nanoparticle. spICP-MS can also detect nanoparticles at very low concentrations which is an advantage in sample processing. Hyphenation of spICP-MS with separation techniques is also studied. The combination of HDC and AF4 with spICP-MS allows for the determination of aggregates and agglomerates since HDC and AF4 determine the hydrodynamic diameter of a particle while spICP-MS determines the spherical equivalent diameter. Very recently, time of flight mass spectrometry has been introduced in spICP-MS allowing true multi-element detection and opening new possibilities.

Conclusions

Mass spectrometry is well on its way to become an important technique in the detection and characterisation of nanoparticles in the environment and in biological and food samples. Especially spICP-MS has become a useful screening method for nanoparticles and combined with electron microscopy as a confirmation method it forms a strong combination.

Novel aspects

The identification and characterization of nanoparticles is a new area of research and one that shows many novel aspects

Abstract

Edible oil production process may cause the formation of degradation products like polycyclic aromatic hydrocarbons (PAHs) or 3-MCPD esters and glycidol esters. Other contaminants include bisphenol A or phthalates from the packaging materials, mycotoxins, such as aflatoxins (AFs), ochratoxin A (OTA), deoxynivalenol (DON) and zearalenone (ZEA) and in some cases antioxidants which are frequently added to cooking oil for prolonged shelf life. These undesired contaminants, if present in significant levels in oil, can pose serious health risk to consumers. Traditionally, these different classes of compounds are usually analyzed by different methodologies. Present study explores the possibility of analyzing all of the above compounds by a simple workflow of dSPE clean-up sample preparation followed by UHPLC-MS/MS analysis.

Methods: Limit 120 words

Oil sample obtained from local stores were extracted with methanol, followed by dispersive solid phase extraction (dSPE) clean-up. Analytes detection were via a highly sensitive PerkinElmer Q-Sight 220 UHPLC-MS/MS system equipped with dual ESI/APCI sources.

Chromatographic separation was performed on a Brownlee™ SPP C18 (100x2.1mm, 2.7µm) column reversed-phase column using a gradient elution.

Under the optimized conditions, the method was validated in terms of its specificity, sensitivity, linearity, accuracy, and precision. Recoveries from sample matrix were evaluated by fortifications of analytes at three different concentrations.

Preliminary results: Limit 300 words

Calibration curves were built by preparing several concentration levels of analytes standards in oil sample matrix (matrix-matched calibration) to overcome any matrix effects. The calibration curves obtained for all analytes were linear over three orders of magnitude with a R² value greater than 0.990. The LOQs for these analytes ranged from 0.1 to 500 µg/L.

The mean recoveries of those analytes from six samples spiked at different concentration levels were between 70% and 120%. The intra-day and inter-day variations, expressed as RSD, were less than 8%, respectively. The results demonstrated that the accuracy and precision of the present method were acceptable for routine monitoring purposes.

Identification and confirmation of the analytes in investigated real sample was achieved by comparing their respective retention times and peak area ratios between the quantifier and qualifier MRM transitions with those from the standards. Overall, the method developed in this study is simple, rapid, sensitive and robust. Demonstrated

performance indicates that such unified method can be applied to determination of certain undesired substances in edible oil.

Future work would include further development of LC method for better separation which includes optimization of mobile phase conditions and MS parameters optimization for better sensitivity.

Novel Aspect: Limit 20 words

Simultaneous determination of different classes of undesired substances in edible oil by high pressure LC-MS/MS.

150 - DEVELOPMENT AND VALIDATION OF AN LC-MS/MS METHOD TO QUANTIFY FUMONISINS AND HYDROLYSED FUMONISINS IN PORCINE SERUM

Gerlinde Bichl (1) - Tibor Czabany (1) - Heidi-Elisabeth Schwartz-Zimmermann (2) - Ilse Dohnal (1)

Biomin, Research Center, Tulln (1) - University of Natural Resources and Life Sciences, Department of Agrobiotechnology, Center for Analytical Chemistry, Tulln (2)

Keywords

mycotoxin, fumonisin, serum, LC-MS/MS, ¹³C-labelled standards

Introduction

Fumonisin is a mycotoxin that negatively impacts animal and human health. The predominant form is fumonisin B₁ (FB₁), followed by FB₂ and FB₃. A novel feed additive, containing fumonisin esterase (FUMzyme®), can enzymatically remove the tricarballic acid groups of fumonisins [1], dramatically reducing their toxicity [2]. We aim to quantify toxins and reaction products in biological matrices.

Methods

We describe an analytical method for the quantification of FB₁, FB₂, FB₃ and all their fully (HFB) and partially (pHFBa/b) hydrolysed forms in pig serum. Due to their low bioavailability, the concentration of these twelve analytes in serum is in the low µg/L range. The sample extraction with acidified methanol-acetonitrile mix was optimised, prior to analysis by HPLC-ESI-MS/MS in MRM-mode.

Results

To compensate for losses during sample preparation and for matrix effects in ESI-MS/MS analysis, ¹³C-labelled internal standards (IS) proved necessary. They were generated by enzymatic hydrolysis of fully ¹³C-labelled FB₁, FB₂ and FB₃.

Moreover, the chromatographic separation had to be fine-tuned, especially for pHFB2a/b and pHFB3a/b: FB₂ and FB₃ are positional isomers and fragment ions of sufficient intensity are not isoform-specific.

The optimised method was validated by spiking the twelve analytes into blank serum in ten different concentrations on three different days in triplicates.

The overall recoveries were between 85 and 110% for all analytes. In contrast, recoveries without IS-correction were only between 40 and 75% for FB₂, FB₃ and their pHFBs. The limit of quantification was between 0.14 and 0.67 ng/mL, except for FB₁ and FB₂ (2.9 and 1.5 ng/mL, respectively).

Conclusions

The quantitative determination of biomarkers in different biological matrices is a prerequisite for detailed analysis of animal health studies.

The validation data demonstrate the usability of the developed analytical procedure and measurement method for accurate identification and quantification of fumonisins and their hydrolysis products in pig serum.

Novel Aspect

A validated method to analyse FB₁, FB₂, FB₃ and their hydrolysis products in serum, using enzymatically produced, ¹³C-labelled internal standards.

822 - IDENTIFICATION OF SYNTHETIC FOOD DYES BY NANO-ELECTROSPRAY IONIZATION

Lucie Borovcová (1) - Eva Máčalová (1) - Karel Lemr (1)

Department of Analytical Chemistry, Faculty of Science, Palacký University, Olomouc (1)

Keywords: dyes, food additives, mass spectrometry, nano-electrospray ionization

Introduction:

Food color is an important parameter making a product more attractive for customers. Food dyes, natural or synthetic, are commonly used for compensation of the loss of natural colors due to the processing or storage of food. Synthetic dyes are strictly regulated. In adulterated food amount of dyes can exceed permitted limits or dyes are not mentioned in the list of ingredients [1,2]. Identification of dyes by nanoESI applying simple sample preparation is presented.

Methods:

Experiments were carried out using a Xevo TQD triple quadrupole mass spectrometer (Waters, Manchester, UK). The commercial inlet of instrument was replaced by a custom-made inlet with a sample cone and a heated capillary allowing nano-electrospray ionization (nanoESI). Nano-electrospray tips ($2 \pm 1 \mu\text{m}$ I.D., PicoTips emitter, New Objective, Woburn, USA) were filled with sample solutions. Standards of fifteen synthetic food dyes were obtained from Sigma Aldrich (Prague, Czech Republic).

Results:

Food dyes were successfully ionized by nano-electrospray ionization (nanoESI). NanoESI was applied for its tolerance to components of matrix and lesser contamination of a mass spectrometer due to significantly smaller flow rate of sample solution in comparison to electrospray. Mainly sodium adducts $[\text{M}+\text{Na}]^+$ or $[\text{M}-\text{Na}+2\text{H}]^+$ were observed in spectra of dyes in positive mode. Better ionization was observed in negative mode, typical ions $[\text{M}-\text{Na}]^-$, $[\text{M}-2\text{Na}+\text{H}]^-$ (generally $[\text{M}-n\text{Na}+(n-1)\text{H}]^-$) and $[\text{M}-3\text{Na}+\text{H}]^{2-}$, $[\text{M}-3\text{Na}]^{3-}$ were formed. Simple dissolution of dyes from real food samples was applied. For example, the presence of declared dye brilliant blue FCF was confirmed by nanoESI and MS/MS experiment in blue candy M&M's after its dissolution in methanol:water (1:1, v/v).

Conclusions:

NanoESI allowed analysis of synthetic food dyes with simple and fast sample pretreatment. Typically better ionization efficiency was observed in negative mode. Applicability was confirmed by identification of dyes in real food samples.

Novel Aspect:

NanoESI and MS/MS experiments represent a useful tool for simple identification of synthetic food dyes in food samples.

1279 - DEVELOPMENT OF A RAPID METHOD FOR ANALYSIS OF HETEROCYCLIC AROMATIC AMINES, BY QUECHERS EXTRACTION AND UHPLC-APCI-MS/MS ASSAY.

Sylvie Chevolleau (1) - Jade François (1) - Alyssa Bouville (1) - Laurent Debrauwer (1)

INRA /Toxalim, Metatoul-AXIOM Platform, Toulouse, France (1)

Keywords: Heterocyclic Aromatic Amines, QuEChERS, UHPLC-APCI-MS/MS, meat, cooking

Introduction:

Heterocyclic Aromatic Amines (HAs) are neo-formed compounds during the cooking of meats and are known or suspected to be mutagenic and carcinogenic for rodents and man. More than 20 HAs have been classified according to their structures and physico-chemical properties. They have been characterized at concentrations in the ng/g (ppb) range in most meat cooked under normal time and temperature conditions, but the analysis procedure is still long and tedious.

Methods:

We present the development of a methodology for the quantification of 16 HAs by UHPLC-APCI-MS/MS after QuEChERS extraction and SPE purification of beef meat samples. Protocols, using an internal standard, were optimized in order to reach quick analysis, a good repeatability and a maximum recovery yield for each HAs. Quantification was achieved by UHPLC-APCI-MS/MS (MRM mode) on a triple quadrupole instrument by monitoring two specific transitions for each HAs.

Results:

The objective of this work was to develop a simple and fast method to overcome the traditional time-consuming extraction method of HAs using diatomaceous earth and large volumes of solvent. For that, the performance of the QuEChERS) method combined with UHPLC-APCI-MS/MS was investigated. Due to, the particular physicochemical properties of the HAs, as well as the fatty nature of the beef matrix, the classical QuEChERS method was modified, by carrying out a solid phase extraction (SPE) in mixed mode combining a polymer adsorbent and a cation exchange, for the purification of the extract in order to minimise matrix effects and signal extinction.

This method takes advantage of the rapidity, specificity and sensibility of both QuEChERS and UHPLC-APCI-MS/MS. Its performances will be presented in terms of selectivity, sensitivity, linearity, carry-over, recovery, matrix effect, repeatability, accuracy and intermediate precision in doped beef meat extracts (15% fat), according to the European Medicines Agency (EMA) validation guidelines.

Conclusions:

An original methodology has been developed to quickly and easily assess 16 HAs in complex beef meat matrices by UHPLC-APCI-MS/MS. After validation, this method will be applied to implement a strategy allowing a reasoned choice of curative ingredients (marinades ...) to mitigate the formation of HAs during the cooking of meat products and provide possible recommendations to minimize the formation of HAs during meat cooking and to reduce consumer exposure towards HAs.

Novel Aspect:

Easy rapid and repeatable extraction and purification method suitable for complex and fatty meat matrix combined with a sensitive and specific UHPLC-APCI-MS/MS assay method.

Title: A Study on Migration of Heavy Metals from Ceramics and Glassware using Inductively coupled plasma mass spectrometry(ICP-MS)

Authors: KyungChul Cho*, Yongchjun Park, Dongmi Choi, Meehye Kim

Topics: Food and beverage – Food additives and contaminants

Abstract type: Poster

Keywords: ICP-MS, heavy metal, glassware, ceramics

Introduction:

When ceramics and glassware come in contact with food, a migration of heavy metals such as lead and cadmium may occur [1]. The presence of heavy metals in foodstuff represents a crucial problem around the world. The risk associated with the exposure to heavy metals in food products had brought widespread concern in human health. This study investigated the migration level of heavy metals (lead, cadmium, arsenic and etc.) from food contact articles into a food simulant.

Methods:

All the food contact articles (80 ceramics and 80 glassware) were purchased in domestic markets around South Korea. The articles were eluted with a food simulant (4% acetic acid) for 24hr at 25°C in laboratory oven [2,3]. Heavy metals including lead and cadmium that migrated from articles into a food stimulant were analyzed by Inductively Coupled Plasma Mass Spectrometry (ICP-MS).

Results:

The migration levels of heavy metals in all the samples were compared with the migration limits of Ministry of Food and Drug Safety (MFDS) in South Korea.
(in progress)

Conclusions

Analytical methods were successfully validated by evaluating linearity, LOD, LOQ, precision (intra/inter-day) and recovery.

Novel Aspect:

The result of this study can be used as valuable data for the safety control of the food contact materials.

473 - ACRYLAMIDE DETERMINATION IN POTATO AND/OR CEREALS BASED FOOD BY LC-MS/MS METHOD: ONE YEAR OF MONITORING IN NORTH-WEST ITALY.

Valentina Ciccotelli (1) - Lucia Anna Masiello (1) - Valentina Savio (1) - Barbara Vivaldi (1) - Carlo Ercolini (1)

Istituto Zooprofilattico Sperimentale del Piemonte, Liguria e Valle D'Aosta, sezione di Genova, Genova (1)

Keywords: acrylamide, LC-MS/MS, carbohydrate-rich food

Introduction:

Acrylamide (2-propenamide) is a water-soluble molecule, which is formed by Maillard reaction during manufacturing or home-cooking of carbohydrate-rich food at high temperature [1], especially during browning process at temperature higher than 120°C, in food with high level of sugar and asparagine, like potato chips, French fries, crackers, bread, coffee and biscuit.

In 2002 the International Agency for Research on Cancer (IARC) classified Acrylamide in Group 2A as a probable human carcinogen [2], for this reason European Union established mitigation measures and reference levels for reducing the presence of acrylamide in food with the Regulation 2158/2017 [3].

The aim of this work was to develop and validate a method in LC-MS/MS coupled with QuEChERS approach to carry out a monitoring of processed foods in North-West Italy from 2017 to 2018.

Methods:

An aliquot (2 g) of ground rehydrated sample was homogenized with 10 ml of acetonitrile. A prepared mix of QuEChERS was added and shaken for 10 min. The organic phase was separated by centrifugation. An aliquot of upper layer was dried in water bath at 45°C and 120 mbar. The sample was dissolved in a volume of Milli-Q water and filtered through a 0,22 µm PES membrane into vial, ready for analysis in LC-MS/MS.

Analysis was performed by an HPLC Accela 1250 pump (Thermo Scientific). Chromatographic separation was obtained by a reversed-phase Kinetex Biphenyl (100 x 2.1 mm ID, 2.6 µm) (Phenomenex). The eluents were 0,1% formic acid aqueous solution (eluent A) and 0,1% formic acid in methanol (eluent B), the elution was carried out in isocratic mode (total run 7 min), at flow-rate of 200 µl/min at 20°C. The injection volume was 5 µl. Mass spectral analysis was performed on a TSQ Vantage triple quadrupole mass spectrometer (Thermo Scientific), equipped with a heated ion spray interface (HESI). Two mass transitions (72.1/55.1 and 72.1/27.4) were monitored for acrylamide, providing unequivocal identification of it and only one mass transition (75.3/58.6) was used for the internal standard (acrylamide-d3).

Method evaluation included: linearity, matrix effect, recovery, precision (as intra- and inter-laboratory RSD%) and LOQ, using certified reference materials (CRM) and spiked samples.

Results:

Method validation was performed at three concentration levels: 25 µg/Kg, 120 µg/Kg and 625 µg/Kg. For the first level, we used a cereal based baby food spiked with a standard solution of acrylamide, we decided to fix the LOQ at this level; for the second level a biscuit based CRM and for the last level a potato based CRM, to cover all matrices of routine samples.

Linearity was evaluated over the concentration range from 25 µg/Kg to 1000 µg/Kg by constructing a calibration curve in solvent. Matrix effect was verified by comparing the calibration curve in solvent with calibration curve in matrix-post for the matrices: potato chips, biscuits, flakes and mashed potatoes.

Fourteen samples of different cereals or potato based matrices were extracted and analyzed. The occurrence of possible interferences was tested by plotting the acrylamide selected-ion chromatograms at the relative retention time interval ($\pm 2,5\%$) expected for its elution. Satisfactory selectivity is achieved when area peaks was under 10% of medium area peaks of sample at LOQ in the corresponding retention time windows for the quantification SRM transition.

Intra- and inter-day precision were determined by assaying six replicates of sample at three concentration levels in two different analytical batches. Repeatability was calculated by applying the Horwitz equation and the acceptable criteria was based on this equation: intra-repeatability RSD = 0,66*inter-repeatability RSD[3].

The recovery was evaluated on the same samples and ranged from 90% to 101%.

Fifteen samples of crackers, chips, baked potatoes, rice cream for children, cereals, biscuits, bread, rusks were purchased on the North-West Italian market. Baby food, bread and rusks showed values lower than LOQ; the highest concentration of acrylamide was found in potato chips (average concentration of 600µg/Kg), the baked potatoes showed an average content of 269µg/Kg; breakfast cereals, biscuits and crackers had concentrations from 27 µg/Kg to 54µg/Kg.

Conclusions

The study describes a quick and easy method for acrylamide determination by QuEChERS approach coupled to LC-MS/MS.

Validation of this method fulfilling recoveries (90%-101%), and showing a good linearity (from 25µg/Kg to 1000 µg/Kg). Precision varies from 1,43% to 6,38% of intra-repeatability and from 3,73% to 10,36% of inter-repeatability.

The method was applied to food matrices such as crackers, chips, biscuits, bread, rusks and baby food. Results confirm that acrylamide was found in ordinary consumer products, this underlines the importance of these monitoring to ensure consumer health.

Novel Aspect:

There are relatively few methods in the scientific literature addressed to the analysis of acrylamide in processed food, baby food included. Our protocol distinctively combines simplicity of sample treatment but effective, applicability to very different matrices and compliance of the sensitivity requirements expected by European and Italian legislations.

454 - DETERMINATION OF PESTICIDES IN FRUIT, VEGETABLES AND FEED BY MULTIRESIDUE METHODS: ONE YEAR OF MONITORING IN NORTH-WEST ITALY.

Valentina Ciccotelli (1) - Raffaella Nappi (2) - Barbara Rutigliano (2) - Annamaria Galleggiante Crisafulli (2) - Elisabetta Poma Genin (2) - Enrico Alesso (3) - Barbara Vivaldi (3)

Istituto Zooprofilattico Sperimentale del Piemonte, Liguria e Valle D'Aosta, N.R.L. for pesticides in cereals and feed, sezione di Genova, Genova (1) - Istituto Zooprofilattico Sperimentale del Piemonte, Liguria e Valle D'Aosta (sezione di Cuneo), sezione di Cuneo, Cuneo (2) - Istituto Zooprofilattico Sperimentale del Piemonte, Liguria e Valle D'Aosta (sezione di Genova), N.R.L. for pesticides in cereals and feed, sezione di Genova, Genova (3)

Keywords: pesticides, cereals, fruit, vegetables, monitoring

Introduction:

Pesticides are used in various combinations at different stage of cultivation or postharvest storage, to protect crops against a wide range of pests and fungi or to provide quality preservation. Numerous monitoring studies have demonstrated the presence of pesticide residue and their degradation products (metabolites) on crops, in environments and in the diet. These residue levels are usually low, below of effective action and interaction is not expected to occur. At the same time, literature data indicate that presence of pesticide mixtures in food and feed could be a potential risk to human and animal health.

The aim of this study was to monitor pesticides in fruit, vegetables and cereals through using of screening-quantitative multiresidue methods (GC MS/MS and UHPLC MS/MS) developed and validated for selected analytes. The survey was conducted in North West Italy (from 2016 to 2017) and these regions constitute one of the main cultivation areas of Italy. In these areas the main crops were cereal grains, rice, corn, fruit, vegetables and vineyards.

Methods:

Screening quantitative multiresidue method (GC-MS/MS and UHPLC-MS/MS) were developed and validated for selected pesticides and their metabolites in fruit vegetable and cereals. The homogeneous sample was extracted with the help of acetonitrile. Samples with low content (<80%) require the addition of water before the initial extraction to get a total of approximately 10 g of water. After addition of magnesium sulfate, sodium chloride and buffering citrate salts, the mixture was shaken intensively and centrifuged for phase separation. An aliquot of the organic phase was cleaned-up by dispersive solid phase extraction (D-SPE) employing bulk sorbents as well as magnesium sulfate for the removal of residual water. Following clean-up with amino-sorbents (e.g. primary secondary amine sorbent, PSA) extracts were acidified by adding a small amount of formic acid, to improve the storage stability of certain base-sensitive pesticides. The final extract was carried out by GC- and LC-based determinative analysis.

In addition of these method a multi-residue quantitative method for the analysis of 103 gas-chromatography amenable pesticides in dry cereal based animal feed was developed. The method entails a simple extraction of the rehydrated sample with acidified ethyl acetate. The organic phase was then separated by centrifugation, after the addition of anhydrous sodium sulphate, and filtered prior the final determination by GC-MS/MS.

Two mass transitions were monitored for each pesticide, providing unequivocal identification of contaminants. Where the method didn't include any clean-up step, the choice of the mass transitions to be monitored was a key-point of method development. Detected pesticides were then quantified using triphenyl phosphate as internal standard.

Method validation was carried out according to European guideline document SANTE 11945/2015 [1]. All the parameters studied (specificity, linearity, matrix effect, LOQ, recovery, precision and ruggedness) met the criteria set in the guideline at the three different spiking levels investigated (0,010 – 0,050 and 0,10 mg/kg). Also expanded uncertainty of the result was calculated using a top-down approach as indicated in the Codex Guidelines on estimation of uncertainty of results (CAC/GL 59-2006 amendment 2011).

Results:

National monitoring results of the 2016 year have shown that nearly 48% of the foods sampled had no pesticide residues detected. Pesticide residues were detected in 52% of samples analyzed and the results showed a different distribution of active substances in the various commodity: 76% in fruit/vegetable, 33% in cereals and 80% in wine grapes/wine. The most frequently detected pesticide was fungicide and insecticide, followed by acaricide and herbicide. The study showed that pesticide residues exhibited a seasonal variation in terms of detection frequency and concentration, with spring and summer as critical seasons.

In particular N.R.L. for pesticides in cereals and feed analyzed 93 samples of feed and cereals, in 56 samples, from one to six pesticides were detected in quantifiable quantities (>LOQ 0.010 mg/Kg) but below the MRL (Maximum Residue Level).

The most common detected substances are: pirimiphos-methyl, most times associated with piperonyl-butoxide (used as preservative and not yet normated) and cis-deltamethrin.

While cypermethrin, chlorpyrifos-methyl, chlorpyrifos, endrin, malaoxon, desmediphamresmethrin, permethrin, azoxystrobin, fenazaquin and difeconazole were determined with less frequency. The most contaminated matrices are feed, rice and wheat.

Conclusions:

Pesticide residues were detected in different matrices examined at values below to the legal limit. Active substances were identified in high percent in fruit/vegetable and wine/wine grapes with fungicide and insecticide mainly detected. However, for national application in monitoring programs it is necessary to develop new methods in multi and monoresidue screening which cover a broad spectrum of pesticides and metabolites.

1136 - ROBUST MULTIRESIDUE PESTICIDE ANALYSIS IN BABY FOOD WITH ENHANCED SENSITIVITY GC-MS/MS TECHNOLOGY

Elena Ciceri (1) - Richard Law (2) - Tim Anderson (3) - Cristian I. Cojocariu (2)

Thermo Fisher Scientific, CMD, Milan (1) - Thermo Fisher Scientific, CMD, Runcorn (2) - Thermo Fisher Scientific, cmd, Austun (3)

Keywords: Pesticides, food, GC-MSMS, TSQ9000

Introduction:

Pesticides are widely used in food production and to control and manage various unwanted species. The detection, quantification, and confirmation of pesticide residue in food at trace levels require sensitive, selective and robust analytical instrumentation.

With ever increasing pressure to analyze contaminants at very low levels in a greater number of samples and with shorter turnaround times, laboratories seek continuous improvements in analytical instrumentation in order to maximize productivity and reduce downtime.

Methods:

This study describes an optimized sample extraction and the analysis of multi-residue pesticides in baby food using femtogram-level sensitivity on a Thermo Scientific GC-MS/MS system. Sensitive detection and quantification of pesticides in baby foods is of particular importance as infants are more vulnerable to adverse health effects from these chemicals than adults. In this work, commercially available fruit and vegetable based baby-food samples were subjected to an optimized QuEChERS extraction method to isolate the pesticide residues using acetonitrile as the final extraction solvent. Direct analysis of extracts in acetonitrile is desired to avoid the need for solvent exchange to a more GC amenable solvent. The QuEChERS extracts were then analysed for pesticide residue content using a fast, targeted, timed-SRM method for >200 pesticides (inclusive of priority pesticides). The performance of the method focused on assessing various quantitative parameters for analysis of over 200 pesticides.

Results:

The results show outstanding LODs (as low as 0.005 µg/Kg), robustness (over 900 matrix injections with no maintenance) and linear responses over up to 5 orders of magnitude (0.025 – 250 µg/kg) for the compounds investigated.

Conclusions The data presented in this study demonstrates unprecedented method performance from sample preparation to sensitive and robust GC-MS/MS analysis in addition to automated data processing and reporting capabilities.

1138 - SENSITIVE AND ROBUST DETERMINATION OF PHTHALATES IN COOKING OIL USING ADVANCED ELECTRON IONIZATION SINGLE QUADRUPOLE GC-MS TECHNOLOGY

Elena Ciceri (1) - Aaron Lamb (2) - Cristian I. Cojocariu (2)

Thermo Fisher Scientific, CMD, Milan (1) - Thermo Fisher Scientific, CMD, Runcorn (2)

Keywords: Pesticides, food, GC-MSMS, TSQ9000

Introduction:

Phthalates are emerging food contaminants linked to endocrine disruption through ingestion of foods exposed to these common plasticizers. Due to their endocrine mimicking properties, phthalates are considered as priority pollutants and various countries around the world have already introduced maximum acceptable levels in food contact materials (FCMs) for compounds such as DMP, DEP, DAP, DIBP, DBP, DXHP, BBP, DCHP, DEHP, DINP, DNOP and DIDP.

Phthalates are lipophilic in nature and the propensity for these compounds to leach from FCMs into food products such as cooking oils is significant. Oils are complex mixtures of triacyl glycerides that are difficult to chromatograph and present a challenge in terms of selectivity, sensitivity and robustness for GC-MS analysis of phthalates.

Methods:

With the innovative design of the new advanced electron ionization source however less frequency of source cleaning is required as the axial ionization in this source leads to increased ionization efficiency. This means the source filament can be operated at a reduced emission current which in turn means less ionization of complex matrices in the source reducing the cleaning interval.

Results:

The enhanced sensitivity of the new source down to low ppt levels (0.01 ng/mL) also means that the sample matrix can be diluted more or the split ratio can be increased which further reduces the amount of contamination in the GC flow path.

Here the use of a novel AEI high performance electron ionization (EI) source in conjunction with a new single quadrupole mass spectrometer provides the sensitivity and selectivity to analyze phthalates in cooking oil at low part per trillion (ppt) levels with low liquid injection volumes.

Conclusions:

In this work the Thermo Scientific™ ISQ 7000™ GC with Advanced Electron Ionization Source mass spectrometer was evaluated for phthalate selectivity, sensitivity, recovery, repeatability, robustness and linearity of response.

Austrian Agency for Health and Food Safety, Group for Contaminant and Special Analysis, Wien (1)

Keywords: pyrrolizidine alkaloids, fragmentation, isomers, food analysis

Introduction:

Pyrrolizidine alkaloids are natural toxins which are produced by numerous plant species and may contaminate food such as honey or herbal teas. This substance group exhibits a huge structural variety, which, however, can be clustered into several classes which share common structural elements. Several of these alkaloids are isomeric to one another, thus complicating their differentiation during food analysis.

Methods:

The analysis of pyrrolizidine alkaloids is commonly performed by LC-MS/MS. Therefore, the in-depth knowledge of their fragmentation behaviour is of great importance for a selective and sensitive analysis. The fragmentation patterns of more than 30 pyrrolizidine alkaloids were studied by low- and high-resolution mass spectrometry on a triple-quadrupole and a QTOF instrument. Food samples were analysed by LC-MS/MS utilising the previously obtained information.

Results:

The obtained product ion spectra and accurate masses of the fragments of the different pyrrolizidine alkaloid species allowed the deduction of the structures of the fragments and their assignment as characteristic product ions of certain pyrrolizidine alkaloid classes. These structural relationships will be presented and discussed in detail. It was observed that isomeric pyrrolizidine alkaloids – both stereoisomers as well as structural isomers – have all the same fragments; however, the relative abundancies of the different fragments were found to vary dramatically between the isomers. For a correct differentiation between these isomers in the course of the LC-MS/MS analysis a chromatographic baseline separation is essential, otherwise the obtained quantitative results will strongly depend on the ratio of the isomers and the analytes may fail common identification criteria based on MRM ratios. Results of real-life honey and herbal tea samples will be shown that highlight the need for a careful differentiation between the isomers.

Conclusions:

A detailed understanding of the fragmentation of pyrrolizidine alkaloids is of great value for a correct analysis of food products for these compounds. Stereoisomeric pyrrolizidine alkaloid species can exhibit significantly different mass spectrometric behaviours, thus calling for a sophisticated chromatographic separation to allow a careful differentiation between them in order to obtain a true picture of contamination levels in food products.

Novel Aspect:

The fragmentation behaviour of pyrrolizidine alkaloids was elucidated in detail and its impact on the correct determination of contamination levels in food demonstrated.

Keywords: Yeast cell wall; efficacy; zearalenone; toxicokinetic; piglets; biomarker.

Introduction

The use of yeast cell wall (YCW) derivatives as mycotoxin binders (MB) can be considered a promising approach to protect livestock against the harmful effects of mycotoxin exposure. Several in vitro studies confirmed the potential of YCW in binding mycotoxins. As in vitro studies do not always predict in vivo results, the European Food Safety Authority (EFSA) guidelines state in vivo trials are needed. This work was aimed to determine the in vivo efficacy of a YCW, obtained from Lesaffre International, in reducing oral bioavailability of zearalenone (ZEN) in piglets.

Methods

In order to investigate the in vivo efficacy of a YCW in reducing ZEN bioavailability, a toxicokinetic study focusing on the plasma concentration-time profiles of ZEN was performed. The study was conducted on 32 healthy 5-week-old piglets, sexes equally divided. The pigs were randomly allocated in 2 groups of 16 animals, a control group (C) (treated with a single oral bolus of 0.3 mg/kg BW ZEN) and a treatment group (T) (treated with a single oral bolus of 0.3 mg/kg BW ZEN in combination with the detoxifier).

Results

Plasma concentrations of ZEN were quantified with a validated LC-MS/MS method. Limit of detection (LOD) and limit of quantification (LOQ) were 0.1 and 0.5 ng/mL, respectively. As plasma concentrations of ZEN after oral administration were below the LOQ, ZEN-glucuronide was quantified as plasma biomarker for ZEN. Non-compartmental toxicokinetic modeling was performed using Phoenix 64 (Certara, USA). The effect of the mycotoxin detoxifier on the oral absorption of the mycotoxin was evaluated by statistical comparison of toxicokinetic parameters between the C and T groups, with special emphasis on area under the curve from time zero to infinite ($AUC_{0 \rightarrow \infty}$), maximal plasma concentration (C_{max}), time at maximal plasma concentration (T_{max}) and relative oral bioavailability (F).

The mycotoxin detoxifier significantly reduced oral ZEN absorption in piglets (pvalue < 0.05).

Conclusions

A YCW based product, produced at lab and industrial level, was selected after showing high efficacy in adsorbing ZEN in vitro. In vivo efficacy testing of the YCW based mycotoxin detoxifier revealed a significant reduction of ZEN oral bioavailability in piglets.

Novel Aspect

In vivo efficacy testing of a safe YCW based product to be proposed as detoxifier for reducing ZEN exposure, and consequently estrogenic effects of ZEN, in farm animals.

Acknowledgments

The present work has received funding by the European Union's Horizon2020 Research and innovation programme under Grant Agreement No.678781 (MycoKey).

1276 - EXPLOITING THE POTENTIAL OF HR-MS FOR DECIPHERING MYCOTOXIN MODIFICATION IN MICROPROPAGATED WHEAT: THE CASE OF DEOXYNIVALENOL

Tito Damiani (1) - Laura Righetti (1) - Enrico Rolli (2) - Michele Suman (3) - Renato Bruni (1) - Chiara Dall'Asta (1)

University of Parma, Department of Food and Durg, Parma, Italy (1) - University of Parma, Department of Biosciences, Parma, Italy (2) - Barilla G.R. F.lli SpA, Advanced Laboratory Research, Parma, Italy (3)

Keywords: deoxynivalenol, wheat, metabolism, HRMS, untargeted

Introduction

Deoxynivalenol (DON) is a mycotoxin produced by *Fusarium* spp. Plants mechanisms to counteract mycotoxins include phase I and II reaction. The resulting modified forms have different structures and chemical formulas, making difficult their detection by routine analytical approaches. In this study, liquid chromatography coupled to high resolution mass spectrometry (LC-HRMS) was employed to identify DON metabolites produced by in-vitro micropropagated wheat plantlets.

Methods

Two wheat varieties (Kofa and Svevo) were grown in a DON-spiked medium. After 14 days, media and plant samples underwent to LC-HRMS analysis. DON absorption and translocation to the aerial part were evaluated. Phase I and II metabolites were hypothesized, respectively, by Sites of Metabolism (SOM) prediction and based on the known plant detoxification pathways. Their identification was achieved using accurate mass, isotopic pattern and HRMS/MS spectra.

Results

At the end of the experiment, in vitro plantlets showed no visible damages. After 14 days, a reduction of 10% and 30% of DON was observed in the growing media of Kofa and Svevo, respectively. The more efficient DON absorption of Svevo is in accordance with previous results [1].

Quantification of DON was carried on different plant organs to evaluate the mycotoxin absorption and translocation. In the plant material, an extensive conversion of the DON into its conjugate forms, among them DON-3-Glucoside (DON-3-Glu) and other analogues, was observed.

Untargeted profiling was carried out to identify the DON biotransformation products. Metabolites annotation was performed as already proposed by other authors [2]. Full identification was achieved when commercial standards were available. For the remaining DON metabolites, they were putatively identified considering accurate mass, isotopic pattern distribution and the comparison between experimental and in silico predicted fragmentation pattern (<http://cfmid.wishartlab.com>).

Conclusions

Although the conditions applied do not represent the complexity of an actual environment, in vitro wheat culture has proved to be suitable for the investigation of mycotoxin metabolism in plant.

Svevo showed a larger DON absorption from the growing medium. However, no considerable differences were observed in the DON-3-Glu conversion ability, between the two varieties.

A considerable number of the hypothesized metabolites was identified through the untargeted LC-HRMS analysis.

Novel Aspect

The integration of in-vitro plant cultures and HR-MS is an effective workflow for the elucidation of the metabolic fate of mycotoxins and other xenobiotics.

Keywords: Pyrrolizidine alkaloids, bee pollen, LC-MS/MS, food safety

Introduction:

Pyrrolizidine alkaloids (PAs) and their N-oxides (PANOs) contamination in foodstuffs and dietary supplements, such as honey and bee pollen, represents a potential health risk for consumers. This study aimed the development and validation of an LC-MS/MS method to quantify PAs/PANOs levels in bee pollen samples coming from local beekeepers (LB; Veneto/ Italy), great retail and web (GR).

Methods:

The developed method was validated according to the Commission Decision 2002/657/EC. For this purpose, blank bee pollen samples were spiked with 17 PAs/PANOs standard solutions at three levels (2, 10 40 µg/Kg). PAs and PANOs were extracted from pollen using PLEXA cartridges (200 mg/6 mL, Agilent, USA) and the LC-MS/MS analysis was conducted on an LTQ-XL Ion trap operating in positive ion mode.

Results:

All results obtained for recovery, linearity, repeatability and reproducibility in the validation study were in agreement with the limits reported by Decision 2002/657/EC. The limit of quantification was 0.4 µg/kg for all analytes. The validated method was applied to 81 bee pollen samples, of which 50 were positive: 20 were from LB and 30 from GR. The average total concentration of PAs/PANOs in samples from LB and GR were 27.8 µg/kg and 470.9 µg/kg, respectively. The identified PAs/PANOs could be categorized into three classes and their average concentrations were as follows: Eupatorium-Type 42.90 µg/kg (LB) vs. 162.76 µg/kg (GR); Echium-Type 7.46 µg/kg (LB) vs. 465.54 µg/kg (GR); Senecio-Type 16.24 µg/kg (LB) vs. 176.62 µg/kg (GR). Most samples (17) from LB presented Senecio-Type PAs/PANOs, whereas most samples (24) from GR presented Eupatorium-Type PAs/PANOs.

Conclusions:

The validated LC-MS/MS method showed to be sensitive and suitable for the quantification of the 17 selected PAs/PANOs markers in bee pollen. Samples from LB and GR presented a very different PAs/PANOs contamination profile reflecting their different botanical and geographical origin. The average total concentration of PAs/PANOs was 17 times lower in samples from LB than in those from GR.

Novel Aspect:

This study should highlight any hazard due to the import/export of pollen and suggest management strategies to beekeepers to ensure a healthy product.

Keywords: UPLC-HRMS; foodomics; contaminants; chemometrics; trace analysis

Introduction

Ensuring food safety remains a major public health issue. Recent food safety crisis (i.e. eggs contaminated by fipronil in Europe) clearly illustrated the limits of analytical targeted approaches. The need for untargeted approaches has recently merged, especially for detecting non expected contaminants [1]. These new approaches raise many analytical challenges, due to contaminants diversity, low-levels concentrations ($\mu\text{g}/\text{kg}$) and food matrices complexity.

Methods

An untargeted foodomics approach was developed for blind food chemical contaminants detection. It relies on four pillars from metabolomics and chemometrics: (i) a broad-range UHPLC-HRMS method based on minimal sample treatment; (ii) feature detection based on XCMS and data cleaning tools; (iii) blind discrimination of sample groups by Independent Component Analysis; (iv) powerful data exploration strategies for annotation of suspect compounds.

Results

Tea has been chosen as a development food matrix since it is the most consumed hot beverage over the world, offering a high diversity and complexity as well. The proof-of-concept was initially developed on a rather simple case (known contaminants characterizing the potential diversity at different levels with a homogeneous matrix), and then successfully applied on more complex cases, such as the detection of an unknown contamination or the simultaneous analysis of samples from different brands of black and green tea. Efficient data filtration, normalization and scaling strategies are key issues since a discerning choice of tools enables a blind discrimination between control and spiked sample groups at levels as low as $10 \mu\text{g}/\text{kg}$, as well as the detection of unexpected contaminants. Annotation step appears to be the main challenge, but in-house data mining tools are key factors to reduce data complexity and also provide the user a quick feedback about potential identity or property (presence of an isotope or potential adduct) of unexpected compounds.

Conclusions

In this work, a metabolomics-like strategy was set up to detect and characterized a contamination in complex food samples at level down to $10 \mu\text{g}/\text{kg}$. On top of that, the approach, based on open and free tools, was shown to have the capability to detect unexpected contaminants, which is critical for future chemical food safety assessment. No doubts that our results will encourage the development of such strategies for chemical food safety assessment within the next years.

Novel Aspect

We propose an original methodology for untargeted food safety assessment (down to $10 \mu\text{g}/\text{kg}$) validated on several contamination scenarios for a complex real food matrix (tea).

1303 - SENSITIVE MASS SPECTROMETRIC METHOD FOR THE DETECTION OF PALYTOXINS IN SHELLFISH USING LITHIUM CATIONIZATION

Arjen Gerssen (1) - Mirjam D. Klijnstra (1)

RIKILT, Wageningen University and Research, Wageningen, Netherlands (1)

Keywords: Cationization, palytoxins, food safety

Introduction

Palytoxins (PITXs) are produced by marine dinoflagellates, cyanobacteria and certain corals and is a neurotoxic compound that can end-up in shellfish. PITXs are within the classes of marine biotoxins the largest non-protein molecules with m/z 2700. To protect shellfish consumers EFSA established an acute reference dose of 0.2 $\mu\text{g}/\text{kg}$ b.w. which can be translated to 30 μg PITX-eq/kg shellfish (400g shellfish by 60kg person). Sensitive methods for analysis are lacking.

Methods

Shellfish homogenate was extracted in triplicate with 50:50 v/v water/methanol. Subsequently extracts were purified with SPE clean-up. For the LC chromatographic separation a Phenomenex Kinetex (2.1 x 100 x 1.7) column was used. Mobile phases consisted out of 0.25mM LiI and 0.31mM formic acid in water and 0.25mM LiI and 0.31mM formic acid in 90% acetonitril. The LC effluent was directed into a Q-Orbitrap-MS or tandem quadrupole MS both equipped with ESI operating ESI+.

Results

When analysed by mass spectrometry complex spectra are obtained with multiple adducts, charges states and in source water losses. To gain sensitivity there was attempted to simplify the spectrum by the formation of lithium adducts. Without the addition of lithium in the mobile phase the most abundant ion present is less than 30% of the sum of all ions formed. However with the addition of lithium the main adducts formed were $[\text{M}+\text{H}+2\text{Li}]^{3+}$ and $[\text{M}+\text{H}+\text{Li}]^{2+}$ where the abundance of $[\text{M}+\text{H}+2\text{Li}]^{3+}$ was around 60% of the total abundance of all ions formed. In MS/MS the most abundant fragments are mainly due to losses of H_2O . Also more structural fragments were obtained, the most sensitive transition is $[\text{M}+\text{H}+2\text{Li}]^{3+}$ m/z 897.8 > 1215.7. When measured with MS/MS the method has an LOQ of 1 ng/mL for a standard solution. Subsequently the method was successfully validated for PITX in shellfish at levels of 10, 30 and 60 μg PITX/kg.

Conclusions

A sensitive method based on cationization with lithium for the detection of PITXs in shellfish was developed. Subsequently the method was validated with good recoveries (70-120%) and repeatability RSDs below 20%. The method described is a novel method for the detection of intact palytoxins in shellfish which can measure these compounds at the relevant levels ($\mu\text{g}/\text{kg}$ range).

Novel Aspect

Application of cationization in the field of marine biotoxin research for the development of an intact palytoxin LC-Q-Orbitrap and LC-MS/MS method.

519 - THE SWEET DEAL OF ADDING ION MOBILITY TO FULL SCAN ACQUISITIONS TO PROFILE STEVIOL GLYCOSIDES KNOWN AND KNOWN-UNKNOWN IN FOOD MATRICES

S verine Goscinny (1) - M lanie Herman (1) - Els Van Hoeck (1) - Mike McCullagh (2)

Sciensano, Organic Contaminants and Additives, Brussels (1) - Waters Corporation, Science Operations, Wilmslow (2)

Keywords: Steviol glycosides, isomers, Collision Cross Section (CCS), ion mobility spectrometry (IMS), known-unknowns

Introduction:

In 2011, the EU authorised steviol glycosides as a sweetener food additive (E960), its natural origin is key to success in the food market. Like many botanical extracts, E960 is a complex mixture of compounds, with diverse physico-chemical/organoleptic properties and is a challenge to analyse. Hence its characterisation in complex food matrices requires a variety of analytical tools. Here, we present a simple screening method using ion mobility mass spectrometry.

Methods:

For the assays, RP-C18-Ion Mobility-HRMS analyses were performed on a Synapt G2-Si using standard solutions and real samples. The sample treatment comprises the extraction of the steviol glycosides, followed by C18-SPE clean-up prior to analysis. Mass spectra were collected from m/z 50 to 2000 (resolution 20000 FWHM). The mobility drift gas used was nitrogen and mobility cell calibration was carried out using poly-DL-alanine.

Results:

From the analysis of steviol +10 steviol glycosides standards, CCS values, Rt, and fragmentation patterns were derived for precursor, formate adducts and labile fragments ions. These results were entered into a screening library. Regardless of the molecular complexity of the food additive, co-eluting critical pairs were ion mobility resolved. Using the method, E 960 was profiled in food matrices. The results show the efficiency of CCS values in simplifying the screening workflow, while other isomeric steviol glycosides were detected. Characterization of these known-unknowns without standards was performed using IMS. Drift time aligned fragment spectra, confirmed the origin of the fragment ions and in combination with Zimmermann [1] fragmentation rules, sugar moiety positions were identified. These compounds were inserted into the library and used for retrospective analysis. The CCS specificity of known-unknowns enabled the distinction of multiple isomers within complex mixtures of food extracts, providing enhanced profiles.

Conclusions

Using IM-HRMS analysis methodology, multiple identification parameters for the same steviol glycoside have been determined. As a result, the screening workflow has been drastically simplified and successfully applied to the analysis of a variety of food matrices containing the E 960 food additive. The additional CCS metric has enhanced confidence in identification of steviol glycosides at trace levels, which is critical considering the sweetness potency of E 960.

Novel Aspect:

This work demonstrated the benefits of combining ion mobility to full scan acquisitions to build a comprehensive screening analysis, even when standard references are unavailable.

1084 - CHARACTERISATION AND QUANTIFICATION OF KNOWN/UNKNOWN MIGRATING SUBSTANCES IN FOOD USING LC & GC HIGH RESOLUTION MASS SPECTROMETRY

Yves-Alexis Hammel (1) - Baptiste Bodet (1) - Sander Koster (1)

Nestle Research Center, Institute Food Safety & Analytical Science, Lausanne (1)

Keywords: Food Contact Material, Mass Spectrometry, semi-quantitation, food simulant

Introduction:

A method was developed that enables to 1) detect and categorise known and unknown migrating substances from packaging into food, 2) to semi-quantify these known and unknown substances using CAD and FID and 3) define an exposure threshold of unknown substances above which these will be identified. The methodology is applied to packaged food in comparison with measurements performed in so-called food simulants.

Methods:

The developed approach consists of a QuEChERS extraction applied to the food sample and a migration with food simulant of the corresponding empty packaging. Then the extracts are analysed using GC-FID/PCI-HRMS and LC-CAD-HRMS. A semi-quantitation based on FID and CAD detection is applied. LC-HRMS and GC-PCI are used for identification purpose.

Results: A process was developed that enables to classify detected substances into known and unknown substances that migrate from the packaging material into food. Using our quantification/exposure based method, it is possible to focus on substances that are relevant to be considered for risk assessment.

Conclusions

The strategy for sample preparation of unknown substances will be presented together with measurements in food and food simulant. Levels of migrating substances in food will be compared with those in simulant which helps to mitigate the concern of these migrating molecules in the risk assessment of packaging materials.

Novel Aspect:

The approach allows to analyse known/unknown migrating substances in food giving real levels of migrating molecules in contrast to approaches used today that rely on food simulants.

Metabolomics, Untargeted Mercapturic acid, 4-HNE

Introduction:

The link between food-toxic effect and disease occurrence requires, the most complete characterization of exposure. In food safety, consumption data crossed with food contamination data or biomonitoring data allow evaluating exposure only in a targeted way. Based on our previous results in exposomic [1], food or environmental toxicology should focus on mixture of compounds, mostly at low doses, and in an untargeted way to identify unknown compounds.

Methods:

We developed an untargeted method to profile electrophilic metabolites which are most of the time toxic, due to their chemical reactivity towards bio-molecules such as DNA. The main line of cellular defense against that is the conjugation to the tripeptide glutathione, which is metabolized in mercapturic acid conjugate to be excreted into urine. Therefore, mercapturate conjugates were monitored through their characteristic neutral loss observed in MS/MS.

Results:

This approach was applied to the study of different groups of rats fed diets containing various oils. According to our previous results on lipid peroxidation [2] these diets led to the production of different aldehydes conjugated to mercapturic acid. The most famous is DHN-MA which corresponds to the mercapturate conjugate of 4-hydroxynonenal (4-HNE), which is commonly used as a biomarker of lipid peroxidation [2]. Using our methodology, we were able to detect without a priori, dozens of mercapturate conjugates, including DHN-MA and other known conjugated aldehydes. Furthermore, our approach also allowed the detection of conjugates of unexpected aldehydes, and of other chemical classes, for which putative identifications have been proposed based on complementary structural analyses. Interestingly, multivariate statistical analyses of the HRMS signals carried out on the mercapturate conjugates yield a better characterization of the studied animal groups compared to results obtained from a classic untargeted metabolomic approach.

Conclusions

Using the "all ions MS/MS" mode (MSE) of a Synapt G2-Si mass spectrometer it is possible to detect all the metabolites displaying the characteristic loss of a mercapturate conjugate, which represents a reactive metabolites. Thus, among these numerous metabolites representative of our exposure, it seems possible by our approach to focus on toxic ones.

Novel Aspect:

We developed an untargeted profiling method of mercapturate conjugates, which are representative of reactive metabolites in our exposome.

808 - FAST AND AUTOMATIC DATA PROCESSING FOR TARGETED AND NON-TARGETED PESTICIDE ANALYSIS

Julia Jasak (1) - Jasmin Meltretter (1) - Jianru Stahl-Zeng (1) - Vanaja Raguvaran (2) - David Cox (2)

SCIEX, Germany, Darmstadt (1) - SCIEX, Canada, Concord (2)

Fast and Automatic Data Processing for Targeted and Non-targeted Pesticide Analysis

Jasmin Meltretter, Jianru Stahl-Zeng, Vanaja Raguvaran, David Cox, Julia Jasak
SCIEX, Darmstadt, Germany
SCIEX, Concord, Canada

Pesticides are widely used in agriculture, growing of fruit and vegetables, and in lots of garden plots. The main aims are to protect the crops from pests and to control the growth of unwanted plants, both to minimize crop loss. The use of pesticides is strongly regulated to ensure that any hazards for humans, animals, and the environment are minimized. To monitor pesticide residues in food, LC-MS/MS in combination with QuEChERS sample preparation is today the method of choice for the majority of the relevant pesticides. With the SANTE/11813/2017 document, the European Commission published specific guidelines on quality control and validation procedures for analytical methods for pesticides in food and feed. In order to analyze more than 1000 pesticides, powerful data processing software, which ensures fast and easy data review, is strongly demanded by routine food testing labs.

The new SCIEX OS 1.4 software makes the data processing fast and easy. It includes powerful features like the automatic outlier removal feature, which will automatically fit the regression type and remove standard outliers from the calibration curve based on regression fit, accuracy, precision of replicates, and a user-defined outlier tolerance. This automatism tremendously reduces the time to check the calibration curves for all analytes.

Furthermore, the pesticide data have to be reviewed in accordance to the SANTE/11813/2017 document. All identification requirements of this guideline for both unit mass resolution and accurate mass measurement including retention time, mass accuracy of two ions and their specific ion ratio can be easily and fast reviewed in the software using a user-friendly traffic light system.

The SCIEX OS 1.4 software supports both QTOF data acquired with the SCIEX X500R QTOF system and the SCIEX TripleTOF® system and unit mass resolution data acquired with a SCIEX QTRAP® or SCIEX Triple Quad™ system.

SCIEX OS software 1.4 is perfectly fit for the analysis of pesticides in compliance with EU regulations.

173 - SIMULTANEOUS DETERMINATION OF PROPOXYCARBAZONE AND ITS METABOLITE IN FOOD BY UHPLC-MS/MS, APPLYING A QUECHERS EXTRACTION BASED METHOD

Marta Vargas Pérez (1) - Jesús Marín Sáez (2) - María Luisa Jiménez Medina (1) - Francisco Javier Egea González (1) - Antonia Garrido Frenich (1)

University of Almería, Almería/Dept. Chemistry and Physics, Almería (1) - Univeristy of Almería, Almería/Dept. Chemistry and Physics, Almería (2)

Simultaneous determination of propoxycarbazone and its metabolite in food by UHPLC-MS/MS, applying a QuEChERS extraction based method

Marta Vargas-Pérez, JesúsMarín-Sáez, María Luisa Jiménez Medina*, Francisco Javier Egea González, Antonia GarridoFrenich

Research Group "Analytical Chemistry of Contaminants", Department of Chemistry and Physics, Research Centre for Agricultural and Food Biotechnology (BITAL), University of Almeria, Agrifood Campus of International Excellence, ceiA3, E-04120 Almeria, Spain. Email: mjm696@inlumine.ual.es; grassmarta@gmail.com

Keywords: Propoxycarbazone, metabolite, 2-hydroxy-propoxycarbazone, QuEChERS, UHPLC-MS/MS

Introduction:

Nowadays, it is of great importance the monitoring of parent compounds as well as potential metabolites, otherwise the effects of the use of chemicals would not be fully studied. The analysis of pesticide residues including metabolites in food matrices is a challenge, especially due to the low concentration of analytes and the large quantities of interfering substances that can be coextracted.

Methods:

For the extraction of the compounds, several modifications were performed to the acetate-buffering QuEChERS method [1] depending on the commodities tested (lettuce, beetroot, honey and soybean meal). For analyte determination, ultra high performance liquid chromatography coupled to a triple quadrupole mass spectrometry analyzer was used. In addition, the cleaning stage was optimized, evaluating the effect of several sorbents, as well as the effect of the matrix during the quantification stage.

Results:

The suitability of the method for the analysis of the target compounds in the different commodities was properly validated according to the SANTE document. [2] Linearity was evaluated using matrix matched standard calibration by analyzing spiked blank samples of each of the matrices under study at six concentration levels (from 5 to 200 µg/kg). R² was 0.99 in all the tested matrices. Lettuce and beetroot did not show significant matrix effect; however, honey and soybean meal have shown a strong matrix-effect. Recovery and precision was studied at two concentration levels (10, 50 µg/kg), obtaining adequate recoveries (73-110%), intra-day (4 - 19%) and inter-day precision (5 - 20%). The limits of detection (3-6 µg/kg) and quantification (10-25 µg/kg) were lower than the maximum residue limits (MRLs) [3] in the matrices evaluated. The validated method was applied to the analysis of 20 samples, but residues of target compounds were not detected in any of the samples analyzed.

Conclusions

The modified QuEChERS approach followed by clean-up in combination with liquid chromatography coupled to triple quadrupole method provided suitable selectivity and sensitivity for the simultaneous determination of propoxycarbazone and its metabolite in lettuce, beetroot, soybean meal and honey. The method is appropriate for routine monitoring of residues in vegetables, cereals and food samples to ensure food safety.

Novel Aspect:

This is the first method that includes the simultaneous determination of propoxycarbazone and its metabolite in foodstuffs, as it is established by regulations.

406 - SENSITIVE DETERMINATION OF TOXIC PYRROLIZIDINE ALKALOIDS IN SPICES AND CULINARY HERBS USING LIQUID CHROMATOGRAPHY TANDEM-MASS SPECTROMETRY

Florian Kaltner (1) - Michael Rychlik (2) - Manfred Gareis (1) - Christoph Gottschalk (1)

Chair of Food Safety, Ludwig Maximilian University of Munich, Oberschleissheim (1) - Chair of Analytical Food Chemistry, Technical University of Munich, Freising (2)

Keywords: pyrrolizidine alkaloids, spices, culinary herbs, method development, tandem mass spectrometry

Introduction:

1,2-dehydropyrrolizidine alkaloids (PA) and their N-oxides (PANO) are phytotoxins with hepatotoxic and mutagenic potential. PA presumably occur in plant species worldwide and are responsible for various recorded food and feed poisonings. Main source of consumers' exposition is food contaminated with seeds, pollen, nectar or parts of PA plants. Especially (herbal) tea infusions, food supplements, honey and, recently, spices can be contaminated with PA [1].

Methods:

In total, 210 samples of spices and culinary herbs from Europe, Asia, Africa and America were investigated for occurrence of overall 49 PA. Therefore, a sensitive LC-MS/MS method was developed and validation was done for each group of spice and culinary herb matrices. Samples were extracted under acidic conditions and extracts were cleaned using strong cation exchange cartridges. Quantification was performed via external matrix-matched calibration.

Results:

The method allowed the analysis of 49 PA within a total runtime of 16.0 min after a 6.5 min equilibration of the column. Limits of detection (LOD) and quantification (LOQ) ranged from 0.01 to 0.17 µg/kg and from 0.03 to 0.54 µg/kg, respectively. Precision of the method, expressed as the coefficient of variation of a six-fold determination of respective samples, was 0.9 % and 8.0 % for all analytes, except merepoxine and merenskinine and their N-oxides. Obtained recoveries lay between 45.1 % and 118.4 %, only single PA showed outlier data.

After the investigation of 151 of the 210 samples, in 60.3 % at least one PA was found. The obtained sum levels of PA-contamination ranged from 0.13 µg/kg in a rosemary sample to 24.62 mg/kg in an oregano sample. Including all positive samples, mean PA-sum level was 967.62 µg/kg. The most abundant detected PA in the samples were europine/-N-oxide, heliotrine/-N-oxide and lasiocarpine/-N-oxide, which occur in plants of *Heliotropium* spp., a genus of the Boraginaceae family[2].

The final results will be reported.

Conclusions:

A LC-MS/MS method for the analysis of 49 PA in spices and culinary herbs was developed and validated. The applicability was successfully proven by investigating 210 samples of different origins. The study showed that spices could contribute to the overall exposition to PA/PANO. However, this contribution is generally quite low due to the small daily intake of herbs and spices in comparison to other food commodities.

Novel Aspect:

The developed method is the first target LC-MS/MS method being able to quantify 49 different PA and which was applied to a representative number of spice and culinary herb samples.

745 - ANALYTICAL METHOD DEVELOPMENT OF MULTI RESIDUE PESTICIDES IN LIVESTOCK PRODUCTS BY GAS CHROMATOGRAPHY-MASS SPECTROMETRY(GC-MS/MS)

Hye Soon Kang (1) - Eun Jeong Kim (1) - Moo-Song Lim (1) - Eun Jung Chang (1) - KiMi No (1) - Dong me Choi (1) - Hyun-cheol Choi (1)

Gyeongin Regional Office of Food and Drug Safety, Division of Hazardous Substances Analysis, Incheon (1)

Analytical method development of multi residue pesticides in Livestock Products by Gas chromatography-mass spectrometry(GC-MS/MS)

Hye Soon Kang, Eun Jeong Kim, Eun Jung Chang, Moo-Song Lim, KiMi No, Dong me Choi and Hyun-cheol Choi

Introduction

The Gas chromatography-mass spectrometry(GC-MS/MS) multi-residue method for the analysis of 55 pesticides in livestock products has been developed. The monitoring of pesticide residues in food is nowadays a priority objective in order to get extensive evaluation of food quality and to avoid possible risks to human health. The pesticides included in this study belong to different chemical families of insecticides, herbicides, fungicides and so on. GC-MS is rapidly becoming an accepted technique in pesticide residue analysis for regulatory monitoring purposes. This survey was aimed to establish for determination of multi-residue method for 55 pesticides in commercial livestock products by GC-MS/MS.

Method

Briefly, the homogenized samples were mixed with 1% acetic acid in acetonitrile. The mixture was vigorously shaken, then added sodium chloride and MgSO₄ repeated the shaking process, and cleanup. After a centrifugation step, the resulting extract with solid-phase extraction using Florisil cartridge. The extracts were transferred to vials for analysis by GC-MS/MS. Pesticides were confirmed by their retention time and multiple reaction monitoring of three fragment ions by GC-MS/MS.

Results & Conclusions

Recovery, precision, accuracy, linearity, limit of determination (LOD), and limit of quantification (LOQ) in the analytical method were validated in different matrices(Pork, Beef, Chicken, Egg, Milk). Calibration curves were linear for most of the compounds studied. The recoveries obtained at fortified levels of 0.001~0.05 mg/kg were 60~120%, with relative standard deviations (RSDs) of $\leq 30\%$, with a few exceptions. This method we have developed can quickly and accurately analyze 55 kinds of pesticides used in livestock products. The methods will be proposed in the Korean Food Standards Codex as the analysis of residual pesticides in livestock products.

Novel Aspect

A GC-MS/MS multi-residue method for the simultaneous analysis of 55 kinds pesticides in livestock products .

600 - LIMITATIONS OF GAS CHROMATOGRAPHY–SINGLE QUADROPOLE MASS SPECTROMETRY IN THE IDENTIFICATION OF COMPOUNDS MIGRATING FROM FOOD CONTACT MATERIALS

Csaba Kirchkeszner (1) - Zsuzsanna Eke (1) - Zoltán Nyiri (1) - Noémi Petrovics (1)

Joint Research and Training Laboratory on Separation Techniques, Eötvös Loránd University, Budapest (1)

Keywords: food contact materials, migration, GC-EI-Q-MS, GC-EI-TOF-MS, non-intentionally added substances

Introduction:

Plastics are commonly used for food packaging. From these plastics potentially hazardous compounds can migrate into the food. It is difficult to establish the chemical structure of migrated compounds especially for the non-intentionally added ones. They are often detected with GC-EI-Q-MS and identified using NIST database without any further confirmation [1]. But to what extent can such results be confirmed?

Methods:

The ability of GC-EI-Q-MS to identify migrating compounds was tested using plastic food contact materials (FCM). Degradation and migration into a food simulant was assisted with microwave radiation. The extracts were analyzed by GC-EI-Q-MS. Preliminary identification of the migrants was based on the obtained mass spectra and a NIST library search. Confirmation was attempted using GC-EI-TOF-MS measurements and analytical reference materials, if available.

Results:

As a result of the microwave irradiation of the polypropylene samples plenty of compounds were formed and migrated to 90 V/V% isooctane and 10 V/V% ethanol (solution for simulating fatty food). With GC-EI-Q-MS at least four compounds could be detected for all 26 samples. Using the NIST mass spectral database 11 different compounds could be preliminarily identified with good matching factors (>80%). Out of these, 8 could be confirmed with GC-EI-TOF-MS with less than 5 ppm mass difference for all occurrences. On the other hand the Irgafos 168 – a commonly used antioxidant – and a degradation of it was found in 24 cases with relatively low matching factors (40–55%). All these occurrences could however be confirmed with both GC-EI-TOF-MS and analytical reference materials. Furthermore another common antioxidant, the butylated hydroxyl toluene (BHT) was first identified in 12 samples, but always under 70%. All these samples also contained its degradation product that was consequently misidentified with the NIST library search.

Conclusions

Our results prove that the GC-EI-Q-MS is a powerful tool in the detection of compounds migrating from FCM. However, identification of these compounds cannot reliably be based solely on a NIST mass spectral database search even though it is a rather widely used approach. Reliability of the identification can notably be improved with GC-EI-TOF-MS and analytical reference materials.

Novel Aspect:

The identification of semi-volatiles migrating from FCM is often based on mass spectra of a single type of MS. Reliability of this approach is questionable.

960 - MULTI-ANALYTE METHOD BASED ON LIQUID CHROMATOGRAPHY COUPLED WITH SINGLE QUADRUPOLE MASS ANALYZER FOR FAST AND EFFECTIVE CONTROL OF FOOD ADDITIVES

Ales Krmela (1) - Vera Schulzova (1) - Jana Pulkrabova (1) - Jana Hajslova (1)

UCT Prague, Department of Food analysis and nutrition, Prague (1)

Keywords: food additives; liquid chromatography; mass spectrometry

Introduction:

Food additives are widely employed by food industry to provide number of benefits. The use of food additives is regulated, for some of them maximum limits have been established. To control safe use of food additives and protect consumers' health, effective methods are needed. In line with current trends, this study was performed to replace number of 'conventional methods' based on LC-UV by multi-analyte method employing MS detector with single quadrupole analyzer.

Methods:

Presented method uses an ultra performance liquid chromatography (UPLC Acquity, Waters) coupled to a simple single quadrupole MS (QDa, Waters) using a gradient of 5 mM aqueous solution of ammonium acetate and methanol while separating analytes on reversed phase BEH C18 column (Waters).

Results:

The developed method enables simultaneous determination of number of synthetic food additives fairly differing in physicochemical properties. Synthetic dyes, sweeteners, preservatives and several other compounds, vanillin, ethyl vanillin, theobromine and caffeine, were involved on the analytes list. Method was validated for sweet drinks and fruit concentrates. Repeatability, expressed as relative standard deviation (RSD), is less than 10 % for all analytes with recovery ranging from 80 to 120 %. Limits of quantification range from 0.1 to 1 µg/mL which is still considerably lower than legislation limits for food additives which are often ten or hundred times higher. Considering all, QDa seems to be a suitable detector for this kind of analysis. Method was applied for the analysis of fruit concentrates and fruit wines revealing a wide use of food additives.

Conclusions:

QDa MS is an appropriate tool for rapid screening of synthetic food additives of which analyzed samples contained a significant amount despite not exceeding legislative limits.

Novel Aspect:

Presented method enables simultaneous determination of 19 synthetic food additives fairly using a relatively cheap and simple single quadrupole MS.

716 - AFLATOXIN M1 RESIDUES DETECTION IN MILK, INFANT FOOD AND CHEESE BY LC-MS/MS

Gian Luca Ferro (1) - Stefania Massafra (1) - Paola Stella (1) - Enrico Pennazio (1) - Marta Leporati (2) - Daniela Marchis (2) - Marilena Gili (1)

Istituto Zooprofilattico Sperimentale del Piemonte, Liguria e Valle d'Aosta, S.S. Ricerca Residui, Torino (1) - Istituto Zooprofilattico Sperimentale del Piemonte, Liguria e Valle d'Aosta, S.S. Igiene dei Mangimi, Torino (2)

Keywords: Aflatoxin M1, milk, food safety, LC-MS/MS

Introduction

Aflatoxins are mycotoxins produced by some species of *Aspergillus*. In dairy cows, ingested Aflatoxin B1 is metabolized into Aflatoxin M1 (AFM1), which is eliminated through milk. Due to its high hepatocarcinogenic potential, the level of AFM1 permitted is strictly regulated: EU Commission has established a maximum limit of 0.050 µg/kg for AFM1 in milk and a more restrictive limit of 0.025 µg/kg in milk and food intended for consumption by nursing infants and children [1].

Methods

First, a liquid-liquid extraction (LLE) was performed on 20 g sample. As extraction solvent, ethyl acetate was chosen for milk and dichloromethane for infant food, dessert and cheese. A delipidation was needed for creamy infant food and cheese. LC-ESI-MS/MS analysis was carried out using a Zorbax SB Phenyl RRHT column (2.1 x 50 mm, 1.8 µm). The method was fully validated as screening assay; the validation as confirmatory quantitative analysis is in progress.

Results

Milk extraction was performed as reported by Biancardi et al [2]; regarding to infant food, dessert and cheese, LLE has to be performed by homogenization with 100 ml dichloromethane and 10 g diatomaceous earth; after filtration, 20 ml of raw extract was dried under a stream of nitrogen; the residue was dissolved in HCOOH 0,1%:CH₃CN (90:10, v/v) and defatted with hexane.

This clean-up step allowed a good recovery and a low matrix effect for all kind of food examined.

Instrumental response was linear in 0.010-0.100 µg/kg range.

Specificity was evaluated on 30 different milk sample (fresh, pasteurized, UHT, bovine, ovine, liquid or powdered), 20 different infant food (milk, milk flour, cheese, dessert, yogurt) and 20 different dairy products (cheese, dessert, yogurt, ice cream): no interference was found.

Accuracy was evaluated on the same samples spiked before the extraction with AFM1 at 0.015 µg/kg for milk and infant formula and at 0.040 µg/kg for dessert and cheese. AFM1 was identified in all samples, and accuracy error was less than 5% at the interesting level.

Conclusions

The Official Method [3], based on the use of immunoaffinity chromatography columns (IAC) clean up and HPLC-FLD detection, can't to be used for infant food analysis, due to its higher detection limit. The developed method is able to detect AFM1 in infant food at concentration levels lower than 0.5 LM.

Furthermore, in this case no IAC clean up is required, with a significant gain in time and in reagent costs, even for milk and cheese.

Novel Aspect

A new, faster and cheaper approach for official controls on food safety, based on a fast and very sensitive LC-MS method, AFM1 residues detection was developed and validated.

1387 - DEVELOPMENT OF A SIMPLE MULTI-RESIDUE DETERMINATION METHOD OF 80 VETERINARY DRUGS IN FISH TISSUES BY LIQUID CHROMATOGRAPHY COUPLED TO QUADRUPOLE ORBITRAP MASS SPECTROMETRY

Luo Xin Luo (1) - Tang Zhixu Tang (1) - Niu Zengyuan Niu (1) - Ye Xiwen Ye (1) - Zhao Fei Zhao (1)

Qingdao Customs, Inspection and Quarantine Technical Center, Qingdao, China (1)

Keywords: Veterinary drugs; Multi-residue; Fish tissues; Extraction optimization; Orbitrap

Introduction:

There is no doubt that veterinary drugs are very important for aquaculture. But inappropriate and commonly subtherapeutic use of veterinary drugs may result in the presence of drug residues in the fish tissues even food products. Most of the published multi-residues detection methods commonly employed the LC-triple-quadropole tandem MS techniques, which requires extensive compound-dependent parameter optimization. And due to the great differences in the physicochemical properties of the various targets, we need an appropriate extraction procedure to ensure that all compounds can be extracted effectively. On the other hand, protein, fat and many other interferences are abundant in fish. There is an effective clean-up procedure still needed to eliminate background matrix interferences.

Methods:

A simple, rapid and sensitive multi-residue analytical method was developed and validated for 80 veterinary drugs in fish tissues using ultrahigh performance liquid chromatography-Orbitrap high resolution mass spectrometry (LC-HRMS). The analytes belong to 12 different families include benzimidazoles, β -lactams, lincosamides, macrolides, nitromidazoles, quinolones, sulfonamides and trimethoprim, tetracyclines, triphenylmethane dyes, amphenicols, nonsteroidal estrogens and steroid hormones. The sample preparation was optimized base on QuEChERS (quick, easy, cheap, effective, rugged and safe) procedure. A very simple and sufficient preparation procedure without salting-out and complex clean-up process was studied. It had been proved that water in the extract was helpful for extracting hydrophilic compounds and precipitating the lipids during the subsequent cleaning process. In addition, an appropriate percent of methanol was necessary to some analytes.

Results:

Finally, a mixture of acetonitrile, methanol and water (3:1:1, v/v/v) which include 1% acetic acid and 10 mMethylenediaminetetraacetic acid disodium salt 2-hydrate was selected as the extraction solvent, and the clean-up step consisted of a low temperature procedure and two times of high-speed centrifugation to deproteinize and remove lipids. The detection and quantification of all compounds were performed by ultrahigh performance liquid chromatography coupled with electrospray ionization quadrupoleOrbitrap high resolution mass spectrometry in positive and negative ion mode. This methodology was validated according to the Commission Decision 2002/657/EC and SANTE/11945/2015. The recoveries ranged from 60.74%-109.85% with relative standard deviations (RSDs) < 20%. The limits of quantification (LOQs) were 0.25 to 25 ug/kg, for the analytes which the MRL or MRPL had been established in fish tissue, the LOQs were all lower than their own legal tolerances. The values of decision limit ($CC\alpha$) and detection capability ($CC\beta$) were in the range of 1.91-1001.13 ug/kg and 3.52-1002.26 ug/kg, respectively. This validated method has been successfully applied on the determination of veterinary drugs in real commercial oplegnathuspunctatus samples.

Conclusions:

A very simple, rapid and efficient multi-residue and multi-class analytical method for the simultaneous determination of 80 veterinary drugs in fish tissue by ultrahigh performance liquid chromatography coupled with quadrupole Orbitrap high resolution mass spectrometry has been developed. To the best of our knowledge the proposed method is the simplest way reported in literature for multi-residue and multi-class determination in fish. The method was validated with linearity, recovery, precision, sensitivity and tested the $CC\alpha$ and $CC\beta$ for each analyte. The satisfactory performances were achieved mainly depended on the high efficiency of extraction solution

and the excellent selectivity and sensitivity of Orbitrap. This efficient and rapid method is a good way to screening for large batches of fish samples.

527 - ANALYTICAL METHOD BASED ON UHPLC-ESI-MS/MS FOR QUANTIFICATION OF PLANT TOXINS IN HERBAL FOOD SUPPLEMENTS

Svetlana Malysheva (1) - Jean-Francois Picron (1) - Bart Huybrechts (1)

Sciensano, Organic contaminants and additives, Brussels (1)

Keywords: plant toxins; pyrrolizidine alkaloids; UHPLC-MS/MS; food supplements; method

Introduction:

Pyrrolizidine alkaloids (PAs) and their N-oxides (PANOs), secondary metabolites of plants, are hepatotoxic to humans and animals and their ingestion in some cases might lead to death[1]. One of the sources of PA-intoxication is herbal remedies and food supplements that (un)intentionally contain material from PA producing plants. The objective of this study is to develop a simple and sensitive method for analysis of 35 PAs and PANOs in different food supplements.

Methods:

The analytical method is based on ultra-high performance liquid chromatography (UHPLC) coupled to mass spectrometry (MS), as this technique can detect both tertiary PAs and their N-oxides. LC separation of the analytes is performed on a 1.7 μm BEH C18 column using alkaline mobile phase. Detection is done by a triple quadrupole MS (Xevo TQ-S, Waters) operated in positive electrospray ionization mode. The data are acquired in MRM mode.

Results:

The method targets different PA types, namely senecionine-, lycopsamine, heliotrine- and monocrotaline-type compounds. The herbal dietary supplements are divided into several groups. In order to represent all the groups model matrices, namely seed powder of milk thistle, propolis, vegetable oil and herbal infusion, are selected for method development. These samples are free from PAs and PANOs or contain trace amounts. The optimization of sample preparation includes several techniques, such as a dilute-and-shoot approach, a QuEChERS-based protocol and different sorbent materials for solid-phase extraction (SPE). The QuEChERS-method and SPE with ion-exchange mode as well as SPE with reversed-phase mode show promising results with regards to recovery; however, matrix effect is unavoidable in all cases. The ultimate aim is to select a procedure that has a minimal number of involved manipulations, assures good recovery of the target analytes and is applicable for the analysis of a variety of food supplements. The developed method will be in-house validated and limits of quantification, linearity, recovery, repeatability and reproducibility will be determined.

Conclusions:

This analytical method allows for the simultaneous determination of 35 PAs and PANOs in food supplements at low levels, and can be used as a tool for collection of PA occurrence data, which is highly demanded by the European Food Safety Authority in order to perform more accurate exposure assessment.

Novel Aspect:

The outlined method is able to provide information about the quality of herbal food supplements.

511 - COMPARISON BETWEEN HPLC-ESI-QTOF-MS AND SPME-GC-MS TECHNIQUE FOR ACRYLAMIDE DETERMINATION IN POTATOES CHIPS

Silvia Marzocchi (1) - Sara Marziali (1) - Maria Fiorenza Caboni (2)

University of Bologna, Department of Agro-Food Science, Cesena (1) - University of Bologna, Department of Agro-Food Science, Cesena (2)

Comparison between HPLC-ESI-QTOF-MS and SPME-GC-MS technique for acrylamide determination in potatoes chips

Silvia Marzocchi, Sara Marziali, Maria Fiorenza Caboni

Keywords: HPLC-ESI-QTOF-MS, SPME-GC-MS, acrylamide, potatoes

Introduction:

In April 2002, researchers at Swedish National Food Administration and Stockholm University published data about acrylamide content in fried and baked starch-based food [1,2]. Acrylamide formation in food is attributed to the Maillard browning reaction; because of the interaction between amino group of asparagine free amino acid and carbonyl group of reducing sugar [3].

Methods:

Acrylamide in two different potatoes varieties, after frying, was determined by HPLC and GC coupled with MS. In the first case a HPLC-ESI-QTOF-MS was used, SPE extraction and chromatographic conditions were according to Calbiani et al [4]; using acrylamide-d3 as internal standard. The method used for SPME-GC-MS was according to Ghiasvand & Hajipour [5] using a calibration curve for quantification.

Results:

Fragmentation of acrylamide and acrylamide d3 involves in NH₃ release, leading to a product ion at m/z 55 and 58 [4]. Regarding HPLC, positive electrospray proved to be the most sensitive mode for acrylamide determination [6]. Acrylamide identified in the samples was quantified using a calibration curve based on response ration of acrylamide/acrylamide d3. Considering GC, the quantification was made using a calibration curve, in the linear range 2-500 mg mL⁻¹ with a correlation coefficient (R²) of 0.997. The two different analytical techniques allowed to determine different values for the same potato variety, due to the different sensitivity of the two instruments, but only with HPLC-MS were obtained results according to literature [4,7]. In both cases the two different potatoes varieties have shown the same content difference, about 30%, probably due to the different asparagine content.

Conclusions:

Both liquid and gas chromatography are able to determine acrylamide in food. This study confirmed HPLC-ESI-QTOF-MS as the most suitable chromatographic technique to determine acrylamide in potatoes sample, according to literature. At the same time, also SPME-GC-MS is able to determine acrylamide in food, but without the same sensitivity as the previous technique.

Novel Aspect:

SPME-GC-MS technique was tested for acrylamide determination and quantification to find an alternative to the well-established HPLC-ESI-QTOF-MS method.

1029 - A MULTI-RESIDUE CONFIRMATORY METHOD FOR THE DETERMINATION OF SEDATIVES BY HPLC-MS/MS

Pavel Metalnikov (1) - Ilya Batov (1) - Renat Selimov (1) - Alexander Komarov (2) - Vyacheslav Nikulin (2)

VGNKI, Food Safety, Moscow (1) - VGNKI, VGNKI, Moscow (2)

Keywords: mass spectrometry, HPLC, sedatives, validation

Introduction:

Sedatives are injected right before transport of the animals to reduce the stress of animals generated during handling and transport to the slaughterhouse. Thus, animal tissues have become major targets for residue analysis of sedatives and adrenergic blockers. Therefore, simple and reliable analytical methods are required to monitor these drug residues in food of animal origin. LC-MS/MS was the technique of choice due to its high specificity and sensitivity.

Methods:

Samples were homogenized and fortified by addition of Internal Standard Mixture. Liquid-Liquid extraction was carried out by using acetonitrile. SPE was performed on silica gel cartridges. The HPLC-MS system consisted of HP 1290 Infinity (Agilent Technologies, USA) and 6500 QTRAP (Sciex, Canada) hybrid linear ion trap/triple quadrupole mass spectrometer. MS/MS parameters were optimized for each compound. The analysis was carried out with gradient elution.

Results:

Several types of liquid-liquid extraction and SPE cartridges were tested during the study. The method was validated for muscle, liver and milk matrices. The validation study consisted of 4 individual experiments with two factors: operator and storage time before LC-MS/MS analysis. The validation levels for muscle matrix were 1, 10, 20, 100, 200 ng/ml for azaperol, azaperone, acepromazine, haloperidol, detomidine, carazolol, xylazine, medetomidine, meperidine, triflurpromazine and fluphenazine. 5, 25, 50, 100, 250, 500 ng/ml for diazepam, metoprolol, promazine, propionylpromazine, romifidine, and chlorpromazine. Quantification was performed using individual matrix calibration curve for each series with the same concentration levels for each analyte. In order to prove the specificity and the lack of susceptibility to matrix interferences, several blank samples fortified with internal standard were additionally analysed in each series. The recovery was in the range of 45 – 74 % for all analytes in the validated concentration range.

Conclusions:

Method was developed and successfully implemented for analysis of sedatives in samples of animal origin in the frames of the National Program of Monitoring of prohibited and regulated substances in food in Russian Federation.

Novel Aspect:

A rapid and sensitive method for the determination of sedatives in meat, plasma and liver by HPLC-MS/MS was developed.

1400 - COMPARISON OF DIFFERENT STRATEGIES FOR THE DETERMINATION OF VETERINARY DRUG RESIDUES IN FOOD BY UPLC-MS/MS USING ORBITRAP ELITE

Pavel Metalnikov (1) - Renat Selimov (1) - Alexey Efimov (1) - Ilya Batov (1) - Ayshat Dzhatdoeva (1) - Alexander Komarov (2)

VGNKI, Food Safety, Moscow, Russian Federation (1) - VGNKI, VGNKI, Moscow, Russian Federation (2)

Keywords: Mass Spectrometry, Orbitrap, Veterinary Drugs

Introduction:

Analysis of veterinary drug residues in food matrices usually is performed for a specific group of drugs. Now, with the advent of high resolution mass spectrometry, it's getting possible to use accurate masses, measured during analysis, for unambiguous identification of potential contaminants, and so-called "general unknowns" as well. The aim of the work was to compare different strategies for identification of analytes of different drug groups in large scale.

Methods:

Samples of food matrices (milk or meat) were originally homogenized, fortified with veterinary drug mixture solutions, and subjected to liquid-liquid extraction. Then, Solid Phase Extraction (SPE) was applied. Analysis was done on UPLC-Orbitrap system (Ultimate 3000 – Orbitrap Elite (Thermo Scientific, USA)) in gradient mode.

Results:

Orbitrap is a complex mass spectrometer, measuring masses of peaks with accuracy about 1 ppm and providing MS/MS data of high quality. Veterinary drugs were identified either by determination of their elemental composition based on accurate mass determination from spectra, detected in electrostatic ion trap (FT mode), or by fragmentation spectra, registered in linear ion trap (IT mode). Fragmentation spectra matched to in-house built Spectra Library or to other available data bases.

Conclusions:

Despite accurate mass determination is enough for compound identification, in some cases (e.g. overlapping peaks) confirmation by fragmentation spectra is important.

Novel aspect:

New strategies for veterinary drug residues determination in food matrices were developed.

Kyonggi University, Chemistry, Suwon (1)

Keywords: LC-MS/MS, Honey, Fenpyroximate, Pesticide

Introduction

Fenpyroximate is used to treat honey bee colonies in beekeeping farms. This not only deteriorates the quality of the honey, but also affects the health of humans who ingests it [1-2]. However, since there is no effective analytical method for the residual fenpyroximate in different types of honey, this study aims to establish an LC-MS/MS-based analytical technique after simple and rapid pretreatment with a minimum amount of sample.

Methods

5 mL of a saturated aqueous NaCl solution and 15 mL of purified water were added into 5 g of honey sample and then 10 mL of dichloromethane was added. After mixing and centrifuging, and the dichloromethane layer was then transferred to a new tube. 2 mL of the dichloromethane extract was loaded onto a SPE cartridge, and then eluted with 6 mL of dichloromethane/n-hexane (65:35%, v/v). The eluate was redissolved with 0.2 mL of acetonitrile and injected into the LC-MS system.

Results

Experiments were carried out to determine the optimal values of parameters such as sample pH, type of solid-phase cartridge, type and volume of extraction solvent, loading sample volume, type and volume of eluent for effective sample extraction, purification, and concentration. Chromatographic separation was performed using a C18 (3.0 mm i.d. × 50 mm length, 2.7 μm particle size) column under isocratic conditions of water and acetonitrile (30:70). The optimized parameters for the extraction of fenpyroximate are as follows: sample pH, 7; type of sorbent solid phase, aminopropyl; volume of extraction solvent, 20 mL; volume of loading sample, 2 mL; eluent, dichloromethane/n-hexane (65/35%, v/v); eluent volume, 6 mL. The limits of detection and quantitation for spiked honey samples were 1.56 and 5.00 μg/kg, respectively. Linear correlation coefficient (r^2) obtained from a concentration range 5.00–50.0 μg/kg was 0.9914–0.9977, while the accuracy and precision were 87.99–119.06% and 0.68–14.71 % (RSD), respectively.

Conclusions

The LOQ for the established analytical method was 5.0 μg/kg, which is 10 times lower than the EU-regulated concentration of 0.050 mg/kg. After monitoring 30 honey products, obtained from the market, using the established method, no residual fenpyroximate was detected in any sample. Compared with other studies, the novel aspects of this study are that method validation of four species of honey (acacia honey, wild honey, manuka, and chestnut honey) has been performed.

Novel Aspect

The LLE-SPE combined method does not require additional cleaning procedures, and good sensitivity can be obtained even with low-capacity cartridges.

463 - GUM ARABIC CHARACTERISATION AND ITS DETECTION IN WINE USING HIGH RESOLUTION MASS SPECTROMETRY

Tiziana Nardin (1) - Giulia Ferrari (1) - Roberto Larcher (1)

Fondazione E. Mach, CTT, San Michele a/A (1)

Keywords: adjuvant, OrbitrapTM, characterization, wine addition

Introduction:

Gum Arabic is a dried exudate obtained from several Acacia species from the sub-Saharan region of Africa [1]. It is a complex mixture of macromolecules, mainly carbohydrates and proteins, widely used as an edible ingredient in various types of food as well as for non-food applications [2]. For oenology, OIV approves the use of both *A. senegal* and *A. seyal* gums. Europe indicates a maximum of 200 mg/L as the recommended technological dosage [3].

Methods:

The study was performed using a Thermo Ultimate R3000 UHPLC equipped with a biphenyl column (3 x 150 mm, 2.7 μ m). Separation was obtained at a flow rate of 0.3 mL/min with a ternary mobile phase with 2% formic acid, acetonitrile and water. Mass spectra were acquired through a full MS experiment at 70,000 FWHM resolution using a Q-ExactiveTM HRMS equipped with a heated electrospray ionization (HESI-II) interface working in both positive and negative ion modes.

Results:

The full scan MS profile, both in positive and negative ionization, of 45 gum Arabic samples was evaluated in order to check if specific ions could selectively characterise the botanical (*A. seyal* and *A. senegal*) and/or the geographic origins of gums (Kordofan, Hashab and Verek). The PLS-DA statistical approach indicated 18 masses as possible predictive origin markers, allowing the correct reclassification of 98% of the samples to the corresponding cases. Moreover, we analysed 40 micro-winery genuine wines (8 varieties) and then reanalysed the same ones after randomly adding 200 mg/L of gum Arabic of the 2 origins (*seyal*, n=10; *senegal*, 10). Comparing their ion profiles, 5 of the previous 18 masses, not detected in genuine wines, permitted the identification of the addition of gum Arabic. PCA based on the 5 masses allowed us to distinguish between wines added with *A. senegal* and *A. seyal*. Finally, each isotopic patterns and ion fragmentation allowed us to define their molecular formulas and structures.

Conclusions

The HRMS untargeted approach allowed us to identify, through PLS-DA analysis, 18 masses (m/z) that could be proposed as possible markers for the differentiation of the commercial gum Arabic samples, both with respect to the botanical (*A. seyal* and *A. senegal*) and geographic (Kordofan, Hashab and Verek) origin. 5 of these 18 masses (m/z 152.1067, 166.1225, 181.0459, 585.1428, 643.1403) were also effective in detecting the presence of 200 mg/L gum Arabic in wine.

Novel Aspect:

A new rapid untargeted high resolution MS approach allows us to predict gum Arabic origin and detect its presence in wine.

1187 - DIRECT FOOD ANALYSIS BY (TRANSPORTABLE) AMBIENT IONIZATION MASS SPECTROMETRY

Michel W.F. Nielen (1) - Marco Blokland (2) - Arjen Gerssen (2) - Michael van Dam (2) - German Augusto Gomez Rios (3) - Janusz Pawliszyn (3)

Wageningen University, Wageningen, The Netherlands - RIKILT, Wageningen, The Netherlands (1) - RIKILT, Wageningen, The Netherlands (2) - University of Waterloo, Waterloo, Canada (3)

Keywords: food analysis, ambient ionization, mass spectrometry, sample preparation, on-site detection

Introduction:

Many health and food related apps have been developed in recent years, followed by the development of wearable sensors for blood pressure, heart beat, moisture and biochemical parameters such as blood glucose levels. Obviously, mankind gets used to measuring all kinds of parameters themselves and subsequently take control over their own life, based on analytical data. In the near future, also the pre-screening of residues and contaminants in food will be performed on-site at the farm, in industry, in retail and, eventually, even done by consumers at home. Typically, three different approaches to selectivity in portable food analytics (each at different development stages), can be distinguished: (1) generic spectral profiles from smartphone-linked optical spectroscopy sensors, such as near infrared (NIR) combined with chemometric models; (2) smartphone-based biorecognition assays; and (3) higher resolution spectral data, such as available from mass spectrometry (MS). With respect to the MS option, there is an urgent need for (trans)portable MS, elimination of tedious sample clean-up, simplified sample introduction, and data evaluation tools that communicate wireless to smartphones, tablets and servers of relevant stakeholders, including the consumer. Sample introduction can, at least in theory, partly be replaced and simplified by one of the >70 Ambient Ionization MS (AIMS) techniques.

Methods:

In this research, different AIMS techniques with potential for coupling to (trans)portable mass analyzers have been critically investigated for their applicability towards the analysis of pesticides, banned veterinary drugs such as β -agonists and steroids, regulated drugs such as analgesics and antibiotics, and natural toxins in various food matrices. Four different AIMS techniques were explored: Matrix Assisted Ionization (MAI), Handheld Desorption Atmospheric Pressure Chemical Ionization (DAPCI), ID-CUBE Direct Analysis in Real Time (DART) and Coated Blade Spray (CBS), either in combination with a benchtop Orbitrap or a transportable single quadrupole MS.

Results:

MAI is one of the most simple ionization options since no high voltage, lasers or gas supplies are needed, the sample or extract is mixed with a matrix and simply tapped against the opening of the cone or heated inlet of the MS. Secondly, a handheld battery powered DAPCI device, just using ambient air, can be used to ionize analytes directly from a sample surface. Third, a mini-DART setup (a modified version of the ID-CUBE) can be used but would require a helium gas supply. With this technique the sample is simply transferred onto a metal mesh sample card having the size of a credit card. Fourth, the recently developed CBS technique, only requires a high voltage. Both the metal mesh card and the CBS technique offer the benefit of trace enrichment following coating with a selective adsorbent. In this presentation an overview is given about the requirements, challenges and preliminary results of direct food analysis by these different (transportable) AIMS approaches.

Conclusions

All tested devices were able to successfully ionize some of the tested analytes, some of them even in various food commodities. A general drawback of these ambient ionization techniques is the poor reproducibility, but, where feasible, isotope dilution of the sample may compensate for that to a large extent. Detection limits will be typically (much) higher when compared to state-of-the-art high-end MS instruments so applications may be limited to regulated substances having relatively high maximum limits values, unless selective enrichment approaches, such as CBS, are being exploited. Nevertheless, the initial applications underline the great potential of ambient ionization

with (trans)portable MS. Hence, it is realistic to envisage that portable MS, already successful in battlefield- and forensic applications for many years, will soon show up in food control as well.

Novel Aspect:

A paradigm shift in food control, from the laboratory to on-site pre-screening using, among others, (trans)portable MS is upcoming.

draft

1003 - SUPERCRITICAL FLUID CHROMATOGRAPHY – MASS SPECTROMETRY AS A NEW TOOL FOR DETERMINATION OF SYNTHETIC FOOD DYES

Volodymyr Pauk (1) - Martina Uhrová (1) - Karel Lemr (1)

RCPTM, Department of Analytical Chemistry, Palacky University in Olomouc, Olomouc (1)

Keywords: electrospray ionization; multiple charged ions; polar analytes; supercritical phase; subcritical phase.

Introduction:

Comprehensive analytical techniques are required to meet the increasingly stricter regulations on food safety. Supercritical fluid chromatography with mass spectrometric detection (SFC-MS) was assessed for analysis of food dyes. Fourteen synthetic dyes representing azo, triphenylmethane, xanthone, indigoid, and quinoline classes and covering a broad range of polarities (logD from -8 to 3.5) were selected from the list of permitted additives [1].

Methods:

An Acquity UPC2SFC system coupled to a Xevo TQ-S triple quadrupole mass spectrometer with electrospray ionization (all from Waters) was used for analysis. A sharp gradient (5 to 100%) of methanolic ammonia modifier was employed on a 2-ethylpyridine column. Pseudo-SPE extraction on nylon syringe filters was utilized for real samples.

Results:

Owing to the presence of multiple sulfonic groups as Na⁺ salts, multiple charged ions were observed and development of SRM transitions required careful optimization. Addition of 10 mM ammonia and 5% water into a modifier allowed separation of a wide range of analytes in a single run without using ion-pairing agents. Thus, MS compatibility, good sensitivity and wide linear range were maintained: LLOQ 4-36 ng/ml, except Brilliant black BN 255 ng/ml; ULOQ 2000 ng/ml. Mobile phase properties changed continuously from supercritical to subcritical and liquid state and did not affect the method performance, which is confirmed by validation parameters: retention time repeatability (RSD < 0.6%) and peak area precision (RSD < 8.9%). Brilliant blue dye was determined in a sports drink (1.9 µg/ml) and in candies (10.5 µg/g), as well as indigocarmine in candies (5.9 µg/g), which fits well within the legislative limit. The total analysis time including equilibration was 16 minutes.

Conclusions:

A new SFC-MS method was developed for quantitative analysis of permitted synthetic food dyes and its essential validation parameters were evaluated. The results indicate that SFC-MS might serve as a reliable tool for analysis of both moderately polar and highly polar dyes in the context of food safety.

Novel Aspect:

SFC-MS was used for analysis of ionic sulfonated dyes. A sharp modifier gradient suggested operation far from supercritical region but results were reproducible and quantitative.

528 - SIMULTANEOUS SCREENING OF 6 DIFFERENT ANTIBIOTIC FAMILIES IN MEAT USING LDTD-MS/MS QUANTITATION AT 9 SECONDS PER SAMPLE

Pierre Picard (1) - Jean Lacoursiere (1) - Serge Auger (1)

Phytronix Technologies inc, R&D, Quebec (1)

Keywords: Antibiotic, Meat, screening, LDTD-MS/MS

Introduction:

Food quality is a fundamental aspect of public health and is determined by innocuity associated to it. The absence of contaminants can only be validated by adequate measurement. Antibiotics in meat represent a challenge in terms of sample complexity. Until now, only a statistical sample of the total animals is tested due to the throughput. We present a new approach to screen 6 different families of antibiotics simultaneously with LDTD-MS/MS at 9 seconds per sample.

Methods:

1g of pork meat is weighed and placed in a 24 wells plate. Sample preparation is accomplished at a low temperature and reduced light. Extraction solution of MeCN:Water (80:20) is added using a CERTUS FLEX to create a concentration of 1g/mL. The samples are blended in parallel for 3 minutes and centrifuged for 3 minutes. 30 μ L of supernatant is mixed with 150 μ L of Methanol:Water (75:25) and vortexed for 30 seconds. 4 μ L are deposited and dried into the analyzing Lazwell plate.

Results:

Strategies have been applied to find adequate markers for thermally unstable molecules. Beta-Lactam Amoxicillin and Ampicillin are detected at the methanolic adduct formation¹. Ceftazidime undergoes a thermal fragmentation which is reproducible and the fragment containing the beta-lactam ring allows a sensitive measurement for screening purposes. The other molecules tested are detected at their pseudo molecular mass M+H⁺. The extraction efficiency using a simple approach for the 6 types of antibiotics (Beta Lactam, Sulfonamide, Phenicol, Lincosamide, Tetracycline and Macrolides) ranges from 67 to 93%. QC samples at 50, 100 and 150% of cut-off values for each antibiotic do not overlap and exhibit sufficient signal levels for detection. Calibration curve linearity (R²) reaches values greater than 0.993. Accuracies between 86.5% and 112.3% are observed and reproducibility ranges from 7.2 to 13.7%. Automation is optimized to achieve 96 samples in less time (12 minutes) than LDTD-MS/MS analyses (14.4 minutes) at 9 seconds per samples.

Conclusions:

A complete workflow solution has been developed to extract simultaneously 6 types of antibiotic in meat. Mass spectrometer allows simultaneous specific quantitation of those compound at 9 seconds per sample using LDTD-MS/MS. Thermally unstable compounds are monitored on reproducible fragment. Sample preparation automation match the analyzing speed to enable real high throughput analysis.

Novel Aspect:

Simultaneous LDTD-MS/MS screening of 6 antibiotic families in meat

892 - NDL-PCBS, PBDES, HBCDS LEVELS AND TEMPORAL TRENDS IN MUSSELS (MYTILUS GALLOPROVINCIALIS) FROM MIDDLE ADRIATIC SEA

ARIANNA PIERSANTI (1) - TAMARA TAVOLONI (1) - TOMMASO STECCONI (1) - ARIANNA STRAMENGA (1) - ROBERTA GALARINI (2)

ISTITUTO ZOOPROFILATTICO SPERIMENTALE DELL'UMBRIA E DELLE MARCHE "TOGO ROSATI", SEZIONE DI ANCONA, ANCONA (1) - ISTITUTO ZOOPROFILATTICO SPERIMENTALE DELL'UMBRIA E DELLE MARCHE "TOGO ROSATI", SEDE DI RUGIA, PERUGIA (2)

Keywords: PBDEs, HBCDs, NDL-PCB, mussels, temporal trends

Introduction:

Mussels harvesting is a relevant commercial activity along the Adriatic Sea. Mussels are often used as sentinels for pollution monitoring, too. The aim of this study was to compare "old" contaminants like PCBs and contaminants not yet included in monitoring programs (PBDEs and HBCDs), studying temporal trends in *M. galloprovincialis* collected along the Marche Coast (2001, 2011 and 2017).

Methods:

Thirteen sampling stations (9 breeding and 4 wild) along Marche Coast (Italy) were included in this study. Breeding were distributed along the Coast from North to South, while the wild ones were around Ancona. Thirty-three mussel samples were analyzed for a series of environmental pollutants: 6 PCBs, 15 PBDEs (GC-MS/MS) [1,2] and 3 HBCDs (LC-MS/MS). All data were processed using STATA software.

Results:

The average concentrations of 6 PCBs were 3.75, 3.42 and 2.75 ng/g for mussels collected in 2001, 2011 and 2017, respectively and the predominant congeners were 153>138>101. No significant concentration differences were highlighted among the years. Mussels collected in the wild sites showed PCB levels significantly higher respect to the breeding ones ($p < 0.001$) irrespective of the sampling period. The wild sites are closer to the coast (<1 km) and therefore subjected to higher anthropic impact. The PBDEs levels significantly decrease going from 2001, 2011 to 2017 ($p < 0.001$) [3]. The 15 PBDE medium bound decreases from 458 pg/g in 2001 to 432 and 306 pg/g, respectively, in 2011 and 2017. PBDEs contamination pattern was dominated by tetra- and penta-BDE: 47, 99 and 100 were measured in all samples and the PBDE-47 was the highest, accounting for 60% of the quantified congeners. The results were comparable with those reported in literature for European mussels [4,5]. No significant differences were observed for HBCDs among the three sampling periods. The 3 HBCDs were 273, 448 and 227 pg/g in 2001, 2011 and 2017, respectively. 2-HBCD was measured in all the mussel samples, accounting for roughly 90% of the HBCD contamination. In 20 out of 33 mussel samples, also 2-HBCD was detected [4].

Conclusions:

NDL-PCB, BDE-47 and 2-HBCD were detected in 100% of the analyzed samples. PCBs did not reduce significantly in mussels with time, but the wild sites seem more contaminated than the breeding ones. The results obtained show a PBDE decrease in the years. The BDE-47 levels were generally lower than 2-HBCD's.

Novel Aspect:

This study reports for the first time the concentrations of HBCDs in Adriatic mussels, confirming the predominance of the 2-HBCD isomer.

709 - AUTOMATED SOLID PHASE MICROEXTRACTION (SPME) WITH UHPLC-MS/MS TO DETERMINE VETERINARY DRUGS IN CHICKEN MEAT

Jingcun Wu (1) - Abir Khaled (2) - Feng Qin (3) - Janusz Pawliszyn (4)

PerkinElmer, 501 Rowntree Dairy Road,, Woodbridge (1) - University of Waterloo, University of Waterloo, Waterloo (2) - PerkinElmer, PerkinElmer, Woodbridge (3) - University of Waterloo, University of Waterloo, Waterloo (4)

Keywords: Multiclass multi-residue method, automated solid phase microextraction (SPME),UHPLC-MS/MS, veterinary drugs, chicken tissues

Introduction:

Veterinary drugs are used in animal production to treat diseases and protect growth of animals. However, improper use of drugs can lead to residue violations in food products and possible health risks. Regulatory agencies around the world have established maximum residue levels or tolerance levels of veterinary drugs in foods. A common goal in drug analysis is to get acceptable results for many analytes by a cost-effective method in a single run. However, it is challenging to develop such a method for animal tissues due to the complexity of sample matrices and diversity of analytes from various classes of chemical properties. Sample preparation has always been the major bottleneck in any analytical procedure for the determination of chemical residues in food products. For veterinary drugs analysis, the most often used method has been the modified QuEChERS method with d-SPE clean-up [1-2]. However, some analytes could be lost during sample preparation due to adsorption to the sorbents. To overcome this problem, the method of direct injection of the sample extract without d-SPE cleanup has also been applied for veterinary drugs analysis recently [3]. Solid phase microextraction (SPME) is a solvent-less, effective and versatile sample preparation technique, which has been widely used in environmental and other applications including foods [4-5]. Recently, with the development of new extraction phases and devices, SPME has found increased applications in food analysis [6]. In this study, a multiclass, multi-residue method for analysis of 73 veterinary drugs (covering 13 different classes with various physical and chemical properties) in chicken muscle was developed by coupling automated SPME sample preparation with UHPLC-MS/MS. To get good analyte recovery, reduce sample matrix effects and carryover, the parameters affecting SPME performances were evaluated and optimized, such as different SPME extraction phases, extraction and desorption conditions. The method was validated according to regulatory guidelines and compared with the currently used sample preparation Methods:

Methods:

Chicken samples were homogenized and ground with dry ice to obtain uniform powder and kept at -20 °C overnight to allow sublimation of residual dry ice and then stored at -20 °C until analysis. Certified organic samples were used as matrix for method validation. 2 g of sample was weighed into a 15 mL centrifuge tube, spiked with internal standards and fortified with targeted analytes, vortex for 1 minute and leave the sample on an agitator for 1 hour. Finally equilibrate the samples overnight in the fridge before extraction by SPME and other Methods:

SPME sample preparation method: place sample tubes in the agitator for 1 hour, then add 6 mL of LCMS grade H₂O for each sample and vortex for 1 min. Transfer 1.5 mL of sample to 96 well plates. Perform static extraction for 60 min and 20 min desorption in 400 µL of desorption solvent (25:37.5:37.5 H₂O: MeCN:MeOH + 0.1%FA).

Other sample preparation methods: samples were extracted with 10-mL of extraction solution (MeCN/Water, 4/1 in v/v). After centrifugation, the extract was analyzed by LC-MS/MS directly or after d-SPE clean-up with different sorbents.

UHPLC-MS/MS method: analytes were separated using an UHPLC column on a PerkinElmer UHPLC system with a gradient program with mobile phase A (water containing 0.1% formic acid) and B (MeCN containing 10% MeOH and

0.1% formic acid). Mass detection was carried out on a PerkinElmer QSight™ 220 triple quadrupole mass detector with a dual ionization source. Optimization of MS/MS parameters (choice of ions, collision energies and so on) was done by infusion of standards and use of the software. Source conditions were optimized by flow injection (FIA) method. Since the mass detector is capable of fast polarity switching, both positive and negative ionization modes were used. All instrument control, data acquisition and data processing was performed using Simplicity 3Q™ software. Calibration curves were built by standards prepared in reagents only (RO) and in sample matrix. Matrix effects were evaluated by comparison of the slopes obtained from RO and sample matrix.

Results: (Limit 900 characters without spaces)

Mass detection method for 73 drugs was developed using time-managed-MRM algorithm of the QSight Simplicity 3Q™ software; the optimum dwell time of multiple MRM transitions was generated automatically for the targeted analytes, which saved time in method development and improved data quality and analytical performance. All calibration curves built from both the reagents only (RO) and chicken sample matrix showed good linearity (0.1X to 2X, X are the tolerance levels) with correlation coefficient (R^2) larger than 0.99 for most the analytes studied. In this study, sample matrix effects were evaluated by comparing the slopes of calibration curves obtained from RO with slopes obtained from chicken sample matrix. Sample matrix effect (%) was calculated by the percentage difference between the slopes. When the percentage difference is positive, there is a signal enhancement effect, whereas a negative value indicates signal suppression effect. It was found that sample matrix effects are significantly reduced during SPME sample preparation (only 4 out of 73 analytes have matrix effect > 20%) compared to other sample preparation method (12 out of 73 analytes have matrix effects >20%). To overcome matrix effects and reduce variations in analytical results, matrix-matched calibrations were used in all the methods for quantification of all analytes. For SPME method, the method accuracy (or relative recovery) was evaluated by spiking the analytes to the samples at three concentration levels of 0.3X, 0.9X and 2.5X, respectively and the recoveries of analytes ranged from 70% to 120 % with RSD < 20% for almost all the analytes studied, demonstrating good accuracy and precision of the method. To compare with other sample preparation methods (direct injection and d-SPE clean up), the recoveries of analytes were also evaluated by spiking the analytes to the samples at two concentration levels of 0.5X and 1X, respectively and the recoveries of analytes ranged from 70% to 120 % with RSD < 20% for most of the analytes studied when the extract was analyzed directly without clean-up. However, the recoveries for several classes of analytes are lower after d-SPE clean-up, such as for fluoroquinolones, tetracyclines and some tranquilizers. Similar results were also obtained using different sorbents such as end-capped C18 and Z-Sep+ for d-SPE in this study, which are in good agreement with the published results[1-3]. The limits of quantification (LOQs) for the drugs studied are all below the tolerance limits or the maximum residue levels (MRLs), but SPME method provided lower LOQ compared with other Methods: The developed SPME-LC-MS/MS method can be applied for the fast screening and quantification of multi-class veterinary drug residues in chicken samples.

Conclusions (Limit of 400 characters without spaces)

A multiclass, multi-residue method for analysis of 73 veterinary drugs in chicken muscle was developed by coupling automated solid-phase microextraction (SPME) sample preparation with UHPLC-MS/MS. To get good analyte recovery, reduce sample matrix effects and carryover, the parameters affecting SPME performances were evaluated and optimized. The method was validated according to regulatory guidelines, taking into account Canadian maximum residue limits (MRLs) and US maximum tolerances for veterinary drugs in meat. A multi-day validation demonstrated that the developed method is suitable for fast and reliable quantitative analysis of 73 veterinary drugs in chicken muscle at half or below the maximum regulatory levels. Compared with other sample preparation methods such as direct injection and the frequently used modified QuEChERS method, SPME method demonstrated the following advantages: it requires less sample and solvents, easy to be automated, has less sample matrix effects and has the potential to be used for in-vivo animal sampling and fast screening by direct coupling to mass spectrometry. The selectivity and sensitivity of SPME can be tuned by using different extraction phases.

Novel Aspect: (Limit of 150 characters without spaces)

A new, fast, effective and automated SPME sample preparation method coupled with UHPLC-MS/MS for high throughput multi-class multi-residue analysis of veterinary drugs in chicken

Kean University, STEM, Union (1)

Title:UHPLC-HRMS Analysis of Theobromine in Costa Rican Theobroma Cacao

Katarina Mladenovic; Yuriko Root; Dil Ramanathan

Kean University, Union, New Jersey, USA

Keywords: High Resolution Mass Spectrometry, Costa Rican Cacao, UHPLC-HRMS, Theobromine

Abstract:

INTRODUCTION:Costa Rican Cacao has been a staple within Costa Rican culture for many centuries. Within the past 10 years, Costa Rican cacao has made a return for chocolate enthusiasts, helping to provide antioxidants to humans and satisfy sweet cravings. One of the major components of chocolate is Theobromine. Theobromine is a bitter alkaloid/flavonoid beneficial in the treatment of hypertension, arteriosclerosis, and angina pectoris.

METHODS:The samples were centrifuged and vortexed numerous times to give a purified product. A three-minute gradient method with a flow rate of 300 $\mu\text{L}/\text{min}$ was developed on the UHPLC-HRMS using HPLC-grade water and acetonitrile. Quantitative analysis on Theobromine was completed on the Thermo Scientific UHPLC and LTQ Orbitrap Discovery equipped with an ESI ion source. 2-Hydroxyethyl theophylline was used as the internal standard.

RESULTS: In a previous study from our laboratory, Headspace GC-MS analysis was used to identify flavonoids from Cocoa Beans. Theobromine was the major component found. To give the precision of the theobromine extraction process, the recovery analysis was 86%. Raw, unroasted, roasted, and 100% cacao was analyzed in concentrations of ng/mL . Raw cocoa had a concentration of 586 ng/mL and unroasted cocoa had a concentration of 747 ng/mL . Roasted cocoa had a concentration of 521 ng/mL and 100% cacao had a concentration of 1018 ng/mL . Roasted cocoa had the lowest concentration of theobromine.

Unroasted cocoa had a higher concentration of theobromine prior to roasting cacao. Theobromine could have been lost based on the roasting process or choice of roasting. The 100% cacao chocolate bar had the highest amount of theobromine. Additional theobromine existed and contributed to a more bitter and rich cocoa flavor. Theobromine levels in popular commercially available chocolates such as Lindt, Hershey, Mars, etc will be discussed.

CONCLUSIONS: Theobromine levels in popular commercially available chocolates such as Lindt, Hershey, Mars, etc. were determined by UHPLC-HRMS and compared between raw, unroasted, and roasted chocolates.

NOVEL ASPECT: A sensitive and selective UHPLC-HRMS method to quantify Theobromine levels in chocolates.

796 - SIMULTANEOUS QUANTITATION OF FAT SOLUBLE VITAMINS IN INFANT MILK FORMULAE USING 5500 QTRAP LC-MS/MS SYSTEM

³SCIEX, 121, Udyog Vihar, Phase IV, Gurgaon, Haryana, India

Introduction:

Fat-soluble vitamins play an important role in the stimulation of synthesis and degradation of nutrients enhancing immune function and growth performance of living organisms. In recent years there has been great emphasis on simultaneous analysis of fat-soluble vitamins. The most commonly used methods of sample preparation for the analysis of fat-soluble vitamins in foods and pharmaceuticals include sample saponification and later extraction of the vitamins from the unsaponifiable matter. Saponification process exhibits disadvantage such as oxidation, low recovery, decomposition of vitamins labile under alkaline condition. Also there are few methods reported for simultaneous determination of fat-soluble vitamins in biological fluids and food matrices, the reported methods have only enabled determination of few vitamins, which usually have been vitamins A and E and hydroxy metabolites of D2 and D3 vitamins because other vitamins are present at extremely low concentrations. The present work aims at development of highly selective and sensitive LC-MS/MS method in order to determine complete profiles of fat-soluble bioactive compounds and to design a sample treatment method without hydrolysis for the simultaneous determination of fat soluble vitamins in infant milk formulae.

Methods:

Standard Stock Solution of each vitamin (A, A acetate, A palmitate, D2, D3, E, E acetate, E Succinate, K1, K2) was prepared by mass in ethanol containing 0.025% (m/v) of BHT to provide a concentration of 1 mg/mL for all the fat soluble vitamins. Chromatographic performance was optimized using different combination of mobile phase applied to variety of C18 column to achieve optimum chromatographic resolution. Best chromatographic performance was achieved by using Phenomenex Kinetex 2.6 μ m C18 (100X4.6) mm column with mobile phase A: 2mM Ammonium tetra fluoro acetate and B: 100 % Methanol. Sciex QTRAP[®] 5500+LCMS/MS mass spectrometric system was used in multiple reaction monitoring (MRM) mode. Analysis was carried out in positive polarity with electron spray ionization mode. Multiquant[™] 3.0.2 software was used for quantitation analysis.

Preliminary Data

Protein precipitation followed by liquid-liquid extraction was used as extraction technique. Ethanol containing 0.025% of Butylated hydroxytoluene was used as precipitating agent and Dichloromethane was used as extraction solvent. Calibration curve with the range of 5 to 500 ppb was plotted with linear regression coefficient (R²) value greater than 0.99 for each analyte. Percent recovery ranged from 50 to 85 % for all the vitamins. Matrix effect was also calculated in terms of matrix factor and percent CV was found to be less than 15 % for each analyte. Multiquant[™] 3.0.2 analysis revealed 6 orders of linear dynamic range of quantitation. Limit of quantitation (LOQ) was achieved in nanogram level for all of the vitamins. Ion ratio of quantifier to qualifier was used for quantification.

Novel aspect:

Highly sensitive and selective method with good chromatographic resolution for simultaneous quantification of fat soluble vitamins in the concentration range of 5ppb to 500 ppb in infant formulae without hydrolysis(saponification) has been developed.

705 - MULTICLASS METHOD FOR THE QUANTITATIVE ANALYSIS OF 108 VETERINARY DRUGS IN MEAT AND MILK BY LIQUID-CHROMATOGRAPHY QUADRUPOLE-ORBITRAP MASS SPECTROMETRY

Giorgio Saluti (1) - Irene Diamanti (1) - Rosanna Rossi (1) - Carolina Barola (1) - Danilo Giusepponi (1) - Simone Moretti (1) - Roberta Galarini (1)

Istituto Zooprofilattico Sperimentale dell'Umbria e delle Marche "Togo Rosati", Centre for Development and Validation of Methods, Perugia (1)

Keywords: veterinary drugs; meat; milk; LC-Q-Orbitrap

Introduction

Multiclass approaches are more and more appreciated since they improve the cost effectiveness of monitoring programs to detect residues in food. Starting from our previous works [1; 2] in which we developed procedures for the determination of 62 antibiotics in meat and milk, the aim of this study was the widening of the method scope including 46 new veterinary drugs.

Methods

Sample preparation and instrumental conditions were those reported by Moretti et al. [1;2] with some modifications. The analysis was performed using liquid chromatography/quadrupole-orbitrap mass spectrometry. The acquisition was carried out in positive ionization mode (ESI+), except for closantel and nitroxinil (ESI-).

Results

Some slight modifications of sample treatment and chromatographic conditions were required to obtain satisfactory quantitative performances (accuracy) for the new 46 analytes, most of which were antiparasitic drugs such as avermectins and benzimidazoles. Only an example: prior to LC injection the dried residue had to be dissolved in a mixture containing ammonium acetate/acetonitrile (50:50, v/v), instead of ammonium acetate as previously optimized [1;2]. In fact, the introduction of lipophilic drugs such as ivermectin or closantel required a certain percentage of organic solvent to avoid insufficient solubilization of these analytes and, therefore, scarce accuracy. At the end of the development, a full validation study was carried out. The observed recoveries were generally higher than 70% and precision (inter-lab reproducibility) lower than 20% both for meat and for milk.

Conclusions

The widening of the number of analytes (from 62 to 108) included in our previously developed multiclass methods for antibiotics in food has been successfully achieved. The validation study demonstrated that the new procedure is fit for purpose [3] and therefore applicable in the official monitoring programs.

Novel Aspect

The flexibility of multiclass approaches must be experimentally verified when quantitative confirmatory methods are developed, as here demonstrated.

Keywords: red wine; pesticides; residues; agrochemicals

Introduction:

Attack of the grapevines by fungi is one of the main challenges facing producers as it compromises the production volume and quality of grapes destined for wine production. Due to these diseases, fungicides are routinely used. Thus, the objective of this work was to evaluate the presence of fungicides in 190 wines produced in southern South America to promote discussion regarding the importance of monitoring pesticide levels in wines.

Methods:

A total of 190 red wines were analysed; 41 of which were Brazilian, 75 were Chilean, 30 were Uruguayan, and 44 were Argentinian. The fungicides were analysed by LC-MS/MS and GC/MS using a method validated according to the SANTE recommendations [1]. This work proposed an advancement in the quantification of dithiocarbamate in which the levels are determined in mancozeb equivalent.

Results:

Of the 190 wines analysed, 76 contained fungicide residues (40%), and of those, 31 (16.3% of the total analysed) presented values above those allowed for the grape, which would lead to them being classified as irregular. Among the 44 pesticides evaluated, dithiocarbamate was the most prevalent as it was found in 16.3% of the samples (n = 31); the next most common was azoxystrobin, which was found in 14% of the samples (n = 26), and of those, 11 were irregular. Carbendazim was found in 13% of the samples (n = 25), of which 12 were outside the limits set for grapes. Almost 20% of the samples (n = 32) contained residues of 2 or more pesticides. One of the wine samples (a blend from 2014) had five different pesticides, carbendazim, metalaxyl-M, azoxystrobin, dithiocarbamate and dimethomorph. In addition, 8 samples showed cyprodinil residues, a fungicide prohibited in grapes.

Conclusions:

The main fungicides found were dithiocarbamates, azoxystrobin, carbendazim, difenoconazole, dimethomorph and cyprodinil. Of the 190 wines analysed, 40% contained at least one pesticide, and 16.3% had levels above the MRL (irregular). The present work emphasizes the importance of the creation of laws regulating pesticides in wines, which will facilitate foreign trade.

Novel Aspect:

To date, this is the largest study on pesticide residues in South American wines.

986 - A ROBUST AND SENSITIVE METHOD FOR THE DIRECT ANALYSIS OF POLAR PESTICIDES IN FOOD AND ENVIRONMENTAL SAMPLES

Detlev Schleuder (1) - Ugo Chiuminatto (2) - Wim Broer (3)

AB SCIEX Germany GmbH, Support, Darmstadt (1) - SCIEX, Support, Milano (2) - Nofalab, Laboratories, Schiedam (3)

A Robust and Sensitive Method for the Direct Analysis of Polar Pesticides in Food and Environmental Samples

Wim Broer¹, Jianru Stahl-Zeng², Detlev Schleuder²

1. Nofalab Laboratories, Schiedam, NL; 2. SCIEX, Darmstadt, DE

Introduction

The prevalence of multi-residue LC-MS/MS analyses for the quantification of pesticides in food and environmental samples has been steadily increasing for many years, and they are now considered to be a minimum requirement of most laboratories working in these fields. Modern tandem quadrupoles are capable of detecting such regulated compounds at very low levels with minimal sample preparation, such as QuEChERS, thereby enabling labs to process large numbers of samples for many analytes with a fast turnaround. However, some very polar analytes which are not amenable to the extraction procedure, chromatographic method or are poor ionisers require additional single-residue methods which involve time-consuming preparation and separation and often involve derivatisation to improve detection.

Recent increase in public concern regarding the presence of glyphosate has significantly increased the requirement to analyse it and its metabolites in food, feed and the environment, so has accelerated the need for a more efficient and robust analytical method. The extraction and chromatography of these compounds is well described in the EURL-QUPPE method, but the separation is not robust in practice, so system and method maintenance are intensive. Several different HPLC or HILIC based methods have failed to address the issues of reproducibility and sensitivity, so Fmoc derivatisation prior to analysis is often still employed for glyphosate, AMPA and glufosinate. Although possible to automate, this procedure is still time consuming or expensive, and is not applicable to the other polar pesticides of interest.

Method

Nofalab is an independent sampling and testing laboratory based near Rotterdam, NL specialising in the fields of food, feed and environmental safety. The increasing pressure to provide fast, quantitative analysis has driven them to invest in additional LC-MS/MS instrumentation and develop a new method which covers as many of these polar pesticides in a single analysis as possible. Ion chromatography has been shown to be beneficial for separation, but the need for a suppressor is detrimental to MS analysis and the problem of changing inlet systems on a heavily used mass spectrometer makes it impractical in a busy lab performing primarily reverse-phase LC. So, the final method, presented here, makes use of an IC column in a method-switching RP system with MS amenable mobile phases at pH 9. Such conditions configure glyphosate ideally for MS detection with good retention and separation of the other analytes and matrix interferences. The method meets the Sante requirements of reproducibility (<20%) and recovery (80-110%), and the LOD of the method is below 0.01 mg/kg. Excellent long-term stability and robustness were achieved throughout the validation of this method for food samples extracted by the QUPPE procedure.

Results

Where environmental samples require testing, the regulatory limits are much lower and interference from matrix more problematic in traditional analyses with a short retention time, so derivatisation is often the only option. However, since glyphosate is well retained in this new method, the potential to further develop it for direct large-volume injection was investigated in collaboration with SCIEX. By modifying the gradient conditions and optimising the injection parameters, a second method specific to environmental water samples has been developed. Although the LVI is more susceptible to changes in pH (for example, due to evaporation of mobile phase) robustness has been shown to be similarly good, and allows detection of the same suite of analytes with a LOD of <0.02 ng/l.

596 - NON-TARGETED FAST SCREENING OF HUNDREDS RESIDUAL PESTICIDES ON FRUITS, EGGS AND SOIL USING AMBIENT MASS SPECTROMETRY

Jentaue Shiea (1)

National Sun Yat-Sen University, Department of Chemistry, Kaohsiung (1)

Keywords: non-targeted screening, pesticide, ambient mass spectrometry, miniature, high-throughput

Introduction:

Thermal desorption-electrospray ionization (TD-ESI) source[1] combined with a miniature triple quadrupole mass spectrometer (Ultivo, Agilent) was applied to rapidly screen hundreds of residual pesticides on fruits and in soils and eggs without or with minimal sample pretreatment.

Methods:

The TD-ESI/MS system consists of sampling probe, heated oven, electrospray device, and mass analyzer. For sampling analytes on the fruit, a stainless steel probe gently scrapes through the fruit surface for 2 cm. Since soil contains complicated components, ca. 2 μ L of the organic solvent extracts was collected on the sampling probe after rapid extraction. The probe was then inserted into a heated oven to thermally desorb the analytes on it, the analytes were subsequently carried by a nitrogen gas stream to join in an ESI plume, the analyte ions were formed by ion-molecule reactions between the charged species (H_3O^+ , CH_3OH_2^+ , $(\text{H}_2\text{O})_2^+$, etc) in the ESI plume and analytes. The analyte ions were detected by the miniature triple quadrupole mass spectrometer attached to the TD-ESI source.

Results:

Without redundant extraction and separation processes, the analysis of each sample is completed in 15 s. Pesticide database was well-established by using TD-ESI coupled with a miniature triple quadrupole mass spectrometer. In addition, approximate 200 pesticides can be simultaneously detected in one analysis. The detection limit of pesticides in fruits were in sub ppm level and below the legal limit of their respective concentrations.

Conclusions:

Thermal desorption-electrospray ionization/mass spectrometry is a sensitive, reproducible, qualitative, and rapidly analytical technique; it is also suitable for large-scale screening and high throughput analysis of fruits and soil to assure consumer's health.

Novel Aspect:

Non-targeted screening of hundreds residual pesticides can be rapidly done by using thermal desorption-electrospray ionization/mass spectrometry.

57 - THE TIME TREND OF PBDE IN BREAST MILK FROM BEIJING WITHIN THE FIRST SIX MONTHS POSTPARTUM

shuling Song (1)

National research center for geoanalysis, Department of organic analysis, Beijing (1)

Keywords: polybrominated diphenyl ethers; variation trend; lactation; breast milk; Beijing

Introduction: (Limit of 400 characters)

Polybrominated diphenyl ethers (PBDEs) are flame retardants [1-2]. Numerous studies have proved that PBDEs showed the hepatotoxicity, embryotoxicity, thyroidogenic and estrogenic effects on animals [3-5]. So the residue levels of PBDEs in human are of great concern because of their potential toxicity. In this study, 7 PBDEs in breast milk from Beijing were determined, and the variation trend from 5 donors during the first six months lactation was dominated.

Methods: (Limit of 400 characters)

55 breast milks were collected from 30 donors living in Beijing over 5 years. Five of donors provided one sample per month and sampled for six months. The sample was treated with liquid-liquid extraction method (LLE). In general, 10 ml of sample was extracted by mixture of ethanol, diethyl ether and hexane, and then cleaned up by packing columns and detected by GC-NCI-MS. An external standard method was applied to qualitative and quantitative analysis.

Results: (Limit 900 characters)

The results showed that PBDE28, PBDE47 and PBDE153 were detected in samples, and the detected rates were 23.3 % for PBDE28, 26.7% for PBDE47, and 60.8 for PBDE153, respectively. Except for PBDE28, the result was similar to the research result reported by Li J.G. [2]. The concentration of PBDE47 was ranged from 0.21 to 1.21 ng/g fat, with 0.78 ng/g fat of mean value (n=30). Compared to PBDE47, PBDE28 and PBDE 153 were detected with higher average value, which were 5.40 ng/g fat for PBDE28, and were 2.73 ng/g fat for PBDE153, respectively (n=30). The analytical results of PBDE28, PBDE47 and PBDE153 in breast milk, during the first six months lactation, indicated that the three compounds were not always detected, and the concentrations don't decrease gradually, but shaved.

Conclusions (Limit of 400 characters)

The level of PBDEs was lower than the value reported by Li in 2010. This indicated that the residue level of PBDEs in local residents or exposure risks of local residents to PBDEs have decreased. It was well known that the diet exposure was the main exposure pathway. So we take the daily intake from diet into account for the waving change of PBDEs in breast milk during the first six month lactation.

Novel Aspect: (Limit of 150 characters)

The updated residue levels of PBDEs in breast milk from Beijing.
A time trend of PBDEs in breast milk was monitored during the first six months lactations.
The level of PBDE in breast milk may not, in some extend, showed its accumulated level in human body.

Screening and Quantitation for Food Matrices using scanning SWATH acquisition.

David M. Cox, Jeff Rivera, Holly Lee, Vanaja Raguvaran, Jianru Stahl-Zeng,

Introduction

MSMS data is important in confidently identifying a compound in a screening assay. Obtaining an MSMS for every compound in a run can be a challenge.

SWATH acquisition can acquire MSMS that represent every precursor mass of interest at every time point. However, the deconvolution of MSMS requires that each fragment ion have a different chromatographic profile or elution time. Information dependent acquisition (IDA) will consistently trigger on the most abundant compounds, but can occasionally miss some candidates. Combining SWATH with IDA improves the identification of compounds in screening assays.

Methods

X500R, LC, pesticide kit. Acquire SWATH, IDA, and SWATH+IDA data. Process with SCIEX OS.

Preliminary Data

SWATH acquisition uses precursor isolation windows that typically range from 5-25 Da wide. Even when two or more compounds fall within a SWATH precursor isolation window, and have similar elution times, deconvolution of the MSMS is usually possible using a PCA/PCVG based technique. This MSMS is used for library searching and subsequent compound identification.

With IDA, the precursor isolation window is 1 Da wide, which greatly reduces, but does not eliminate, the chance of two compounds being in the same window. However, if IDA does not trigger on a candidate, there is no MSMS data to confirm a compound identification with.

The amount of time spent on each cycle of acquisition is limited by how many points across an LC peak are required. With SWATH acquisition, this limit determines how wide the precursor isolation window for each SWATH experiment must be. Wider windows increase the chance of deconvolution failing, narrow windows take more time. With IDA, this limit determines how many candidates can be selected each cycle. Fewer candidates increases the chance that a candidate ion is missed, but more candidates take more time. In both cases, this trade-off follows a typical pareto principle (80/20- rule) where the majority of performance is achieved early (wide SWATH windows or small number of IDA candidates). Combining these two scan modes into one acquisition method enables a few wide SWATH windows and a small number of IDA candidates to perform well.

Novel Aspect.

Data independent acquisition (SWATH) combined with IDA to improve screening assay performance.

698 - LC-MS/MS VERSUS GC-MS/MS FOR HEXABROMOCYCLODODECANES (HBCDS) ANALYSIS IN FOOD

ARIANNA STRAMENGA (1) - TAMARA TAVOLONI (1) - TOMMASO STECCONI (1) - ARIANNA PIERSANTI (1)

ISTITUTO ZOOPROFILATTICO SPERIMENTALE DELL'UMBRIA E DELLE MARCHE "TOGO ROSATI", SEZIONE DI ANCONA, ANCONA (1)

Keywords: HBCDs, LC-MS/MS, GC-MS/MS, Food, BFRs

Introduction:

HBCDs are used as additives in plastic polymers to reduce flammability; they can be released in the environment and accumulate in food chain. Technical mixture contain mainly diastereomers α , β and γ [1]. Both gas-chromatography (GC) and liquid chromatography (LC) are used for HBCDs analysis, but GC does not resolve the diastereomers. The aim of this study was to set up the best analytical method for HBCDs in food comparing GC-MS/MS and LC-MS/MS.

Methods:

α , β and γ HBCD were analyzed in isotopic dilution after QuEChERS-like extraction, acidic Extrelut-NT3[®]/Si-SPE and GPC clean up. Instrumental analysis was performed in GC-MS/MS on a RTX-1614 (15m x 250 μ m x 0.10 μ m) column and PTV injection (10 μ L) [2]. A LC-MS/MS method was also developed, using a Kinetex XB-C18-100 \AA column (2.6 μ m, 100 x 2.10mm) and, as mobile phase, MeOH (phase A) and 2 mM CH₃COONH₄/MeOH (50:50) (phase B) [3]. The method was validated in muscle at 10, 20, 50 and 100 pg/g.

Results:

Literature reports that GC does not enable the resolution of α , β and γ isomers: HBCDs can be quantified only as sum. Furthermore, the development of the GC method is extremely tricky because the 3 isomers inter-convert at T > 160 $^{\circ}$ C and decompose at T > 240 $^{\circ}$ C or in dirty GC systems [4]. The performances for GC-MS/MS method were not satisfactory, because of the impossibility to separate the three isomers yielding in a not completely accurate quantification. During method set up, we experienced LC-MS/MS to be the method of choice for HBCDs analysis, because of the absence of thermal degradation and the ability to resolve the α , β and γ isomers. Therefore the analytical performances were systematically studied in LC-MS/MS. Accuracies, in intra-laboratory reproducibility conditions, were satisfactory for all the isomers: apparent recoveries were between 92 and 107% and precisions between 9 and 22%. Recoveries of the surrogate labelled standards were higher than 70%. No laboratory background contamination was measured.

Conclusions:

The results confirmed LC-MS/MS as the method of choice for HBCDs analysis enabling to reach good performances also at 10 pg/g, which was set as method LOQ. The procedure performs well in fish products and lean terrestrial muscles. The applicability to other food matrices should be further tested.

Novel Aspect:

Few data are available in Italy about HBCDs in food, therefore this method enables an extensive monitoring at very low contamination levels.

Keywords: PBDEs, HBCDs, LC-MS/MS, GC-MS/MS, Fish

Introduction:

PBDEs and HBCDs are brominated flame retardants (BFRs) used as additives in plastic polymers to reduce their flammability. They can be released in the environment and accumulate in food chain. Few data are available in Italy about their environmental levels and dietary exposure [1,2]. In this study, levels of PBDEs and HBCDs were measured in marine fish samples collected in local markets.

Methods:

This study involved the analysis of 15 PBDE congeners (28, 47, 49, 66, 77, 85, 99, 100, 138, 153, 154, 183, 197, 206, 209) and 3 HBCD (2, 2', 2''-HBCD) in 18 marine fish samples collected from local markets in Central Italy. The samples were analyzed either by GC-MS/MS (PBDEs) or LC-MS/MS (HBCDs) in isotopic dilution, performing a QuEChERS-like extraction followed by a two steps clean-up [3].

Results:

PBDEs and HBCDs were measured above the MDL in most of the samples. Their concentrations were generally in the range of ppt, only BDE47 reached ppb level in one sample. BDE47 is the dominant congener in all species and its concentration was >LOQ in 16 out of 18 samples; in 12 samples also BDEs 100, 99, 49 and 154 were measured. Total PBDE contamination was estimated as sum of the 15 congeners adding 0.5 LOQ in case of not quantified. The highest PBDE levels were measured in a spiny dogfish and mackerel (Sum: 3057 and 874 pg/g respectively), while cod and hound shark showed the lowest levels (Sum: 301 and 311 pg/g respectively). The highest HBCD isomer was always the 2, which was quantified in 13 out of 18 samples [4]. Only in one mackerel also 2''-HBCD was identified. The total HBCDs content ranged from <LOQ (cod and hound shark) to 3160 pg/g (mackerel).

Conclusions:

The average concentration (N=18) was 616 pg/g for 15 PBDEs and 104 pg/g for 3 HBCDs. The highest levels for both classes were measured in spiny dogfish (lipid 7.7%), confirming that fatter species are generally the most contaminated [1] while lean ones (cod and hound shark - lipid <1%) had lower concentrations. No data are available in spiny dogfish in literature while comparable results are reported for all the other species [5,6].

Novel Aspect:

Among food, fish highly contribute to PBDEs and HBCDs human intake. Few data are available in Italy about BFRs in fish, therefore these results may help in assessing background levels.

Keywords: PBDEs, NDL-PCBs, Heavy metals, wild boar, hunting.

Introduction:

Wild boar is an omnivore species often used as environmental pollution sentinel. It is hunted and consumed as food, therefore may expose population to relevant levels of contaminants. This study investigate the presence of some organic (PCBs and PBDEs) and inorganic (Cd, Hg, Pb, As, Ni, Mn) pollutants in wild boars caught in Central Italy.

Methods:

Samples were caught in a rural area close to the Appenninimountain in the Macerata district (Marche). Muscle, fat and liver of 44 wild boars hunted in 2017/18 season were selected. The samples were grouped by organ type, sex and weight to yield 21 laboratory pools. NDL-PCBs and PBDEs were analyzed by GC-MS/MS [1,2], Pb, Cd, As, Ni andMn by ICP-MS and Hg by AAS (FIMS).

Results:

PCBs, Pb, Cd and Mn were above LOQ in all the selected tissues, PBDEs only in muscle, As was not detected in almost all the samples while traces of Ni and Hg were measure only in livers. PCBs were all below MRLs [3] and the highest levels measured in muscle (mean 13 ng/g fat), in liver mean PCBs was 0.5 ng/g; congener 153 was dominant, followed by 138 and 180. The concentration increases with weight in males while decreases in females, where the levels are generally lower, probably because they can transfer contaminants to their progeny [4]. Also for PBDEs, muscle was more contaminated than liver where almost all the BDEs were below LOQ. In muscle dominant congeners were 47> 99> 100. 15PBDEs in muscle (mean 848 pg/g) was generally higher than the ones reported from other authors [5]. Cd in muscle (mean 0.028 mg/Kg) was lower than MRL (0.050 mg/Kg) except for two samples (0.057 and 0.053 mg/Kg). None of the livers exceeded MRL (mean 0.25 mg/Kg) [3]. The results are comparable with previous studies [6, 7]. Pb values fell between 0.025 and 6.99 mg/Kg in muscle while in liver the mean level was 0.04 mg/Kg. Six out of 7 muscles exceeded Pb MRL; this could be related to Pb dispersion in muscle due to bullet fragmentation. Mean levels of Mn were 0.482 (muscle) and 1.774 mg/Kg (liver).

Conclusions:

Muscle resulted to be the most contaminated tissue respect to liver and fat for all the considered contaminants. Pb residues in muscle were very high as a result of fragmentation of bullets used in hunting.

Novel Aspect:

Few data are available about contamination of wild fauna in Central Italy, therefore these results may help to start assessing background levels in Italy.

1254 - LC-MS/MS METHOD TO EVALUATE THE PRESENCE OF EXOGENOUS GLYCEROL IN WINES

Loris Tonidandel (1) - Sergio Moser (2) - Debora Trainotti (2) - Roberto Larcher (2)

Edmund mach foundation, CTT, Edmund Mach foundation, Italy (1) - Edmund Mach foundation, CTT, San Michele all'Adige, Italy (2)

Keywords: LC/MS/MS, glycerol, wine, cyclic diglycerols, 3-methoxypropane-1,2-diol

Introduction

Glycerol is a natural constituent of wine being produced by yeast during fermentation and its concentration ranges between 5 and 11 g/L depending on yeast strain. It plays an important role on the sweet taste of wine [1]. The addition of synthetic glycerol to wines in order to increase this parameter is not allowed by the European oenological legislation [2]. Actually, the strategy to investigate the presence of exogenous glycerol in wine is based on the detection of impurities produced by the industrial processes on its production [3], which are absent in wines. Synthetic glycerol contains the following impurities: 3-methoxypropane-1,2-diol (3-MPD) and cyclic diglycerols (CycDs) formed during the purification of the rough industrial product conducted through a distillation process. Currently, the determination of these impurities are carried out by a GC/MS method after an extraction step in ethyl ether. As an alternative to this "old" method has been proposed an innovative approach based on liquid chromatography coupled to the mass spectrometry (LC-MS/MS).

Methods

The chemical analysis of 3-methoxypropane-1,2-diol (3-MPD) and cyclic diglycerols (CycDs) has been performed using an Acquity Liquid Chromatographer (UPLC Waters Corporation, Milford, MA, USA) coupled to an Xevo TQ Mass Spectrometer (Waters Corporation, Milford, MA, USA). Chromatographic separation has been performed with an C18 HSS T3 column (2.1 mm x 100 mm, 1.8 µm); flow rate 0.45 ml/min; Eluent A, Water + NH₄Ac (5 mM); Eluent B, Methanol. Mass spectrometer was equipped with an electrospray ion source operating in positive ion mode; capillary voltage 1.5 kV; nitrogen gas flow, 1000 L/h; source temperature, 150 °C. Acquisition was carried out in MRM (multiple reaction monitoring).

Results

Gas chromatography mass spectrometry (GC-MS) is the analytical method adopted by the OIV to detect the fraudulent addition of glycerol by measuring these two contaminants [4]. To the best of our knowledge, this is the only validated method to detect and quantify 3-MPD and CycDs in wine. However, the application of the GC-MS method shows serious difficulties: sample preparation and time analysis (runtime about 42 min); dirty injections with early consumption of the column (particularly in the case of sweet wines); mass spectrometer ion source must be cleaned very often to improve the required sensitivity. In order to overcome these limitations a simple LC-MS/MS method has been developed.

Conclusions

The proposed method could be a useful tool to rapidly screen wine suspected of fraudulent glycerol addition. Keeping GC-MS analysis to further confirm positive results.

Novel Aspect

High throughput LC-MS/MS method respects the official method (using GC/MS) proposed by OIV.

550 - SCREENING AND QUANTITATIVE ANALYSIS OF NON INTENTIONALLY ADDED SUBSTANCES ELUTED FROM POLYETHYLENE TEREPHTHALATE BOTTLE BY HIGH-RESOLUTION MASS SPECTROMETRY

Atsushi Yamamoto (1) - Taro Murakami (2) - Motohiro Shizuma (3) - Eri Kishi (2) - Asako Ozaki (2)

Tottori University of Environmental Studies, Faculty of Environment, Tottori (1) - Osaka Institute of Public Health, Food Chemistry 2, Osaka (2) - Osaka Research Institute Industrial Science and Technology, Biomaterial, Osaka (3)

Keywords: Food safety, NIAS, high-resolution mass spectrometry, fragmentation

Introduction:

Food packaging materials can contain a wide range of known and unknown substances [1]. Chemicals such as impurities of ingredient, by-products, and degradation products are also plausible. These chemicals are referred to as non-intentionally added substances (NIAS). In this study, NIAS from polyethylene terephthalate (PET) bottles were examined by liquid chromatography high-resolution mass spectrometry (LC/HRMS).

Methods:

To understand migration of NIAS to bottled beverages, non-volatile polar NIAS was assigned as a main objective in this study. An LC/HRMS system comprising ExionLC AD and X500R (SCIEX) was used for non-target analysis. X500R mass spectrometer, which had a mass accuracy of 2 ppm, was used to acquire the HR mass spectra with a mass resolution of 30,000. Material tests and long storage tests of PET bottles obtained in Japan, were carried out.

Results:

Several compound series with a constant interval of m/z 192.042 were present. This value corresponded to $C_{10}H_8O_4$, a monomer unit of PET. The mass spectrum includes much information such as fragmentation, exact mass, neutral loss, adduct ion formation, and isotopic pattern. Each element sticks to fundamentals and overlapped one another, so that the mass spectrum looks complex. It is cumbersome but usually possible to interpret the mass spectrum to determine a structure. The congener with the highest abundance in the material tests was cyclic PET trimer. Monomers and oligomers whose one terminal was carboxy group were also identified by the interpretation of mass spectra and confirmed by reference standards. One-year long storage tests with simulated food solvent showed a gradual release of these substances to the contents. PET bottles obtained from 8 manufacturers showed roughly similar migration profiles.

Conclusions

Unlike other plastic materials and articles, PET bottles obtained in Japan included less additives. In the examination by non-target analysis using LC/HRMS, PET congeners were the main migrants from PET bottles. One-year long storage tests with simulated food solvent showed a gradual release of these substances to the contents. The highest concentration of 4-[(2-Hydroxyethoxy)carbonyl]benzoic acid was 4.6 ng/mL and detected in one-year long storage test sample.

Novel Aspect:

NIAS from PET bottles was examined by non-target analysis with LC/HRMS. Several PET congeners were identified from HRMS data and confirmed by reference standards.

355 - VALIDATION OF AN ACCURATE MASS SCREENING METHOD FOR PESTICIDE RESIDUE ANALYSIS IN COCOA BEANS AND EVALUATION OF COLLISION CROSS SECTION VALUES USING ION MOBILITY QTOF MASS SPECTROMETRY

Badrul Hisyam Zainudin (1) - Salsazali Salleh (1)

Malaysian Cocoa Board, Cocoa Downstream Technology Division, Nilai (1)

Keywords: Cocoa beans; Pesticide residues; Ion mobility; Collision cross section; QuEChERS

Introduction:

Multiresidue screening method for the analysis of pesticide residues in dried cocoa beans was validated and applied to imported and domestic cocoa beans samples. The screening method covers 130 pesticides (insecticides, fungicides, herbicides) of different chemical classes.

Methods:

The method was based on modified QuEChERS (Quick Easy Cheap Efficient Rugged Safe) extraction method [1] and detection using ion mobility quadrupole time-of-flight mass spectrometry (IMS-QTOF). Acetonitrile was used as extraction solvent and the effect of d-SPE clean-up procedure was studied relative to detection rate and screening detection limit.

Results:

In the present work, pesticide multiresidue screening method was proposed based on the application of UPLC-IMS-QTOF-MS. The screening method was validated and applied to the screening of 130 pesticides in cocoa beans samples and was found to be more selective towards the studied pesticides. The optimized screening criteria consisted of mass accuracy (± 5 ppm), RT (± 0.2 min) and CCS ($\pm 2\%$) could decrease the false positive rate while maintain its detection rate at 98% compared with analysis without CCS values. Under this screening conditions, 33% of the investigated pesticides gave SDL of 10 $\mu\text{g}/\text{kg}$, whereas 44% and 15% of them presented SDL of 50 and 150 $\mu\text{g}/\text{kg}$, respectively. Finally, the automated screening workflow was applied to real cocoa beans sample through a monitoring study and 20% out of 60 samples were tested positive, in which drift time filtering improved the detectability and identification of the pesticides.

Conclusions:

IMS allows for the measurement of the CCS values, which provide information on the charge, shape and size of the pesticides [2]. Additional information in the form of CCS value provide more confidence in the identification process and lessening the probability of false positive during the pesticide screening process. Finally, a database of pesticide residues that consist of accurate mass, retention time, fragment ions, and CCS values was developed for cocoa beans.

Novel Aspect:

Intensive monitoring has been reported in this study using accurate mass screening with the help of CCS database for cocoa beans across wide range of different chemical classes.

1338 - APPROACHES TO MINIMIZE AND CONTROL EXTERNAL CONTAMINATION DURING SAMPLE HANDLING AND ANALYSIS OF UBIQUITOUS ENVIRONMENTAL PHENOLIC COMPOUNDS IN FOOD SAMPLES

Aida Zuberovic Muratovic (1) - Urszula Rybinska (1) - Karl-Erik Hellenäs (1)

National Food Agency, Department of Chemistry / Division of Science, Uppsala, Sweden (1)

Keywords: food analysis, external sample contamination, ubiquitous environmental phenolic compounds, UPLC-ESI-MS/MS

Introduction:

Phenolic compounds belong to a group of substances that might be of synthetic or natural origin. Synthetic phenolic compounds are present in our environment in pharmaceuticals, preservatives, personal-care products (e.g. synthetic fragrances and surfactants), as pesticides and miscellaneous industrial chemicals and byproducts (e.g. from plastic industry) [1,2].

As such, they can be detected in food and beverages in which they might originate from additives, food processing and packaging materials or as contaminants from the environment including the analyst. Many of the synthetic phenolic compounds are suspected to have the ability to affect the human body acting as estrogen mimics and are collectively termed endocrine disrupting compounds (EDCs). EDCs are substances that “interfere with the synthesis, secretion, transport, binding, action or elimination of natural hormones in the body that are responsible for the development, behavior, fertility and maintenance of homeostasis (normal cell metabolism)” [3]. EDCs are still not regulated at the EU level, but the work is ongoing to develop scientific criteria and properties for regulation. This causes intense discussion over these substances’ toxicity and mutagenicity which is reflected in ever growing interest in the question of their presence in foods. Thus, analytical methods for reliable quantitative determination of ubiquitous environmental phenolic compounds in food are desirable, but the analysis represents a substantial challenge due to the overwhelming risk of unintentional sample contamination from the laboratory environment. Such contamination complicates the quantitative measurements of the initial amounts of phenolic compounds in foods, especially when they are present at low nanogram levels.

Method:

The method is an UPLC-ESI-MS/MS based multi-analyte method that applies multiple reaction monitoring (MRM) and isotope labeled internal standards for quantitative determination of phenolic compounds.

Results:

This poster focuses on analysis of a selected number of most relevant phenolic compounds that can be found in foods, as well as approaches to minimize and control the external contamination from the laboratory environment during sample handling and analysis. The method is not validated yet and the findings from pre-validation measurements of phenols in some food samples, after preventive measures to reduce the external contamination sources in our laboratory were implemented, are presented. The levels of the found compounds were clearly higher than in the reagent blank.

Conclusions:

According to the present experience, the analysis of phenolic EDCs at low concentration levels in mixed and complex food matrices using regular analytical methods and laboratory equipment seems to be practically unfeasible until all the environmental sources of these chemicals are identified and maximally reduced to minimize their recurrence and impact on the analysis in order to ensure the validity of the data.

Novel Aspect:

The method used to analyze phenolic compounds in food is fast and straightforward. It allows analyzing different groups of phenolic compounds in the same analysis. The method also comprises important measures that have to be considered to minimize external contamination during the sample pre-treatment and thereby ensure contamination free extraction and reliability of the measurements.

505 - PIGMENT PROFILING IN OLIVE OILS BY ULTRA-HIGH PERFORMANCE LIQUID CHROMATOGRAPHY – ATMOSPHERIC PRESSURE CHEMICAL IONIZATION-HIGH RESOLUTION MASS SPECTROMETRY

Ane Arrizabalaga (1) - Pilar Rodriguez (2) - Mireia Medina (2) - Encarnación Moyano (1)

University of Barcelona, Chemical Engineering and Analytical Chemistry, Barcelona (1) - Government of Catalonia, Agri-Food Laboratory, Barcelona (2)

Keywords: edible oils, adulteration, food fraud, pigments, dyes

Introduction

The color is considered an important characteristic for consumers to evaluate olive oils quality. Pigments such as carotenoids and chlorophylls are the main responsible of this property but the color changes from green to yellow-brown due to the production processes or inadequate storage. In order to regreen the olive oils, instead of adding 20-30% of extra virgin olive oil, as it is established, different dyes or oil mixtures are used to adulterate [1,2].

Methods

A UHPLC-APCI-HMRS (Q-Orbitrap) method was developed to quantify chlorophylls, chlorophylls derivatives and carotenoid pigments and to detect adulterated olive oil samples due to the addition of dyes. A SPE procedure was performed using Silica SPE cartridges to clean-up the sample extracts. The UHPLC-APCI-HRMS method was achieved using an Accucore C18 column and working in positive ion mode and full scan acquisition mode (range 200-1000 m/z, Rs 70,000).

Results

The chromatographic separation of pigments was achieved in less than 15 min under gradient elution with a quaternary mobile phase. All pigments were ionized with APCI in positive ion mode. Chlorophyll and its derivatives generated the protonated molecule $[M+H]^+$ as base peak of the mass spectra with no significant in-source CID fragment ions. Concerning carotenoids, most of them also generated $[M+H]^+$ as base peak with significant in-source CID fragment although, in the case of lutein, the in-source CID fragment ion $[M+H-H_2O]^+$ dominated the mass spectrum. Moreover, tandem mass spectrometry has been used to obtain structural information for further confirmation of these analytes in olive oil samples.

The UHPLC-APCI-HRMS/MS method was applied achieving a pigment profile (relative concentrations between the different pigments) useful for the detection of adulterated olive oils. Additionally, the pigment profile of different potential fraudulent colorants was also studied in order to identify further adulteration evidences.

Conclusions

The proposed UHPLC-APCI-HRMS/MS method showed good quality parameters and allowed the accurate pigment profile of olive oil samples. Moreover, this method provided enough evidences for the detection of adulterated olive oil by the addition of dyes.

Novel Aspect

This is the first time that UHPLC-APCI-HRMS is applied for the olive oil pigment profiling to detect a fraud due to addition of dyes.

621 - ISOTOPIC MAPPING OF MILK AND GROUNDWATER IN THE PRODUCTION AREA OF PARMIGIANO REGGIANO FOR FOOD TRACEABILITY

Marta Boito (1) - Paola Iacumin (1)

Università degli Studi di Parma, Dipartimento di Scienze Chimiche, della Vita e della Sostenibilità Ambientale, Parma (1)

Keywords: isotopes, milk, origin, Parmigiano Reggiano, feeding regime

Introduction

Determination of the geographical origin of foodstuffs is becoming of increasing interest to consumers and producers, since it may be used as a criterion for certifying quality and authenticity.

The Protected Designation of Origin (PDO) trademark has been assigned to numerous local products based on their area of origin. In order to obtain this designation, the raw materials must have been produced and processed in the specific region from which the product gets its name. [1][2]

Methods

To make a check at the base of the production of "Parmigiano Reggiano" we began to collect monthly samples of groundwater, milk, hay and fodder from ten cattle-sheds in the production area. Sampling will last for at least a year. The stable isotope composition of the elements, such as O, H, C, N, have been evaluated with the aim of characterizing the milk of the Consortium areas and defining the isotopic fractionation of water ingested/milk produced and milk produced/food supplied.

Results e Conclusions

From the first results obtained it was possible to notice a differentiation of the isotopic values of O and H between plain and mountain milk. Even, the hay produced locally by breeders is different compared to the one purchased by import. Even, these greater characterizations could increase the added value of one producer's cheese.

Novel Aspect

The results of the present study could be helpful for consumers, the food industry and government regulatory agencies as it can prevent fraudulent labelling of organic food. [3]

Keywords: HS-SPME, GC-MS, wine, volatile organic elements, aromatic molecules

Introduction

Gas chromatography-mass spectrometry is widely employed to obtain important information on the aromatic profiles of wines, which are widely employed for differentiation and classification of wines based on geographical origin and grape cultivar. Wine is recognized to be very important in the human diet: the worldwide consumption of red wines reached over 240 mhl in 2017 [1].

Methods

On the basis of the general interest for local and sustainable products, we decided to focus our attention on some not yet studied Piedmont hillock wines. The volatile molecules were extracted by means of headspace microextraction (HS-SPME) with a triphasic fiber (CAR/PDMS/DVB 30/50 μ m), and were quantified by means of gas chromatography-mass spectrometry. This extraction technique has gained universal approval and is employed in many applications such as aromas and fragrances recognition in food area, toxicology, environmental and biological matrices [2].

Results and Conclusions:

Multivariate chemometric approach allowed the identification of the representative profile of the selected typical Piedmontese wines, which will be useful for traceability and safeguard from food frauds.

645 - WINE TRACEABILITY: "VIGNETO ITALIA" PROJECT

Claudio Brilli (1) - Benedetta Bronzi (1)

Ruffino srl, Laboratory, Pontassieve (1)

Keywords: wine, traceability, ICP-MS, Chianti

Introduction:

The project aims to classify wines on the basis of different geographical origin of the grapes.

246 and 393 grapes from known provenance are collected during 2013 and 2014 harvests. Then they are turned into wine by a vinification procedure that simulates the industrial process. Elemental composition of these samples is analyzed with ICP-MS and the resulting data are used to train a classification model that discriminates Chianti from other wines.

Methods:

Two quantitative procedures are used depending on the concentration level of the analytes. Most elements (10 ppb - 1000 ppm) are analyzed directly after 1:20 dilution and standard nebulization into the ionization chamber. For ultratrace elements (conc. < 100 ppt) the sample is diluted 1:5 after mineralization of the matrix; in this case the sample introduction system (Apex-Q with Spiro TMD) is designed to increase analytical sensitivity and to reduce interferences.

Results:

After statistical pre-processing of the data, three classification models are obtained through chemometric elaboration of ICP-MS analysis results: Linear Model and Similarity Model are based on supervised pattern recognition methods; Non Linear Model is based on Artificial Neural Networks (ANNs) which is one the most promising techniques to cope with the problem of automatic and intelligent classification. An additional model (Consensus) calculates the average between the results of the previous three models.

The predictive models are validated by testing 134 wine samples with known geographical origin: the Consensus Model shows a non-error rate (NER%) of 89,9% with 18,7% of non-classified samples.

Wine adulteration is also evaluated by analysing Chianti and non-Chianti samples blended at different rates: the results demonstrate that Consensus Model is able to detect down to (at least) 25% addition of non-Chianti wine to a Chianti sample, since it classifies such mixture as non-Chianti.

Conclusions:

The predictive model Consensus shows a satisfying percentage of correct classification. Some regions (such as Sicily) are difficult to differentiate from the Chianti area. But many regions with high wine production (Sardinia, Piedmont, Puglia, Marche, Campania, Basilicata, Umbria) are correctly identified.

Besides the total overlapping of samples from vintages 2013 and 2014 suggests that correlation is not affected by vintage.

1322 - PROTEOMICS APPROACH FOR THE DIFFERENTIATION OF TUNA SPECIES

Ina Brümmer (1) - Jens Brockmeyer (1)

University of Stuttgart, Food Chemistry, Stuttgart, Germany (1)

Keywords: Authenticity, Food, Proteomics, HPLC-MS/MS, Tuna

Introduction:

Worldwide studies prove that food fraud of fishes is a relevant issue[1][2]. Tuna species (*Thunnus* spp.) are often affected caused by limited availability and high price differences [3]. As methods for the differentiation of tuna species like polymerase chain reaction (PCR) and isoelectric focusing (IEF) are not sufficient, the aim of this project is to develop a method for tuna differentiation based on species-specific marker peptides.

Methods:

Tryptical digested peptides of each species were measured with HPLC-MS/MS by information dependent acquisition (IDA). The identification of de novo peptides was done using the software PEAKS, comparison was done manually. The identified potential marker peptides were verified by targeted experiments using HPLC-MS/MS. Finally, a targeted method for the differentiation of all relevant tuna species was developed.

Results:

In this project, we included all eight tuna species (*Thunnus* spp.) and two close related tuna species, skipjack tuna (*Katsuwonus pelamis*) and mackerel tuna (*Euthynnus affinis*). After manually comparison of all de novo peptides, species-specific marker peptides which are present in all analyzed fishes of these species were found for all relevant species. After verifying these potential marker peptides, it was possible to develop a targeted method using HPLC-MS/MS.

In addition, marker peptides for the group of all three Bluefin tunas (*Thunnus thynnus*, *Thunnus maccoyii* and *Thunnus orientalis*) and also for the genus *Thunnus* were found.

Conclusions:

Although tuna species are close related it had been shown that tuna species differentiation is possible using marker peptides analyzed with a targeted approach. In contrast to molecular biological methods, species mixtures can be also detected. After validation, this method could be implemented for routine analysis.

Novel Aspect:

This developed method is the first method for the differentiation of all tuna species based on mass spectrometry using a Proteomics approach.

184 - UHPLC-ESI-MS/MS FOR THE DETERMINATION OF POLYPHENOLS IN SPANISH PAPRIKA (CAPSICUM ANNUUM L.). APPLICATION TO PROTECTED DESIGNATION OF ORIGIN (PDO) CLASSIFICATION BY CHEMOMETRICS.

Guillem Campmajó (1) - Sergio Barbosa (1) - Oscar Núñez (1) - Javier Saurina (1) - Lluís Puignou (1)

University of Barcelona, Department of Chemical Engineering and Analytical Chemistry, Barcelona (1)

Keywords: Polyphenols; Spanish Paprika; Food Authentication; UHPLC; Tandem Mass Spectrometry

Introduction

Polyphenols are a large family of aromatic secondary metabolites well-known for their health beneficial effects and for contributing to sensorial attributes [1]. These compounds are mainly distributed in food of plant origin such as paprika, which is a dried and ground spice obtained from red pepper. In Spain, only La Vera and Murcia varieties are distinguished with protected designation of origin (PDO) and their polyphenolic content may allow to classify them.

Methods

A UHPLC-ESI-MS/MS (QqQ) method was developed to determine 37 polyphenols in paprika samples. A simple sample extraction procedure using H₂O:ACN (20:80, v/v) was employed. The chromatographic separation was optimized using an Ascentis Express C18 reversed-phase (10 cm × 2.1 mm, 2.7 μm) fused-core column (analysis time of 30 min). Paprika polyphenolic contents were subjected to principal component analysis (PCA) using PLS_Toolbox 7.8.2 (Eigenvector Research).

Results

The developed UHPLC-ESI-MS/MS method showed satisfactory limits of detection (down to 0.012 μg/L), linearity ($r^2 \geq 0.995$), run-to-run and day-to-day precisions (RSD ≤ 20%), and trueness (relative errors below 15%). 111 paprika samples from La Vera and Murcia (Spain), and from Czech Republic were analyzed, and the polyphenolic content quantified by external calibration. Chlorogenic, ferulic and p-coumaric acids, hesperidin, homoplantagin, rutin, and vanillin were found in all the samples. Polyphenolic composition was considered as a source of potential descriptors to be exploited for the classification of paprika according to the PDO and region of production. The plot of scores showed a successful separation in accordance with both PDO and production region. Moreover, a discrimination between Murcia and Czech Republic paprika varieties (sweet and spicy) was also possible. The PCA loading plots revealed that homoplantagin, betulinic acid and kaempferol were among the most relevant polyphenols to achieve this discrimination.

Conclusions

A simple and reliable UHPLC-ESI-MS/MS method for the quantitation of 37 polyphenols in paprika samples was developed. The characterization and classification of paprika samples according to the PDO and production region was achieved by employing polyphenolic content as chemical descriptors for PCA. This method will be useful to guarantee PDO attributes and for the prevention of frauds in paprika samples.

Novel Aspect

Fast UHPLC-ESI-MS/MS method for the determination of polyphenols and the classification of paprika samples in the authentication of PDOs.

Keywords: Non-targeted mass spectrometry; Extra Virgin Olive Oil; Food frauds; LC-HRMS

Introduction

High resolution mass spectrometry was used in the past for the detection of frauds on extra virgin olive oil products [1] [2] [3].

However, at the moment, scientific studies are not largely focused on the detection of soft refinements of Olive Oils, even if the dilution of EVOO with these samples is probably one of the most common frauds applied on the market.

This inter-laboratory work would like to identify some chemical markers responsible of this process.

Methods

Refined oils (deodorized and deacidified) were created on a laboratory scale starting from low quality olive oils and were analyzed together with a set of pure EVOO samples.

Sample preparation was executed according to previous works [4] [5].

UHPLC- HRMS analyses were performed with a SCIEX® triple TOF 6600 analyzer and with a Thermo® Q-Exactive Orbitrap analyzer.

Instrumental conditions were the same for all the instruments involved in the project.

Results

Raw data were processed with PeakView® (for triple TOF data) and Compound Discoverer® (for Orbitrap data); chemometric data analyses were performed with Markerview® (Sciex) and SIMCA® software (Umetrics).

Different PCA models were created and the scores plots clearly highlighted a separation between the pure Extra Virgin Olive Oil samples and the soft refined samples.

The features responsible of these clusterizations were selected and an attempt of compound identification was performed.

A group of molecules related to the adulteration processes were identified: they were at least upregulated in the refined oils or even only detected in these fraudulent samples and in their mixtures.

The markers selected applying the same experimental design with different instruments in different laboratories were compared.

Conclusions

This inter-laboratory research represents a robust untargeted metabolomic approach able to identify specific compounds that can be considered markers of soft refinement processes in Extra Virgin Olive Oils.

The detection of these molecules (performed with easier “target” methods) will be a proof of fraudulent issues in commercial samples.

Novel Aspect

Chemical markers for this important fraud in EVOO have not been largely studied yet. The multi-platform non-targeted approach could also be used for retrospective analyses.

1302 - IDENTIFICATION AND QUANTIFICATION OF POLYPHENOL IN COCOA EXTRACT, STUDY OF THE EFFETS OF FERMENTATION.

Guillaume Cazals (1) - François Guéhi GBOGBRI (2) - Alain Michel (2) - Christine Enjalbal (1)

LMP, Université de Montpellier, Montpellier, France (1) - UMR Qualisud, Université de Montpellier, Montpellier, France (2)

Keywords: polyphenol, identification, quantification, cocoa, fermentation

Introduction:

Regular consumption of chocolate is associated with beneficial effects on health [1]. Cocoa processing processes degrade the polyphenols it contains; the fermentation alone reduces by 90% the content of the polyphenols. It is therefore important to know its impact on the content and / or composition of polyphenols. Polyphenols were extracted from the post-harvest cocoa beans and the chemical compounds present in the cocoa extracts were identified and quantified by LCMS

Methods:

Identification of polyphenol were done by using UPLC separation coupled with high-resolution MSMS (QToF analyser). Identification of compounds were based on their exact mass and MSMS profile based on literature. Some of the flavanols identified were quantified by UPLC-MRM (triple quadrupole) with external calibration [2].

Results:

The post-harvest cocoa beans were divided into two batches (fermented and unfermented). In order to study difference between these two batches we achieved to build a robust chromatographic method [3] in order to get a good separation of compounds contained in the extracts.

In unfermented extract we observed twenty different compounds (eg. Catechin, procyanidin B...) while in fermented extract we only observe seven compounds.

From these observed compounds we choose three of them (catechin, epicatechin, procyanidin B) well identified to achieve quantification in both extract. Quantification results show decrease in the concentration of this compound in fermented extract. For example, epicatechin is present at 5.9 µg/g of cocoa in unfermented extract and at 0.21 µg/g of cocoa in fermented extract.

Conclusions:

Cocoa is a natural substance rich in polyphenols [4,5,6]. Fermentation is one of the essential processes in the processing of cocoa beans. This study demonstrated that this process degrades the polyphenols responsible for the health effects of cocoa. However, because of conflicting data reported in the literature, in-depth studies to fully identify different methods of cocoa fermentation are required [7]. In addition, to gain benefit, the research should take into account all the possible parameters such as the temperature, the fermentation time and the room in which the beans that deposit the initial content of the polyphenols during the fermentation processes are deposited. This would make it possible to avoid uncontrolled phenomena of natural, artificial or accidental origin that interfere during the fermentation of cocoa.

Novel Aspect: Relationship between post-harvest treatment of cocoa and its composition in polyphenol

1155 - SHRIMP FRAUD: EVALUATING CHARACTERISTIC METABOLOMIC FEATURES FOR AUTHENTICATION BY HIGH AND UNIT MASS RESOLUTION SPECTROMETRY

Olivier Chevallier (1) - Niladri Chatterjee (2) - Ewa Wielogorska (3) - Connor Black (4) - Christopher Elliott (4)

Queens University Belfast, Mass Spectrometry Core Unit, Belfast (1) - ICAR, Central Institute of Fisheries Technology, Cochin (2) - Queens University Belfast, School of Pharmacy, Belfast (3) - Queens University Belfast, Institute for Global Food Security, Belfast (4)

Keywords: Food fraud, Food authenticity, LC-HRMS, LC-MS/MS, chemometric

Introduction: (

Unfortunately fishery products occupy the second highest ranking position among commodities that are at most risk of food fraud. Among these, marine shrimps and prawns accounts for more than 17% of the global seafood consumption. As per Article 35 of the EC regulation 1379/2013, commercial designation of the species, production method and geographical origin have to be provided to consumers.

Methods:

Authentic samples were collected either directly from aquaculture farms or through local supermarket chains. Six species of shrimps namely Tiger Prawn, King Prawn, Indian Prawn, Pink Speckled Shrimp, Argentinian Red Shrimp and Red Prawn were included in the study. Among Tiger Prawns, wild caught prawns from India and Madagascar; and farmed prawns from Vietnam were sources as were farmed King Prawns were from India, Thailand, Vietnam and Honduras.

Results:

Methanolic extracts of freeze-dried samples were analysed in full scan positive and negative ionisation mode using a Waters Acquity I-Class UPLC coupled to a Xevo G2SQToF. Chromatographic alignment, peak picking and feature identification of the acquired data were carried out on Progenesis Q1 software followed by multivariate analysis in SIMCA-P software. OPLS-DA chemometric models could discriminate between species, geographical origin and production method. The R² and Q² values for all the models were >0.9. Further, characteristic metabolomic features for each species were determined by group wise comparison of the data. These features were evaluated in a targeted, triple quadrupole LC-MS/MS method and at least one exclusive biomarker for each species was selected. Subsequently, a confirmatory LC-MS/MS method for authentication of species was developed. An OPLS-DA model built using the characteristic features of Tiger Prawns and King Prawns was shown to discriminate between the geographical origins of these species.

Conclusions

The data generated gives a strong indication that the routine testing for species authenticity as well as the geographical origin of the prawns can be achieved using triple quadrupole LC-MS/MS.

Novel Aspect:

This innovative methodology based on LC-HRMS and LC-MS/MS can present an alternative to DNS testing or isotope based assays

616 - OPTIMIZATION, VALIDATION AND APPLICATION OF GC-FID AND GC-IRMS METHODS FOR THE DETERMINATION OF FATTY ACIDS WITHOUT DERIVATISATION

Andrija Ciric (1) - Jasmina Masten (1) - Lidija Strojnik (1) - Nives Ogrinc (1)

Jozef Stefan Institute, Department of Environmental sciences, Ljubljana (1)

Andrija Ciric, Jasmina Masten, Lidija Strojnik, Nives Ogrinc

Keywords: Fatty acids, FFAP, stable isotope ratio

Introduction:

The fatty acid (FA) composition of food is a recurring point of attention in government policy concerning nutrition and health, since they are source of energy, components of biological membranes, precursor for many different molecules and as transporters for vitamins such as A, D, E and K [1]. Further the stable isotope composition of carbon and hydrogen in fatty acids can be used to assess the geographical origin and authenticity of food products [2]. The aim of this presentation was to develop a simple, robust, and derivatization-free GC method suitable for the routine analysis of the major FA components and their isotope compositions.

Methods:

All analyses were performed using an Agilent model Hewlett-Packard 6890 gas chromatograph equipped with a flame ionization detector (GC-FID), while for stable isotope analysis an isotope ratio mass spectrometer IsoPrime (GV Instrument) with a combustion interface (GC-C-IRMS) was used. Separation was achieved using a Phenomex ZEBRON FFAP (30 m × 0.25 mm with film thickness of 0.25 μm) capillary column. The temperature program was as follows: 130 °C to 255 °C at rate of 20 °C/min. Helium was used for the carrier gas at a flow rate of 2.6 mL/min.

Results:

The separation of the FA was optimized by adjusting both the initial oven temperature and the temperature ramp. It was noticed that a faster temperature rate resulted in better resolution between palmitic and palmitoleic acid. The linearity of the method was verified between 50 - 200% of the injection volume as prescribed by the method. The results show an acceptable RSD% and mass deviation for all 16 major and minor constituents and confirm the linearity of the method. Method precision was checked in terms of repeatability and reproducibility. When the method was optimized using GC-FID, it was also applied to determine the stable isotope composition of C by GC-C-IRMS.

The stable carbon isotopic values are expressed in the usual ‰ notation as the per mill (‰) deviation of the isotope ratio of a sample relative to that of a standard. The $\delta^{13}\text{C}$ values of the 16 main FA vary from -30.9 to -28.6 ‰. The developed method was further tested on milk and oil samples.

Conclusions:

The method for determining the FA profile of different food samples has been optimized for the nitroterephthalic acid phase. Results showed that the method has acceptable selectivity, linearity precision, detection and quantification limits, robustness and stability. The method is suitable for the routine determination of the amount and isotope composition of FA in vegetables and food of animal origin with a distinct FA profile.

Novel Aspect:

Determining the fatty acid profile of different food samples without the need for derivatisation. The method can be used for food nutritional labelling, authentication, traceability and quality control.

Acknowledgment:

The study is part of two EU projects: MASSTWIN (H2020, grant agreement no. 692241) and ERA Chair ISO-FOOD (FP7, grant agreement no. 621329).

444 - DETECTING FOOD FRAUD: DETERMINATION OF A POTATO'S VARIETY AND ITS GEOGRAPHICAL ORIGIN IN ONE ANALYSIS VIA UPLC-IMS-QTOF

Christin Claassen (1) - Juergen Dr. Kuballa (2) - Sascha Prof. Dr. Rohn (3)

GALAB Laboratories GmbH, University of Hamburg/Department of Chemistry, Hamburg (1) - GALAB Laboratories GmbH, -, Hamburg (2) - -, University of Hamburg/Department of Chemistry, Hamburg (3)

Keywords: Food fraud, Metabolomics, Lipid Profiling, potato variety, geographical origin

Introduction:

In recent years, consumers increasingly claim for regional potatoes of certain varieties. Suitably labelled products are considered to be of higher quality and prices what might result in increased rates of food fraud.

While regulators enhance consumer protection, existing analytical methods cannot ensure compliance of food properties and its labelling sufficiently. Therefore, a Metabolomics-based approach was developed to evaluate potatoes' authenticity.

Methods:

About 200 organic and conventionally produced potato samples of known variety were collected from various German regions in 2016 and 2017.

Samples were cryomilled, lyophilized and extracted with a Liquid-Liquid-Extraction protocol including Chloroform, Methanol and water. The analysis of the nonpolar extracts was performed by an UPLC-IMS-QToF system. Obtained data sets were evaluated via multivariate data analysis using commercial and open source programs.

Results:

PCA and OPLS-DA analysis were carried out to differentiate between the varieties Belana, Gunda, Wega and Queen Anne. Additionally, samples were distinguished according to their growing regions. The structural elucidation of biomarkers was performed considering the retention time, precise molecular mass, MS/MS fragmentation data, isotopic patterns and ion mobility spectra provided by the UPLC-IMS-QToF analysis platform.

A set of more than 60 lipid biomarkers was identified which allows a reliable discrimination of the four potato varieties on the one hand and their cultivation region on the other. Characteristic substances, predominantly tri- and diglycerides, were found to differentiate potatoes originating from Thuringia, North Rhine-Westphalia, Bavaria, Schleswig-Holstein and other German production areas.

These generic markers withstand impacts like different farming methods and multiple harvesting periods. Furthermore, the reliability of the model was tested by analyzing mixtures of varieties and geographical origins.

Conclusions:

The results demonstrate that this metabolomics-based approach in conjunction with a comprehensive biomarker database has potential as a future screening tool for the investigation of labelled potato tubers regarding their variety and their German cultivation region to prevent food fraud. This tool may be used to preserve consumer interests and support regulators' efforts to keep pace with fraudsters.

Novel Aspect:

This approach determines a potato's variety and its cultivation region within one analysis whereas methods like electrophoresis and isotope analysis require multiple tests.

1283 - INVESTIGATION INTO THE CIS ISOMERS OF DICHLOROGENIC ACIDS IN COFFEE

Silvia Colombari (1) - Elena Guercia (1) - Elisabetta De Angelis (1) - Luciano Navarini (1)

illycaffè spa, Aromalab, Trieste, Italy (1)

Keywords: chlorogenic acids, isomers, UHPLC-MS, green coffee

Introduction:

Chlorogenic acids (CGAs) are a large class of esters formed between quinic acid and hydroxycinnamic acids frequently present in plants as a complex mixture of positional and geometric (cis/trans) isomers, however not easily and univocally identified [1]. Additionally, the UV light exposure is proven to convert the trans double bond to cis and structure and activity relationship for these cis/trans isomers have not been the subject of detailed investigations in spite of the need to deepen the knowledge on these biologically active polyphenols [2,3].

Methods:

Separation of analytes was achieved by UHPLC system equipped with a C18 column coupled to a Triple Quad MS, and, in order to discriminate isomers for dicaffeoylquinic acids (diCQA), a targeted MS3 mode (m/z 515.0 + 353.0 on negative mode) experiment was used.

Ad hoc UV light exposure experiments were performed on standard solutions and green coffee extracts.

Results:

Results confirmed that geometrical isomerism does not influence the fragmentation pattern, as previously reported in the literature [2], and an identification of the positional isomers is possible by means of an accurate chromatographic separation. Different behavior of light exposed green coffee extracts were evaluated, showing how differences in chlorogenic acids profile of different species could lead to different mixture of isomers after UV treatment.

Conclusions:

This work showed that UV irradiation of diCQA samples produce three positional isomers, and separation of these isomers could be efficient with the use of a LC-MS/MS method. Differences in chlorogenic acids profile of various green coffee samples were shown and these findings could represent an important step in the detection and discrimination of isomeric plant metabolites.

Novel Aspect:

UV irradiation experiment on green coffee extracts of different species with characterization of isomers of diacylchlorogenic acids.

1342 - COMPARATIVE PROTEOMIC ANALYSIS OF THE METABOLIC FRACTIONS COMPOSITION IN MODERN AND OLD WHEAT GENOTYPES

Antonella Di Francesco (1) - Rosaria Saletti (1) - Vincenzo Cunsolo (1) - Vera Muccilli (1) - Pasquale De Vita (2) - Salvatore Foti (1)

University of Catania, Department of Chemical Sciences, Catania, Italy (1) - CREA Cereal Research Centre, CREA Cereal Research Centre, Foggia, Italy (2)

Keywords: wheat, old genotypes, label free quantification, high resolution mass spectrometry

Introduction

Most of the modern wheat genotypes are derived from old wheats and have appreciable properties in terms of grain yield [1]. Wheat-derived products play an important role in many adverse reactions, such as celiac disease (CD), non-celiac wheat sensitivity (NCWS) and allergies. This has led to an increasing interest for the old wheat genotypes which are generally considered better tolerated than the modern ones, but without any scientific evidence.

Methods

Metabolic fractions were extracted from flours using 0.4 M NaCl, 0.067 M K₂HPO₄, pH 7.6 for 15 min at 20°C and a final centrifugation at 12,000 x g for 15 min. The extraction was repeated twice. 50 µg of each protein extract were reduced, alkylated, digested and analysed by high resolution mass spectrometry. MS data were processed by PEAKS Q and searched against a protein database, including only entries of *Triticum*, *Oryza*, *Hordeum*, *Avena*, *Secale*, *Maize* and *Brachypodium*.

Results

The aim of the present work is the qualitative and quantitative comparison by a proteomic approach of the metabolic protein fractions extracted from the mature kernel of two old Sicilian durum wheat landraces (Russello and Timilia restebianche), and Simeto, an improved durum wheat variety, widely spread in Italy and other Mediterranean countries, chosen as representative of the most widely commercial cultivars. The qualitative comparison of the protein composition revealed a remarkable similarity between old and modern cultivars. In particular, for each cultivar about 450 proteins were identified. The quantitative evaluation of the identified proteins detected that some proteins including avenin, NLTPs and β amylase, are over-expressed in the old genotypes compared to Simeto. On the other hand, differential expression is also observed in the comparison of the two old cultivars. In particular α -amylase inhibitor 0.28 is over expressed in Timilia whereas serpin Z2A is over expressed in Russello.

Conclusions

This study represents the first exhaustive qualitative and quantitative characterization of the metabolic protein fractions of the old Sicilian landraces Russello and Timilia restebianche and its comparison with a modern cultivar.

Novel Aspect

This comparison would help to understand the relationship occurring between protein profile of old wheat varieties and potential benefits for human consumption.

1290 - PROTEOMICS GOING NUTS? PROTEOME PROFILING OF WALNUT KERNELS

Benjamin Dreyer (1) - Dennis Kroesser (1) - Hartmut Schlueter (1)

University Medical Center Hamburg-Eppendorf, Mass spectrometric proteomics, Hamburg, Germany (1)

Keywords: Food authenticity, Walnut, food fraud, reference protein barcodes

Introduction:

Food authenticity is nowadays highly relevant since food fraud of expensive foods is a common problem. Differential proteomics approaches are powerful tools in this regard. Proteomics needs a tailored sample preparation for every kind of food. Especially foods with high content of lipids like nuts are challenging. In this study different sample preparation methods suitable for downstream LC-MS/MS analysis were tested for obtaining proteome profiles of the walnut.

Methods:

In the 1st approach nutmeat was grinded and defatted with hexane. Proteins were extracted by boiling in a sodium deoxycholate (SDC) containing buffer and then proteolytically digested with trypsin. In the 2nd approach grinded nutmeat was boiled in SDC containing buffer for protein extraction. Proteins were precipitated with acetonitrile (ACN) and then digested with trypsin. Peptides were analyzed by LC-MS/MS and raw data was processed with Proteome Discoverer 2.0.

Results:

The two protein extraction methodologies were compared regarding the quantity of the extracted protein amount in relation to the weighed portion of nutmeat and the number of unambiguously identified proteins and peptides respectively. Protein amounts were determined with a BCA assay and the recovery per weighed in mg of nutmeat was calculated. The protein recovery was approx. 38 % higher if the nutmeat was defatted first. Nevertheless the protein yields of both methods were sufficient for LC-MS/MS analysis. Although the ACN precipitation procedure yielded less protein, it performed superior in terms of the number of peptide and protein identification. Approximately 3.5 times more peptides and about six times more proteins were identified by the 2nd approach using the ACN precipitation. Most abundant in all samples were seed storage proteins like legumin B-like and 11S globulin seed storage protein 2-like with up to 1000 peptide spectrum matches. The data suggests that the walnut nutmeat proteome has a large dynamic range.

Conclusions:

Using ACN for precipitation of extracted proteins shows advantages over first extracting lipids with hexane for walnut sample preparation for proteomics applications. To overcome problems associated with large dynamic range proteomes 2-D LC approaches will be used to build spectral peptide libraries in the future and data independent acquisition will be used for reliable quantification to generate reference protein barcodes as fingerprints for authentic foods.

Novel Aspect:

This study presents evidence that defatting of walnut nutmeat prior to protein extraction isn't beneficial for differential proteomics applications.

827 - MULTI-CLASS LC-MS AND GC-MS METHODOLOGIES TO DISCRIMINATE EXTRA VIRGIN OLIVE OILS FROM DIFFERENT PROTECTED DESIGNATIONS OF ORIGIN

Lucía Olmo-García (1) - Karin Wendt (2) - Aadil Bajoub (3) - Carmen María Sánchez-Arévalo (1) - Arsenio Muñoz de la Peña (4) - Carsten Baessmann (2) - Alegría Carrasco-Pancorbo (1) - Alberto Fernández-Gutiérrez (1)

University of Granada, Department of Analytical Chemistry, Granada (1) - Bruker Daltonik GmbH, Bruker Daltonik GmbH, Bremen (2) - National School of Agriculture, Department of Basic Sciences, Meknès (3) - University of Extremadura, Department of Analytical Chemistry, Badajoz (4)

Keywords: virgin olive oil; protected designations of origin; LC-MS, GC-MS; chemometrics.

Introduction:

Product labeling has gained considerable attention over the last years, as a means to both provide product-specific information and reduce the quality uncertainty faced by consumers. Implementation of Protected Designations of Origin (PDOs) is one of the most prominent differentiation strategies used in olive oil market. They are often perceived as valuable tools that promote specific attributes of the oil linked to its geographical provenance.

Methods:

126 oil samples from 6 Mediterranean PDOs were analyzed by LC-MS and GC-MS combined to chemometrics. The extracts were eluted in LC using a C18 (2.1x 100 mm, 1.8 µm) column, with acidified water and acetonitrile and a flow gradient (0.4-0.6 mL/min) at 40°C. The derivatized extracts were injected in GC, using a BR-5 column with a T gradient from 150 to 320°C (4°C/min rate). Both systems were coupled to a Compact™ QTOF MS (Bruker) by an ESI interface for LC and an APCI source for GC.

Results:

Samples from six different Mediterranean PDOs (Meknès and Ouazzane (Morocco), Priego de Córdoba and Baena (Spain), Kalamata (Greece) and Toscana (Italy)) were collected and analyzed. Sample prep. (unselective 3-steps liquid-liquid extraction) and experimental conditions facilitated the determination of a great number of minor compounds (phenolic compounds, triterpenic acids and dialcohols, sterols, tocopherols, free fatty acids, etc.) within a single run. Non-targeted and targeted approaches were used to offer maximum coverage of the olive oil metabolome's chemical space in a 1st step, and the possible validation of the identified markers afterwards. Data treatment (PCA, PLS-DA) -done by using MetaboScape®- led to a noticeable discrimination among the six evaluated PDOs taking into account the data coming from both platforms. Several compounds such as elenolic acid, luteolin, oleuropein and ligstrosideaglycones, and some other tentatively identified substances, were pointed out as possible PDOs distinctive markers.

Conclusions:

- Multi-class LC-MS and GC-MS methodologies together with chemometrics made possible the discrimination among different PDOs, identifying potential origin markers.
- The combined use of non-targeted and targeted approaches can enhance or reinforce the outcomes of any study.
- GC-APCI-Q TOF can preserve the pseudo-molecular ion information, which is a great advantage over the "classical" GC systems and facilitates the identification.

Novel Aspect:

Combination of non-targeted and targeted approaches implying the use of powerful platforms (LC-ESI-Q TOF/GC-APCI-Q TOF) to identify potential "PDOs' markers".

1329 - UNTARGETED HIGH RESOLUTION MASS SPECTROMETRY METHODS TO ASSESS SALMON AUTHENTICITY

Giuseppina Maria Fiorino (1) - Marion Fresch (2) - Ina Brümmer (2) - Jens Brockmeyer (2) - Ilario Losito (3) - Linda Monaci (1)

National Research Council of Italy (CNR), Institute of Sciences of Food Production (ISPA), Bari, Italy (1) - University of Stuttgart, Institute of Biochemistry and Technical Biochemistry, Department of Food Chemistry, Stuttgart, Germany (2) - Institute of Sciences of Food Production, National Research Council of Italy (ISPA-CNR), Department of Chemistry and SMART Inter-department Research Center, University of Bari "Aldo Moro", Bari, Italy (3)

Keywords: Salmon authenticity; Direct analysis in Real Time; Liquid Chromatography; High Resolution Mass Spectrometry; Multivariate statistical analysis.

Introduction:

Two different untargeted approaches based on Direct Analysis in Real Time (DART) and Liquid Chromatography coupled to High Resolution Mass Spectrometry (LC-HRMS) were applied to the lipid and protein fraction of 50 farmed or wild-type salmons belonging to *Salmo salar* species to assess the feasibility of MS-based untargeted analysis for the discrimination between the two groups of salmons.

Methods:

Salmon lipid extracts were analyzed by DART coupled to an Orbitrap mass spectrometer. For the proteomics approach, proteins were extracted using Urea buffer systems and subjected to trypsin digestion and sample cleanup. Samples of farmed and wild-type salmon were analyzed by LC-MS/MS on TT6600 triple TOF-MS in DIA and SWATH mode and data evaluation was performed employing different chemometric approaches.

Results:

Lipids or peptides retrieved from DART-HRMS and LC-HRMS spectra, respectively, and exhibiting significant spectral intensity were selected as variables for multivariate statistical analysis. The latter allowed to distinguish clearly wild-type from farmed salmons on the scatterplot based on the first two principal components, accounting for the 77% of the total variance.

The subsequent search in the online databases showed that some of the selected variables might belong to the fatty acids class. In particular, three saturated fatty acids (14:0, 16:0, 18:0) had the main discriminating loading for wild-type salmons, whereas unsaturated fatty acids (18:1, 18:2, 18:3) and several oxidized forms arising from them were found to have a higher incidence in farmed salmons, due to their relevant incidence in the feeding mixtures adopted in salmon aquaculture plants [1]. Similarly, samples were clearly distinguishable using proteomics approaches.

Conclusions:

The application of untargeted DART/LC-HRMS approaches, integrated by multivariate statistical analysis, appears to be a promising tool for the discrimination of farmed and wild type salmons. DART/LC-HRMS spectra provide a set of variables able to distinguish salmons on the basis of their different living conditions.

Novel Aspect:

A novel coupling between DART and Mass Spectrometry has been investigated and exploited in the untargeted mode to discriminate between wild-type and farmed salmons.

1255 - CHARACTERIZATION AND QUANTITATION OF WATER-SOLUBLE VITAMINS IN WINE BY LIQUID CHROMATOGRAPHY-HIGH RESOLUTION AND TANDEM MASS SPECTROMETRY

Giovanni Inzalaco (1) - Francesca Borghini (2) - Alessandro Cavaglioni (2) - Gianluca Giorgi (3)

Università degli Studi di Siena, Dipartimento Scienze della vita, Siena, Italy (1) - ISVEA srl, Dipartimento di chimica, Poggibonsi, Italy (2) - Università degli Studi di Siena, Dipartimento Biotecnologie, chimica e farmacia, Siena, Italy (3)

Keywords: water-soluble vitamins, wine, HPLC-HRMS

Characterization and quantitation of water-soluble vitamins in wine by liquid chromatography-high resolution and tandem mass spectrometry

Introduction:

Wine is the oldest alcoholic beverage obtained from the fermentation of grapes. Among micronutrients, vitamins play a role in wine production. Some have origin from grapes and/or are formed during fermentation, others may be added for fine-tuning some properties or for avoiding undesired processes.

In this study we set up a simple and reliable method by using liquid chromatography-high resolution (HR) and tandem mass spectrometry (MS) for characterization and quantification of water-soluble vitamins (vitamins B, C and J) in Italian red and white wines. Furthermore, the method is applicable to beers, grapes and grape juices.

Methods:

Preliminary studies by direct infusion have been carried out on vitamin standards using both HRMS (Q-Exactive Hybrid quadrupole-Orbitrap, Thermo Scientific) and an ion trap instrument (LCQ Deca, Thermo Scientific) both equipped with an ESI source in positive mode. MS/MS experiments by using higher-energy collisional dissociation (HCD) in the Orbitrap and low-energy collision induced dissociations (CID) in the ion trap have been carried out to choose the appropriate reactions to be monitored. Successively, real samples have been filtered and injected in the HPLC equipped with a C18 column (Acquity BEH 100 × 2.1mm 1.7µm) and analyzed by HRMS. Analysis have been performed in Full MS-ddMS2; quantification by external standard method.

Results:

Vitamin fragmentation patterns show differences between HCD and CID spectra. The former, acquired in high resolution, generally show a higher number of product ions and ions that in the CID spectra are shown only in MS3. The quantities measured in wine are not relevant in terms of daily vitamin intake, but the study is of oenological interest. Vitamin B12 and pyridoxal were not detected and folic acid was found in trace only in beer samples. Ascorbic acid was detected only in white wines. Vitamin C is a quick-acting and powerful antioxidant that can be added in white winemaking to protect against light and short aerations, preserving freshness and fruitiness [1]. Also, thiamine is an allowed additive. Some compounds (e.g. pantoic acid) were in higher amounts in grapes than in wines, indicating that these vitamins are used by yeasts [2]. Others (vitamin J, B2) showed a reverse trend probably because they are not used by yeast alcoholic fermentation [3] and they are released in the medium as the result of yeast cellular lysis. Some are present only in wines (nicotinamide) and are produced by yeast metabolism during fermentation [4,5].

Conclusions

We developed an HPLC-HR-MS/MS method for the determination of water-soluble vitamins in wine and also can be extended to beer, grapes and grape juices. Vitamin concentrations are comparable with those reported in wines by other Authors. Different vitamin profiles were found in the analyzed matrices. Changes between grapes and wines might be attributed to the fermentation process.

Novel Aspect:

Quite large-scale screening of water-soluble vitamins in Italian wines. Method fast, sensitive, specific and robust without any sample pretreatment.

172 - DETERMINATION OF MELATONIN AND RELATED COMPOUNDS IN BEVERAGES USING LIQUID CHROMATOGRAPHY COUPLED TO LOW AND HIGH RESOLUTION MASS SPECTROMETRY

María Luisa Jiménez Medina (1) - Lorena Manzano Sánchez (1) - Jesús Marín Sáez (1) - Roberto Romero González (1) - Antonia Garrido Frenich (1)

University of Almería, Almería/Dept. Chemistry and Physics, Almería (1)

Determination of melatonin and related compounds in beverages using liquid chromatography coupled to low and high resolution mass spectrometry

María Luisa Jiménez Medina*, Lorena Manzano Sánchez, Jesús Marín-Sáez, Roberto Romero González, Antonia Garrido Frenich

Research Group "Analytical Chemistry of Contaminants", Department of Chemistry and Physics, Research Centre for Agricultural and Food Biotechnology (BITAL), University of Almería, Agrifood Campus of International Excellence, ceiA3, E-04120 Almería, Spain. Email: mjm696@inlumine.ual.es

Keywords: Melatonin, related compounds, beverages, triple quadrupole, high resolution mass spectrometry

Introduction:

Melatonin (N-acetyl-5-methoxytryptamine) is an endogenous indolamine hormone, synthesized from tryptophan [1] and it has a significant role in regulation of the circadian rhythm, mitigation of sleeping disorders and jet lag. Melatonin can also be found in a variety of foods including edible plants, fruits and beverages [2] in addition to isomers or related compounds, but their identification is not a straightforward process [3].

Methods:

For the determination of melatonin and related compounds, a simple dilution of the beverage, including different types of beer (alcoholic and non-alcoholic), wine, aloe vera drinks and cherry juice, was performed prior determination applying liquid chromatography (LC) coupled to triple quadrupole tandem mass spectrometry (QqQ-MS/MS) or high resolution mass spectrometry analyzer as Exactive-Orbitrap.

Results:

First, a nontargeted approach based on LC coupled to Exactive-Orbitrap has been used for the reliable identification of melatonin related compounds in beverages. Thus, in addition to melatonin, tryptophan ethyl ester, which has the same molecular formula than melatonin, was detected. All ion fragmentation (AIF) mode was used to get MS/MS spectra and different ions were obtained for both compounds. Then, an analytical method based on LC-QqQ-MS/MS has been validated in terms of selectivity, limit of quantification (0.01 µg/L) and precision, for the determination of melatonin and tryptophan ethyl ester in beverages. It was observed that tryptophan ethyl ester was detected at higher concentrations (from 0.2 to 90 µg/L) than melatonin (<2 µg/L) in the tested samples. In addition, the concentration of tryptophan ethyl ester was higher in alcoholic beers than in non-alcoholic, indicating that the fermentation could affect the concentration of this compound.

Conclusions

Melatonin related compounds, as tryptophan ethyl ester, has been identified in several beverages using Exactive-Orbitrap analyzer and combining the information provided by AIF mode and characteristic fragmentation pattern of the molecule. Because both compounds have similar retention time and common ions, false positives of melatonin could be reported in some beverages due to tryptophan ethyl ester was detected at higher concentrations.

Novel Aspect:

The combination of several MS platforms allows for the reliable identification and determination of melatonin and related compounds in different types of beverages.

Keywords: Food-authenticity, Cloud-based application, Sample Profiler

Introduction:

Confirming food authenticity is important not only for consumers and the food industry but also for government regulators. There is often the need to detect trace levels of contaminants in complex matrices, which requires the use of state-of-the-art mass spectrometers. Sophisticated software tools are needed to quickly process large data sets generated in these studies.

Thermo Scientific™ Sample Profiler is a new cloud-based software application that can be applied in diverse fields such as food authenticity, environmental monitoring, metabolomics, and detection of new designer drugs. Using this application, large data sets can be processed to detect and integrate compound peaks. Further, compound identification is automated by comparing the fragmentation spectra of compounds against mzCloud™, a web-based spectral database.

Using the Sample Profiler application, chemical profiles of samples of known quality and authenticity can be created within minutes. Individual samples of suspect/questionable quality can be readily compared against these profiles. Statistical evaluation of these comparisons helps users identify certain compounds of interest or 'marker compounds' that are present in significantly different concentration levels in the two sets – authentic and suspect samples. Thus, the presence or absence of marker compounds helps with the quick verification of authenticity and/or characterization of challenge samples when compared against profiles of samples of known/desired characteristics.

In this study, we used Sample Profiler to distinguish between soy sauce samples that were brewed during manufacturing from those that were not.

Methods:

Sample Preparation

Different brands of soy sauces were purchased locally. Samples were prepared in triplicate by diluting aliquots of soy sauce with water (3:1). Pooled quality control (QC) samples were prepared by combining a fixed amount of each soy sauce into a pool and preparing a set of dilution samples as normal.

Test Method

Analysis was performed by LC-MS with separation achieved by reversed-phase linear gradient (ACN/ water, 0.1% formic acid) with a run time of 10 min. Mass spectrometric analysis was performed on a Thermo Scientific™ Q Exactive™ HF hybrid quadrupole-Orbitrap mass spectrometer operated in positive mode with electrospray ionization. Full scan MS1 (120,000 resolution FWHM at m/z 200) and precursor selected MS/MS (30,000 resolution) data was acquired. Sample injection order was randomized with QC samples injected every 10 injections.

Data Analysis

Mass spectral data for different types of soy sauces, such as those manufactured in different regions, stored in different types of containers, and even processed differently (by brewing or by not brewing), were collected. Data

for blanks and QCs were also obtained. Raw data files were uploaded to Thermo Fisher Cloud and imported into the Sample Profiler application for further processing. The components were detected in samples after the application aligned all the retention times in all samples. Compound identification was done by matching fragmentation (MS2) spectra against the mzCloud spectral database. Sample Profiler aggregated the name, predicted formulae, m/z, RT, and area counts of each compound from all the samples.

Results:

Background

Soy sauce is a popular condiment manufactured and consumed in many Asian countries. Traditionally, soy sauces are prepared by two methods: a) by naturally brewing fermented soya beans with wheat and brine, which can take several months, or b) by using hydrolyzed vegetable protein (HVP), which takes only days. Soy sauces manufactured by the two processes differ in their physical characteristics such as aroma, flavor, and texture. In addition, soy sauces made by acid-hydrolysis of soy proteins have a longer shelf life.

In this study, different brands of soy sauces purchased locally were analyzed to determine the differences in their compositions and identify spurious samples based on our knowledge of genuine products. HRAM data of each sample was collected in triplicate followed by statistical analysis using Sample Profiler, an application hosted in Thermo Fisher Cloud.

Data Processing in the Cloud

Large data sets uploaded to the Data Manager in the Thermo Fisher Cloud can be easily added to projects created in Sample Profiler and processed using suitable processing Methods: Data processing involves aligning the chromatographic peaks, followed by component extraction. The accurate mass information was used to predict elemental composition for detected components. Finally, compounds were identified by matching the predicted formula and MS2 fragmentation data against ChemSpider and mzCloud™ databases, respectively.

Creating Profiles

The application also allows the user to aggregate samples with similar characteristics such as packaging and or manufacturing process which can be pre-defined as “Study Factors” prior to data analysis. These sample subsets that share one or more study factors can be then used to establish a ‘product-profile’. Other samples having same or even different study factors can be compared against chosen profiles to evaluate the extent of similarity.

After all samples including QCs and blanks are processed, two databases of compounds or profiles, a) All Samples and b) All QCs samples, are automatically created by the application. The user can also create additional profiles or subsets of the All Samples profile by partitioning it based on study factors or criteria such as manufacturing region or packaging material used to characterize the samples. For example, in the present study, a database or a profile of compounds present in soy samples that were brewed during manufacture was created.

In the present study, a profile of soy sauces that were brewed during manufacturing was used to determine the quality of soy samples that were not brewed. The data indicated that the chemical compositions of both types of soy sauce are similar in that they contain same compounds in similar concentration range. Yet, some compounds were either not found at all or found in much lower concentrations in soy sauces that were not brewed. Similarly soy samples manufactured in different regions or samples stored in different containers can be compared and statistically distinguished from one another.

The application displays the profile of “Brewed” soy-sauces, in a tabular format which includes details such as compound name, predicted formula, MW, RT, and highest intensity value from all samples for 11,572 compounds found in this subset of soy sauces. The spread in the intensity values found across all samples is shown as distribution plots. The ‘Compoundstable’ can be filtered to show the compound details in any of the profiles created in the project.

Trendline Plots

Sample Profiler also allows for visualization of the trends in compound areas. When trendlines for compound areas across all samples in the profile are plotted, those samples that may have significantly higher or lower concentrations of one or more compounds can be easily identified. These samples can then be investigated further to get a better understanding of the products’ chemical composition.

Comparing Different Types of Samples

Using Sample Profiler, comparisons between different types of soy sauces can be easily set up and data processed at different fold changes and adjusted p-values. In the present study, a profile of brewed soy sauces was created and used for comparing against not-brewed samples. Data analysis performed by setting the fold change value to 8 and adjusted p-value to > 0.001. It was found that of a total of 11,803 compounds, the not-brewed samples were found

to contain 267 compounds in significantly higher abundance, and 1791 compounds in significantly lower abundance than in brewed samples.

Marker Compounds

Once a product's profile is well understood, certain compounds when present in a product can be labeled as markers of authenticity or contaminant. These marker compounds are not only useful in qualifying study samples but also for setting up targeted data acquisition.

In this study, Sample Profiler was used to search for genistein and glycitein specified by name. Post search, the table was updated with formulae, MW, and RTs of the two compounds along with the total number of samples and QCs in which they were found. After the compounds are added to the table, Sample Profiler will automatically search for their presence in any comparison set up in the project.

The relative distributions of the two marker compounds in the comparison between brewed and not-brewed soy sauces were determined. From the results obtained, brewed soy sauces are understood to have higher abundances of these two marker compounds.

This knowledge can be applied to quickly verify the authenticity of a challenge sample(s) by setting up appropriate comparisons between them and known profiles and studying the relative distributions of marker compounds.

Conclusions

Sample Profiler helps in the creation of chemical profiles of authentic samples and identification of 'marker compounds'. Marker compounds help with easy verification or characterization of suspect/challenge. The application also allows for visualization of trends in the data in addition to TIC and XIC traces. In the present study, it has been shown that soy sauces manufactured in different regions or packaged differently can be easily differentiated by the Sample Profiler application. Compounds such as glycitein and genistein were found to be present in higher abundance in brewed soy sauces as compared to not-brewed samples.

Novel Aspect:

Sample Profiler, a cloud-based data analysis software that can process large data sets has been used for establishing food authenticity.

115 - NOSESPACE ANALYSIS BY PTR-TOF-MS FOR THE EXTRA VIRGIN OLIVE OIL CHARACTERIZATION

Luliia Khomenko (1) - Eugenio Aprea (1) - Flavia Gasperi (1)

Edmund Mach Foundation, Food quality and nutrition, San Michele all'Adige (1)

Nosespace analysis by PTR-ToF-MS for the extravirgin olive oil characterization
Luliia Khomenko 1,2), Eugenio Aprea 1), Flavia Gasperi 1)

Fondazione Edmund Mach, Research and Innovation Center, Department of Food Quality and Nutrition – via E. Mach 1, 38010 San Michele all'Adige (TN, Italy)

Institute for Ion Physics and Applied Physics, University of Innsbruck, Technikerstr. 25, Innsbruck (Austria)

Keywords: direct injection, volatile organic compounds, inter-individual differences

Introduction:

Extravirgin olive (EVO) oil aroma and taste influence consumer preferences. Volatile organic compounds (VOCs) release from food within oral cavity is a complex process. Nose-space (NS) analysis should unravel the retro-nasal olfaction processes happened during olive oil tasting. Proton Transfer Reaction-Mass Spectrometry with Time-of-Flight analyser (PTR-ToF-MS) was already successfully applied for NS analysis of apples [2], cereal bars [3], coffee [4,5].

Methods:

In this study 2 Italian EVO oils were used: commercial vs home made (Lago di Garda, TN). Pure oil, oil mixed with tomato sauce, oil on bread prepared for each EVO oil were used for headspace (HS) and NS measurements by PTR-ToF-MS 8000. The samples were presented to 8 assessors in duplicate. For NS sampling a glass nose-piece with silicone rubber tube was fitted into assessors' nostrils and connected to PTR-ToF-MS. The method for HS analysis was described elsewhere [6].

Results:

26 out of 319 mass peaks of NS dataset displayed signal related to olive oil, tomato or bread aroma. Peaks related to human metabolism were eliminated. The individual profiles differed in peak intensity and duration. However it was possible to distinguish the two types of EVO oils. HS data confirmed diversity of the oils. Home-made EVO oil in all products was characterized by significantly higher concentrations of mass peak 99.081 tentatively identified (t.i.) as (E)-2-hexenal associated to a green-leaf and fruity flavor [1]. Commercial EVO oil was richer in t.i. pentanal, acetic acid, butanal, and several esters which are reported as oxidation products of olive oil [7]. The samples of olive oil on bread showed the best performance (higher signals intensities) for all panellists due to an increased release surface area, prolonged presence in mouth, increased interaction with saliva and mucosal surfaces. Adding tomato sauce to olive oil decreased the olive oil aroma release in NS and contaminated it with tomato aroma.

Conclusions

NS analysis performed by PTR-ToF-MS discriminated different EVO olive oils. HS and NS data were consistent. The next steps are the optimization of sample preparations, tasting protocol, and the improvement of PTR-ToF-MS sensitivity by applying an ion funnel.

The optimized methods will be applied to study different EVO olive oils within the project "VIOLIN" aiming to the valorisation and promotion of Italian EVO oils.

Novel Aspect:

For the first time NS analysis was applied for olive oil profiling taking into consideration individual perception and the combination with different food matrices.

1229 - RAPID AND DIRECT ANALYSIS OF COFFEE BEANS (GREEN AND ROASTED) AND ONLINE MONITORING OF COFFEE ROASTING BY SIFT-MS: FOCUS ON VOLATILE ALDEHYDES

Iuliia Khomenko (1) - Andrea Caretta (2) - Valentina Lonzarich (3) - Franco Biasioli (1) - Luciano Navarini (4)

Edmund Mach Foundation, Department of Food Quality and Nutrition, San Michele all'Adige, Italy (1) - SRA Instruments S.p.A., technical assistance, Cernusco sul Naviglio, Italy (2) - Aromalab illycaffè S.p.A., Research & Innovation, Trieste, Italy (3) - illycaffè S.p.A., Research & Innovation, Trieste, Italy (4)

Keywords: direct injection, volatile organic compounds

Introduction:

Aroma of coffee beans (*Coffea arabica*) contributes to its quality evaluation and its origin tracing. The part of coffee aroma such as volatile aldehydes is linked directly to volatile organic compounds (VOCs) naturally occurring in green coffee beans as well as to roasting process. Fast and direct volatile aldehydes detection in green beans, during coffee roasting, and in roasted beans by a selected ion flow tube mass spectrometer (SIFT-MS) may possibly be a way for characterization of coffee origins.

Methods:

VOCs of coffee beans of 5 geographical origins and 3 batches each were measured by SIFT-MS (SYFT VOICE200 ultra, Syft Ltd, New Zealand). 5 green coffee beans were placed in a 22 mL glass vial, incubated at 37°C for 30 min, and measured for 1 min by an autosampler coupled to SIFT-MS. Single bean was placed in a vial and roasted in the oven at 211°C for 20 min. SIFT-MS monitored roasting through the oven ventilation. Then vials were closed and measured in the same way as green beans.

Results:

Twenty one aldehydes, two alcohols, and two methoxypyrazines were monitored in green beans along with a unspecific monoterpene peak. Some typical compounds such as furans, pyridine, and pyrazine were added to the list of monitored compounds for the online monitoring of coffee bean roasting and the screening of roasted coffee beans. During roasting two types of evolution curve of VOC emissions were observed: the peak of emission at the beginning (2-nonenal, benzaldehyde, and 2-pentylfuran) and at the end of the roasting (hexanal, 2-hexenal, and others).

The special attention was paid for the possibility of aldehydes to discriminate the coffee bean origin. In green beans origin was characterized by the significant differences in the concentrations of five aldehydes such as benzaldehyde, hexanal, 2-methyl-2-propanal, 2-methylbutanal, and pentanal. The concentration of aldehydes in roasted beans was significantly different from green ones but no significant difference according to their origin was observed.

Conclusions:

The technique was successfully applied for screening of green and roasted coffee beans and for online monitoring of the coffee bean roasting. The main differences in aldehyde content in coffee beans were found in green beans rather than in roasted ones.

Novel Aspect:

For the first time the analysis of green and roasted coffee beans and online monitoring of VOC emission during coffee roasting was performed by SIFT-MS. Moreover for the first time SIFT-MS was coupled with a multipurpose GC automatic sampler.

1287 - DIFFERENTIAL PROTEOMIC PROFILING OF TRUFFLES

Dennis Kroesser (1) - Benjamin Dreyer (1) - Hartmut Schlueter (1)

University Medical Center Hamburg-Eppendorf, Mass Spectrometric Proteomics, Hamburg, Germany (1)

Keywords: Proteomics, Truffle, LC-MS/MS, Food Authenticity

Introduction:

Food fraud is becoming an increasingly critical topic. For expensive foods like truffle, incorrect labeling or contamination of premium products with inferior products are common. Truffles are scarcely researched and thus detection of food fraud challenging. Here, protein extraction methods were tested and a LC-MS/MS based differential proteomics approach was developed for determining reference LC-MS/MS data for future validation of truffle quality.

Methods:

Homogenates from authentic European and Asian truffle samples were obtained by picosecond infrared-laser (PIRL) ablation or by lyophilization and grinding of truffles. Protein extracts were boiled in presence of sodium deoxycholate and enzymatically degraded by trypsin. Peptides were analyzed by LC-MS/MS in data-dependent acquisition mode to generate spectral libraries and, for obtaining reference LC-MS/MS data, in data-independent acquisition mode.

Results:

The quantitative comparison of homogenates from PIRL ablation and classical homogenization of truffle showed an at least twofold change in relative amount for 15 % of extracted proteins. There was no preference towards a certain method. In the differential proteomic analysis of truffles by measurements in DIA mode, reference LC-MS/MS data were generated for the samples available at the moment. By hierarchical clustering analysis and principal component analysis samples from European truffles could be well distinguished from Asian truffles.

Conclusions:

The quantitative differential proteomics approach generated reference LC-MS/MS data by which truffles of different origin can be distinguished. Therefore this approach is a future tool for food fraud detection.

Novel Aspect:

This is the first study presenting LC-MS/MS-based data as reference for validation of truffle quality.

1073 - ULTRA-FAST IDENTIFICATION OF FISH SPECIES BY PAPERSPRAY COUPLED TO A BENCHTOP ORBITRAP MASS SPECTROMETER

daniel lopez-ferrer (1) - Greg Foster (2) - Mari Prieto (3)

Thermo Fisher Scientific, Vertical Marketing, San Jose (1) - Thermo Fisher Scientific, Marketing, San Jose (2) - Thermo Fisher Scientific, Product Marketing, San Jose (3)

Keywords: Food authenticity, PaperSpray, Orbitrap technology, Automations

Introduction:

The largest seafood fraud investigation in the world to date found that 33% of seafood samples are mislabeled in the U.S. Seafood fraud hurts consumers and also raises serious preservation concerns for our oceans. DNA-based analytical techniques are commonly used to determine the species that belongs to a given sample. However, the long analysis time complicates its applicability to be enforced. Here, we present a protein based method that identifies the most common commercially available salmon species in minutes using a simple protein extraction protocol coupled to PaperSpray® and top-down proteomics. The high mass accuracy and resolution of the benchtop quadrupole orbitrap MS allows not only the classification of proteins with high protein sequence homology, but also species dependent amino acid substitutions. The use of PaperSpray, a direct ionization technique, enabled us to simplify the mass spectrometric analysis and subsequent identification of the target proteins.

Methods:

Seven reference samples from commercial species and 50 commercial foodstuffs were included in the work. Protein extraction was carried out by homogenizing 1 g of muscle. Water soluble proteins were centrifuged, the supernatant heated at 70 °C for 5 min and centrifuged again. Soluble proteins then were cleaned using automated microSPE devices. The analytes were then spotted onto the PaperSpray cassette and placed into the ProSolia Velox™ 360 PaperSpray® system coupled to a Thermo Scientific Q Exactive HF mass spectrometer. PaperSpray technology relies on cellulose paper and ions are generated directly from paper when an applied high voltage induces electrospray from the sharp tip of the wet paper. Proteins migrate through the paper and are directly ionized into the mass spectrometer. Extraction solvent used was 95/5/0.01 methanol/100 mM ammonium acetate/formic acid. Full MS spectra of intact thermostable proteins were analyzed using Thermo Scientific Biopharma Finder 2.0 software for molecular mass determination and the protein identities were confirmed by MSMS.

Results:

The main goal of this work was to develop a simple and fast strategy that allows the authentication of fish species and be widely applied to enforce the guidelines from the U.S. Food and Drug Administration. The work was divided in two phases; primarily a discovery phase to develop the analytical workflow and to choose the best protein biomarker from standardized samples. This phase was followed by a validation phase to determine whether a commercial sample is mislabeled or not. During the discovery phase, a two-step workflow was created. First, the fraction of thermo-stable proteins from the tissue was purified because most of the commercial foodstuff has already been cooked. The second step, consisted of an ultrafast top-down proteomic approach of the purified proteins. Samples were cleaned up using reverse phase micro-spe cartridges. Proteins were eluted using 50% acetonitrile enabling easy spotting into the paperspray cassette while significantly reducing the drying time before being the proteins are electrosprayed into the mass spec. The overall sample preparation workflows allows for automated sample preparation and clean-up of the samples before been introduced in the MS system without impacting the throughput. A 1 min acquisition was performed and the proteins were then analyzed doing a top-down msx in the HCD cell of a benchtop quadrupole orbitrap mass spectrometer. For all the samples, an 11 kDa protein was the most abundant protein and identified as a parvalbumin (PRVB). This protein is highly conserved between different species. However, slightly mass differences in the mass of the PRVBs corresponding to amino acid substitutions allow for unambiguous systematic discrimination of the different species. Further validation on

commercial samples demonstrated that over 10% of the samples were mislabeled. We believe that this workflow coupled to the PaperSpray technology platform could represent the ultimate payoff to reliable and widely used top down proteomics to trace and authenticate food.

Conclusions

In this work, we coupled PaperSpray ionization with high resolution accurate mass (HRAM) Orbitrap technology for authentication of fish products. PaperSpray demonstrated that qualitative analysis of proteins is possible without time consuming sample preparation and advance chromatography techniques. This work also demonstrates the potential use of PaperSpray coupled to mass spectrometry as an emerging approach to protect customer rights and preventing fraudulent practices. And that can be useful to food industries that are seeking the opportunity to assure their food products labeling.

Novel Aspect:

Fish traceability in minutes using a high throughput PaperSpray-Orbitrap MS platform and top-down proteomics.

1335 - A NOVEL ROBUST PROBE FOR THE RAPID, ON-LINE CHARACTERISATION OF FOOD SAMPLES USING RAPID EVAPORATIVE IONISATION MASS SPECTROMETRY

Andras Marton (1) - Julia Balog (1) - Richárd Schäffer (1) - Steven Pringle (2) - Zoltán Takáts (3)

Waters Research Center, -, Budapest, Hungary (1) - Waters Corporation, -, Wilmslow, United Kingdom (2) - -, Imperial College, London, United Kingdom (3)

A Novel Robust Probe for the Rapid, On-Line Characterisation of Food Samples using Rapid Evaporative Ionisation Mass Spectrometry

Keywords: Ambient ionization method, Rapid Evaporative Ionization Mass Spectrometry (REIMS), Food authenticity,

Introduction:

There has been a significant increase of the incidence rate of food fraud cases related to products originating from uncontrolled origins. Rapid Evaporative Ionization Mass Spectrometry (REIMS) has been used for the analysis of various meat samples and has shown to be capable of the fast identification of diverse tissue types based on their lipid fingerprints. We aimed to test the feasibility of REIMS combined with our robust sampling probe for different food products.

Methods:

Authentic mangalica pork and carp fish samples from 6 different suppliers based in Hungary were sourced. All samples were analysed using a custom built bipolar sampling probe. The aerosol generated by the thermal ablation of the samples was introduced into the REIMS source of a Xevo G2-XS ToF MS and spectra were acquired between 150-1500 m/z. By the application of multivariate algorithms, our goal was to identify the species or location of origin of each sample.

Results:

The original monopolar sampling probe was modified forming a robust bipolar probe to allow rapid on-line sampling of products. The spectra acquired from the samples were first pre-processed (lock mass correction and background subtraction), then subjected to Principal Component Analysis with the results processed using Linear Discriminant Analysis. All classification models were tested on leave-one-sample out cross-validation, and an independent validation set. In the case of the pork study, the cross-validation resulted in >80 % accuracy, with 12 out of 15 samples correctly identified from the independent validation set. The most significant peaks in the spectra were identified using tandem MS/MS measurements and featured mainly fatty acids, glycerophospholipids and triglycerides. In case of the carp study, the location of origin showed good separation in the first three principal components, and the cross-validation resulted in an 85% correct classification rate.

Conclusions:

The results demonstrate that the lipidomic profiles can be taken in the few seconds timeframe and the profiles show good species- and origin- level specificity. The custom built food probe was found to be suitable for on-line sampling in an industrial environment. REIMS technology was found to be a promising tool for food safety applications providing a reliable and simple method for the rapid characterization of food products.

Novel Aspect:

On site, on-line rapid sample identification with robust sampling probe based on REIMS lipid fingerprints.

1300 - CORRELATING CONSUMER SENSORY EXPERIENCE OF APPLE AROMA WITH VOC PROFILES ACQUIRED BY AUTOMATED TD–GC–MS

Gareth Roberts (1) - David Barden (1) - Nick Bukowski (2) - Laura McGregor (3) - Massimo Santoro (1) - Natasha D. Spadafora (4)

Markes International, Marketing, Llantrisant, United Kingdom (1) - SepSolve Analytical, Product Development, Peterborough, United Kingdom (2) - SepSolve Analytical, Marketing, Peterborough, United Kingdom (3) - Università della Calabria /Markes International, Food Sciences, Rende (CS), Italy (4)

Keywords: automated thermal desorption, apple cultivars, sensory analysis, VOCs

Introduction (400 characters):

The aroma of fruit is regarded as one of the most important quality parameters sensed by consumers, and is influenced by numerous factors including genotype and growth conditions. In this study we determined the VOC profiles of apple cultivars and correlated them to consumer sensory evaluation.

Methods (400 characters):

Apple headspace (cultivars 'Smitten' and 'Granny Smith') was sampled onto sorbent tubes using a micro-chamber system, with analysis by thermal desorption–gas chromatography–mass spectrometry. Twenty panellists were asked to rate the samples according to nine sensory characteristics, and two-dimensional hierarchical cluster analysis (HCA) was performed to relate these scores to the VOC profile.

Results (900 characters):

A total of 29 VOCs were identified across the samples, of which 20 were esters. 'Smitten' was found to have significantly higher hedonic scores on all sensory measurements than 'Granny Smith', and significant positive correlations were found between high 'Taste/Flavour', 'Fruitiness' & 'Aroma/Smell' scores and five of the esters identified in the headspace analysis. These compounds are: (with their odour as described in an olfactometry study of apple cultivars) 2-methylpropyl acetate (pear, apple), n-butyl acetate (sweet, fruity), 2-methylbutyl acetate (fruity, apple), n-pentyl acetate (fruity, banana), and n-hexyl acetate (fruity, pear). In that study, the first three of these compounds were identified as 'principal odorants'.

Conclusions (400 characters):

We conclude that esters could be used as objective markers for the consumer appreciation of fresh apples, enabling optimum conditions for processing and storage to be identified without recourse to expensive sensory panels in every case. Such tests could also be used as part of routine quality control by the producer and retailer.

Novel Aspect (150 characters):

Detection of trace-level VOCs was only possible because of the large micro-chamber sample volumes and the low thermal desorption split ratios.

134 - CHARACTERIZATION AND CLASSIFICATION OF SPANISH PAPRIKA WITH PROTECTED DESIGNATION OF ORIGIN BY UHPLC-HRMS POLYPHENOLIC FINGERPRINTING AND CHEMOMETRICS

Sergio Barbosa (1) - Guillem Campmajó (1) - Oscar Núñez (1) - Javier Saurina (1) - Lluís Puignou (1)

University of Barcelona, Department of Chemical Engineering and Analytical Chemistry, Barcelona (1)

Keywords: Polyphenols; Spanish Paprika; Food Authentication; UHPLC; High resolution mass spectrometry

Introduction:

Paprikais a red powder seasoning with a characteristic flavor obtained from red peppers. Spanish paprikas from La Vera and Murcia have protected designation of origin (PDO), which increases product value but also their production costs, making necessary to properly authenticate them. Polyphenolic contents in these products may be employed as descriptors to achieve their authentication [1].

Methods:

A UHPLC-HRMS (Orbitrap) method was employed to obtain paprika polyphenolic fingerprints. HRMS data was processed with TraceFinder v3.3 software by employing a customized target accurate mass database of 54 polyphenols. Polyphenolic data was considered as a source of potential descriptors for the classification and characterization of paprika by exploratory principal component analysis (PCA).

Results:

111 samples belonging to La Vera and Murcia Spanish PDOs (including sweet, bittersweet and spicy varieties), as well as 15 samples obtained from the Check Republic were analyzed. The plot of scores obtained after PCA using UHPLC-HRMS polyphenolic profiles revealed patterns that were correlated to sample characteristics such as the production country (Spain, Check Republic) and regions, allowing a clear differentiation between paprika PDOs and varieties. Based on the PCA plot of loadings, the most remarkable polyphenols and phenolic acids on each type of paprika PDO and variety were identified, making possible to differentiate them according to their different content and distribution of polyphenols. These polyphenols can be studied as possible future biomarkers to guarantee sample authentication and for the prevention of frauds.

Conclusions

The obtained results demonstrate that UHPLC-HRMS polyphenolic profiles obtained by a simple screening with a customized accurate mass database of polyphenols can be employed to achieve the characterization and classification of paprika samples according to their production region to guarantee product authentication. Potential polyphenolic bioactive compounds for paprika varieties were identified.

Novel Aspect

New analytical approach for the characterization and classification of Spanish paprika based on HRMS polyphenolic fingerprinting.

394 - UHPLC-ESI-HRMS CHARACTERIZATION OF TURMERIC AND CURRY SAMPLES BASED ON PROFILING AND FINGERPRINTING APPROACHES

Nerea Núñez (1) - Oscar Núñez (1) - Sonia Sentellas (1) - Javier Saurina (1)

University of Barcelona, Department of Chemical Engineering and Analytical Chemistry, Barcelona (1)

Keywords: Curcumin; Polyphenols; Turmeric; Food Authentication; UHPLC-HRMS

Introduction

Turmeric (*Curcuma longa*) is a plant related to ginger family that has been used for centuries as a remedy in traditional Asian pharmacy due to its antioxidant, anti-inflammatory and antineoplastic activities [1]. Turmeric is also appreciated worldwide as a condiment in cuisine. Curcumin is the most relevant molecule of turmeric, providing both color and pharmacological activity [1]. Related curcuminoids and polyphenols are important as well.

Methods

The UHPLC-HRMS method used an Accela UHPLC system coupled to a Q-Exactive q-Orbitrap mass spectrometer (Thermo Fischer Scientific) equipped with a heated-electrospray ionization (H-ESI) source. Compounds were separated by reversed-phase mode using an elution gradient based on 0.1 % formic acid in water (v/v) and acetonitrile. Chromatograms were acquired in the negative mode in the range 100 to 1000 m/z. Data was analyzed using PLSToolbox (Eigenvector Research).

Results

Here, UHPLC-HRMS was used to analyze commercial turmeric and curry samples. The resulting data consisting on polyphenolic profiles and UHPLC-HRMS fingerprints was treated chemometrically to tackle characterization and authentication issues. Quality controls (QCs) prepared from all the samples were used to assess the instrumental variability. Principal component analysis (PCA) models from both approaches showed that curry and turmeric samples were clearly segregated. QCs appeared in a compact group in the center of the model, showing the good performance and reproducibility of the proposed method and the obtained data. Principal component 1 (PC1) mainly described quantitative patterns, with samples richer in curcuminoids to the right of the plots and those with lower contents to the left. Turmeric samples were distributed according to plant varieties, e.g., Erode in the top right corner, Allepey in the bottom right corner, and Madras in the top left corner.

Conclusions

UHPLC-HRMS resulted in an excellent approach for a feasible determination of curcumin and its derivatives in food samples. The proposed method revealed a great complexity in polyphenolic composition, showing a variety of components to be elucidated. It was believed that minor curcuminoids could be relevant descriptors for classification and authentication purposes using chemometric Methods:

Novel Aspect

Comprehensive UHPLC-ESI-HRMS characterization of polyphenols and curcuminoids and classification of turmeric products by PCA.

893 - MONOTERPENES CHARACTERIZATION IN GRAPE SPIRITS USING FAST GAS CHROMATOGRAPHY TANDEM MASS SPECTROMETRY

Mauro Paolini (1) - Loris Tonidandel (1) - Sergio Moser (1) - Roberto Larcher (1)

Fondazione Edmund Mach, Technology Transfer Centre, S. Michele all'Adige - Trento (1)

Keywords: Monoterpenes, Fast GC-MS/MS analysis, Grape spirits

Introduction:

Monoterpenes are among the most important aromatic metabolites to be found in a free and bound form in grapes [1]. Aromatic characteristic of grape spirits can therefore be especially attributed to this class of molecules despite the presence of countless volatile compounds produced during alcoholic fermentation [2,3]. The aim of this study was to describe the terpenic profiles responsible for the varietal aroma of a selection of grape spirits produced from 10 different varieties using an innovative fast GC-MS/MS method.

Methods:

20 mL of sample was diluted to 100 mL with Milli-Q water after the addition of 2-octanol as internal standard. Monoterpenes were extracted by adsorption on a SPE cartridge and eluted with dichloromethane [4,5]. The organic phase was analysed using an Agilent Intuvo 9000 GC system coupled with an Agilent 7000 Series Triple Quadrupole MS operating in dynamic MRM mode. Separation was obtained injecting 2 μ L in split mode (1:5) into a DB-Wax UI (20 m \times 0.18 mm \times 0.18 μ m).

Results:

The presented method permitted to qualify and quantify 15 different monoterpenes characteristic of the grape spirits in only 15 minutes. The compounds detected were α -terpineol, β -citronellol, geranic acid, geraniol, HO-diol I, HO-trienol, linalool oxide A, linalool oxide B, linalool oxide C, linalool oxide D, linalool, nerol, rose oxide I, rose oxide II and terpinen-4-ol. All of the measured monoterpenes were found in the 39 grape spirit samples except for HO-diol I and HO-trienol that were detected in only 12 and 30 samples, respectively.

The correlation matrix showed a positive correlation between the amount of linalool oxides, linalool, α -terpineol and HO-diol I. A positive correlation was also observed between β -citronellol, nerol, geraniol and rose oxides.

Principal component analysis (PCA) was used to display the samples in an unsupervised pattern recognition map. The PCA showed that a group of samples was characterised by a high content of linalool oxides and linalool, while another one by a high content of β -citronellol, nerol and rose oxides.

Conclusions:

The proposed method made it possible to obtain a broad monoterpene profile characteristic of grape spirit products in only 15 minutes. 15 monoterpenes were qualified and quantified in 39 grape spirit samples obtained from different grape varieties. The statistical approach highlighted that there was a positive correlation between the different compounds and allowed to discriminate the most aromatic samples on the basis of their different monoterpene profile.

Novel Aspect:

The method developed can be proposed for the fast characterisation of grape spirit samples based on their different monoterpene profile.

263 - ELUCIDATION OF OLIGOSACCHARIDES IN MILK REFERENCE MATERIALS BY HILIC-MS/MS AND THE NIST TANDEM MS LIBRARIES

Connie Remoroza (1) - Stephen Stein (1)

National Institute of Standards and Technology, Mass Spectrometry Data Center, Gaithersburg, Maryland (1)

Elucidation of oligosaccharides in milk reference materials by HILIC-MS/MS and the NIST Tandem MS Libraries

Connie A. Remoroza and Stephen E. Stein

Mass Spectrometry Data Center, Biomolecular Measurement Division, National Institute of Standards and Technology, Gaithersburg, MD, 20899-8362, USA

Keywords: Human Milk Oligosaccharides, Fourier Transform-ITMS, HILIC-MS-HCD, Isomers, MS library

Introduction:

A very low percentage of mothers around the world practice exclusive breastfeeding. The low breastfeeding rate is the driving force for the infant formula manufacturers to produce formula that simulate human milk as closely as possible. However, the information of bioactive molecules in the NIST *SRMs for human and infant formula milk is limited. This study focuses on the method of structural elucidation of a material based mass spectral library of functional oligosaccharides using NIST reference materials.

Methods:

The human milk, infant formula, goat and buffalo milk underwent sample preparation [1]. The purified oligosaccharides were analyzed on Hydrophilic Liquid Interaction Chromatography-electrospray ionization in Fusion Lumos Orbitrap-based MS using HCD & Fourier transform ion trap (FT-IT) fragmentation techniques. The spectra are extracted from LC-MS raw data and processed using in-house algorithm then analyzed using different tools including NIST Tandem mass spectral library.

Results:

The high mass accuracy both for precursor and product ions from FT-IT and HCD data was sufficient to enable the assignment of oligosaccharides including novel oligosaccharide structures with different adduct types in negative/positive detection mode. Core group (Gal-Glc) with different terminal sugars, Fuc-Gal-Glc eluted prior to Sia-Gal-Glc. The elution profile of DP 5 isomers, such as lacto-N-fucopentaose (I, II, III) and LS-tetrasaccharide (a, b, c) displayed different retention times on HILIC that enhances oligosaccharide identification. A clear distinction in the HILIC elution pattern of isomeric oligosaccharides related to size and polarity confirmed the identifications. The base peak chromatogram of infant formula differs from human milk in terms of their glycan profiles. Infant formula contains fucolactose as well as maltodextrins with degree of polymerization 2-13 whereas human milk has over 70 bioactive oligosaccharides. The spectral library of oligosaccharides in human milk demonstrate to aid in identifying glycans and other compounds present in other biological samples such as Asian goat and buffalo milk, which represents a new variety of mass spectral library. Moreover, buffalo milk contains oligosaccharides close to human milk.

Conclusions

The HILIC MS/MS and NIST Tandem MS libraries facilitate the structural assignment of 70 complex oligosaccharides with 470 spectra including newly annotated glycan structures. Infant formula was fortified with maltodextrins and fucolactoses— a concept that can be extended to other varieties of biological fluids such as detection of glycans in other milk and human plasma samples.

Novel Aspect:

A comprehensive structural and tandem MS library of annotated oligosaccharides derived from the NIST milk reference materials: a robust method of detecting other compounds in milk products.

553 - IKNIFE, A NOVEL AMBIENT MASS SPECTROMETRY APPROACH FOR THE REAL-TIME IDENTIFICATION OF FOOD SAMPLES

Francesca Rigano (1) - Domenica Mangraviti (2) - Luigi Mondello (2)

Chromaleont Srl, c/o Dipartimento ChiBioFarAm, University of Messina, Messina (1) - University of Messina, Dipartimento ChiBioFarAm, Messina (2)

Keywords: Rapid evaporative ionization mass spectrometry, electrosurgical knife, food authenticity, food safety, chemometric data analysis

Introduction: (Limit of 400 characters without spaces)

Rapid Evaporative Ionization Mass Spectrometry (REIMS) is a novel ambient MS method that can be used for the real-time identification of unknown samples, without any sample pretreatment. Such an approach is based on the analysis of the vapor produced by thermal ablation. MS profile represents an univocal fingerprinting, usable for geography evaluation and authenticity assessment of foodstuffs. For this purpose, a database of authentic samples need to be created.

Methods:

The REIMS method was employed for the fast characterization of different food products (pistachio, fish, cheese, olive oil). It operates using an electrosurgical knife (iknife), which creates an aerosol that is evacuated from the sample through a transfer line into the ionization source, where a heated collision surface is located for the thermal ionization process. A multivariate statistical algorithm was validated for the real-time identification process.

Results:

High value products, granted with PDO (Protected Designation of Origin) indication, were analyzed and successfully differentiated, without any geographical mismatching, thus demonstrating the applicability of the new technique in the detection of food fraud. The new technology was also applied to commercially popular and genetically similar Mediterranean Sea fish to obtain fast and accurate speciation results.

Marker compounds, responsible of sample discrimination, were determined and confirmed by conventional chromatographic techniques. These results demonstrated the capability of the iknife to provide in few seconds an holistic profile of the matrix.

Moreover, inter-laboratory studies gave proof of the reproducibility of such MS approach and transferability of the statistical model. Within this context, the present study confirmed also the potentiality of the new technique to be easy-to-use by any operator, even not expert, after the building of a reliable database and a statistical model by an analytical chemist.

Conclusions

Iknife represents a powerful tool in the preservation of food security and safety. It can be also used as a shotgun approach to achieve a comprehensive characterization of a complex sample and, since lipids are normally the most representative detected molecules, it can be successfully employed in lipidomics. Finally, the comparison with chromatography methods made marker identification very reliable, conversely from the tentative assignment of previous works.

Novel Aspect:

Among ambient methods, the iknife has been developed in close combination with a dedicated statistical software, that made the identification process very straightforward.

584 - DETERMINATION OF CROCIN ISOMERS AND ISOFORMS BY MEANS UHPLC-MS/MS AS QUALITY MARKER FOR SAFFRON

Rachele Rocchi (1) - Marcello Mascini (1) - Manuel Sergi (1) - Dario Compagnone (1) - Paola Pittia (1)

University of Teramo, Faculty of Bioscience and Technology for Food, Agriculture and Environment, Teramo (1)

Keywords: saffron, crocins, UHPLC-MS/MS, process marker, multivariate analysis

Introduction

Saffron is a precious spice known as “red gold” obtained from the dried stigmas of the *Crocus Sativus* L., a plant of the Iridaceae family. Its importance is related to the peculiar quality and sensory properties, in particular aroma, colour and taste that are mainly due to the presence of safranal, crocins and picrocrocin, respectively [1]. Recent studies have highlighted the different beneficial health values beyond its colouring and flavouring abilities [2].

Methods

Forty-two saffron samples of different origin, drying process and age were collected. An UHPLC equipment composed by a Nexera LC20AD XR apparatus (Shimadzu, Tokyo, Japan) coupled with a 4500 Qtrap mass spectrometer (Sciex, Toronto, Canada) equipped with a Turbo V ESI source, was used for analysis. The target analytes were separated using a Kinetex C18 column in 9 minutes. The results were analysed by means of principal component analysis (PCA) using XLSTAT2016.

Results

A preliminary experimental design was applied to optimize the extraction of crocins. UHPLC-MS/MS conditions were set to obtain the best analytical performances in terms of sensitivity and selectivity; the selected experimental conditions allowed to determine all crocin isomers and isoforms in a single run.

The crocin content in the samples was significantly different and resulted affected by process, age and origin, with a clear separation between the mild and high thermally processed samples. In particular results indicate that, increasing the drying temperature, a degradation of the crocin isomers with high number of glucose moieties occurs. Principal Component Analysis of all crocin data allowed to discriminate samples based on origin (Italy vs. other countries) and age and to confirm the feasibility of the use of crocin pattern as marker of quality of saffron.

Conclusions

A simple and fast procedure for the simultaneous determination of crocins has been developed by UHPLC-MS/MS. Multivariate analysis was used to distinguish saffron samples with different storage and process and data also confirmed that geographical traceability can be obtained by crocins concentration and isomers pattern.

Novel Aspect

The experimental data confirmed the feasibility to use -cis and -trans isomers of crocins as markers of quality, process and traceability.

469 - REAL-TIME AUTHENTICATION OF FOOD AND BEVERAGES USING DART-QDA LIVEID ANALYSIS

Sara Stead (1) - Jayne Kirk (2) - Kari Organtini (3)

Waters Corporation, Scientific Operations, Manchester (1) - Waters Corporation, Product Management, Manchester (2) - Waters corporation, Scientific Operations, Milford (3)

Keywords: DART; mass detection; food fraud; chemometrics

Introduction: (Real-Time Authentication of food and beverages Using DART-QDa LiveID Analysis)

Currently there's no globally harmonised definition for "food fraud". Food and beverages of high commercial value are subject to fraudulent practice. Whiskey is sold as the product of one distillery or as a blend. Analytical methods are required for process control and formulation. Whiskey characteristics are influenced by the cereals used in fermentation, distillation, maturation and blending regimes. Palm oil is also a commodity of socioeconomic importance.

Methods: (Real-Time Authentication of food and beverages Using DART-QDa LiveID Analysis)

DART was coupled to a single quadrupole MS to produce profile data. Linear X rail module was used for direct sample Introduction: The DART source was operated with a helium gas flow of 1.5 L/min at 400°C. The MS was operated in full scan mode (mass range m/z 150-950) in positive and negative polarity; cone voltage 5-30 V; scan rate of 2 Hz. Chemometric models were generated using authentic samples, these models were used for real-time classification of whiskey and palm oils.

Results: (Real-Time Authentication of food and beverages Using DART-QDa LiveID Analysis)

Within this study we have investigated the potential for the implementation of DART QDa LiveID as solution for the rapid authentication of high value food and beverage samples of both liquid and solid types with minimal sample preparation. Multivariate models for product authenticity have been generated using a collection of authentic reference samples of single malt whiskey and palm oils from different geographical locations. In whiskey, ions with m/z between 50–300 we seen to be responsible for the brand level differences whereas ions at between m/z 300-400 drove the differences between the authentic and adulterated samples. In the palm oil, ionized species suspected to be generated from saturated fatty acids; carotenoids; vitamin A; tocopherols; tocotrienols; diglycerides and triglycerides were evident in the full scan spectral data. On the basis of these spectral features, it is possible to generate a multivariate model using a combination of PCA for data dimension reduction and LDA for class discrimination to distinguish between grades of palm oil processing and production type.

Conclusions (Real-Time Authentication of food and beverages Using DART-QDa LiveID Analysis)

DART produces relatively simple mass spectra characterized by M^+ , $[M+H]^+$ in positive mode and M^- , $[M+H]^-$ in negative mode. Fragment ions are observed for some compounds, the degree of fragmentation can be influenced by the choice of gas. In both the whiskey and palm oil applications, positive polarity ionization was found to give most abundant spectral features and considered to be the more diagnostic mode for model training.

Novel Aspect: (Real-Time Authentication of food and beverages Using DART-QDa LiveID Analysis)

DART QDa with LiveID for rapid characterization and authentication of solid and liquid food and beverages

1007 - EVALUATION OF SOLID-PHASE MICROEXTRACTION FOR THE ISOTOPIC ANALYSIS OF VOLATILE COMPOUNDS IN APPLE

Lidija Strojnik (1) - Federica Camin (2) - Luca Ziller (2) - Nives Ogrinc (1)

Jožef Stefan Institute, Department of Environmental Sciences, Ljubljana (1) - Fondazione Edmund Mach, Department of Food Quality and Nutrition, Research and Innovation Centre, San Michele all'Adige (2)

Keywords: SPME; GC-C-IRMS; apple; flavor compounds; authenticity

Introduction

The use of solid-phase microextraction (SPME) coupled with isotope ratio mass spectrometry (IRMS) for the $\delta^{13}\text{C}$ and $\delta^2\text{H}$ analysis of flavor compounds from apple fruit and recovery aromas has been evaluated using headspace sampling (HS). The method can be used to differentiate between natural and synthetic apple aroma compounds [1] and it can be easily transferred also to other commodities.

Methods

Factors affecting SPME were optimized [2], and the suitability of coupling SPME and gas chromatography-combustion-IRMS (GC-C-IRMS) [3] for determining $\delta^{13}\text{C}$ and $\delta^2\text{H}$ values was investigated. To do this, we investigated if HS-SPME extraction and analysis conditions result in isotopic fractionation. This was done by making a comparison of $\delta^{13}\text{C}$ and $\delta^2\text{H}$ values obtained by HS-SPME by GC-C-IRMS and $\delta^{13}\text{C}$, and $\delta^2\text{H}$ values determined using bulk analysis of reference material.

Results

Volatile components were extracted in 10 mL SPME vials containing 1 mL of the sample prior to gas chromatographic analyses. Optimal parameters were selected based on DVB/CAR/PDMS coated fibre and headspace sampling mode. Optimized SPME conditions were based on an adsorption time of 20 min at 30 °C and desorption time of 60 s at 250 °C. It is also shown that neither the analyte concentration nor the split/splitless mode affects $\delta^{13}\text{C}$ values. Finally, we verified that there are no matrix effects from the apple fruit or apple juice medium and that the technological production from apples to apple recovery aromas cause no isotopic fractionation. Therefore, comparison of $\delta^{13}\text{C}$ values is possible, and the use of cheaper apple samples instead of expensive recovery aromas for creating an apple aroma compound $\delta^{13}\text{C}$ database is appropriate. Such a database is required to provide reliable results for determining the authenticity of flavorings.

Conclusions

Our results show that by using an optimized SPME method we can obtain highly reproducible results and that SPME is, therefore, an appropriate tool for the isotopic analysis of volatile apple compounds extracted from fruit, juice or recovery aroma. Since many different compounds with different concentrations are present in one sample the selection of reference material and appropriate processing and interpretation of the results obtained is crucial.

Novel Aspect

We report for the first time how different HS-SPME extraction parameters and analysis conditions affect the $\delta^{13}\text{C}$ and $\delta^2\text{H}$ values of apple aroma compounds obtained by GC-C-IRMS.

A story on food, faith and fraud – detection of the fakes

Keynote – general introduction of the topic

Food fraud is a form of criminal behaviour, no matter the definition of crime. Its consequences are devastating. The interaction between motivated offenders, and the opportunities presented by victims and lack of control measures favour occurrence of food fraud. Control measures help to counteract fraud opportunities and motivations. Analytical testing is one of those control measures. Traditional measurements have focused on the analysis of one or a few product characteristics. However, nowadays analytical techniques generating detailed analytical fingerprints are used to determine the identity of foods, and many techniques are available. Mass spectrometry methods are an important sub-group of these Methods: Sensitive targeted methods will be presented, for instance for authentication of olive oil grades, as well as various fingerprint approaches. They include for instance broad anomaly methodology for authentication of spices, as well as for the characterization of organic products. Furthermore, MS-based breath analysis will demonstrate the importance of the origin of cocoa beans for a distinct identity of chocolates.

Conclusions

Food fraud is everywhere and its management requires analytical methods for detection of anomalies and confirmation of the authenticity of food products. Mass spectrometry offers a wide range of high value authentication applications.

1313 - FOOD PROTEOMICS: A NOVEL APPROACH TO FOOD AUTHENTICATION USING GLOBAL PROTEIN SIGNATURES AND SPECIES SPECIFIC MARKER PEPTIDES

Laura Viet (1) - Pauline Krimm (1) - Jens Brockmeyer (1)

University of Stuttgart, Food Chemistry, Stuttgart, Germany (1)

Keywords: proteomics, food authenticity, LC-MS/MS, global marker peptides

Introduction:

Food fraud by undeclared blending of meat from different species is a highly relevant topic in food industries as shown by the European horse meat scandal in 2013 [1]. For the detection of fraudulent blending with undeclared species to the earliest stage highly efficient methods for identification and quantification are necessary.

Methods:

Peptide based high performance liquid chromatography-multiple reaction monitoring methods using species specific marker peptides allow the detection of less than 1 % horse meat or pork in a beef matrix [2]. Additionally, unspecific marker peptides - present in numerous species - have been discovered. Both specific and unspecific marker peptides have been discovered using information dependant acquisition and subsequent de novo sequencing of tryptic peptides.

Results:

In this study, we investigated the ratios of species specific markers and global markers for different binary mixtures of beef and pork, beef and horse and pork and horse as well as the amounts of the global markers in different mammalian meat products by means of high resolution-multiple reaction monitoring. Considering the constant ratio of specific and global markers for each species, these ratios can be used to detect alterations of food products. While the amount of species specific marker peptides decreases in case of food fraud, the amount of global markers remains more or less the same. Thus, a decrease of the ratio can be used to prove the presence of species mixtures even in cases where the substituting species are not known (untargeted food authentication). Furthermore, a linear correlation between this change of ratios and the extend of the alteration offers an approach to quantify the addition of undeclared meat. The results show that for most cases a good linear correlation with correlation coefficients of $R^2 > 0,95$ can be achieved.

Conclusions:

Our data shows that the targeted analysis of species specific and global markers and the evaluation of their ratio is a promising way of detecting food fraud and additionally relatively quantifying fraudulent blending of meat from undeclared species.

Novel Aspect:

This food authentication method uses unspecific markers instead of species specific ones allowing the detection of food fraud even when the substituting species are not known.

911 - A NEW ANALYTICAL METHOD FOR THE QUANTIFICATION OF THREE LIGNANS IN ESPRESSO COFFEE BY USING HPLC-MS/MS TRIPLE QUADRUPOLE

Simone Angeloni (1) - Giovanni Caprioli (1) - Gulzhan Khamitova (1) - Luciano Navarini (2) - Gianni Sagratini (1) - Sauro Vittori (1)

University of Camerino, School of Pharmacy, Camerino (1) - illycaffè S.p.A., Research & Scientific Coordination, Trieste (2)

Keywords: Espresso Coffee, EC, Lignans, HPLC-MS/MS

Introduction:

Lignans, phenolic compounds that are present in a number of foodstuffs, possess some biological activities i.e., antioxidant and antiestrogenic [1,2]. The aim of our work was to develop a new analytical method to quantify three lignans, i.e., secoisolariciresinol (SECO), lariciresinol (LARI), matairesinol (MAT) from espresso coffee (EC) by using HPLC-MS/MS Triple Quadrupole.

Methods:

Different sample preparation methods, including dilutions, acidic hydrolysis and enzymatic digestions were evaluated and, once validated, the most performing was applied for the quantification of target compounds in coffee samples. The HPLC-MS/MS Triple Quadrupole, equipped with electrospray ionization (ESI) source, operating in negative ionization mode, was used for the analysis. Detection was performed in multiple reaction monitoring (MRM) mode.

Results:

Each lignan showed different transitions with different intensities of MS/MS acquisition parameters in MRM mode; the highest product ion abundances for all three compounds were found at 350°C as temperature of the drying gas of ionization source. At this temperature the precursor ions for lignans were the deprotonated molecules [M-H]⁻ in negative polarity; therefore, those conditions were chosen for lignan monitoring. About the sample preparation process, the most performing was the enzymatic digestion with the Clara-Diastase (mixture of enzymes), because it showed the highest recovery values (93.55 – 97.62 %). The analytical method was characterized by short chromatography run time (the separation of target compounds was obtained within 4 minutes) and high sensitivity (LOD ranging from 2 to 3 µg l⁻¹ and LOQ ranging from 5 to 10 µg l⁻¹).

SECO and LARI were found in all nine EC samples from 27.9 to 52.0 µg l⁻¹ and from 5.3 to 27.8 µg l⁻¹, respectively, contrary to MAT that it was not possible to detect it in each type of coffee.

Conclusions:

A new analytical method for the quantification of three lignans that avoided long clean up and enrichment sample procedures has been developed and validated. The application of our method to EC samples showed that SECO was the lignan present at the highest concentration (27.9 – 52.0 µg l⁻¹) followed by LARI (5.3 – 27.8 µg l⁻¹). Therefore, regular consumption of EC can contribute to the dietary intake of lignans.

Novel Aspect:

The developing of a new analytical method for the quantification of three lignans in espresso coffee by using HPLC-MS/MS and their determination in different coffee samples.

1280 - INVESTIGATION OF THE GLIADIN FRACTION COMPOSITION IN OLD AND MODERN WHEAT GENOTYPES

Vincenzo Cunsolo (1) - Michele A. De Santis (2) - Antonella Di Francesco (1) - Rosaria Saletti (1) - Marcella M. Giuliani (2) - Zina Flagella (2) - Salvatore Foti (1)

Department of Chemical Sciences, University of Catania, Catania, Italy (1) - Department of the Science of Agriculture, Food and Environment (SAFE), University of Foggia, Foggia, Italy (2)

Keywords: proteomics; old wheat genotypes; gluten; allergens; celiac disease

Introduction

Over the last years, old wheat varieties have gained increasing attention since they have been suggested to present health benefits when compared with modern cultivars of bread and durum wheat and are generally considered better tolerated, even if without any scientific evidence based data [1]. Modern wheats have beneficial properties in terms of yield compared with older varieties, but information about changes in gluten proteins are still scanty.

Methods

In order to investigate the effects of the breeding that took place during the 20th century on gluten composition, a modern and an old Italian durum wheat genotypes were studied by coupling 2D-PAGE of the gliadin fraction and a bottom-up approach consisting of specifically designed enzymatic digestion (trypsin plus chymotrypsin), high resolution mass spectrometry analysis and database search using a manually curated database (GluPro V1.0) of gluten proteins [3].

Results

A previous comparison of a set of old and modern Italian durum wheat genotypes [2] showed that 2D-PAGE profiles of the gliadin fractions did not present significant differences in relation to the expression of α - and γ -type gliadins. Conversely, they evidenced a drastic decrease in the expression of ω -type gliadins in the modern genotypes, with the highest content of ω -gliadins observed in the old genotype Dauno III and the lowest in modern genotype Saragolla. Particularly, the two genotypes presented differences in both the number and position of ω -gliadin spots. Here we report the preliminary results about the MS analysis of these spots. Taking into account that the main difficulties in ω -gliadin structural analysis are related to the presence of repeated peptide blocks rich of glutamine and proline, and to the very low level of lysine and arginine residues, a mixture of trypsin and chymotrypsin was employed with the aim to obtain an efficient ω -gliadin spots digestion.

Conclusions

The dedicated enzymatic digestion provided a lot of medium-sized peptides, which were analysed by MS/MS. Because proteomic methods require comprehensive and well annotated sequence databases, which are lacking for gluten, more reliable identifications were obtained searching MS data in a manually curated database of gluten proteins. This approach allowed the identification of some ω -gliadins responsible for the differences observed in 2D-PAGE profiles.

Novel Aspect

Provision of a custom approach together with the use of a curated and appropriate database will improve the reliability of gluten protein identification by proteomic analysis.

1184 - HOW FAR CAN WE TRUST UNTARGETED HRMS-BASED EXPOSOMICS TO ASSESS FOOD VALUE AND SAFETY FOR THE CONSUMER: THE CASE OF EXPOSURE TO PESTICIDES

Laurent Debrauer (1)

INRA, UMR 1331 TOXALIM, TOULOUSE, France (1)

Keywords: food safety, metabolomics, pesticides, high resolution

Introduction:

The presence of chemical contaminations in the environment and food can lead to human exposure to various molecules (including pesticides), which could be responsible for adverse effects for the Human consumer. Biological monitoring allows improving the exposure assessment, but this usually concerns a limited number of compounds analyzed in a targeted way, while untargeted approaches should provide a wider and more relevant assessment of this exposure.

Methods:

HRMS data were acquired on LTQ-Orbitrap XL (Thermo) and Synapt G2-SI (Waters) mass spectrometers running under both positive and negative electrospray ionization modes. Both spectrometers were fitted with UHPLC systems using generic H₂O - MeOH gradient elution on classical C18 columns. Data were treated using various software solutions including MassLynx and Progenesis from Waters, Xcalibur, MetWorks and TraceFinder from Thermo Scientific, XCMS, SIMCA-P.

Results:

A non-targeted UHPLC-ESI-HRMS exposomics workflow has been developed [1] and applied to the analysis of Human cohort urine samples. After HRMS detection, data can be processed in two ways: (i) focusing on a list of suspected metabolites generated from selected contaminants (e.g. pesticides), or (ii) starting from all features for identification of discriminant metabolites (including both endogenous and xenobiotic metabolites). From the same dataset, the first approach allows untargeted exposure assessment whereas the second can highlight possible impact of these exposures on the health status.

Through few examples, this lecture will give illustrations of how untargeted HRMS allows characterisation of pesticide metabolites as well as other chemicals, representing markers which enable classifying various population groups [2]. Other complementary strategies can also be implemented in order to get more toxicological relevance, by focusing e.g. on toxic reactive metabolites formed *in vivo*.

Conclusions:

The combination of untargeted and suspect screening approaches, constitutes an efficient tool for exposomics studies, and could be used as an upstream multi-exposure assessment step for food and environmental exposure evaluation. The relevance and limitations of those untargeted or semi-targeted approaches for better assessment of food safety in the context of multi-exposure to contaminants will be discussed.

Novel Aspect:

Untargeted and suspect screening data acquisition strategies for evidencing potentially new biomarkers of exposure to chemical contaminants

741 - CATABOLIC MARKERS 24,25-DIHYDROXYVITAMIN D₂/D₃ IN BOVINE AND PORCINE SERA SHOW INTER-SPECIES DIFFERENCES BETWEEN VITAMIN D₂ AND VITAMIN D₃ METABOLISM

K. G. Dowling (1) - G. L. J. Hull (1) - A. Hayes (1) - S. K. Duffy (2) - A. K. Kelly (2) - J. V. O'Doherty (2) - K. D. Cashman (1)

Cork Centre for Vitamin D and Nutrition Research, School of Food and Nutritional Sciences, University College Cork, Cork (1) - School of Agriculture and Food Science, University College Dublin, Dublin (2)

Keywords: 24,25-dihydroxyvitamin D, vitamin D biofortification, beef, pork, LC-MS/MS

Introduction: (Limit of 400 characters)

Supplementation of animal feeds with vitamin D₂ (VitD₂) is less effective than vitamin D₃ (VitD₃) at increasing serum 25-hydroxyvitamin D [25(OH)D; status marker] of beef cattle and pigs [1,2]. A faster rate of degradation of VitD₂ may explain this finding, and measurement of the serum 24,25-dihydroxy catabolic markers, 24,25(OH)₂D₂ and 24,25(OH)₂D₃, by LC-MS/MS would test this hypothesis.

Methods: (Limit of 400 characters)

Sera were obtained from animal feeding trials in which beef cattle received diets containing 0 IU/kg VitD or 4000 IU/kg as VitD₂ or VitD₃, and pigs received diets containing 2000 IU/kg as VitD₂ or VitD₃ (n=8/10 per group). [1,2] Sera were analysed with a validated LC-MS/MS method for 24,25(OH)₂D₃, 25(OH)D₃ and 25(OH)D₂ in 150 µL serum [3] which was extended to include the analyte 24,25(OH)₂D₂.

Results: (Limit 900 characters)

The majority of the 30 beef sera analysed had concentrations of 24,25(OH)₂D₂ (90%) or 24,25(OH)₂D₃ (77%) below the LOQs (0.68 and 1.09 nmol/L, respectively). By contrast, 7 out of 8 pigs receiving VitD₂ had quantifiable 24,25(OH)₂D₂, ranging from 1.85-4.77 nmol/L, and 24,25(OH)₂D₃ concentrations in pigs from both treatment groups ranged from 2.6-24.2 nmol/L. These differential 24,25(OH)₂D findings were despite the fact that mean+SD serum 25(OH)D was higher in beef cattle compared to pigs (122+37 and 53+18 nmol/L, respectively), which suggests a slower 24-hydroxylation rate in beef cattle. In relation to catabolism of the vitamers amongst pigs, the mean+SD serum 24,25(OH)₂D₃ of pork receiving VitD₃ was 21.0+2.8 nmol/L with no detected 24,25(OH)₂D₂, and the mean+SD serum 24,25(OH)₂D₃ and 24,25(OH)₂D₂ of pork receiving VitD₂ was 4.5+1.8 nmol/L and 2.3+1.3 nmol/L, respectively.

Conclusions: (Limit of 400 characters)

Differences in serum 24,25(OH)₂D₂ and 24,25(OH)₂D₃ concentrations of beef cattle and pigs shows that regulation of the vitamin D degradation pathway is not the same in these two species. Amongst pigs, the catabolic rate of 25(OH)D₂ is lower than that of 25(OH)D₃, suggesting that different rates of catabolism do not account for the difference in efficacy of VitD₂ and VitD₃ feed supplementation.

Novel Aspect: (Limit of 150 characters)

Most 24,25-dihydroxyvitamin D methods measure only 24,25(OH)₂D₃. Including 24,25(OH)₂D₂ allowed direct comparison of vitamin D₂ and D₃ metabolism.

425 - NOVEL IDENTIFICATION OF 3-EPI-25-HYDROXYVITAMIN D3 IN PORK AND BEEF LONGISSIMUS THORACIS STEAKS CONFIRMS THE PRESENCE OF THIS METABOLITE IN THE HUMAN FOOD CHAIN

K. G. Dowling (1) - A. Hayes (1) - K. Galvin (1) - S. K. Duffy (2) - A. K. Kelly (2) - J. V. O'Doherty (2) - K. D. Cashman (1)

Cork Centre for Vitamin D and Nutrition Research, School of Food and Nutritional Sciences, University College Cork, Cork (1) - School of Agriculture and Food Science, University College Dublin, Dublin (2)

Keywords: 3-epi-25(OH)D3, 25-hydroxyvitamin D3, beef, pork, LC-MS/MS

Introduction: (Limit of 400 characters)

The source of the C3 epimer (3-epi-25(OH)D3) of 25-hydroxyvitamin D3 (25(OH)D3) in human serum may arise, in part, from exogenous intake [1]. While pork and beef contain 25(OH)D3 [2,3], it is not known if pork and beef supply 3-epi-25(OH)D3 to the human diet. Measurement of 3-epi-25(OH)D3 in pork and beef and in the corresponding serum of domestic animals may provide clues to the epimer's origin.

Methods: (Limit of 400 characters)

A UPLC-MS/MS method in serum [4] was adapted for the analysis of 25(OH)D3 in Longissimus thoracis steaks (LT). The pentafluorophenyl (PFP) column was able to separate isobaric 3-epi-25(OH)D3 from 25(OH)D3 in both matrices. Quantification of 3-epi-25(OH)D3 in LT was achieved using 25(OH)D3-d6 as the IS and applying a correction factor to adjust for different ionization efficiencies of the epimers.

Results: (Limit 900 characters)

The LOD for 3-epi-25(OH)D3 in LT was 0.008 ng/g, and the RSD% of minced beef control (n=13 over 7 days) was 30%. The concentrations of 3-epi-25(OH)D3 in LT (n=18 pork, n=19 beef) ranged from 0.016-0.670 ng/g. There was no significant difference between mean 3-epi-25(OH)D3 concentrations in pork and beef (P>0.05), and the overall mean+SD was 0.102+0.070 ng/g. Thus, a typical 150g pork or beef steak would provide 15.0 ng 3-epi-25(OH)D3. In serum collected from the same animals, the mean+SD 3-epi-25(OH)D3 was higher in porcine (2.9+0.9 ng/mL) compared to bovine serum (1.9+0.7 ng/mL). 3-epi-25(OH)D3 was positively correlated to 25(OH)D3 in both LT (R=0.570) and serum (R=0.444). The %epimer (ie. 3-epi-25(OH)D3/(3-epi-25(OH)D3+25(OH)D3)*100) was equivalent in matched LT-serum pairs (P>0.05), and the mean+SD% epimer in beef LT was 6.2+3.5%, compared to 4.0+1.8% in pork LT.

Conclusions: (Limit of 400 characters)

This is the first known evidence of 3-epi-25(OH)D3 in the human food chain originating from pork and beef LT steaks. The %epimer in LT was the same as that in the circulation of both species, which suggests epimerisation occurs endogenously within the animals. The difference in %epimer content in pork compared to beef highlights species-related differences in the rate of epimerisation.

Novel Aspect: (Limit of 150 characters)

The PFP column commonly used to separate 25(OH)D3 epimers in serum was used to identify 3-epi-25(OH)D3 in pork and beef LT steaks.

135 - ARTIFICIAL INTELLIGENCE ENABLES THE DETECTION OF PATHOGENS IN FOOD AND OTHER COMPLEX BIOLOGICAL MATRICES BY MASS SPECTROMETRIC ANALYSIS OF RNA MODIFICATIONS

Botros Toro (1) - Reza Nemati (2) - Mehraveh Salehi (3) - Will McIntyre (2) - Colin Aldrich (2) - Daniele Fabris (4)

University at Albany, Biological Sciences, Albany, NY (1) - University at Albany, Chemistry, Albany, NY (2) - Yale University, Electrical Engineering, New Haven, CT (3) - University at Albany, Chemistry and Biological Sciences, Albany, NY (4)

Keywords: machine learning; pathogen detection; biomarker panels; food safety; medical diagnostics.

Introduction

We have recently demonstrated that a variety of microorganisms and viruses can be accurately differentiated according to their specific RNA post-transcriptional modifications (PTMs) observed by MS analysis [1]. We have now employed machine learning to establish a classification and identification platform that capitalizes on comprehensive PTM profiles to enable pathogen detection not only in cell cultures, but also in actual biological samples and materials.

Methods

Comprehensive PTM profiles were obtained from total RNA extracts treated with exonucleases to generate mononucleotide mixtures, which were analyzed by direct infusion nanospray MS on either an Orbitrap Velos (Thermo) or a Synapt G2 (Waters) instrument [2]. A non-redundant database of RNA modifications created in house was employed to perform data interpretation and generate final datasets used for training machine-learning algorithms written in Python.

Results

Machine learning constitutes an ideal approach for establishing a classification/identification platform in which the unique differentiating feature consists of an entire panel of biomarkers, including identities and corresponding abundances, rather than an individual biomarker. In our case, each unique panel consists of covalent ribonucleotide variants (i.e., PTMs) identified according to their characteristic masses, fragmentation patterns, and arrival time distributions. In this report, we show that the PTM profile of a typical microorganism –comprising on average ~30 PTMs– can be unambiguously retraced to its source. We demonstrate the ability of either supervised or unsupervised algorithms to properly classify labeled samples and recognize unlabeled (“unknown”) ones. Among the different systems included in the study, our classification/identification platform correctly differentiated milk contaminated by *S. typhimurium* from uncontaminated samples, as well as mosquitoes infected by Zika virus from healthy controls.

Conclusions

We demonstrated that different machine learning algorithms enable the correct identification of bacterial/viral pathogens in samples containing high backgrounds of foreign RNA, which were afforded, for example, by milk somatic cells or mosquito tissues. The ability to identify pathogens in their typical biological matrices and without analytical separations has an enormous potential for a broad range of food safety and medical diagnostic applications.

Novel Aspect

Demonstration of the ability of artificial intelligence to support pathogen identification through the analysis of large biomarker panels.

74 - EVALUATION OF OXIDATIVE STRESS MARKERS IN HUMAN BIOLOGICAL MATRICES BY MEANS OF UHPLC-MS/MS

Federico Fanti (1) - Flaminia Vincenti (2) - Nicola Bernabò (3) - Mauro Serafini (3) - Dario Compagnone (1) - Manuel Sergi (1)

University of Teramo, Faculty of Bioscience and Technology for Food, Agriculture and Environment, Teramo (1) - Sapienza University of Rome, Department of Chemistry, Teramo (2) - University of Teramo, Faculty of Bioscience and Technology for Food, Agriculture and Environment, Rome (3)

Keywords: Oxidative Stress Markers, Oxysterols, Isoprostanes, UHPLC-MS/MS

Introduction

Oxidative stress (OS) is a risk factor for human health, and several stress markers have been proposed for the evaluation of OS, and many of them are available for this purpose. The induction of organ function disorders can lead to age-related decline in biological functions in human [1]. The aim of work is to create suitable methods for identification of oxidative stress markers by means of UHPLC-MS/MS techniques applied in human samples, in particular for Oxysterols and Isoprostanes [2-3].

Methods

In this project, methods for extraction from various tissue has optimized for little amounts of samples (for example sperm and plasma) or for analyte enrichment (urine). After extraction, a clean-up procedure has performed in the samples using SPE methods for each type of analytes. For each of them a UHPLC-MS/MS experiments was performed, being careful to take every possible parameter into account, using different source (ESI or APCI) and optimizing every instrument parameter.

Results

For the analytes different experiments was performed, for the oxysterols the best condition for analyst was obtained through using of APCI source operating in positive ion scan, in according with literature [4], using C18 column for the separation of analytes. In other hand, isoprostanes were more responsive by using of ESI source operating in positive ion mode; for the liquid chromatographic separation a C18 column was used. SPE clean up methods were optimized for the selected classes of analytes: for Isoprostanes SPE step was used to concentrate the OS markers present in urine before injection in the auto sampler. The extraction protocols of Oxysterols has been optimized, starting from bovine sperm procedures [5]: the protocols were miniaturized to allow the use of small sample amount. The developed methods were tested for different biological samples (human).

Conclusions

UHPLC-ESI(APCI)-MS/MS methods for the detection and quantitation of OS markers were optimized. These markers were detected and quantified in different human biological matrices both for oxysterols and Isoprostanes; both groups of samples were taken from subjects that followed controlled feedings, adapted to modify the levels of oxidative stress.

Novel Aspect

New analytical methods for detection and quantitation of OS markers were developed and validated, increasing sensitivity and reliability in the different matrices.

Keywords: MiniMas, mass spectrometry, food supplement

Introduction

Food supplements are intended to support, maintain or optimize physiological parameters, therefore the organism's homeostasis. The complex mechanisms that contribute to the maintenance of homeostasis have brought researchers to move from a reductionist to a holistic vision of physiology, biology and medicine. In this panorama, natural complex food supplements play a key role as all the compounds presents forms a natural complex system ready to interact at various level with the complexity of human organism[1].

Methods

To reach the global characterization of Minimas, different chromatographic methods based on mass spectrometry have been used. Volatile organic compounds have been analysed by means GC-QqQ and Head Space sampling. Organic polar compounds have been analysed by means UHPLC-qToF. The metal part of inorganic compounds have been analysed by means ICP-MS.

Results

The quality assurance of all natural complex food supplements is a very important goal particularly that of Minimas, a food supplement that helps to maintain the homeostasis of blood pressure and cardiac functions. The old fashion of analyze only few marker compounds is not enough, as the activity of Minimas, as well that of all natural complex products, cannot be referred to the presence of few compounds. All the compounds of the product are important as they express an effective complex natural system. Therefore, a comprehensive product characterization is necessary to assure batch compliance and efficacy through the time. In this work, plant dried-extracts ingredients of Minimas and Minimas itself have been analyzed by means of GC-QqQ and UHPLC-qToF. Methods: Inorganics have been characterized by means of ICP-MS. All the data collected have been matched with an in-house library containing more than 1000 natural compounds providing the identification of several compounds, that than have been quantified[2].

Conclusions

The potency of the developed analytical approach applied to the natural complex food supplement Minimas led to its comprehensive characterization, getting a quali-quantitative identity card of its complexity. The analysis performed by different mass spectrometry techniques permits to check the presence of all Minimas ingredients, opening new perspective to the routine quality control of natural complex food supplements.

Novel Aspect

A complete mass spectrometry based analytical platform is available and it represents a very important tool to get the broader compositional knowledge of all natural complex products, included Minimas.

946 - THE SYNERGISM OF MALDI LIFT-TOF/TOF MS AND ESI-Q-TOF MS INSTRUMENTS TO DISCOVER NEW ISOFORMS OF ALLERGENS FROM HAZELNUT OLEOSIN EXTRACT.

Sterfano Nebbia (1) - Cristina Lamberti (1) - Marcello Manfredi (2) - Emilio Marengo (3) - Laura Cavallarin (1) - Maria Gabriella Giuffrida (4)

CNR, ISPA, Grugliasco (TO) (1) - ISALIT, Spin-off of DISIT, University of Piemonte Orientale, Italy, Alessandria (2) - University of Piemonte Orientale, Department of Sciences and Technological Innovation, Alessandria (3) - CNR, ISPA, Colletterto Giacosa (TO) (4)

Keywords: MALDI-TOF/TOF, ESI-Q-TOF, hazelnut allergens, allergens

Introduction:

Oleosins are proteins associated to oil bodies of seeds and investigated because demonstrated to be responsible of severe allergic reaction in allergic patients [1]. During the characterization of hazelnut oleosins, selected by immunoreaction with the sera of allergic Italian children, the analyses with two MS instruments improved our capacity of data interpretation and allowed to identified a new isoform probably more reactive than the two oleosins already known.

Methods:

A protocol for the extraction of oil bodies associated proteins was optimized and SDS-PAGE was performed. The PMF method ("in gel" trypsin digestion, peptide collection and MS analysis) was applied to the bands at 14 and 17 kDa. All protein bands were identified by both MALDI-TOF/TOF and LC-MS/MS analyses. MALDI-TOF/TOF spectra were manually interpreted, if necessary, and results were used to refine LC-MS/MS interpretation.

Results:

The electrophoresis profile of the oil bodies associated proteins showed two most abundant bands. MALDI TOF/TOF analysis was performed on bands at 14 and 17 kDa from SDS-PAGE of hazelnut extract, where 100% of protein content resulted to be oleosins Cora12 and 13, already known as allergens. The LC-MS/MS analysis confirmed the same results. However, the manual checking of major signals of the MALDI-TOF spectra of the band at 17kDa revealed that only minor signals identified the oleosinCor a 12 and that at least two high intensity signals were without any protein attribution. The fragmentation spectra from LIFT-TOF/TOF of two major picks were analyzed using MS-Tag Protein Prospector software in identity mode and didn't give any protein identification. When the software was set in homology mode with Cor a 12 as template, a new N-terminal was revealed indicating the presence a new isoform not present in the NCBI database.

Conclusions

In protein identification the dependence of MS techniques from the DNA and protein database is very strong and new isoforms are rarely identified. In this work a new isoform of oleosins from hazelnut was identified combining manual and software-assisted interpretation of MALDI LIFT-TOF/TOF spectra.

Novel Aspect:

Sometimes old practices like to have look at spectra and try to assign almost all signals by manual interpretation of MS/MS spectra allow to really discover something new that normally miss out on automatic data interpretation.

409 - DETERMINATION OF PYRROLIZIDINE ALKALOIDS IN PLANT MATERIAL USING ON-LINE SPE COUPLED TO UHPLC-MS/MS

Anja Grüning (1) - Julia Sander (1) - Sven Vedder (1)

Shimadzu Europa, CIPS, Duisburg (1)

Keywords: Pyrrolizidine alkaloids, on-line SPE, UHPLC-MS/MS

Introduction:

Pyrrolizidine alkaloids (PAs) are secondary plant metabolites that are supposed to be carcinogenic and genotoxic. They occur mainly in plants of the Boraginaceae, Asteraceae and Fabaceae families. Plant food and beverage, phytopharmaceuticals or even animal feed can easily be contaminated with PAs and enter the food chain. Currently there are discussions on possible regulatory measures caused by the presence of PAs in honey, tea, herbal infusions and food supplements.

Existing methods include laborious sample preparation, e.g. solid-liquid extraction followed by solid phase extraction for clean-up.

Here we report an on-line SPE UHPLC-MS/MS method, which overcomes the difficulties of combining

Methods:

Tea samples were extracted twice with 0.05M sulfuric acid by sonication. Before centrifugation the pH of the extract was adjusted with ammonium hydroxide. These samples were put into the autosampler and transferred to the on-line SPE column using an aqueous solution. After washing the sample was eluted and trapped into a loop. By switching the loop the eluted sample was transferred to the analytical column. A binary gradient separated the PAs for quantification. Due to this hardware set-up UHPLC with high backpressure and on-line SPE which is pressure limited were successfully combined. By careful fine-tuning of the SPE elution and the chromatographic conditions the separation of critical peak pairs could be maintained.

Results:

By using the reported instrument set-up, analysis and thus the quantification of 16 PAs (Indicine, Trichodesmine, Senkirkine, Senecivernine, Senecyphilline, Senecionine, Retrosine, Monocrotaline, Lycopsamine, Lasiocarpine, Jacobine, Intermedine, Heliotrine, Europine, Erucifoline, Echimidine) and 14 of their related N-Oxides (Echimidine-N-oxide, Lasiocarpine N-oxide, Jacobine N-oxide, Intermedine N-oxide, Heliotrine N-oxide, Erucifoline-N-Oxide, Europine -N-Oxide, Indicine N-oxide, Senecivernine N-oxide, Senecyphilline N-oxide, Senecionine N-oxide, Retrosine N-oxide, Monocrotaline-N-oxide, Lycopsamine N-oxide) could be performed. Calibration curves showed good precision and accuracy and even in a complex matrix like tea we were able to easily quantify the PAs in at least the range of 10 to 300 µg/kg. This is consistent to established methods using manual sample preparation, but less time consuming and less tedious. For all analytes, linear weighted regression resulting in $r^2 > 0.99$ could be achieved, with S/N > 10 for LLOQ levels.

Conclusions

A method for high-sensitivity analysis was successfully developed for PA analysis in plant material. The manual sample preparation could be reduced to a minimum as the set up of on-line SPE followed by UHPLC-MS/MS saves additional clean-up steps without compromising the performance of the assay.

Novel Aspect:

On-line SPE of Pyrrolizidine alkaloids coupled to an UHPLC-MS/MS system which overcomes the problems with the different pressure ranges.

689 - FREE FATTY ACIDS AND HEXANAL AS SHELF LIFE MARKERS IN CHEESE: EVALUATION OF FOOD PACKAGING EFFICIENCY THROUGH A QUANTITATIVE HS-SPME-GC-MS METHOD.

Astride Franks Kamgang Nzekoue (1) - Elisa Vittori (2) - Sauro Vittori (2) - Giovanni Caprioli (2) - Gianni Sagratini (2)

University of Camerino, School of pharmacy, Camerino (1) - University of Camerino, School of Pharmacy, Camerino (2)

Keywords: Cheese shelf-life, free fatty acids, hexanal, food packaging, HS-SPME-GC-MS.

Introduction:

This study aims to develop a quantitative HS-SPME-GC-MS method to monitor concomitantly the evolution of short and medium chain free fatty acids and hexanal during cheese storage. Indeed, food storage is associated with the production of these markers whose amounts determine the taste and the spoilage level of cheese [1,2]. Therefore, their analysis can be useful in the evaluation of dairy product shelf-life [3].

Methods:

Hexanal, butanoic, isovaleric, hexanoic, octanoic and decanoic acids were analyzed by optimizing the GC-MS conditions in SIM mode. Moreover, different salting-out agents and SPME-fibers were compared to improve their extractions. This optimized method was validated and applied on two cheese samples (Grana Padano and Fresh Asiago) to compare the efficacy of two packaging systems: a polycoupled packaging named Ideabrill® and a HDPE film.

Results:

The trapping abilities of 4 fiber types (100 µm PDMS, 75 µm CAR/PDMS, 50/30 µm DVB/CAR/PDMS and 85 µm PA) was evaluated and followed by the comparison of 4 salts (NaCl, Na₂SO₄, NaH₂PO₄ and Na₂CO₃) on the extraction of FFAs and hexanal.

The 75 µm CAR/PDMS fiber and the use of NaH₂PO₄ as salting-out agent resulted to be the most appropriate conditions for the extraction of analytes. A progressive increase of hexanal and FFAs during storage was noted confirming that these compounds are sensitive markers of cheese deterioration. All along storage, the concentrations of these markers became higher in the HDPE film. After 12 weeks of study for Grana Padano (GP) and 4 weeks for Fresh Asiago (FA), the Ideabrill® packaging allowed a lower increment of FFAs (11.6-fold increase for GP and 5.9 for FA) in comparison with the HDPE film (21.5-fold increase for GP and 7.4 for FA). The amounts of hexanal were also lower in the Ideabrill® packaging (0.58 against 1.04 mg/kg in GP and 0.38 against 0.55 mg/kg in FA).

Conclusions

By slowing down the increment of FFAs and hexanal, the Ideabrill® packaging has proved to be more effective than a common HDPE film in the preservation of the cheeses studied.

This method can represent an important solution in the food industry sector, whose growth requires the optimization of fast and performing analytical methods that could help for example in shelf life studies, quality control or active packaging development.

Novel Aspect:

Hexanal and FFAs are good chemical markers of cheese shelf-life. This is the first GC-MS method reported to quantify simultaneously these markers in cheese.

Non-targeted Characterization of the Degradation Products of Soybean Oil After Frying Process by HS-SPME-GC-MS and LLE-LC-HRMS

Keywords: non-targeted analysis, degradation products, soybean oil, thermal processing

Introduction

Soybean oil has a maximum total production currently in edible oils and mostly used in the world. Furthermore, a high temperature thermal processing, such as frying and stir-frying have been proceeded in traditional Chinese cooking Methods: The degradation compounds of soybean oil after thermal processing might cause the damage of human health like cancers [1]. Hence, to develop an efficiency analytical method for identification of degradation compounds of soybean oil after high temperature processing is important in food safety and toxicology. In this study, HS-SPME-GC-MS and LLE-LC-HRMS methods were developed for characterization of components produced in soybean oil before and after fried. Multivariate analysis has been widely used in non-targeted analysis in recent years. Principal components analysis (PCA) was utilized to assist the identification of the biomarkers used for distinguishing the fried and un-fried soybean oil.

Methods

The manual SPME holder and three kinds of SPME fibers including 65 μ m Polydimethylsiloxane/Divinylbenzene (PDMS/DVB), 75 μ m Carboxen/Polydimethylsiloxane (CAR/PDMS) and 50/30 μ m Divinylbenzene/Carboxen/Polydimethylsiloxane (DVB/CAR/PDMS) were obtained from Supelco (Bellefonte, PA, USA). These coated fibers were conditioned according to manufacturer's recommendation before the first use. 4 mL of soybean oil sample was placed in a 15 mL brown sample vial then sealed with a PTFE septum cap. Subsequently, the oil sample was heated to 175 $^{\circ}$ C in oil bath with stirring bar at 300 rpm for imitating the heating processing while unheated oil at 50 $^{\circ}$ C. Optimum incubation time was 3 min, and then extracted via headspace for 30 min at 175 $^{\circ}$ C. After 30 min, the SPME fiber was desorbed in the GC injector. The separation of volatile analytes were performed with a TSQ Quantum GC system (Thermo Scientific, San Jose, CA, USA). Compounds were separated on a DB-5MS capillary column (30 m \times 0.25 mm i.d., 0.25 μ m film thickness). The injector was set at 270 $^{\circ}$ C for 5 min. Ultra-high purity helium was used as the carrier gas at flow rate of 1 mL/min. The column temperature program was set as following: initial temperature 50 $^{\circ}$ C for 2 min, subsequently raised to 300 $^{\circ}$ C at the rate of 15 $^{\circ}$ C/min, then held at 300 $^{\circ}$ C for 5 min at splitless mode. The GC/MS transfer line temperature was set at 275 $^{\circ}$ C. Mass spectrums were obtained with full scan and mass range was from m/z 50 to 550. Library search was operated on NIST MS search 2.0.

Results

In order to extract all volatile compounds in soybean oil, the oil samples were incubated at 175 $^{\circ}$ C for 3 min. After incubation, the volatile components were extracted by CAR/PDMS, DVB/CAR/PDMS and PDMS/DVB SPME fibers at 175 $^{\circ}$ C for 30 min as heated oil. Un-heated oil was processed at 50 $^{\circ}$ C. The adsorbed extracts were desorbed in GC linear under 270 $^{\circ}$ C for 5 min then analyzed by GC-MS/MS. For comparing the volatile compounds in standard soybean oil, brand A and B soybean oil, statistic technology was used for handling the GC-MS/MS data. PCA is most widely multivariate statistical method used to highlight similarities and differences. In this study, the obviously difference between heated and un-heated soybean oil was found by using PCA under 95% confidence interval. The volcano plot was used to discover the potential biomarkers for distinguishing the heated and un-heated soybean oil.

The potential biomarkers was characterized by NIST database matching in the end. The matching results showed 1-Dodecene, 1-Undecanol, 1-Tridecanol, Hexanal, Ttrahydrofuran and 1-Tetradecanol were potential biomarkers in standard soybean oil; Nonanal, Dodecane, Benzaldehyde, 1-Octene, 1-Tridecanol and 1-Undecanol were potential biomarkers in brand A; Trimethylene oxide, Trichloromethane, Acetic acid, Ttrahydrofuran and 1-Tridecanol were potential biomarkers in brand B. In these compounds, Ttrahydrofuran, Trichloromethane were possible carcinogens. The biomarkers found in this study could be used for differentiation between the fresh soybean oil and recovered soybean oil.

Conclusions

This study concentrates on finding the possible biomarkers between fried and un-fried soybean oil by using HS-SPME-GC/MS and LLE-LC-HRMS. Use three kinds of fibers to make the data completed. We used heated oil to imitate fried oil. The experimental results indicated that there are significant differences between heated and unheated soybean oil in standard and two brands of oil. PCA will be employed to assist the classification and identification of biomarkers between fried and un-fried soybean oil. According to PCA and volcano plots, we can find a possible biomarkers by NIST. In the end, we find some possible biomarkers and google for their carcinogenicity. The experimental progress and results could assist us to distinguish fresh oil or not.

Novel Aspect

HS-SPME-GC-MS/MS and LLE-LC-HRMS combined with PCA was developed and used to characterize the biomarkers for soybean oil adulterating.

Bioactive compounds of brazilian green coffee beans collected in different levels of maturation by ESI-LTQ-ORBITRAP

Mayara Fumiere Lemos^{1,2} ; Consuelo Perez²; Demian R. Ifa²; Rodrigo Scherer^{1*}

Keywords: Conilon coffee; chlorogenic acids; caffeine; trigonelline

Introduction:

Harvesting coffee beans at different cultivating conditions may influence their chemical composition and the quality of the beverage [1,2]. Considering the economic importance of conilon coffee, the objective of the study was to identify the presence of metabolites in inedited conilon coffee clones and to compare them with known species, using a high resolution technique, as well as to verify if different maturation times can affect the composition of the coffee.

Methods:

Green coffee beans were collected in Espirito Santo, Brazil (3 cultivars of Arabica coffee, 3 clones of conilon coffee and one cultivar of Robusta Tropical). The samples were harvested in 3 different levels of ripeness (60%, 80% and 100% of mature) and the extracts were prepared with methanol. The extracts were injected into a mass spectrometer (LTQ-Orbitrap Elite) equipped with an electrospray ionization (ESI) source, operating in positive and negative ion modes.

Results:

A total of 21 coffee bean extracts were characterized in positive and negative ion modes by ESI-MS and tandem MS. Coffee bean metabolites, such as caffeine, trigonelline, and some sugars were observed in positive and a wide range of polyphenols such as chlorogenic acids in negative ion mode. It was found that coffee bean species Arabica, Robusta and clones 101,105 and 108 showed similar metabolomic profiles but distinct relative abundances. In positive ion mode, trigonelline was the most abundant compound with higher concentrations in Arabica samples and in clones 105 and 108. No trend was observed regarding to the maturation of this compound. However, the content of caffeine was higher in Robusta coffee and also in clones 105 and 108, increasing with maturation. In negative ion mode, caffeoylquinic acid was the most abundant compound with higher concentrations in Robusta coffee and in clones 105 and 108. The polyphenols and chlorogenic acids detected showed constant concentrations during the maturation in almost the samples.

Conclusions:

Among the 3 clones studied, it was possible to conclude that clone 105 and 108 were similar to Arabica coffee (better quality) and Robusta (higher productivity), being promising for a good quality. Trigonelline and caffeoylquinic acid were the main compounds detected in coffee beans. It was observed that maturation may affect some metabolites and it is important to monitor these changes because these compounds are scent and flavor precursors of the final beverage.

Novel Aspect:

To understand the conilon coffee quality, as well as the effects of different harvesting conditions, which could impact the composition and quality of the beverage.

Igiene dei Mangimi, Torino (1) - Università degli Studi di Milano, Dipartimento di Scienze Farmaceutiche, Milano (2) - Istituto Zooprofilattico Sperimentale del Piemonte, Liguria e Valle d'Aosta, S.C. Neuroscienze con annesso CEA, Torino (3)

Keywords: PAPS, peptides, proteins, LC-MS/MS, BSE

Introduction

Ruminant PAPS (Processed Animal Proteins) were forbidden in feed since 2001 [1], while non ruminant PAP were reauthorized in aquaculture in 2013 [2]. A PCR method is used in official controls: it permits to discriminate between ruminant and non-ruminant materials [3]. Mass-spectrometry can be helpful in identifying peptides from specie-specific muscular proteins, since milk is an allowed ingredient in feed and PCR is not able to discriminate the origin of DNA.

Methods

High resolution mass spectrometry was applied to identify specie-specific peptides from bovine muscular proteins. Then, a LC-MS/MS method was developed in order to detect these peptides in animal feed samples eventually contaminated/adulterated with bovine PAPS. Sample preparation consists of a proteins extraction step, followed by an accurate extract purification by means of SDS-PAGE and by an enzymatic proteins digestion in order to obtain the peptides [4].

Results

Three peptides, TR-12, TR-14 and YK-16, have been identified as markers of bovine PAPS presence by means of high resolution mass spectrometry. They derived from three bovine skeletal muscle proteins, Desmin, Vimentin and Myoglobin respectively. Proteins' specificity has been carefully evaluated, excluding all proteins also contained in milk, colostrum and in other sources. Then, an accurate selection has been executed on peptides found, excluding all peptides not specie-specific and with no adequate physical/chemicals properties.

A LC-MS/MS method for the simultaneous detection of these peptides in animal feed samples was developed. This method is able to detect a contamination of animal feed with bovine PAP 0.1% w/w.

Validation as qualitative method is in progress. The method was also applied to a real sample resulted non-compliant for ruminant DNA at PCR analysis and not reporting milk or milk by-products as ingredients: peptide TR-12 has been correctly identified.

Conclusions

The bovine peptides identified appear to be excellent biomarkers for detection of bovine PAP in animal feed. Their presence is an indisputable signature of bovine PAP, as they were selected from bovine meat protein sequences, and no possible cross reactivity appear to exist with dairy products. This could be of primary importance, as it will allow official and in house laboratories to detect unquestionably the presence of bovine PAP in feed.

Novel Aspect

A new approach to detect bovine PAP contamination was developed. It permits to discriminate between milk and bovine PAP addition in feed, unlike currently official Methods:

1204 - METABOLIC SURVEY OF ITALIAN VEGETABLES: FTICR-MS AND NMR-BASED UNTARGETED ANALYSES

Alessandro Maccelli (1) - Anatoly P. Sobolev (2) - Donatella Capitani (2) - Barbara Chiavarino (1) - Simonetta Fornarini (1) - Luisa Mannina (1) - Maria Elisa Crestoni (1)

Sapienza Università di Roma, Dipartimento di Chimica e Tecnologie del Farmaco, Roma, Italy (1) - CNR, Istituto di Metodologie Chimiche, Laboratorio di Risonanza Magnetica "Annalaura Segre", Monterotondo, Italy (2)

Keywords: ESIFT-ICR, NMR, metabolomics, White Celery, Red Pepper

Introduction

Untargeted analyses of complex biological mixtures such as vegetable extracts is a rapidly expanding field. Combined use of Fourier transform ion cyclotron resonance mass spectrometry (FT-ICR MS) and nuclear magnetic resonance (NMR) spectroscopy allows to increase metabolome coverage devoid of authentic standards[1] and is applied here to characterize white Celery of Sperlonga (WCS) and "Cornetto diPontecorvo" red pepper (CPRP) samples.

Methods

Both vegetables are endowed with Protected Designation of Origin and Protected Geographical Indication mark. Extracts from fruit (peel, pulp and seeds of CPRP) and plant (heart, stalk and leaves of WCS) were obtained by the Bligh-Dyer method. High resolution mass analyses were conducted with an ESI source coupled to a 4.7 T FT-ICR (BioApex, Bruker Daltonics) mass spectrometer; NMR spectra were recorded on a Bruker AVANCE 600 spectrometer equipped with a multinuclear z-gradient 5 mm probe head.

Results

Use of both NMR spectroscopy and FT-ICR MS has allowed a comprehensive metabolite profile of pulp, peel and seeds hydroalcoholic and organic extracts of CPRP grown in open field (OF) and in green house (GH), revealing the presence of sugars, amino acids, organic acids, polyphenols, flavonoids. The very low content of biogenic amines and mycotoxins verified quality and freshness of the vegetables. Interestingly, the main features of CPRP are preserved in either OF or GH cultivation. Methods: [2] The same experimental approach applied to hydroalcoholic extracts of WCS revealed that leaves and stalks present a similar composition, including choline, sugars, polyalcohols, amino acids, phenols, glycosylated compounds, free organic acids, including chlorogenic and ascorbic acids. In organic extracts, major peaks correspond to phtalides, as senkyunolide, responsible for organoleptic properties, chlorophyll a, linoleic and linolenic fatty acids, the latter more abundant in leaves.

Conclusions

The high sensitivity, resolution and mass accuracy of FT-ICR MS and the powerful quantitative and structural characterization allowed by NMR spectroscopy have provided a detailed metabolic description of different vegetable extracts. The large variety of secondary metabolites reflects the expression of biosynthetic pathways influenced by the environment.

Novel Aspect

These data may support efforts in preserving biodiversity and in developing new cultivation strategies.

957 - GC/MS MONITORING OF VOLATILES IN GRAPPA DURING AGING IN TWO DIFFERENT WOOD BARRELS

Mirko de Rosso (1) - Christine M. Mayr (2) - Roberto Castagner (3) - Roberto Sonogo (3) - Riccardo Flamini (1)

Council for Agricultural Research and Economics, Viticulture & Oenology (CREA-VE), Conegliano (TV) (1) - University of Padova, Department of Agronomy, Food, Natural Resources, Animals and Environment (DAFNE), Legnaro (PD) (2) - Distillerie Acquavite S.p.A., -, Visnà di Vazzola (TV) (3)

Keywords: Grappa, GC-MS, volatiles, barrel aging

Introduction:

The name "Grappa" is reserved exclusively for the grape pomace distillate obtained from raw materials produced in Italy and distilled and bottled in plants located in Italy (CE Regulation n. 110/2008). This research project aimed to investigate different conditions (wood type and alcohol percentage during aging) in the production of two high quality distillates.

Methods:

Grappa produced from a white marc (Prosecco) and a red blend (Cabernet Sauvignon/Merlot), at 55% and 68% Ethanol each, were aged over 6 month in 225 L, middle toasted cherry and oak barrels, which were selected on the basis of previous findings [1,2]. After one, three, and six month, samples were taken, volatiles isolated by SPE and analyzed by GC/MS. In particular, the evolution of variety aroma compounds from the marc and volatiles released from the woods, was monitored.

Results:

The analysis of the different grappa samples before ageing allowed the identification of more than 50 volatiles, mainly higher alcohols, aldehydes, acids, ethyl esters and acetates. The main differences between the two types of samples was, as expected, the higher abundance of variety aroma compounds, mainly terpenes, in the white marc grappa. Samples analyzed after one month showed already a slight increase of some phenolic compounds from the wood, but due to the low levels the impact on the overall aroma can be neglected. After three month the aroma of the grappa was already characterized by a wood aged aroma, and the concentration of phenolic compounds increased significantly.

Conclusions:

At the end of the process the different distillates showed characteristic profiles due to the different varieties and the wood type used. Main volatiles detected in the samples markedly characterized the organoleptic profile of the final products.

Novel Aspect:

This is a systematic GC/MS investigation of the impact of wood type and alcohol percentage on the aroma profile of grappa aimed to make new products.

631 - HYDROGEN/DEUTERIUM EXCHANGE IS AN EFFECTIVE METHOD FOR THE STRUCTURAL RESOLUTION OF ISOMERIC PROANTHOCYANIDINS IN WINE AND OTHER DIETARY SOURCES

Vakare Merkyte (1) - Edoardo Longo (1) - Fabrizio Rossetti (2) - Emanuele Boselli (1)

Free University of Bozen - Bolzano, Free University of Bozen - Bolzano/Faculty of Science and Technology, Bolzano (1) - Università Politecnica delle Marche, Università Politecnica delle Marche/Department of Agricultural, Food and Environmental Sciences, Ancona (2)

Keywords: isotopic exchange; high resolution mass spectrometry; proanthocyanidins, wine

Introduction:

Proanthocyanidins(PAC) show high degree of isomerism, which makes it difficult to confirm the identification of new congeners. A novel class of PACwith a macro-cyclic structure has been recently found in wine[1, 2].Hydrogen/deuterium isotopic exchange (HDX) combined to high resolution MS is discussedfor the disambiguation of suchcyclic B-type class from otherisomeric PACpresent in wine and other significant dietary sources.

Methods:

HPLC-HDX-HRMS and HPLC-HRMS/MS were applied to an SPE purified and concentrated Lagrein (a red wine from South Tyrol, Italy), a peanut skin extract and a cranberry extract. For SPE purification a published methodology was followed [3]. The instrumental method was adapted from a published report [1].

Results:

A series of 4-, 5- and 6-mers PAC were tentatively identified by HPLC-HRMS/MS in wine and (inlower extent) in cranberries. Their MS/MS fragmentations and retention time profiles showed remarkable differences with non-cyclic B-type analogues (already known and studied):a) beside the expected -2H difference, much lower degree of MS/MS fragmentations and very different retention time distributions distinguished the cyclic B-type PAC from the more abundant non-cyclic B-type PAC; b) tentative cyclic analogues eluted faster and showed fewer (often only one) isomeric peaks. However, cyclic PAC could not theoretically be distinguished from the isomeric non-cyclic A-type PAC. HPLC-HDX-HRMS was applied with this aim: the analysis of a peanut skin extract provided evidences thatupon HDX the isomeric A-type PAC exchange one proton less than the cyclic B-types. By means of this approach, several cyclic B-type 4-, 5- and 6-merPAC were confirmed in wine, whereas mostly non-cyclic A type were confirmedin peanut skin.

Conclusions:

Isotopic exchange HPLC-HRMS proved to be a powerful tool, complementary to NMR and other techniques, to investigate the macromolecular structure of proanthocyanidins from several plant-derived foods. In fact, a whole series of novel cyclic B-type 4-, 5- and 6-mer proanthocyanidinscould be distinguished from their isomeric non-cyclic A-type analogues by isotopic exchange mass spectrometryonly.

Novel Aspect:

A mass spectrometric method based on hydrogen/deuterium exchange for the resolution of novel cyclic isomeric proanthocyanidins in wine and plant-derived foods is presented.

Keywords: mass spectrometry, metabolism, coffee diterpene, cafestol, in silico

Introduction: Coffee bean has a kaurane diterpene, cafestol [1], that acts as anti-inflammatory and anticancer (among others) [2], although being hypercholesterolemic [3]. It remains partially intact in the intestinal tract, and little is known about its metabolites. To understand what we really drink in the coffee beverage and its impact on health, this work was developed in an *in vivo* Zebrafish (*Danio rerio*) water tank model [4] with LC-MS/MS looking for cafestol metabolites.

Methods: The study was performed in 3 aquariums, 18 zebrafishes/aquarium and cafestol added at 1 mg ml⁻¹. The excretion water was submitted to SPE and then investigated in a Thermo Scientific Q Exactive Plus Orbitrap LC-MS/MS. The metabolites were characterized by at least 3 precursor ions. To corroborate the results and help rationalizing the fragmentation pathways observed, we compared the metabolites found with *in silico* analyses.

Results: Cafestol has a furan moiety linked to the ring A, a -CH₂OH (C17) and a tertiary OH both linked to C-16 at ring D of the diterpene moiety. All typical metabolic transformations were searched in the excretion water which, by tandem analyses, showed five cafestol metabolites with logical fragmentations. The most intense was proposed to be a partial epoxidation of the furan with a hydroxy group at C2 (m/z 349.20095). In other ion metabolites, we propose the intact furan with an aldehyde on C17 (m/z 337.17797); a -COOH at C17 (m/z 331.19038); a -OH at C2 besides -COOH at C17 (m/z 347.18585); and acetylation at -CH₂OH (m/z 359.22224). These showed that the preferential sites of metabolization were at carbons 2, 17, 18 and 19, compatible with *in silico* analyses with SMARTCyp and XenoSite. Although epoxidation was theoretically predicted, hydroxylation at C2 was not in the same metabolite.

Conclusions: Four metabolites observed in the water tank model of Zebrafish associated to LC-MS/MS are correlated to cytochrome P450 and one is a phase II metabolite. All transformations occurred at C- 2, C-17, C-18 or C-19 of the diterpene moiety, in agreement with *in silico* analyses.

Novel Aspect: This work contributes to a better understand of hot coffee beverage metabolites and helped on the fragmentation pathways of a complex structure like the diterpene cafestol, as also its metabolites.

Allergens in food can result in severe or fatal reactions. At present, there is no known cure for an allergenic reaction and the only thing a person can do is to avoid the potential cause eg nuts, milk etc. Food allergens are of increasing interest due to food allergy recalls that have doubled in recent years. To help safeguard consumers from food related allergies, warning labels on packaging and in restaurants are a must these days to allow people to make a decision on what they eat. However, food testing is also important and as a result, it is vital to have a robust and specific analytical method to reliably identify and quantitate allergens that may be present. This work presents data from a method that has been highly characterized and verified to determine several different types of allergens using a tryptic digest and LC-MS/MS analysis to measure allergen peptides with a high degree of flexibility, specificity but also with high sensitivity

Samples were tryptically digested and the resulting extracts analyzed using LC-MS/MS. Peptides that were identified to be associated with a specific allergen were measured using electrospray ionization and scheduled MRM data acquisition. In this presentation a comparison between traditional methods and the LC-MS/MS will be described. Important considerations for method development will be discussed. The ability of the method to identify allergens and to quantify them in food samples will be presented and discussed. The method results from several different food matrices will be presented to demonstrate the potential of this method.

Novel Aspect

This work demonstrates the process for identification of the correct peptide for allergen identification.

922 - LC-MS/MS: A USEFUL TOOL TO INVESTIGATE MARINE LIPOPHILIC TOXINS IN MUSSELS

Melania Siracusa (1) - Simone Bacchiocchi (1) - Sara Evangelista (1) - Arianna Piersanti (1)

Centro Referenza Nazionale controllo microbiologico e chimico Molluschi bivalvi, Istituto Zooprofilattico Sperimentale Umbria e Marche "Togo Rosati", Perugia (1)

Keywords: Marine Lipophilic Toxins, LC-MS/MS, mussels, phytoplankton, profiles

Introduction:

Marine Lipophilic Toxins (MLTs) are compounds produced by marine microalgae. They often accumulate in mussels representing a risk for human health. MLTs include okadaic acid OA, dinophysistoxins DTXs, pectenotoxins PTXs, yessotoxins YTXs and azaspiracids AZAs and are regulated within Europe [1, 2]. The Istituto Zooprofilattico Sperimentale Umbria e Marche "Togo Rosati" is responsible for their monitoring in mussels harvested in the Marche Coast (Italy).

Methods:

The official LC-MS/MS method [3] was adopted to evaluate MLTs contamination in mussels bred and collected along the coast, biweekly or monthly, since March 2012 until December 2017. Mass experiments were performed using a hybrid triple-quadrupole/linear ion trap 3200 Q TRAP spectrometer (AB Sciex, Darmstadt, Germany) in Multiple Reaction Monitoring (MRM) mode. Two transitions were selected for each molecule to allow reliable quantification and identification.

Results:

The data collected about MLTs in shellfish samples (*M. Galloprovincialis*) showed different toxin profiles over the years. OA and YTXs were the only groups present in the analysed mussels. The concentrations of both of them usually increase sharply in autumn-winter, starting from the Northern areas of the coast and afterwards extending southern. Until 2013 YTXs were predominant reaching concentrations that exceed the regulatory limit (MRL) of 1 mg YTX equivalents Kg⁻¹, subsequently increased to 3.75 mg YTX equivalents Kg⁻¹ [4]. In 2015 and 2017, OA was the most abundant toxin measured in the samples with levels four/five times the regulatory limit (160 µg OA equivalents Kg⁻¹), causing closures of local mussel farms. The different toxins profiles characterizing mussels in the years are very likely a result of variable climatic and environmental conditions such as temperature, rainfall, salinity, that may influence the blooms of different phytoplanktonic species.

Conclusions:

The LC-MS/MS method is suitable to monitor MLTs contamination in shellfish. The analytical technique used allows to investigate the profiles in terms of abundance and variety. The hypothetical correlation between climatic and environmental parameters and the observed levels could be useful in the prediction of mussels contamination, therefore a efficient tool to evaluate this threat for public health.

Novel Aspect:

Mass spectrometry applied to MLTs analysis provided detailed information on mussels contamination, enabling the study of temporal trends and toxin profiles.

Recent advances in mass spectrometry have led to the development of new analytical methods applicable in food chemistry. Target and non-target mass spectrometry methods have been applied for the detection of known and unknown chemical contaminants, including pesticides and antibiotics residues in food. Mass spectrometry-based omics sciences have introduced high-throughput methods permitting the assessment of food authenticity and detection of adulteration. In this work, we focus mainly on mass spectrometry-based approaches such as metabolomics and lipidomics for studying small molecules in different food commodities (wine, honey, and olive oil) as well as LC-MS/MS and GC-MS/MS techniques for the detection of chemical contaminants at low concentration level..

572 - MALDI-TOF MASS SPECTROMETRY IDENTIFICATION AND DETECTION OF RELEVANT PATHOGENS IN BEEF CATTLE

Gisele Bacanelli (1) - Cynthia Mantovani (1) - Anna Letícia Louzan (1) - Taynara Pasquatti (2) - Daniele Bier (2) - Gracia Rosinha (3) - Flávio Araujo (3) - Newton Verbisck (3)

Federal University of Mato Grosso do Sul, UFMS, Campo Grande (1) - Dom Bosco Catholic University, UCDB, Campo Grande (2) - Embrapa Beef Cattle, Animal Health, Campo Grande (3)

Keywords: MALDI-TOF, Mycobacterium, Brucella, Salmonella, Beef Cattle.

Introduction:

Mycobacterium bovis, *Brucella abortus* and *Salmonella* species account for significant economic losses in cattle production worldwide, besides being public health threats. We have established MALDI-TOF (Matrix Assisted Laser Desorption Ionization – Time-of-Flight) mass spectrometry with modified protein extraction methods and improved the presently available reference spectra libraries, in order to effectively detect those pathogens from bovine samples.

Methods:

Bacterial isolation from bovine tissue and lesions followed microbiological standard Methods: Heat inactivated mycobacteria from solid media were mechanically disrupted as designed herein. *Brucella* and *Salmonella* were grown in liquid media and processed as described [1]. Mass spectra acquired with alpha-cyano-4-hydroxycinnamic acid on Autoflex III Smartbeam underwent microorganism identification carried out on MALDI Biotyper software (Bruker Daltonik).

Results:

Analysis of mycobacterial isolates revealed that sixty-three classified as *Mycobacterium bovis*, two as *Gordonia sputi* and one as *M. nonchromogenicum*. These results were confirmed by Polymerase Chain Reaction (PCR) specific for *M. bovis* and 16S rDNA sequencing (100% concordance).

Brucella abortus, *B. suis*, *B. ovis* and *B. canis* mass spectra profiles, generated as reference strains, were clearly different and allowed field samples identification. Amongst twelve isolates with gender specific PCR positive, only two were confirmed as *Brucella* by MALDI-TOF, indicating possible contaminations during cultivation. We also tested if *Brucella* fingerprint could be detected directly from tissue lesion homogenates, lacking any microbiological culture, which was successfully demonstrated.

Ninety-six isolates from bovine carcasses were biochemically tested for *Salmonella* and species were identified by MALDI Biotyper analysis. Four isolates showing inconclusive results in biochemistry actually belonged to *Citrobacter* and *Proteus* genera [2].

Conclusions:

The cell processing method established here provides reliable *Mycobacterium* identification at species level, with scores that safely allow *M. bovis* and *M. tuberculosis* distinction of isolates from solid media culture. We have discriminated *Brucella* species and could detect this pathogen directly from bovine tissue lesions, skipping bacterial cultivation step. In addition, MALDI-TOF enabled *Salmonella* identification at species level with serovar indicative.

Novel Aspect:

Distinction of *Mycobacterium Tuberculosis* Complex members at species level and detection of *Brucella* directly from infected tissue by MALDI-TOF mass spectrometry.

KRISS, Center for Analytical Chemistry, Daejeon (1)

Keywords:

Certified reference material, Infant formula, Nutrient elements, Isotope dilution inductively-couple plasma mass spectrometry

Introduction:

Nutritional status of infants and children has great impacts on subsequent health and disease over an entire lifetime. Supplying appropriate nutrition by well-balanced infant formula is especially important considering that it is often the major, or even sole, source of nutrients at particular growth stages of an infant. It is a basic requirement for balanced nutrition and reliable nutritional studies to provide correct information on nutrients in foods and food supplements based on accurate measurements of their contents. Therefore, it is also important to develop a certified reference material (CRM) for the determination of elemental contents in infant formula or similar matrix. For this purpose, KRISS CRM 108-02-004 has been developed. The mass fractions of eight nutrient elements were certified by isotope dilution inductively coupled plasma mass spectrometry (ID ICPMS) and those of four monoisotopic elements were assigned as information values from the consensus values of expert laboratories. The present CRM is expected to provide a robust means for quality control and analytical method validation in the determination of various elements in infant formula or similar products.

Methods:

Raw material of infant formula obtained from a manufacturer was spiked with six hazardous elements, Al, As, Cd, Hg, Sn and Pb, considering future expansion of the present CRM for hazardous element analysis as well as nutrient elements developed in this study. The spiked material was made into a paste form and blended thoroughly to make homogenous mixture. Then, the paste was freeze-dried, pulverized into powders, sieved to obtain particles between 50 to 250 μm , homogenized using V-mixer, bottled in 15 g each, and finally sterilized using 15 kGy ^{60}Co γ -ray irradiation. Twelve bottles from the batch of CRM were systematically selected and used for certification of nutrient elements. For certification of Ca, Cl, Cu, Fe, Mg, Se and Zn, a primary ratio method, ID ICPMS, was used. Monoisotopic element, I, Mn, Na and P, were analyzed using conventional field laboratory Methods: Two expert laboratories in food analysis also participated in the analysis and their consensus values were given as information values instead of certified values.

Results:

Mass fractions of eight elements certified by ID ICPMS showed excellent between-bottle homogeneity with relative standard deviation between 0.2 and 1.1 %. Expanded uncertainties of certified values were 1-4 % as shown in Table 1.

Elements	Certified Values \pm U. (mg/kg)	k (95% level of confidence)	Homogeneity (%)
Mg	582.7 \pm 8.1	2.0	0.27
Cl	3678 \pm 117	2.0	0.43
K	6084 \pm 76	2.0	0.24
Ca	4904 \pm 63	2.0	0.42

Fe	54.9 ± 1.6	2.0	0.96
Cu	3.63 ± 0.12	2.0	0.80
Zn	41.4 ± 1.5	2.0	0.54
Se	0.0905 ± 0.0029	2.0	1.04

In the case of monoisotopic element, Mn, Na and P, consensus values of KRIS and the two expert laboratories were given as information values. Iodine mass fraction was determined by gravimetric standard addition ICPMS with internal standard.

Elements	Information Values ± U. (mg/kg)	k (95% level of confidence)
Na	1377 ± 48	2.0
P	3280 ± 140	2.0
Mn	0.61 ± 0.10	2.0
I	1.55 ± 0.18	2.0

Conclusions

An infant formula CRM for element analysis was developed. Eight nutrient elements were certified, while 4 monoisotopic elements were given as information values. With additional certification including six hazardous elements, it will be the infant formula CRM with comprehensive coverage of analyte elements.

Novel Aspect:

A new CRM for nutrient element analysis in infant formula certified with 8 elements with information values for 4 monoisotopic elements.

905 - ANALYSIS OF PENTA-O-GALLOYL BETA-D-GLUCOSE IN FUNCTIONAL FOODS BY LC-MS/MS

shin Yong-Woon (1)

Ministry of Food and Drug Safety, Nutrition and Functional Research Team, Cheongju-si (1)

Analysis of PGG(Penta-O-galloyl beta-D-glucose in functional foods by LC-MS/MS

Yong Woon Shin, Bo young Oh, Hee Sun Jeong, Jae Myoung Oh, Soo Jung Hu, Jin Hwan Hong and Keum Soon Oh
Nutrition and Functional Food Research Team, National Institute of Food and Drug Safety Evaluation

PGG(Penta-O-galloyl beta-D-glucose is currently used as functional ingredient in health functional food. This ingredient was approved by Korean Ministry of Food and Drug Safety(MFDS) as functional ingredient with the health benefit of the blood sugar level rises after eating. In this study, an analytical method based on High performance liquid chromatography(HPLC) with positive ion electrospray ionization(ESI) coupled to tandem mass spectrometry detection(LC-MS/MS) was developed for the determination of PGG in health functional foods. Performance characteristics such as selectivity, linearity, recovery, repeatability, and intermediate precision were examined. This validated method was successfully applied to the determination of PGG in commercial functional foods

676 - ANALYSIS OF SIGNATURE LIPID BIOMARKERS TO DETERMINE FUSARIUM CONTAMINATION IN MELON

Davila Zampieri (1) - Rodolfo Dantas (1) - Katia Roberta Belaz (2) - Marcos Nogueira Eberlin (3) - Andréia Hansen Oster (4) - Ebenezer de Oliveira Silva (5) - Guilherme Julião Zocolo (4)

Federal University of Ceara, Organic and Inorganic Department, Fortaleza (1) - Federal University of Uberlândia, Institute of Chemistry, Uberlândia (2) - ThoMSon Mass Spectrometry Laboratory, UNICAMP, Campinas (3) - EMBRAPA, Embrapa Agroindústria Tropical, Fortaleza (4) - EMBRAPA, EMBRAPA, Fortaleza (5)

Keywords: Lipid fingerprinting, biomarkers lipid, *Fusarium equiseti*, *Cucumis melo* L., ESI-MS.

Introduction

The cultivation of melon (*Cucumis melo* L.) has become a socio-economic activity of the Brazilian semi-arid. This crop suffers serious damage due to phytopathogens, such as fungi of the genus *Fusarium* which cause melon rot, a disease that leads to total crop loss [1]. The MS has a technique that provides fast, efficient and reliable results to lipid fingerprinting has been for applications like clinical pathogen rapid and identification taxonomic classification of microbial collections [2,3].

Methods

The *Fusarium equiseti* was cultured in PDA for 14 days at 30°C (8 replicates). The pellet and melons were cut in 1x1 cm pieces. Lipids were extracted using CHCl₃/MeOH, according to Bligh Dyer method [4]. ESI-(+)-MS spectra were obtained using Xevo G2-XS Qtof Mass Spectrometer, covering the mass range from m/z 500 to 1000 Da. Peak picking and alignment were performed using MassLynx software and Multivariate analysis by MarkerLink (Waters).

Results

Fusarium equiseti was isolated from contaminated melons in the state of Ceará, Brazil. The lipid analyzes were obtained by ESI-(+)-MS, the exact masses and a fragmentation pattern allowed the use of the LIPID MAPS database and the injections in replicates allowed to perform multivariate analyzes showed characteristic ions of *Fusarium equiseti*, which are not present in the uninfected melon and which are found in the melon when it is infected by the phytopathogen. Based on the analyzes of PCA and O-PLS, the ions m/z 782.5 and m/z 784.5, these ions were identified as phosphatidylcholines (PC). Also observed the ions m/z 736.6 and m/z 783.5, identified as glycerolipids (GL), in the LIPID MAPS database. In all the replicates of the fungus samples, these ions were characteristic and were not found in the melon samples.

Conclusions

ESI-MS fingerprinting of lipid was able to classify if the melon is contaminated or uncontaminated by *Fusarium equiseti*. The PCA and O-PLS analyzes for these lipids, the most evident discrimination was for *Fusarium equiseti*, where highlighted ions which were attributed as GL and PC. Our preliminary results showed the potential of the MS as a tool able for screening of major biomolecules participating in host-pathogen relationships.

Novel Aspect

To use the high efficient screening as quality control for melons, detecting contamination in the initial stage and avoiding losses of the lots during transportation.

C.05 FOOD AND BEVERAGE - NUTRACEUTICS DIRECTIONS

422 - ANCIENT APPLE OF FRIULI VENEZIA GIULIA REGION AS POTENTIAL NEW NUTRACEUTICAL INGREDIENTS.

Stefania Sut (1) - Stefano Dall'Acqua (2)

University of Padova, DAFNAE, Padova (1) - University of Padova, Department of Pharmaceutical and Pharmacological Science, Padova (2)

Keywords: Apple, polyphenols, triterpene, LC-MS, Nutraceutical

Introduction:

Ancient Apple varieties can present different composition compared to commercial ones [1-6]. For this reason they can be valuable starting material for the development of new nutraceutical ingredients. The aim of this study was to evaluate vitamin C and secondary metabolite contents of nine Ancient Apple of Friuli Venezia Giulia region and compare with commercially available fruits for the possible development of new Apple-based nutraceutical products.

Methods:

Peels and pulps were separated, dried and extracted in aqueous methanol in ultrasound bath. Hydroxycinnamic acids, catechin, procyanidins, flavonoids, dihydrochalcone and triterpene derivatives composition were determined using LC-DAD-ESI-MSn, LC-ESI-QTOF and LC-APCI-MSn. A targeted metabolomic approach was used to describe the different composition of the ancient varieties compared to commercial ones.

Results:

Ancient apple variety showed significant differences compared to commercial varieties with high levels of vitamin C in pulps. Furthermore pulps and peels present higher amount of procyanidins, catechins and hydroxycinnamic acids. Different pattern in triterpene contents was also observed showing ancient varieties presenting theannurcoic acid, while ursolic and oleanolic characterize the commercial ones. With targeted MS data PLS-DA model was generated and the ancient varieties of FVG region appear to be clusterized mainly on the basis of triterpene and phenolic contents.

Conclusions

Ancient apple can be used for nutraceutical production due to secondary metabolite contents. LC-MS based metabolomics approaches may be useful for description and valorization of these fruits composition. Further studies are needed to optimize extract production from these fruits. The use of ancient apple in nutraceuticals can be useful to protect these fruits threatened by intensive cultivation, underlying the richness of Italian biodiversity.

Novel Aspect:

This work point out the usefulness of LC-MS for the characterization of food ingredients for nutraceutical applications and show the valorization of apple biodiversity.

27 - PUTTING PIGMENT TO PAPER. THE QUANTITATION OF BIOACTIVE ANTHOCYANINS IN FRUITS AND NUTRACEUTICALS WITH PAPER SPRAY IONIZATION MASS SPECTROMETRY

Robert Cody (1) - Jun Tamura (2) - Kevin Downard (3)

JEOL USA, Mass Spectrometry Division, Boston (1) - JEOL Ltd., Mass Spectrometry Business Unit, Tokyo (2) - University of New South Wales, Medicine, Sydney (3)

Putting Pigment to Paper. The Quantitation of Bioactive Anthocyanins in Fruits and Nutraceuticals with PaperSpray Ionization Mass Spectrometry

Keywords: anthocyanins, quantitation, inhibitor, paper spray, mass spectrometry

Introduction: (Limit of 400 characters)

Ubiquitous in edible plants and fruits, flavonoids constitute part of the human diet. Anthocyanins are a class of coloured flavonoids that have been recognized for their pharmacological properties and have recently been shown to be able to inhibit the replication of the influenza virus. This presentation describes the application of paper spray ionization mass spectrometry to quantify anthocyanins in raw fruits and nutraceuticals to ensure their bioavailability.

Methods: (Limit of 400 characters)

Stock solutions of cyanidin 3-sambubioside, and cyanidin-3,5-diglucoside with malvidin-3,5-diglucoside as an internal calibration standard, were prepared. These solutions and those prepared for three nutraceutical formulations and freeze-dried raw fruit and stems, were analysed on a JEOL AccuTOF mass spectrometer equipped with a prototype paperspray ion source. Anthocyanins detected in the fruit and nutraceutical samples were identified and quantified.

Results: (Limit 900 characters)

The component cyanidinglucosides, including cyanidin-3-sambubioside, cyanidin-3-glucoside, cyanidin-3,5-diglucoside, cyanidin-3-sambubioside-5-glucoside and the aglycone cyanidin were detected in all fruits and nutraceuticals. Solutions of cyanidin-3,5-diglucoside, containing malvidin-3,5-diglucoside as an internal standard at a fixed concentration, established a calibration plot used to quantify the total anthocyanin content (TAC) in the fruit and nutraceutical formulations. Wide 5-fold variations in anthocyanin concentration were detected in the nutraceutical formulations from different suppliers ranging from 1050 to 5430 mg/100g, assessed in replicate measurements over an extended timeframe. These concentrations compared with 500 to 2370 mg/100g measured in the dried stems and fruit. The results demonstrated that anthocyanin levels vary considerably in different elderberry crops, and across various cultivars, and care is needed in the production and storage of nutraceuticals to maintain those levels.

Conclusions (Limit of 400 characters)

The ability to rapidly identify and quantitate, over a wide range of concentrations, anthocyanins in food and therapeutic products is important to gauge their medicinal benefits. Sensitive, yet mild, analysis is required given their susceptibility to degradation and transformation. Paperspray ionization has been used to successfully detect and quantify anthocyanin levels in fruit extracts and three commercially available nutraceutical formulations.

Novel Aspect: (Limit of 150 characters)

Paperspray mass spectrometry is a sensitive and reproducible means to quantify anthocyanins in fruit and therapeutic products and provides a rapid means with which to do so.

Keywords: Antioxidant, polyphenols, nutraceutical, Azorellaglabra, Apiaceae

Introduction:

The genre *Azorella* belongs to Apiaceae family. The Apiaceae includes different plants commonly used as infusion in South America in folk medicine to treat various diseases such as bronchitis, cold, rheumatism and neuralgia [1]. The aim of this study is to investigate the potential antioxidant properties and the phytochemical profile of the aerial parts of *Azorellaglabra* (*A. glabra*) Wedd, an endemic uninvestigated plant from Bolivia.

Methods:

The aerial parts of *A. glabra* were subjected to maceration, solid-liquid, and then to liquid/liquid extraction using different solvents. The polyphenol content, radical-scavenging activity by using DPPH, ABTS, $\cdot\text{NO}$ and $\text{O}_2^{\cdot-}$ radicals, FRAP and inhibition of lipid peroxidation were determined; and these data were used to calculate Relative Antioxidant Capacity Index (RACI) [2, 3]. The identification and quantification of compounds were performed by LC-ESI-MS/MS.

Results:

The ethanol, n-hexane, chloroform, ethyl acetate, n-butanol and water samples were analyzed for their antioxidant activity by different assays. The ethyl acetate fraction reported the highest RACI value (1.17). For this reason, the LC-ESI-MS/MS analysis was focused on the ethyl acetate fraction. The tentative identification and the quantification of compounds present in the ethyl acetate fraction were reached through accurate mass measurements, MS/MS fragmentation patterns and retention times of standards. This fraction revealed the presence of 15 polyphenols and the pentacycliterpenoidoleanolic acid identified for the first time in *A. glabra*. The most abundant present polyphenols are the orientin and 3,5-di-O-caffeoylquinic acid. These health-promoting compounds have medical and nutraceutical applications [4, 5].

Conclusions:

Ethyl acetate fractions of *Azorellaglabra* extract possessed the best antioxidant capacity. The polyphenolic compounds, in particular the abundant orientin and 3,5-di-O-caffeoylquinic acid, may explain the health benefits of the infusions used in folk medicine.

Novel Aspect:

This research has evidenced for the first time that *A. glabra* can represent an important natural source for the pharmaceutical, cosmeceutical and nutraceutical applications.

770 - MICROWAVE-ASSISTED EXTRACTION OF OLIVE LEAVES TO OBTAIN PHENOLIC COMPOUNDS WITH MODULATING ACTIVITY OF AMPK

Beatriz Martin-Garcia (1) - Sandra Pimentel-Moral (1) - Ana Maria Gomez-Caravaca (1) - David Arraez-Roman (1) - Arsenio Muñoz-de-la -peña (2) - Antonio Segura-Carretero (1) - Alberto Fernandez-Gutierrez (1)

University of Granada, Analytical Chemistry, Granada (1) - University of Extremadura, Analytical Chemistry, Badajoz (2)

Keywords: Microwave-assisted extraction, phenolic compounds, olive leaves, HPLC-ESI-TOF-MS, AMPK

Introduction:

Phenolic compounds present in olive leaves possess beneficial effects to prevent chronic diseases [1]–[6]. Concretely, some of them provide the capacity to modulate AMPk activation, so they are proposed as therapeutic target in diseases associated with inflammation (obesity and diabetes)[7]. Microwave-Assisted Extraction (MAE) has demonstrated a great potential for obtaining extracts with higher content in these bioactive compounds.

Methods:

An experimental design Box-Behnken has been performed in which temperature (50-150°C), solvent composition (15-80 % EtOH) and extraction time (5-20 min) have been evaluated to optimize the recovery of phenolic compounds that modulate the AMPk activation using MAE. The resulting extracts were injected into the HPLC-ESI-TOF-MS and phenolic compounds were analyzed following the method of Talhaoui et al. [8].

Results:

A total of 47 phenolic compounds were identified in olive leaves extracts. Among them, a total of 6 compounds, that have demonstrated the capacity to activate AMPk[7], were quantified (hydroxyoleuropein isomer A, rutin, luteolinrutinoside, luteolin glucoside isomer A, hydroxyoleuropein isomer B and verbascoside). Thus, the total concentration of these phenolic compounds ranged from 0.060 mg g⁻¹ to 1.418 mg g⁻¹ depending on the different MAE conditions. The Box-Behnken analysis at 100 °C, 5 min and 15% ethanol were the conditions that showed the highest concentration of phenolic compounds related to AMPK activation.

Conclusions:

MAE has demonstrated to be a useful technique to improve the recovery of phenolic compounds able to modulate the activity of AMPk from olive leaves. Thus, 15 experimental conditions were assayed in the MAE experimental design in which temperature, solvent composition and extraction time were evaluated. The results showed that 100°C, 5 min and 15% ethanol were the optimal conditions to extract this kind of phenolic compounds.

Novel Aspect:

These extract conditions could be used to obtain extracts for in vivo analysis and evaluate their possible anti-inflammatory effect (related to diseases such as the obesity and diabetes).

Development of isotope dilution-liquid chromatography/tandem mass spectrometry for the accurate determination of trans- and cis-vitamin K1 isomers in food

Byungjoo Kim^{1*}, Hyeyoung Lee^{1,2}, Hong Hee Lee¹

1 Korea Research Institute of Standards and Science, Daejeon 34113, Republic of Korea

2 Division of Applied Bioengineering, Dong-Eui University, Busan 47340, Republic of Korea

Keywords: trans- and cis- Vitamin K1, Food, Isotope dilution mass spectrometry, LC/MS

Introduction

Vitamin K1 exists mostly in the trans form in most of foods such as vegetables and unfortified dairy products. However, infant formula and cereals fortified with synthetic vitamin K1 contains both trans- and cis-isomers. To evaluate the nutritional status of general foods (fortified or not), trans- and cis-vitamin K1 must be measured individually because only the trans-isomer has biological activity [1]

Methods

Isotope-dilution mass spectrometry based on LC/MS (ID-LC/MS) for the accurate determination of trans- and cis-vitamin K1 was developed in this study. A C30 column was used to separate and individually quantify the trans- and cis-vitamin K1 isomers. Vitamin K1-d7 was used as an internal standard. The matrix effect profiles were observed by post-column infusion experiment to optimize sample preparation methods and selecting ionization mode for LC/MS [2].

Results

Trans- and cis-vitamin K1 were well separated with the C30 column. The matrix effect profiles showed that APCI was less susceptible to matrix effects than ESI. Therefore, APCI was used to minimize the difference in the ionization efficiency of the target analytes and their isotope analogues. The validity of the method was evaluated by measuring gravimetrically fortified samples of infant formula, kimchi cabbage, and spinach. The measurement results (after subtraction of pre-existing levels) agreed with the fortified values within their uncertainties. The method showed good repeatability and reproducibly (less than 2 % of relative standard deviation of multiple measurements) for both trans- and cis-vitamin K1 in infant formula, with relative expanded uncertainties of approximately 5 %. For unfortified vegetables, its repeatability and reproducibly were less than 2 % for trans- vitamin K1, but around 6 % for cis-vitamin K1 as its abundance in unfortified food is much less than trans- vitamin K1.

Conclusions

An ID-LC/MS method was established as a candidate reference method for the accurate determination of trans- and cis-vitamin K1 in food. The validity test indicates that the method is of higher-order metrological quality in respect of its repeatability, reproducibly, and measurement uncertainty.

Novel Aspect

Compared to currently available methods, this study developed an ID-LC/MS method for the accurate determination of individual trans- and cis-vitamin K1 in food samples.

1225 - MEDICINAL EXTREMOPHILE PLANTS: VALUABLE SOURCE OF "GRAS" AND HEALTH PROMOTING BIOMOLECULES WITH MEDICAL, NUTRACEUTICAL AND FOOD APPLICATIONS

Ksouri Riadh (1)

Head of the Laboratory of Aromatic and Medicinal Plants, CBBC, BP901, 2050 Hammam-Lif, Tunisia (1)

Keywords: Extremophile plants, biological activities, bioactive molecules, functional food, nutraceutical.

Introduction:

Extremophile plants have to deal with frequent changes in salinity/water level by developing adaptive responses including powerful biomolecules synthesis. These plants are traditionally used for medicinal and nutritional purposes. Currently, an increasing interest is granted to these species thanks to their richness on bioactive compounds, which display potent pharmacological activities, and represent key-compounds in preventing diseases and ageing processes.

Methods:

The present research leads to the utilization of extremophile plants as a new source of healthy products. This contribution focuses on the ethno-pharmacological uses of spontaneous species in traditional medicine, reviews our recent investigations on chemical composition (CPC, TOF-LC/MS, RMN), biological activities (in vitro and in vivo) and potential uses after formulation as functional foods, nutraceuticals and cosmetic products by several industries.

Results:

Results showed an appreciable total phenolic content in organ extracts. The estimation of antioxidant capacities using ORAC method and a cell based-assay (WS1) showed that organ fractions exhibit highest antioxidant activities that exceed synthetic phenolics (BHT and BHA) used in Food industry (Ksouri et al., 2012; Oueslati et al., 2012). Moreover, these plants exhibit important pharmacological capacities against emergent diseases. For instance, *L.guyonianum* showed an appreciable anti-amyloidogenic ability as compared to curcumin. *S. fruticosum* fraction displayed the utmost anti-inflammatory activity, inhibiting nitric oxide (NO) release, by 67% in lipopolysaccharide (LPS)-stimulated RAW 264.7 macrophages. Besides, *T. gallica* showed the highest anticancer activity against human lung carcinoma (A-549) and colon adenocarcinoma cell lines (DLD-1, Caco-2 and HT-29). Then, the identification of the main compounds by HPLC-DAD-ESI-MS were assessed and some molecules were purified thanks to CPC apparatus.

Conclusion:

These findings demonstrate the remarkable potentiality of these edible halophyte/xerophyte as valuable source of antioxidants which exhibit original and interesting antioxidant, anti-inflammatory and anticancer capacities which can be used as functional foods and to develop nutraceutical formulation to prevent some diseases.

Novel Aspect:

Clinical trials, photo-protective assays, and formulation are planned thanks to our recent Projects (CMCU, SATREPS, ARIMNET2 and PRIMA) linked to industrial applications.

552 - RELIABLE IDENTIFICATION OF BIOACTIVE COMPOUNDS IN FOODSTUFFS THROUGH THE USE OF A NOVEL DUAL-FILTER MASS SPECTRAL LIBRARY IN LIQUID CHROMATOGRAPHY

Francesca Rigano (1) - Marianna Oteri (2) - Paola Dugo (2) - Luigi Mondello (2)

Chromaleont Srl, c/o Dipartimento ChiBioFarAm, University of Messina, Messina (1) - University of Messina, Dipartimento ChiBioFarAm, Messina (2)

Keywords: Linear retention index, bioactive compounds, mass spectral libraries, dual-filter identification process, food samples

Introduction: (Limit of 400 characters without spaces)

In the present work, a novel identification approach was developed for the determination of bioactives in foodstuffs by Liquid Chromatography (LC) coupled to mass spectrometry (MS). Non-polar lipids were the analytes of interest, mainly due to their regular LC profile under reversed phase conditions.

Marine organisms centralized special attention because of their high content of ω -3 fatty acids, whose nutraceutical activity was widely studied in the last decades.

Methods: (Limit of 400 characters without spaces)

A dual-filter MS/LRI library was built by analyzing more than 30 real-world samples, including vegetable oils, milk and dairy products, sea organisms and food supplements. An odd carbon chain number triacylglycerol series from trinonain to trinonadecanoin was chosen as the basis of the LRI scale, being these compounds rarely present in real samples and an ultra high performance LC (UHPLC) method, able to maximize lipid separation, was developed.

Results:

The MS/LRI contains more than 200 lipid species, including mono-, di- and triglycerides (MG, DG and TG), as well as sterols and sterol esters.

An LRI variability of ± 15 units was obtained for all the compounds, also by changing experimental conditions (column dimension, flow rate, gradient steepness, instrumental setup, temperature), demonstrating the usability of the LRI database at both intra- and interlaboratory levels.

The MS spectrum was essential to discriminate between compounds falling within the same LRI window (completely or partially co-eluted). Under the employed MS conditions, a highly informative fragmentation pattern was obtained. For example, for a TG species, MG and DG fragments were highlighted, so that each MG fragment correspond only to one fatty acid and each DG fragment is related to their combination. The molecule related ion represents the final confirmation of the right fatty acid combination in the TG species.

Conclusions

The novel dual-filter library represents a powerful tool to achieve an univocal identification of non-polar lipids. Further efforts will be required to extend it to other lipid species, such as fatty acids and phospholipids, which represent important components in the clinical application field.

Advancements in software, able to perform an automatic identification on the basis of both LRI and MS data, was essential and has been successfully implementing.

Novel Aspect:

The complementarity between MS and LRI data was exploited for the first time in LC, allowing to obtain for an unknown sample a very narrow list of candidates for each LC-MS peak.

D.01 FUNDAMENTAL MASS SPECTROMETRY - ION SPECTROSCOPY & PHOTODISSOCIATION

809 - STRUCTURAL ELUCIDATION OF METABOLITES USING INFRARED ION SPECTROSCOPY

Herman Bentlage (1) - Jonathan Martens (1) - Giel Berden (1) - Ron Wevers (2) - Jos Oomens (1)

FELIX, Radboud University, Nijmegen (1) - Translational Metabolic Laboratory, Radboud University Medical Center, Nijmegen (2)

Keywords: IRMPD, Metabolomics, IR-IS, FELIX, MS/MS

Introduction:

The identification of molecular biomarkers is critical for diagnosis, treatment and for establishing a fundamental understanding of the pathophysiology and underlying biochemistry of inborn errors of metabolism. We show that, using the free electron laser FELIX and a modified Bruker ion trap, infrared ion spectroscopy (IR-IS) is a powerful technique for identifying metabolites. We also show that with our HPLC we can now investigate complex body fluid samples.

Methods:

The experiments were performed on a modified quadrupole ion trap mass spectrometer¹ (Bruker, AmaZon Speed ETD) coupled to the infrared beam line of FELIX FEL. The FEL produces infrared radiation as 5-10 μ s macropulses at a 10 Hz repetition rate having 40-100 mJ pulse energy and a bandwidth of ~0.4% of the center frequency. After one macropulse dissociation occurs. An infrared vibrational spectrum is created by relating the parent and fragment ion intensities.

Results:

In a first example², we characterize and distinguish two isobaric biomarkers of inborn errors of metabolism, glutaric acid for glutaric aciduria and ethylmalonic acid for short-chain acyl-CoA dehydrogenase deficiency. We show that the metabolites can be identified using an IR spectrum of a reference compound, but also in a reference-free approach by comparing the spectra against quantum-chemically calculated spectra.

In a second example³, we show preliminary results from a project in which we attempt to identify two new biomarkers for phenylketonuria (PKU). Using an untargeted metabolomics strategy based on UPLC-qTOF mass spectrometry, several new m/z features were detected in PKU patients. However, their corresponding molecular structures could not be unequivocally assigned based only on retention time, mass and MS/MS fragmentation. Here we show our recent progress using infrared ion spectroscopy in combination with theoretical predictions and synthetic reference standards.

Conclusions

Infrared Ion Spectroscopy (IR-IS) is a powerful technique for identifying and distinguishing many kinds of molecules. Recently we have shown that the combination of liquid chromatography – mass spectrometry with IR light of FELIX creates a unique pathway to identify metabolites in complex samples. We also show that when reference standards are unavailable we can fall back on quantum-chemically calculated IR spectra for the identification of molecules.

Novel Aspect:

Combining Liquid-Chromatography-Mass Spectrometry and the infrared light from FELIX we are able to identify biomarkers from complex body fluids.

712 - INFRARED ION SPECTROSCOPY OF METAL-LIGAND REDOX PAIRS GENERATED VIA ELECTRON TRANSFER REDUCTION REACTIONS

Musleh Munshi (1) - Jonathan Martens (1) - Giel Berden (1) - Jos Oomens (1)

Radboud University, FELIX Laboratory, Nijmegen (1)

Keywords: infrared ion spectroscopy, electron transfer reduction, metal-ligand complexes, redox pairs

Introduction: Transition metal organometallic complexes are known for their catalytic activation of small molecules. The catalytic activity is typically based on the ability of the metal to shuttle between different oxidation states. Here we present a novel method to spectroscopically investigate both members of a redox pair – a metal(II)-ligand complex and its charge-reduced metal(I)-ligand counterpart – in the complete isolation of the gas phase.

Methods: Infrared ion spectra were recorded using the tunable infrared free electron laser FELIX in combination with two tandem mass spectrometers, a home built Fourier-Transform Ion Cyclotron Resonance (FTICR) instrument and a Bruker AmaZon Speed ETD quadrupole ion trap (QIT) instrument [1]. The electron transfer dissociation (ETD) option of the QIT can also be used for reducing the charge of metal(II) complexes via an electron transfer reduction (ETR) reaction with the fluoranthene radical anion [2] as electron donor.

Results: Here we demonstrate that isolated metal(I) ligand complexes can be prepared through nondissociative gas-phase one-electron reduction of the corresponding metal (II) ligand complexes. The structure of both the precursor and the charge-reduced ion, i.e. both members of the redox pair, were established with infrared ion spectroscopy in combination with quantum-chemical calculations. Several metal-ligand systems have been studied, including Ni-cyclam which is especially interesting for electrochemical reduction of CO₂ [3].

Conclusions: A varied set of Metal(I) ligand complexes have been generated via an electron transfer reduction reaction from the associated metal(II) complexes. The structure of these complexes in both oxidation states have been characterized via infrared ion spectroscopy using the FELIX free electron laser.

Novel Aspect: Electron transfer reduction reactions of metal (II) ligand complexes in the gas phase characterized by infrared ion spectroscopy.

919 - PHOTOCHEMISTRY OF GLYOXYLATE EMBEDDED IN SODIUM CHLORIDE CLUSTERS, A LABORATORY MODEL FOR TROPOSPHERIC SEA-SALT AEROSOLS

Nina K. Bersenkowitsch (1) - Milan Oncak (1) - Christian van der Linde (1) - Andreas Herburger (1) - Martin K. Beyer (1)

Universität Innsbruck, Ionenphysik und Angewandte Physik, Innsbruck (1)

Keywords: marine aerosols, glyoxylate, photodissociation, CO₂•-

Introduction

As the ocean covers more than 70% of the earth's surface, marine aerosols [1] are highly relevant for atmospheric processes. Photochemical processing of organic matter can be initiated by sunlight, where reactive species can be produced. In the present study, sodium chloride clusters serve as laboratory model for sea salt clusters. Doped with the atmospherically relevant glyoxylic acid [2], the photochemistry is investigated experimentally and supported with theory[3].

Methods

The clusters are produced with an Electrospray Ionization Source, and are then guided into a Fourier Transform Ion Cyclotron Resonance Mass Spectrometer. After mass selection of a specific ion, the clusters get irradiated with a tunable laser system and photodissociation spectra are recorded. Via the intensity of the fragments, photodissociation cross sections are calculated. Theoretical calculations support the results.

Results

Photodissociation spectra from 225-400 nm of [Na_nCl_{n-2}(C₂H₃O₃)]⁺, n=5-11, reveal the fragmentation pathway, where glyoxylate is photolysed into HCO• and a stable carbon dioxide radical anion. This is interesting, as the latter species is known to be metastable in free space, which means that the salt environment stabilizes the molecular anion. Also important is that this happens not only in the deeper UV, but also in the actinic region from 300-400 nm, where sunlight reaches the troposphere. Excited state calculations show that the S₀ and S₁ state are well separated for the isolated glyoxylate anion, which renders internal conversion between these states impossible. As soon as glyoxylate interacts with an ionlike H⁺ or Na⁺, the potential energy surfaces show a conical intersection, which can be reached with the energy provided from the excitation into S₁. After funneling into the electronic ground state, the dissociating HCO• may react in the ground state and transfer a hydrogen atom to form formate, which is another observed photochemical fragment.

Conclusions

Photodissociation spectra of sodium iodide clusters of different size doped with a single glyoxylate reveal a fragmentation pathway, where a carbon dioxide anion radical is stabilized in the salt cluster. Quantum chemical calculations show that dissociation along the C–C bond occurs after reaching the S₁/S₀ conical intersection, while this conical intersection is absent in free glyoxylate ions.

Novel Aspect

The photochemistry of glyoxylate embedded in sodium chloride clusters is investigated experimentally, and the results are supported with theoretical calculations.

318 - COUNTER CATION-DEPENDENT ACTION SPECTROSCOPY OF IR-797 AND IR-806 CYANINE DYES

Marius HERVE (1) - Richard BREDY (1) - Gabriel KARRAS (1) - Bruno CONCINA (1) - Franck LEPINE (1) - Isabelle COMPAGNON (1)

University of Lyon, Université Claude Bernard Lyon 1, CNRS, Institut Lumière Matière, F-69622, VILLEURBANNE (1)

Keywords: Cyanine dyes (IR-797, IR-806); Mass Spectrometry; Action Spectroscopy; NIR; Dipole-induced absorption shift

Introduction:

Cyanine dyes form a large class of molecules absorbing in the near-infrared range. Though their aqueous phase absorption properties have been extensively studied [1], little is known about their gas phase optical characteristics. We measured gas phase photodissociation action spectra of IR-797, a heptamethine cyanine dye, and one of its doubly sulfonated derivative IR-806. This revealed absorption shifts depending on the sulfonate presence and counter cation.

Methods:

Gas phase cyanines were produced using electrospray ionization, and transferred into a triple quadrupole mass spectrometer (Xevo TQ-S micro, Waters). Ions selected in charge and counter cation state were irradiated after the first mass selecting quadrupole with tunable femtosecond laser pulses from 710 nm to 900 nm (80 MHz, 140 fs, 25 nJ/pulse, Coherent Chameleon Ultra II). Photofragments were then analyzed by the last quadrupole.

Results:

Photofragmentation yield was recorded as a function of the laser wavelength resulting in NIR photodissociation action spectrum. Maximum photodissociation of $[\text{IR-797}]^+$ is observed at 760 nm, which is blue-shifted compared to the maximum absorption in the aqueous phase, and corresponds to the S_0 - S_1 transition. The addition of sulfonated substituents on the nitrogen atoms leads to an increase of the maximum photodissociation yield to 780 nm for negative $[\text{IR-806}]^-$ ions and doubly protonated $[\text{IR-806}, 2\text{H}]^+$ ions. This is understood in terms of the presence of two sulfonate-counter cation dipoles in the vicinity of the cyanine chromophore [2]. We demonstrated this effect by increasing the strength of the dipole. Changing the counter cation from H^+ to Na^+ further shifts the absorption peak to 790 nm.

Power dependence revealed that two photons are necessary to induce fragmentation in these dyes. It thus implies sequential absorption of the photons to the first excited state S_1 followed by intramolecular relaxation.

Conclusions

Photodissociation action spectroscopy of gas phase IR-797 and IR-806 cyanine ions reported shifts in the absorption to the S_1 excited state. These shifts find explanation in the close environment of the chromophore composed of sulfonate-counter cation dipoles. Control of absorption is possible by control over the counter cation through mass selection. This can have consequences for aqueous phase absorption in the presence of ion pairs [3].

Novel Aspect:

We performed counter cation-dependent action spectroscopy on cyanine dyes using a triple quadrupole instrument coupled to a tunable high-repetition rate femtosecond laser.

228 - ION MOBILITY SPECTROMETRY AND GAS PHASE SPECTROSCOPY OF MASS AND ISOMER SELECTED PORPHYRIN ANIONS

Katrina Brendle (1) - Patrick Weis (1) - Manfred M. Kappes (1)

Karlsruhe Institute of Technology, Karlsruhe Institute of Technology /Institute of Physical Chemistry, Karlsruhe (1)

Ion mobility spectrometry and gas phase spectroscopy of mass and isomer selected porphyrin anions

Katrina Brendle, Patrick Weis, Manfred M. Kappes
Institute of Physical Chemistry
Karlsruhe Institute of Technology
76131 Karlsruhe, Germany

Keywords: Porphyrins, Gas phase Spectroscopy, Ion Mobility Mass Spectrometry, Orbitrap

Introduction:

Even though gas phase studies are essential for the understanding of structure-property relationships in oligomer metal porphyrins – in particular concerning their optical and chemical properties, there is only little information on isolated porphyrin ions in gas phase. Therefore we are presently investigating anionic metal porphyrin oligomers (ligand= meso-Tetra(4-sulfonatophenyl) porphine= TPPS) with different metal centers $M = \text{Cu, Zn, Pd, Mn \& Fe}$ [1,2,3].

Methods:

A combination of an ion mobility drift cell for determination of ion mobilities and isomer separation, quadrupole mass filters and time-of-flight photoelectron spectrometer allows isomer and mass resolved photoelectron spectroscopy (PES) of electrosprayed analytes. Additionally we use a high resolution orbitrap mass spectrometer to identify monomer and oligomer porphyrin ions of the same m/z , which coexist in gas phase and for CID measurements.

Results:

IMS measurements in combination with quantum chemical calculations have shown for $[M(\text{II})\text{TPPS}]$ dimers with $M = \text{Pd, Cu \& Zn}$ two different structure types [1]. They are independent of the metal center and depend strongly on charge state. Dimers in low charge states with a correspondingly larger number of sodium counterion tend to form stacked, cofacial structures. In higher charge states, the stacks form coplanar structures. For the trivalent metal centers Mn and Fe a third “daisy-chain” like structure is observed with bonds between the sulfonic acid group of one porphyrin unit and the metal center of another [2].

Photoelectron spectra upon Soret (around 420 nm) and Q band (around 550 nm) excitation of $[\text{PdTPPS}]_4^-$ reveal different electron loss channels, which were determined to correspond to direct detachment from the S_1 and/or T_1 state as well as tunneling emission from these two states. The first triplet state lifetime of isolated $[\text{PdTPPS}]_4^-$ is longer than 10 μs [3]. Compared to $[\text{PdTPPS}]_4^-$ the photoelectron spectra of $[\text{ZnTPPS}]_4^-$ look quite different.

Conclusions:

We found different structure types depending on the total charge state and the valence of the metal center. The stacked, cofacial structure is reminiscent of H-aggregate motifs observed in solution [4].

Photoelectron spectra obtained upon excitation of the Soret and Q bands of mass selected porphyrin anions are a powerful tool to understand photoelectron detachment mechanisms. They show a strong influence of the metal center on the relaxation dynamics.

Novel Aspect:

The determination of isomer and mass selected porphyrin gas phase structures is new as is the measurement of delayed electron detachment processes via isomer selective PES.

1263 - IRMPD SPECTRA OF PROTONATED HYDROXYBENZALDEHYDES : THE EVIDENCE OF THE TORSIONAL BARRIERS IN CARBOXONIUM IONS

Barbara Chiavarino (1) - Maria Elisa Crestoni (1) - Otto Dopfer (2) - Maitre Philippe (3) - Simonetta Fornarini (1)

Università di Roma "La Sapienza", Dipartimento di Chimica e Tecnologie del Farmaco, Roma, Italy (1) - Technische Universität Berlin, Institut für Optik und Atomare Physik, Berlin, Germany (2) - Université Paris Sud,, Laboratoire de Chimie Physique UMR8000 CNRS, Orsay, France (3)

Keywords: Protonated aromatic compounds, carboxonium ions , IRMPD spectroscopy, DFT calculations,

Introduction: (398)

The basicity of aromatic aldehydes was widely studied. Protonation of benzaldehyde is directed to oxygen yielding a carboxonium ion with bivalent behavior as oxonium and carbenium ion.[1] In substituted benzaldehydes, the prevalence of the carbenium or oxonium character depends on the substituents and on their position. The aim of this work is to characterize the structure of protonated hydroxybenzaldehydes, identified as key inhibitors in biomass hydrolysates.

Methods: (397)

Protonated ortho, meta, and para-hydroxybenzaldehydes (IBZH⁺) were generated in the gas phase by electrospray ionization of hydro-alcoholic solutions, (10⁻⁵ M) of the select isomer, containing 2% acetic acid. Their structure was probed by combining IRMPD spectroscopy in the X-H spectral region with DFT calculations at the B3LYP/6-311++G(2df2p) level. As further inquiry, IRMPD spectra of both p-IBZH⁺ and its fragment ion were recorded in the fingerprint region.

Results: (856)

Similar to protonated aliphatic aldehydes, protonation at the formyl oxygen atom of benzaldehydes leading to the formation of carboxonium ions yields two distinct isomers, depending on the relative orientation of the proton that can stay either in cis or trans with respect to hydrogen on the adjacent carbon [2,3]. In this context, the 3200-3700 cm⁻¹ spectral region results ideal to distinguish the characteristic O-H stretch frequency of either cis and trans carboxonium isomers due to the different O-H bond properties of the two isomers. Comparison between IRMPD spectra and DFT calculations suggests that in the case of both p-IBZH⁺ and m-IBZH⁺ only cis conformers are present in the ionic population analyzed. In the case of o-IBZH⁺, IRMPD spectroscopy points to a mixture of one trans and two cis conformers. The value of energy barrier for the cis-trans isomerization calculated for each IBZH⁺ appears to be a measure of the degree of π -electron delocalization in the considered system.

Conclusions (391)

The present study shows that protonation of hydroxybenzaldehydes is directed only to the formyl oxygen atom to generate a mixture of carboxonium ions, with exclusively cis conformation. Only in the case of protonated o-IBZH⁺, the cis carboxonium ion isomer may overcome the high rotational barrier, and gives partially the more stable trans conformer. Moreover the IRMPD spectra of ap-IBZH⁺ fragment formed by loss of CO corresponds to para-protonated phenol.

Novel Aspect: (139)

This work is the first gas-phase experimental study of IBZH⁺ and reports for the first time an IR spectrum of gaseous protonated phenol in the fingerprint region.

draft

Niklas Helle (1) - Jürgen Grotemeyer (1)

Institute of Physical Chemistry, CAU Kiel, Kiel (1)

Keywords: REMPI, MATI, ionization energies, vibronic structure, pyridine

Introduction:

Pyridine has been extensively investigated by means of REMPI and MATI spectroscopy [1,2]. In contrast, only little information can be found about the vibronic structure of the methyl and halo pyridines in their first electronically excited and ionic ground state. Hence, we focused on analyzing the electronic and geometrical structure of the first excited state S_1 ($1\pi^* \leftarrow n$) and ionic ground state D_0 of the picolines [3], 3-fluoro and 3-chloropyridine.

Methods:

The molecules were investigated by means of REMPI and MATI spectroscopy. The measurements were done with two dye lasers and a home-built ToFMS.

In REMPI mode, the spectra were obtained by scanning the excitation laser. In MATI mode, the excitation laser was kept resonant with an eigenstate and the ionization laser was scanned. The immediately formed ions were separated from the Rydberg neutrals by a spoiling field. Afterwards, the Rydberg molecules were field ionized.

Results:

The excitation energy of the picolines, 3-fluoro and 3-chloropyridine have been determined with a very high accuracy. The influence of the position of the methyl group and the halogen atoms has been identified. All derivatives experience an inplane geometry distortion along the eigenvector of the vibration $6a$ upon S_1 excitation. Except for 3-chloropyridine, this vibration has the highest contribution to the electronic transition. Furthermore, an outofplane geometry distortion along the eigenvector of low frequency vibrations, which have a varying intensity among the derivatives, has been observed.

The adiabatic ionization energy of the picolines, 3-fluoro and 3-chloropyridine has been determined by means of MATI spectroscopy. The picolines and 3-fluoro pyridine experience a geometry distortion along the eigenvector of the vibration $8b$ upon ionization via the S_1 state. In contrast, the corresponding MATI spectrum of 3-chloro pyridine is dominated by low frequency vibrations.

Conclusions:

The ionization energy of the pyridine derivatives were measured with the highest accuracy reported so far. In addition, the ionic structure of the molecules has been determined.

The MATI spectra via the active vibrations in the S_1 state offered the possibility to verify the assignment in the S_1 REMPI spectra. This was especially true for low frequency vibrations, which are symmetry forbidden and were not taken into account for the simulations of the vibrational spectra.

Novel Aspect:

The adiabatic ionization energies of the picolines, 3-fluoro and 3-chloro pyridine were measured with a very high accuracy and the ionic geometries were determined.

1013 - ACTION SPECTROSCOPY WITHOUT A TRAP: ON-THE-FLY SPECTROSCOPY OF IR-797 AND IR-806 CYANINE DYES

Marius HERVE (1) - Richard BREDY (1) - Gabriel KARRAS (1) - Bruno CONCINA (1) - Abdul Rahman ALLOUCHE (1) - Franck LEPINE (1) - Isabelle COMPAGNON (1)

Institut Lumière Matière (ILM), Université Lyon 1, Lyon (1)

Keywords: Cyanine dyes (IR-797, IR-806); Mass Spectrometry; NIR Action Spectroscopy; Triple Quadrupole; Geometry sensitive absorption shift

Introduction:

Ion spectroscopy has become a powerful method in the modern MS toolkit. Numerous experimental setups make use of ion traps to irradiate molecules, thus accessing absorption of ions in the gas phase. We used here a triple quadrupole instrument to measure photodissociation action spectra of IR-797, a heptamethine cyanine dye, and one of its doubly sulfonated derivative IR-806 [1]. This revealed absorption shifts depending on the sulfonate presence and counter cation.

Methods:

Gas phase cyanines were produced using electrospray ionization, and transferred into a triple quadrupole mass spectrometer (Xevo TQ-S micro, Waters). Ions selected in charge and counter cation state were irradiated after the first mass selecting quadrupole with tunable femtosecond laser pulses from 710 nm to 900 nm (80 MHz, 140 fs, 25 nJ/pulse, Coherent Chameleon Ultra II). Photofragments were then analyzed by the last quadrupole.

Results:

Photofragmentation yield was recorded as a function of the laser wavelength resulting in NIR photodissociation action spectra. Maximum photodissociation of $[\text{IR-797}]^+$ is observed at 760 nm, which is blue-shifted compared to the maximum absorption in the aqueous phase, and corresponds to the S_0 - S_1 transition. The addition of sulfonated substituents on the nitrogen atoms leads to an increase of the maximum photodissociation yield to 780 nm for negative $[\text{IR-806}]^-$ ions and doubly protonated $[\text{IR-806,2H}]^+$ ions. This results from the modification of the geometry of the cyanine chromophore with sulfonate groups in the vicinity. We demonstrated this effect by changing the sulfonate counter cation. Changing the counter cation from H^+ to Na^+ further modifies the position of the sulfonate substituents around the chromophore, yielding a supplementary absorption shift to 790 nm.

Power dependence also revealed that two photons are necessary to fragment, implying sequential absorption to the first excited state S_1 followed by intramolecular relaxation.

Conclusions

Photodissociation action spectroscopy of gas phase IR-797 and IR-806 cyanine ions reported shifts in the absorption to the S_1 excited state. These shifts constitute a probe of the change in the geometry of the molecule, where the absorption of the chromophore reveals its close environment composed of sulfonate with or without counter cation [2]. This can have consequences for aqueous phase absorption in the presence of ion pairs [3].

Novel Aspect:

We performed counter cation-dependent action spectroscopy on cyanine dyes using a triple quadrupole instrument coupled to a tunable high-repetition rate femtosecond laser.

Keywords: Cryogenic ion spectroscopy, reaction intermediates, catalysis

Introduction: Over the past decade, the structural characterization of mass-selected ions with vibrational and electronic spectroscopies has evolved from a niche technique in the hands of a few specialists to a powerful new capability for routine chemical analysis. We present recent developments in this approach that are designed to capture fragile reaction intermediates, determine their structures, and photoinitiate product formation.

Methods: Vibrational and electronic structure of cold ions generated by ambient ionization sources are obtained using cryogenic RF ion traps (octopole, Paul) coupled to a triple focusing time-of-flight photofragmentation mass spectrometer. This hybrid approach is presently being integrated with a Thermo LTQ Orbitrap XL instrument to provide a general secondary analysis capability. Vibrational and electronic spectra of the cold ions are obtained by photoevaporation of weakly bound mass "tags" (typically He, H₂ and N₂) or, in the case of bare ions, by two-color, vibrationally mediated photodissociation.

Results:

Two major advantages of the tagging approach are i) high resolution optical spectra can be obtained with the modest power available with table-top laser sources, and ii) the linear spectra of the cold ions can be directly compared with band patterns for candidate structures calculated with widely available electronic structure packages. This scheme has clarified the chemical nature of many molecular ions as well as the docking arrangements of non-covalently bound complexes ranging from polypeptides to unstable reaction intermediates in catalysis. This talk will highlight recent progress in understanding the origin of the strong anharmonicities that are apparent in spectra even when the ions are cooled below 10 K. These effects contribute to broadening and extra features that complicate structural analyses based on fundamentals calculated at the harmonic level. Examples where this occurs typically involve strong hydrogen bonds near charge centers and multi-state Fermi resonances, both of which are common in the vibrational spectra of gas phase peptides. Theoretical markers will be discussed that signal when such complexities are likely to occur. On-going experimental efforts will also be presented involving the development of chemically active ESI ion sources to provide a rational synthetic strategy with which to trap fragile intermediates in the catalytic activation of small molecules. Next-generation opportunities for this rapidly expanding technology will also be noted, such as the prospects for monitoring reaction kinetics in the size-selected solvation regime.

Conclusions: Optical spectra of cold ions yield structures through direct comparison with predictions from electronic structure calculations.

Novel Aspect: Optical spectroscopies of mass selected ions are becoming mainstream capabilities for general chemical analysis.

512 - IR TAGGING PRE-DISSOCIATION SPECTROSCOPY TO REVEAL ISOMERIC COMPOSITION

Pavol Jusko (1) - Aude Simon (2) - Gabi Wenzel (1) - Sandra Brünken (3) - Stephan Schlemmer (4) - Christine Joblin (1)

Institut de Recherche en Astrophysique et Planétologie (IRAP), Université de Toulouse, CNRS, CNES, Toulouse (1) - LCPO, Université de Toulouse, CNRS, Toulouse (2) - FELIX, Radboud University, Nijmegen (3) - 1. Physikalisches Institut, Universität zu Köln, Cologne (4)

Keywords: Cryogenic ion trap, tagging spectroscopy, isomer analysis, tropylium, benzylium

Introduction:

The recent introduction of cryogenic ion traps reaching temperatures of about 4 K opens new possibilities in weak bond ion-neutral attachment, notably the possibility of He/Ne attachment to the ions of interest [1]. The infrared pre-dissociation of these tagged ions can be used in ro-vibrational action spectroscopy. This can be used to infer the isomer composition of the ions.

Methods:

The FELion beamline at FELIX free electron laser facility at Radboud University (Nijmegen, The Netherlands), is equipped with a 22 pole radio-frequency ion trap at 4 K [2]. The ions, produced by electron bombardment are mass selected prior to injection into the trap, where they are tagged with He or Ne. Consecutively tunable FEL light is used to irradiate the tagged ions and obtain a one photon action spectrum (IR pre-dissociation).

Results:

The tropylium (7 carbon-hydrogen aromatic cycle) and benzylium ions (6 carbon-hydrogen aromatic cycle with one hydrogen substituted by methylene CH₂ group) are the two lowest-energy isomers of C₇H₇⁺. Tropylium and benzylium like structures could also be found in larger polycyclic aromatic hydrocarbon (PAH) species, e.g., in a fragment of 1-methylpyrene C₁₇H₁₁⁺ (denoted as PyrC₇⁺ and PyrCH₂⁺) as predicted by Rapacioli et al. [3]. In this study, we will demonstrate how the IR pre-dissociation spectroscopy of cold Ne-tagged ions can reveal the isomeric mixture in situations where the IRMPD spectroscopy fails. We applied molecular dynamics simulations (SCC-DFTB level of theory) in order to analyse the difference between the multiphoton and single photon spectra. We also compare our results with isomer mixture ratios that can be obtained from the variation in reactivity of the two isomers.

Conclusions:

We show, that IR pre-dissociation of the weakly bound Ne cluster can be used as a complementary technique to mass spectrometry, providing information on isomeric composition. We identified the most abundant isomer of cationic 1-methylpyrene fragment, produced by low energy electron bombardment of the neutral 1-methylpyrene, to be PyrCH₂⁺ isomer [4].

Novel Aspect:

The single photon dissociation scheme has a great advantage compared to multi-photon ones, in which consecutive heating can lead to isomerisation.

797 - VALENCE AND CORE ELECTRON INDUCED PHOTOIONIZATION AND DISSOCIATION DYNAMICS OF THE THIAZOLE MOLECULE

Alexsandre Lago (1) - Robin Januario (1) - Reinaldo Cavasso Filho (1) - Marc Simon (2) - Juan Dávalos (3)

Federal University of ABC (UFABC), Federal University of ABC (UFABC) / Center for Natural Sciences and Humanities (CCNH), Santo Andre - SP (1) - UPMC-Univ Paris 06, CNRS, Sorbonne Universités, UPMC-Univ Paris 06 / Laboratoire de Chimie Physique-Matiere et Rayonnement, Paris (2) - Consejo Superior de Investigaciones Científicas (CSIC), CSIC / Instituto de Química Física Rocasolano, Madrid (3)

Keywords: Photoionization, Ionic dissociation, Synchrotron radiation, PEPICO, Thiazole.

Introduction:The thiazole (C₃H₃NS) molecule belongs to the group of organic compounds called heterocycles, which are present in the formulation of important complex chemical entities, such as carbohydrates, proteins, among others, and stand out for their diverse properties and applications important to several fields. The main goal in this project is to provide reliable fundamental spectroscopic and spectrometric data for this group of molecules in gas phase by using synchrotron radiation, photoelectron photoion coincidence and time of flight mass spectrometry techniques.

Methods:TOF-MS and photoelectron photoion coincidence (PEPICO) techniques have been employed. VUV and soft X-ray synchrotron radiation sources were employed as ionizing agents. Total and partial ion yields (TIY,PIY) and PEPICO spectra were recorded as a function of the incident photon energy, covering from the valence region up to the core electronic shells of the molecule. The resulting photoionization ion products and the possible fragmentation pathways leading to those species are presented and discussed.

Results:For the valence photodissociation studies of thiazole, the PEPICO mass spectra have been recorded covering the range from 10 eV to 21 eV. The high photo-stability of this molecule and its molecular parent ion has been confirmed from our results. It has been mainly attributed to the strong bonding resulted from its closed ring molecular structure. The dominant mechanism corresponds to the consecutive dissociations of the C=N and C=C bonds from the thiazole molecular ion resulting in the fragment C₂H₂S⁺ (m/z = 58). The ion yield spectra were recorded by scanning the incident photon energies in the vicinity of the C1s and S1s core edges showing the main spectral features resulting from core electronic excitation transitions from the molecular ground state leading to the core excited and to the corresponding ionic states. In addition, the corresponding mass spectra based on the PEPICO technique recorded at selected photon energies near the core ionization edges provided relevant information leading to the identification of the dissociative photoionization ion products and their corresponding fragmentation pathways.

Conclusions:Time of flight mass spectrometry (TOF-MS) used in conjunction with photoelectron photoion coincidence (PEPICO), total and partial ion yield (TIY and PIY) techniques have been proved powerful tools for the analysis of the electronic structure and photodissociation dynamics of the thiazole molecule in gas phase, which resulted in very interesting chemical and physical insights.

draft

André Oliveira (1) - Thiago Correra (1)

Institute of Chemistry, University of São Paulo, São Paulo (1)

Keywords: IRMPD; theoretical calculations; intramolecular interaction; ion spectroscopy; bioactive molecules

Introduction

Ion spectroscopy are usually compared to theoretical spectra to determine conformation of gaseous ions. DFT methods, mainly B3LYP, are the most used methods to model IR spectra, but some of them are known to provide inaccurate description of highly anharmonic oscillators.[1,2] We aim to assess alternative methods for describing anharmonic oscillators by comparison with experimental IRMPD spectra.

Methods

The benchmarking and validation of our experimental setup was performed with experimental spectra of protonated biotin and tryptophan. Photodissociation was achieved by an OPO/A system in the 2750 – 3800 cm⁻¹ range. Calculations were performed with B3LYP, CAM-B3LYP, M06-2X and MP2 and the basis set of Pople and Dunning type. Anharmonicity and D3 dispersion corrections were also evaluated.

Results

M06-2X/6-31+G** was the most cost effective level of theory. The increase in the job time, compared to B3LYP, was not significant, while the error (RMSD) highly decreases. Extended basis sets were not as much efficient, when associated to M06-2X. CAM-B3LYP was the better method to describe intramolecular interactions and provided good results with extended Dunning type basis sets. Anharmonic calculations were carried out and, but they showed to be extremely expensive when compared to other approaches. The dispersion correction D3, improved the description of O-H vibrations involved in H-Bond, but worsened the description of N-H stretches. None of the correction methods lowered RMSD as the use of well established scaling factors (sf). The M06-2X/6-31+G** and CAM-B3LYP/aug-cc-pVDZ level of theory was also tested against the fingerprint region, showing a good agreement with experimental data.

Conclusions

Our results suggest that M06-2X/6-31+G(d,p) could be the level of theory to be used in predicting IRMPD spectra. On the other hand, CAM-B3LYP/aug-cc-pVDZ was more efficient in describing long-range interactions, despite requiring more time than the previous level of theory. Between the correction approaches, the use of scaling factors remains as the easiest and more efficient strategy.

Novel Aspect

These are first IRMPD done in Brazil. We show the most used levels of theory to predict IRMPD spectra. We suggest the use of M06-2X/6-31+G**.

Keywords: Electron Transfer Dissociation, ion spectroscopy, peptides, radicals, ion chemistry

Introduction:

Peptide sequencing by Electron Transfer Dissociation (ETD) has seen rapid growth especially in top-down applications and for the identification of post-translational modifications (PTM). Understanding its underlying reaction chemistry remains elusive to some extent, in part due to the radical-driven dissociation mechanisms and the open-shell product ion structures. Here we apply IR ion spectroscopy to reveal molecular structures of several ETD product ions.

Methods:

Experiments are carried out in a modified ETD enabled quadrupole ion trap MS connected to the IR beamline of the free electron laser FELIX. ETD fragment ions of doubly protonated precursor peptides are formed by ion-ion reactions with the fluoranthene radical anion. Individual ETD fragments are mass isolated and spectroscopically investigated with IRMPD spectroscopy [1]. IR spectra are compared with DFT computed spectra to derive structural information.

Results:

ETD is known to lead mainly to cleavage of the backbone N-C α bonds in a peptide and results in closed-shell c-type fragments and radical z-type fragments. We have recorded IR spectra for a comprehensive set of c-type ions, mainly to distinguish between possible amide and enol-imine moieties at their C-terminus. Radical z-type ions are also investigated. One of the main questions was whether the radical remains located at the site of cleavage or whether it migrates to a thermodynamically more favorable site. For peptides where ETD occurs at a Cys residue, we observe secondary neutral loss of a thiol radical and spectroscopically establish the formation of a C=C double bond in the so-called w-type fragment ion.

Conclusions

The IR spectra suggest that the c-type ions have an amide moiety at their C-terminal. This may suggest that they are formed via the Utah-Washington mechanism, but post-ETD rearrangement from enol-imine to amide cannot be excluded based on the spectroscopic data. From the spectra of the radical z-ions, we tentatively conclude that radical migration to aromatic side chains does not occur, although other radical migrations have not been exhaustively verified thus far.

Novel Aspect

Systematic investigation of ETD fragment ion structures by IRMPD spectroscopy.

895 - INFRARED MULTIPLE PHOTON DISSOCIATION OF COPPER FORMATE CLUSTERS

Tobias Pascher (1) - Milan Oncak (2) - Christian van der Linde (1) - Josef Lengyel (3) - Martin K. Beyer (1)

Universität Innsbruck, Institut für Ionenphysik und Angewandte Physik, Innsbruck (1) - Universität Innsbruck, Institut für Ionenphysik und Angewandte Physik, Innsbruck (2) - Technische Universität München, Physikalische Chemie, München (3)

Keywords: FTMS, Catalysis, Copper, Formate, IRMPD, Spectroscopy

Introduction:

Copper and copper oxides are widely investigated for their catalytic properties [1,2]. It was shown that the calcination of copper salts can lead to highly active catalysts [3] and that copper hydride-based catalysts show a distinct reactivity [4]. Here, elementary steps in the calcination of copper formate are investigated in the gas phase by means of infrared multiple photon dissociation of $\text{Cu}_n(\text{HCOO})_{2n+1}^-$, $n \leq 4$.

Methods:

$\text{Cu}_n(\text{HCOO})_m^-$ ($n \leq 4$; $m \leq 9$) clusters are prepared using electrospray ionization, transferred into the cell of a Fourier transformation ion cyclotron resonance mass spectrometer and irradiated in the wavelength range of 2500-4475 nm by a tuneable optical parametric oscillator. The decomposition of the ions is investigated by measuring dissociation kinetics at the absorption bands. For theoretical comparison, quantum chemical calculations on the DFT level are used.

Results:

Using action spectroscopy, three intense absorption bands were found in the wavelength range of 3400-3900 nm that shift depending on the size of the cluster and the oxidation state of the copper ions. Using deuterated isotopologues, the character of the vibrations involving C-H/D motion was confirmed and absorptions of C-O combination bands/overtone were identified.

After activating the C-H bonds of the formate ligands with the tuneable laser system, a fragmentation cascade has been observed with heavy secondary fragmentation. Clusters $\text{Cu}_n(\text{HCOO})_{2n+1}^-$, $n = 2-4$, dissociate into smaller $\text{Cu}_n(\text{HCOO})_{2n+1}^-$ species with $n = 1-3$. For $\text{Cu}_2(\text{HCOO})_5^-$, H atom transfer takes place between two formate ligands, resulting in the elimination of CO_2 and HCOOH together with a reduction of the copper centers to +I. For smaller clusters ($n = 1,2$; $m = 2,3$), CO_2 elimination involves the transfer of a hydrogen atom to copper, leading to copper hydrides. Collisional activation leads to the same fragmentation pathway.

Conclusions

Three intense absorption bands of C-H stretching vibrations were found in the wavelength range of 3400-3900 nm that shift depending on the size of the cluster and the oxidation state of the copper ions. The dissociation of copper formate ions was found to lead towards copper hydrides through a reaction cascade. The results were compared to quantum chemical calculations on the DFT level.

Novel Aspect:

Copper formate clusters are activated with infrared laser light to simulate calcination with defined heating. CO_2 elimination leads to copper hydride species.

525 - DEVELOPMENT OF A 3D ION TRAP MASS SPECTROMETER FOR IRMPD SPECTROSCOPY

Tatiana C. Penna (1) - Gustavo Cervi (2) - Andre F. Rodrigues-Oliveira (2) - Jair Menegon (2) - Thiago C. Correra (2)

Instituto de Química, Universidade de São Paulo, São Paulo (1) - Instituto de Química, University of Sao Paulo, São Paulo (2)

Keywords: IRMPD spectroscopy, IRLAPS, CO₂ laser, photofragmentation

Introduction:

Ion spectroscopy experiments are excellent tools to obtain complementary information in mass spectrometry. We describe the development of the 3D ion trap used for IRMPD spectroscopy and IRLAPS experiments, comparing results already present in literature and different ionization sources. This equipment is the first to perform IRMPD experiments in Brazil and is open to use by external users.

Methods:

Experiments were made in a modified Bruker AmaZon SL3D ion trap mass spectrometer. IRMPD experiments used an Laser Vision OPO/A system pumped by Nd:YAG 1064 nm laser to obtain tunable radiation from ca. 2300 – 4000 cm⁻¹. Crystal optimization were performed when necessary to improve laser power in different wavenumber ranges.

Results:

A LabView interface was developed to annotate the actual laser wavelength to the raw MS data, allowing the direct calculation of the photodissociation efficiency. This interface completely controls the MS events and allows for multiple and variable IRMPD steps by customizing CID events.

IRMPD spectra of species previously reported in literature were obtained to verify the instrument performance using ESI-MS. The spectra for biotin, tryptophan, phosphotyrosine were similar to those previously reported which indicates the good performance of our system. [1-3]

IRMPD of the Ag⁺(CH₃CN)₂ species were obtained at the nitrile stretch region as dissociation at 2350 cm⁻¹ was registered, which is unprecedented given the low output power of the OPO/A at this wavelength.

IRMPD spectra of a series of ions were obtained by using other in house built ion sources like, nanospray, EASI and DESI ion sources.

Conclusions:

We have demonstrated that IRMPD spectra obtained in our new instrument are consistent with previous results of the literature. It was also possible to obtain the vibrational spectra from different ionization sources. The optimization of the OPO crystals positions improved the output power of the pulse energy in different ranges of wavenumber and allowed the IRMPD of nitriles at 2350 cm⁻¹.

Novel Aspect:

The recently assembled instrument is the first to perform IRMPD experiments in Brazil. IRMPD were obtained from different ion sources and at 2350 cm⁻¹.

Keywords: UV& IR spectroscopy, IR-IR-UV hole-burning, enkephalin, photodissociation

Cold Ion Spectroscopy (CIS) provides accurate spectroscopic fingerprints for stringent validation of the 3D structures of small biomolecules in the gas phase [1-3]. A fundamental question that still remains open is to what extent the gas-phase structures of these biomolecules resemble their native structures in vivo. It was recently revealed that the pharmacological activity of peptide drugs Enkephalins correlates with their gas-phase geometries, but not with the condensed-phase structures [4]. These peptide ligands adopt their biologically active geometry only when they dock into hydrophobic pocket of their receptors. Isolation of peptides in the gas phase mimics, to some extent, this hydrophobic environment as it removes strong intermolecular hydrophilic interactions.

In order to test this assumption, we applied conformer-selective multi-laser CIS to record conformer-selective vibrational spectra of individual conformers of three stereoisomers of the opioid pentapeptide [Ala2-Leu5]-Enk, isolated in the gas phase. Together with theoretical calculations, experimental spectra allowed for the identification of 3D structures of six conformers of three stereoisomers (3 for DD, 2 for DL, and 1 for LL). The obtained structures fully support the predictions made previously by FRET experiments in the gas phase. Furthermore, we found an evidence of the kinetically trapped, solution-like structure of one of the DL conformers.

Overall, these data confirm that for a large class of biomolecules there is high relevance of gas-phase studies for biology, as they reflect structural preferences of biologically active geometries.

Keywords: UV& IR spectroscopy, peptide bond, photodissociation

UV absorption by aromatic residues in cold, gas-phase peptides is extremely sensitive to their structure. Combined with vibrational spectroscopy (IR-UV double-resonance [1] and IR-IR-UV hole-burning [2, 3] techniques) it allows for accurate validation of calculated geometries, while together with high-resolution mass spectrometry (2D UV-MS [4]) it allows for an identification of isoforms of biomolecules. These photofragmentation techniques are applicable, however, only to those peptides that contain at least one aromatic residue.

Alternatively, peptide bonds can be used as chromophores. In solution, peptides and proteins exhibit strong $\pi \rightarrow \pi^*$ transition at ~ 190 nm and a weak $n \rightarrow \pi^*$ transition at ~ 215 nm. UV absorption of peptides in the gas phase, however, has never been characterized. We report the first gas-phase UV photofragmentation spectrum of a single peptide bond. The influence of vibrational excitation on the electronic spectrum of cold ions is explored and all-conformer IR-UV gain and conformer-selective IR-IR-UV hole-burning spectra of non-aromatic peptides with up to six amino acids are presented.

2D UV-MS spectroscopy of a model helical peptide reveals that the intensities of the $n \rightarrow \pi^*$ transitions of individual peptide bonds correlate with their local structural preferences. This type of transition is, usually, very weak because of small spatial overlap of the atomic non-bonding orbital of oxygen, n , and the molecular delocalized anti-bonding orbital of the peptide bond, π^* . We suggest that the intensity of the $n \rightarrow \pi^*$ transition depends on the degree of distortion of the O=C-N-H planar orientation due to the local, non-covalent interactions. Since 2D UV-MS spectroscopy is able to separate absorptions of individual peptide bonds, it is a promising structural probe for peptides and proteins.

1179 - PHOTOISOMERIZATION ACTION SPECTROSCOPY OF A RUTHENIUM SULFOXIDE COMPLEX

Michael Scholz (1) - James Bull (1) - Eduardo Carrascosa (1) - Gilbert Kosgei (2) - Jeffrey Rack (2) - Evan Bieske (1)

University of Melbourne, School of Chemistry, Parkville, Australia (1) - University of New Mexico, Department of Chemistry and Chemical Biology, Albuquerque, United States (2)

Keywords: ion mobility spectrometry; ruthenium; photoisomerization; laser spectroscopy; dynamics

Introduction:

Understanding the excited-state dynamics of photoactive molecules is essential for the design of new generation photoresponsive materials. One promising family of switching units is based on the reversible linkage isomerism of sulfoxide ligands coordinated to a ruthenium(II) polypyridyl core. In these, the sulfoxide ligands convert between S- and O-bound configurations with quantum yields of up to 79% after metal-to-ligand charge transfer (MLCT) excitation.

Methods:

Photoisomerization action (PISA) spectroscopy was performed using a custom tandem ion mobility mass spectrometer coupled with a tunable laser. In an experiment, electrosprayed isomers were mobility separated in a first drift region, selected with an ion gate, and irradiated with tunable light. Photo-isomers were mobility separated in a second drift region and mass selected with a quadrupole. Resulting PISA spectra plot photo-isomer yield against wavelength.

Results:

The $[\text{Ru}(\text{bpy})_2(\text{bpSO})]^{2+}$ complex (bpy is 2,2'-bipyridine, bpSO is a bidentate bis-sulfoxide ligand) displays stepwise isomerization in solution from $S,S \rightarrow S,O \rightarrow O,O$ with an overall quantum yield of 42% at 355 nm.[1] In the gas-phase, we observed direct S,S to O,O photoisomerization with minor formation of the S,O isomer.[2] Supporting electronic structure calculations suggested that both $n\pi^*$ and $\pi\pi^*$ excitation resulted in isomerization. The difference in photoisomerization yields between the previous measurements in solution and our gas-phase results was attributed to solvent quenching of vibrational energy before activated molecules could traverse excited-state isomerization barriers.

Conclusions:

Ion mobility mass spectrometry is a powerful technique for separating linkage isomers of ruthenium sulfoxide coordination complexes. Different photoisomerization yields were observed in the gas phase and in solution, indicating that solvation strongly perturbs isomerization process. Future studies will aim to elucidate further details of the photochemical dynamics in these systems.

Novel Aspect:

Ion mobility mass spectrometry coupled with laser spectroscopy characterizes the first example of linkage photoisomerization in a gas-phase coordination complex.

Keywords: flavins, ion spectroscopy, dissociation, isomerization, luminescence

Introduction:

Flavins are a ubiquitous family of redox cofactors which serve as blue light sensors in proteins and enzymes responsible for e.g. DNA repair, phototropism in plants and the perception of magnetic fields by some migratory birds. Little is known about how the optical properties of flavins are affected by micro-environmental perturbations, particularly in their reduced and/or deprotonated forms which act as resting or signaling states in some proteins.

Methods:

Flavin ions are produced by electrospray. Photo-induced dissociation (PID) action spectroscopy was performed using a sector instrument and an electrostatic ion storage ring. Photo-induced isomerization action (PISA) spectroscopy was carried out using tandem ion mobility spectrometry (IMS). Laser induced fluorescence (LIF) was measured in a quadrupole ion trap (QIT).

Results:

Using a multi-faceted approach employing state-of-the-art action spectroscopy experiments and concomitant calculations, we are investigating the photophysics and photochemistry of flavin ions in vacuo, with a focus on Flavin Adenine Dinucleotide (FAD). For FAD mono-anions, where the iso-alloxazine chromophore is in its fully oxidized, neutral form, the gas-phase absorption and fluorescence spectra are very similar to solution-phase measurements [1-3]. The gas-phase Stokes shift is considerably larger than previously reported for other molecular ions, implying significant vibronic effects [2]. Deprotonation of the chromophore leads to a significant red-shift relative to solution due to significant charge transfer character, which also gives a high susceptibility to micro-environmental perturbations [3]. Photo-induced intra-molecular proton transfer is found to be an important step in the photo-degradation of flavins [1,3]. Isomer-selective action spectroscopy has revealed deprotomer-dependent photochemistry [3].

Conclusions:

Intrinsic spectroscopic and photochemical data are established. These gas-phase experiments form a baseline for quantitative comparison to theory and to more complex situations in solution or proteins. The photochemistry of flavins is driven by intra-molecular proton transfer. Time-resolved experiments are needed to disentangle excited-state and statistical processes.

Novel Aspect:

First absorption and fluorescence spectra of flavin ions in vacuo. Photochemistry and micro-environmental sensitivity are strongly dependent on (de)protonation state.

900 - PHOTOCHEMISTRY OF $\text{Mg}+(\text{H}_2\text{O})_n$, $n=1-5$: EXPERIMENT AND THEORY

Thomas Taxer (1) - Milan Oncak (1) - Christian van der Linde (1) - Erik Barwa (1) - Martin Beyer (1)

Universität Innsbruck, Institut für Ionenphysik und Angewandte Physik, Innsbruck (1)

Keywords: Photochemical hydrogen evolution; photodissociation;

Introduction:

There has been a long history of studies [1-4] on hydrated metal ions in the gas phase over the last decades. The study of such cluster systems is important to understand the transition of various properties from single molecules to the bulk. In the ground state these systems are already well understood but few studies are available on their excited state reactivity. Here, we investigate the photochemistry and spectroscopy of hydrated magnesium ions $\text{Mg}+(\text{H}_2\text{O})_n$, ($n=1-5$).

Methods:

The experiments were performed on an FT-ICR-MS, using a laser vaporization ion source. Clusters were generated from a target consisting of isotopically enriched ^{24}Mg and supersonic expansion into high vacuum, along with a gas pulse of helium seeded with water vapor. A tunable, pulsed laser system was used to induce photodissociation. Dissociation mass spectra were recorded in a wavelength range from 240 nm up to 2,000 nm and compared with ab initio calculations.

Results:

Photodissociation spectra for $\text{Mg}+(\text{H}_2\text{O})_n$, $n = 1-5$ were measured, at 130 ± 20 K and compared to experiments by Misaizu et al. [2]. The detected fragment ions can be grouped into two different channels. The $\text{Mg}+(\text{H}_2\text{O})_m$ ($m < n$) species are produced by the evaporation of one or more water molecules. The other channel, contributing most to the observed fragmentation, is the hydrogen dissociation reaction producing magnesium hydroxide $\text{MgOH}+(\text{H}_2\text{O})_m$. The additional loss of one or more water molecules was also observed in this dissociation channel. For the $\text{Mg}+(\text{H}_2\text{O})_{4,5}$ clusters, the influence of black-body infrared radiative dissociation was documented. Detailed photofragment branching ratios were evaluated. The main bands in the experimental spectra were assigned to the $3s \rightarrow 3p$ transition. Additional bands were observed at higher photon energies, corresponding to the $3s \rightarrow 3d/4s$ transitions. Resolved vibrational structure was obtained for $\text{Mg}+\text{H}_2\text{O}$. For this system the possibility of a two photon process in the dissociation was investigated theoretically.

Conclusions:

Photodissociation spectra were measured for $\text{Mg}+(\text{H}_2\text{O})_{1-5}$. The results are in good agreement with theoretical predictions and earlier experiments [2]. The $3s \rightarrow 3d/4s$ dissociation bands were observed for $\text{Mg}+(\text{H}_2\text{O})_{3-5}$. For $\text{Mg}+(\text{H}_2\text{O})_{1-3}$, only a single isomer was present, but several isomers contribute to the spectrum of $\text{Mg}+(\text{H}_2\text{O})_{4,5}$. For all investigated cluster sizes, hydrogen dissociation producing $\text{MgOH}+(\text{H}_2\text{O})_m$ was the main observed dissociation channel.

Novel Aspect:

Photodissociation spectra for $\text{Mg}+(\text{H}_2\text{O})_{1-5}$ were measured with high resolution, far into the UV, in a temperature controlled environment.

Keywords: 213 nm UVPD, Native MS, Ion mobility, Protein unfolding

Introduction:

Protein unfolding in its initial stages may be reflective of the stability of the entire fold and reveal local sites that may be perturbed. Ion mobility mass spectrometry (IM-MS) provides insight into global structure while UV photodissociation (UVPD) has been shown to be sensitive to secondary structural elements [1,2,3]. In this work we investigate the initial unfolding of three proteins using 213 nm UVPD combined with IM-MS.

Methods:

Modifications were made to a Synapt G2-S [4] to facilitate injection of a laser beam into the trap cell region. Ubiquitin, cytochrome c and myoglobin were sprayed from ammonium acetate by nanoESI; UVPD spectra using 213 nm photons and arrival times of precursor and photofragment ions were recorded at different source conditions by varying the cone voltage affecting the protein conformation prior to UVPD.

Results:

Native structures and how they alter upon gentle in source activation was assessed. Unfolding from compact to extended conformer was induced in the lowest charge state of ubiquitin and UVPD was performed as a function of activation; the fragmentation yield was higher for the extended conformation. Cleavage in the compact structure was enhanced between residues 12-18 compared to residues 33-47 for the extended structure.

For cytochrome c UVPD was carried out on a compact, an intermediate and an extended conformation. Again the fragmentation yield increased as the protein increased in CCS with distinct UVPD spectra for each conformation; cleavage at residues Phe10, Thr19 and Val20 was only found in activating conditions.

Compact conformations of myoglobin yielded few fragments while a drastic increase was observed after a shift to intermediate and extended structures. The cleavage sites with the highest yield were similar for both native charge states, however fragmentation in the GH loop, H helix and D helix was only found for 9+.

Conclusions:

UVPD-IM-MS discriminates between compact structures and more extended forms. We present differences in terms of fragmentation yield as well as the intensity distribution within the fragmentation pattern. Cleavage sites differ between conformational ensembles revealing areas of local structural changes as a result of progressive in-source activation as well as global changes in terms of ion mobility profiles.

Novel Aspect:

213 nm UVPD-IM-MS is used to identify and locate structural changes upon protein unfolding

746 - PHOTODISSOCIATION SPECTROSCOPY OF M/Z-SELECTED FUNCTIONALISED PROTONATED PYRIDINE IONS: ARE SOME PREDICTIVE PATTERNS EMERGING?

McKinnon Benjamin (1) - Marlton Samuel (1) - Kelly Patrick (1) - Stephen Blanksby (2) - Adam Trevitt (1)

School of Chemistry, University of Wollongong, Wollongong (1) - Central Analytical Research Facility, Queensland University of Technology, Brisbane (2)

Keywords: laser spectroscopy, ions, ion trap, protonation, photodissociation

Introduction:

Protonated N-containing aromatics are ubiquitous fundamental molecules but despite their wide-spread prevalence, there are few predictive models that describe their photostability (and fate). Photostability affects photo-induced proton-transfer, electron-transfer and internal conversion. We are targeting small, protonated N-aromatics to better understand photostability to improve this general understanding.

Methods:

A combination of room temperature ion-trap mass spectrometry [1,2], ion-molecule kinetics [3] and tunable UV-Vis pulsed-laser photodissociation is used to measure the photodissociation of m/z selected ions formed from electrospray ionisation. Computational results for excited-states and ground state photodissociation pathways assist in assigning the spectra and rationalising the formation of product ions.

Results:

The UV photodissociation spectra for ethynylpyridineH⁺ and formylpyridineH⁺ ions (ortho, meta and para, in each case) are presented for first time. In some cases, the spectra exhibit vibronic detail – these are compared to Franck-Condon simulations – and in all cases multiple photodissociation channels are detected. Ion chemistry kinetics assists with assigning product isomers.

For ethynylpyridiniumH⁺ ions, UV photodissociation leads to either retention of the N atom in the ring (from C₂H₂ elimination) or its expulsion (from HCN elimination). It is not clear what mediates this partitioning. UV photodissociation of formylpyridineH⁺ reveals (at least) three distinct photoproduct channels and these are tracked within the action spectra, which are rather different for each isomer. These different spectra are likely the result of varying excited-state lifetime from to the interplay between “bright” excited states – that dominate the spectra – and “dark” states that dominate the deactivation.

Conclusions:

Photodissociation spectroscopy of mass selected ions reveals important new details about their electronic excitation and fate. Although these target molecules are small, there remains many profound unknowns about the fate of their electronic excited states and mechanisms of deactivation. Our study reveals new information about the excited state energy of these species and some plausible mechanisms for their dissociation from UV excitation.

Novel Aspect: New photodissociation spectra are reported for m/z selected ethynylpyridiniumH⁺ and formylpyridineH⁺ ions using ion trap MS combined with tunable UV laser irradiation.

Frantisek Turecek (1)

University of Washington, Chemistry, Seattle (1)

Keywords: DNA cation radicals, UV-Vis action spectroscopy, time-dependent DFT calculations, potential energy surfaces

Introduction:

Radical reactions play an important role in several biological processes. An area of particular interest has been the reactions triggered in nucleic acids and their components by electrons, photons, and high-energy particles. Nucleobase radicals have been previously generated by electron transfer in the gas phase. We now report on the generation of nucleic acid cation-radicals and their characterization by UV-Vis photodissociation action spectroscopy.

Methods:

Electron transfer reduction was used to produce nucleobase cation radicals in a linear ion trap from doubly charged ions formed by electrospray. UV-Vis action spectroscopy was carried out in the 210-70 nm range. Structures were obtained by all-electron molecular dynamics calculations followed by DFT and time-dependent DFT for excitation energies and intensities, including vibronic excitations giving thermal absorption spectra.

Results:

Nucleic acid cation radicals of novel type were produced in high yield by electron transfer reduction and dissociation of crown-ether complexes for DNA dimers (AA + 2H), (GG + 2H), (CC + 2H), (GC + 2H), and (CG + 2H). RNA chimeric dimers (A-spacer-A + 2H) were also produced with rigid ring spacers separating the adenosine cation and radical moieties [1]. Action spectroscopy and UV-Vis spectra interpretation revealed that the cation-radicals underwent a conformational collapse associated with hydrogen atom migrations between the nucleobases, forming new isomers. The hydrogen migrations were very facile for adenine and guanine nucleobases, but less so for cytosine. The RNA chimeras with aromatic ring spacers formed zwitterionic structures upon reduction in which the nucleobases maintained the charge and the electron entered the aromatic ring. The formation of zwitterions is consistent with the mechanism and energetics of DNA ionization, as revealed by detailed structure and energy analysis.

Conclusions

Upon electron transfer, single-strand nucleic acids undergo a conformational collapse driven by attractive interactions of nucleobase cations and radicals.

Novel Aspect:

Use of UV-VIS action spectroscopy in combination with electron transfer and TD-DFT calculations for structure assignment of transient DNA cation radicals.

Keywords: IRMPD, chiral discrimination, axial chirality, noncovalent interactions

Introduction:

Different stability and reactivity of diastereomeric aggregates reflect the number and intensity of the interactions between the chiral species involved. Therefore, investigating diastereomeric aggregates in the gas phase helps to understand the mechanism of chiral recognition through detailed knowledge of the structure of the chiral receptor, as well as of the size- and shape-specific non-covalent interactions in its aggregate with a chiral molecule[1-3].

Methods:

An ESI-MS-IRMPD analysis has been employed to assess the structural features of diastereomeric complexes[4] between an axially chiral receptor (M) and two amino acids, phenylalanine (Phe) and dopa (DOPA), differing only for the aromatic substituents. The results have been interpreted through a computational analysis at the B3LYP/6-31G** level, to assess both the coordination site and the preferential conformation adopted by the complexed guest.

Results:

IRMPD spectra of the $[M \cdot H \cdot Phe]^+$ diastereomeric complexes did not exhibit any appreciable difference, in contrast to the significant discrimination exerted by M on the enantiomers of dopa. The comparison between experimental bands and theoretical results indicate that the guest is located out of the cavity, in close proximity of the binaphthyl moiety of M. Furthermore, the computational analysis performed on several rotamers pointed out that the enantiodiscrimination is mostly due to the short range interaction between the hydroxyl groups and the core of the axial chirality. It is worth noting that the structures spectroscopically observed are not the most stable ones.

Conclusions

The IRMPD of the ESI-formed $[M \cdot H \cdot DOPA]^+$ diastereoisomers were consistent with an out of cavity structure, not corresponding to the lower energy coordination site. The observed discrimination on the dopa enantiomers is due to the hydroxyl groups, absent in the structure of phenylalanine, that are oriented towards the chiral core of M. Finally, the different spectroscopic signatures indicate the coexistence of several conformers for the diastereomeric aggregates.

Novel Aspect:

Subtle structural differences between non-covalent diastereomeric complexes have been pointed out through IRMPD technique.

Masaaki Fujii (1)

Laboratory for Chemistry and Life Science, Institute of Innovative Research, Tokyo Institute of Technology (1)

Keywords: Chirality, Molecular Recognition, ion trap, IR, laser spectroscopy

Introduction:

Understanding stereochemical effects on the structure of molecular aggregates provides insight into the role of chirality in shaping biological supramolecular systems at the molecular level. Here we focus on 1-amino-2-indanol (AI_2H^+), a proto-typical cyclic 1,2-amino-alcohol, and reveal how the chirality of the monomer subunits controls the overall structure of its dimers [1].

Methods:

Here, we apply IR-UV double-resonance laser spectroscopy coupled with ESI / cold ion trap mass spectrometry to the protonated homodimers of (1R,2S)-cis- and (1R,2R)-trans- AI_2H^+ (c- AI_2H^+ , t- AI_2H^+). The IR-UV double-resonance spectroscopy enables us to measure UV and IR spectra of a single conformer. Such conformer selection is a big advantage of mass-coupled laser spectroscopy [1].

Results:

The conformer-selected UV spectra are measured for both cis- and trans-monomers (c- AIH^+ , t- AIH^+) by IR-UV hole burning spectroscopy. The structural analysis with help of quantum chemical calculations at B3LYP-D3/6-31G++(d,p) level show that c- AIH^+ has an intramolecular $\text{NH}^+\cdots\text{O}$ hydrogen bond (H-bond), while t- AIH^+ lacks such an interaction. Conformer-selected UV spectra of cis- and trans- AIH^+ homodimers are measured and three and two conformers are assigned, respectively. Their structures are analyzed by the comparison between conformer selected IR spectra and theoretical IR spectra. The obtained structures of cis- and trans-dimers are clearly different. The structural difference is rationalized by the presence and absence of the intramolecular H-bond in cis and trans monomer subunits.

Conclusions:

This work demonstrates that the combination of ESI cold ion trap mass spectrometry and laser spectroscopy is a powerful tool to study the structure of molecular aggregates and effect of chirality. The methods in this work will allow us to expand the size of molecular systems to biological supramolecular systems. In the presentation, the application to functional peptides and its complex with chiral ligands will also be shown [2].

Novel Aspect:

The approach developed in this work will provide us a deep understanding of the stereochemistry-based control of biological supramolecular system.

37 - DIRECT ENANTIOMER-SELECTIVE MASS SPECTROMETRY OF MULTI-COMPONENT CHIRAL MIXTURES

Maurice H.M. Janssen (1)

MassSpecpecD BV, R&D, Enschede (1)

Direct enantiomer-selective Mass Spectrometry of multi-component chiral mixtures

Maurice H. M. Janssen
MassSpecpecD BV, the Netherlands
www.massspecpecd.com

Keywords: chiral, enantiomeric excess, direct MS, photoionization, instrumentation

Introduction:

Mass spectrometry is chirally blind, it cannot directly distinguish the two enantiomers of chiral molecules. Simultaneous, enantiomer-specific identification of chiral molecules in multi-component mixtures is extremely challenging. Many established techniques for single-component analysis fail to provide selectivity in multi-component mixtures and lack sensitivity for dilute samples.

Methods:

Here we show how enantiomers may be differentiated by Mass-Selected PhotoElectron Circular Dichroism (MS-PECD) using an electron-ion coincidence imaging spectrometer [1-2]. Following an ionizing circular polarized laser pulse, ions and electrons are detected in coincidence on their respective time- and position sensitive detectors. The Mass-Selected PECD reveals that the compound is chiral.

Results:

As proof of concept, vapours containing ~1% of two chiral monoterpene molecules, limonene and camphor, are irradiated by a circularly polarized femtosecond laser, resulting in multiphoton near-threshold ionization with little molecular fragmentation. Large chiral asymmetries (2–4%) are observed in the mass-tagged photoelectron angular distributions. These Mass-Selected PECD asymmetries switch sign according to the handedness (R- or S-) of the enantiomer in the mixture and scale with enantiomeric excess of the chiral molecule [3-5].

Conclusions:

The results demonstrate that direct MS identification of mixtures of chiral molecules is possible using the ultra-sensitive and selective technique of laser-based MS-PECD.

Novel Aspect:

Direct quantitative determination of enantiomeric excess in chiral mixtures is achieved in a table-top instrument using MS-PECD. No prior chiral chromatography or enantiomer-selective clustering is needed.

1143 - CHIRAL DISCRIMINATION IN COLLISION-INDUCED DISSOCIATION EXPERIMENTS: A THEORETICAL APPROACH OF THE CYCLOPHE-HISH+ SYSTEM.

Ariel Pérez-Mellor (1) - Riccardo Spezia (1)

Laboratoire de Chimie Théorique, LCT, Sorbonne Université, CNRS, F. 75005 Paris, France (1)

Keywords: Collision-induced dissociation (CID), diketopiperazine (DKP), chiral discrimination, Born-Oppenheimer molecular dynamic (BOMD).

Introduction:

This theoretical study is inspired by the strong experimental differences observed in the breakdown curves of the collision-induced dissociation of the two diastereoisomers of the diketopiperazine peptide cycloSPhe-SHisH⁺ (SS) and cycloSPhe-RHisH⁺ (SR) (unpublished results). The major chiral discrimination is observed in the carbon monoxide and ammonia loss channels. For the former case, the fragmentation efficiency of the SR diastereomer is larger in contrast to what happens in the latter.

Methods:

A comprehensive picture of unimolecular dissociation is obtained by a Born-Oppenheimer molecular dynamic simulation. Internal energy activation through a micro-canonical ensemble and the RM1-D semi-empirical Hamiltonian has been used for this purpose. The method used showed good balance between accuracy and computational time. All the simulations were carried out coupling VENUS (for dynamics) and MOPAC (for electronic structure calculation) packages.

Results:

Within this level of theory, we are able to reproduce all the main fragmentation channels observed in the CID experiment starting from the geometry determined by infrared multiple photon dissociation spectroscopy. This geometry agrees with the calculated global minimum for both systems and shows that the proton lies in the histidine residue. The main fragmentation products are loss of ammonia, loss of water, loss of CO, loss of formamide or a combination of NH₃+CO (these two last products have the same mass), loss of carbamic acid or a combination of isocyanic acid + H₂O, loss of HCONH₂+CO or a combination of NH₃+2CO, the formation of the iminium ion of Phe and the formation of the iminium ion of His. The Histidine residue plays an important role. It consists in carrying the proton to highly energetic proton sites like oxygen and nitrogen atoms in DKP ring (following the proton mobile model). There is a strong difference in the mobility of the proton in the two diastereomers due to the chirality constraint. In the SS case, the proton mobility is lower in comparison to SR case due to the fact the two residues remain on the same side of the DKP ring interacting. Then, the SR system shows, overall, higher fragmentation yield than SS system in agreement with experiments. This is likely due to a lower activation energy.

Conclusions

The strong experimental differences observed in the CID experiments can be rationalized thanks to theoretical calculations which point out the role of the Histidine residue in the proton mobility which is related to differences between the two diastereoisomers.

Novel Aspect:

This chiral discrimination has been noticed before but a clear rationalization was not found. Calculations can help in understanding it from a molecular basis.

947 - A NEW MS-BASED HYPHENATED METHOD FOR ANALYSIS OF HEXURONIC ACID EPIMERS AND SULFATE PATTERNS IN GLYCOSAMINOGLYCAN OLIGOSACCHARIDES BY MSN COUPLED TO INFRARED ION SPECTROSCOPY

Gina Renois-Predelus (1) - Schindler Baptiste (1) - Barnes Loïc (1) - Chambert Stéphane (2) - Allouche Abdul-Rahman (1) - Compagnon Isabelle (1)

Institut Lumière Matière, Université Claude Bernard Lyon 1, Lyon (1) - Institut de Chimie et de Biochimie Moléculaires et Supramoléculaires, Université Claude Bernard Lyon 1, Lyon (2)

Keywords: Glycosaminoglycan, MS/IR, hexuronic acid epimers, structural characterization, sulfate patterns

Introduction:

We report an original MS-based hyphenated method for the elucidation of sulfate position and the epimerization of hexuronic acids in glycosaminoglycan (GAG) fragments.

Methods: Coupling of mass spectrometry with IRMPD spectroscopy

This method consists of measuring simultaneously the MS/MS spectrum and the gas phase IR spectrum to gain direct structural information. This is possible using a customized MS instrument, modified to allow injection of a tunable IR laser inside the instrument for in situ spectroscopy of trapped ions.

Results:

This approach was tested for the analysis of the hexuronic fragments composing the hyaluronic acid tetrasaccharide [1] and the sulfated GalNAc fragments present in the chondroitin sulfate disaccharides and dermatan sulfate tetrasaccharide [2].

Conclusions

We show that the gas phase IR fingerprint of reference hexuronic acid and sulfated GalNAc monosaccharides are distinct and can be used to detect them in oligosaccharides.

Novel Aspect:

The method presented here is predictive and allows structural elucidation of unknown GAG fragments, even in the absence of referenced standards.

Keywords: Binuclear Cu(II)-L-Histidine Complex, S/R-Naproxen, Chiral Differentiation, Ion-Mobility Spectrometry, DFT Molecular Dynamics Modeling

Introduction:

Naproxen is one of the most consumed nonsteroidal anti-inflammatory drugs and marketed as S-naproxen since its R-enantiomer is hepatotoxic [1]. Developments of efficient and reliable methods for chiral differentiation and quantification of naproxen are thus essential [2].

Methods:

Recognition and quantification of S/R-naproxen enantiomers with commonly used chiral selectors are studied using tandem mass spectrometry (MS/MS). Structures of the most promising diastereomeric precursors are revealed using collision-induced dissociation (CID), ion-mobility spectrometry (IMS), and density functional theory (DFT) and molecular dynamics (MD).

Results:

Among all studied diastereomeric complexes formed between S/R-naproxen and various chiral selectors [3], including $\alpha/\beta/\gamma$ -cyclodextrins, amino acids and their derivatives, glucose, tartaric acid, and vancomycin, a novel binuclear metal bound $[(M(His)_2(S/R\text{-naproxen})-3H)]^+$ complex (M = Cu, Ni, or Co with Cu being the best) can allow effective absolute configuration identification and enantiomeric excess determination for naproxen using MS/MS. The key candidate structure of $[(Cu(His)_2(S/R\text{-naproxen})-3H)]^+$ revealed from CID, IMS and DFT-MD, has an unusual self-assembled, compact geometry with the two Cu(II) ions bridged closely together by the carboxylate groups of the two histidines. The difference in dissociation efficiency of the two diastereomers is attributed to the σ - π interaction between the NH₂ group of one histidine and the naphthyl ring of naproxen in the complex.

Conclusions:

The present report observes and characterizes the diastereomeric complexes of $(Cu(His)_2)$ with aromatic acid, which could contribute to the recognition of chiral aromatic acids, design of catalysts based on binuclear copper-bound complex, as well as the better understanding of metal-ion complexation by His or His-containing ligands.

Novel Aspect:

A novel self-assembled, compact $[(Cu(His)_2(S/R\text{-naproxen})-3H)]^+$ complexes are used for efficient chiral differentiation of naproxen.

1124 - ENANTIOSELECTIVE REDUCTION FROM QUATERNARY COPPER D,L AMINO ACID COMPLEXES:
ORIGIN OF THE WEAK CHIRAL EFFECT OBSERVED WITH D/L ASPARTIC AND GLUTAMIC ACIDS

Jean-Claude Tabet (1)

jean-claude.tabet@upmc.fr (1)

Enantioselective reduction from quaternary copper d,l amino acid complexes:
origin of the weak chiral effect observed with D/L aspartic and glutamic acids

Jean-Claude Tabet

Keywords:

chirality, enantioselective reduction, CID, interpretation

Introduction: (399 characters)

Amino acid enantiomers (AAL/AAD) distinction was a challenge solve after the 2000s. A method proposed by G. Cooks (1) was based on (i) electrospray formation of quaternary $[2AA'L+AAL/D-H+Cu(II)]^+$ complex diastereomers (AAL' as reference, AAL/D, that of unknown chirality) and (ii) their comparative dissociations by CID. Applying this approach and using AA'L=phenylglycine, an enantioselective reduction accompanying expected chiral effects were observed (2).

Methods: (378 characters)

Each AA was dissolved with $CuCl_2$ in MeOH/H₂O (50:50) within 20 pmol.mL⁻¹. HD exchanges were performed. Experiments were done positive ESI with ion trap, and with LTQ/Orbitrap. Solutions were respectively infused at a flow rate of 160 mL/h and 100μL/h. Resonant excitation (CID) and non-resonant (HCD) were used. The source settings are as follows: capillary voltage, -3.5 kV; heat temperature, 100°C; The image signal was amplified and digitized using 1M data points.

Results: (858 characters)

Using the Cooks' approach (1), the phenylglycine (PhgL)(2) was used as chiral selector in the quaternary complexes. The main cleavage of $[2PhgL+AAL/D-H+CuII]^+$ involved the competitive formal Phg and $[Phg-H]^+$ losses yielding the $[CuII,(Phg,AAL/D-H)]^+$ and $[CuI,(PhgL,AAL/D)]^+$ ions, respectively. In fact, the $[Phg-H]^+$ loss is not direct and requires a stepwise pathway through the prompt CO₂ release concomitant with CuII reduction. This process was therefore at the origin of the observed enantiomeric reduction. Its extent depends on the one hand, the respective chirality of the partners of the quaternary complex, and on the other hand, the basicity and acidity in the gas phase of the amino acid of unknown configuration. Concerning the thermochemical correlation, singular points appear on the one hand, for very basic and very acidic amino acids (R, K, H) and on the other hand, for D and E which are weakly basic and strongly acidic. Indeed, they exhibit a strong degradation of the enantioselective reduction.

Conclusions (Limit of 399 characters)

The use of particular reference such as Phg allows to yield distinction of the chirality of AAL,D by two means either from chiral effects on the diastereomeric quaternary coppered complexe dissociations described by the Cooks works or by the observed enantioselective reduction. The lowering yields of the latter for certain AA, was explained either by the presence of zwitterion for R,H and K or by the particular reactivity of mobilizable proton on D and E in canonic form.

Novel Aspect: (148 characters)

AA configuration by enantioselective reduction by cleavage of quaternary complexes with Phg as reference can be explained by considering AA canonic/zwitterion structures

Magdalena Zimnicka (1)

Polish Academy of Sciences, Institute of Organic Chemistry, Warsaw, Poland (1)

Keywords: ion mobility mass spectrometry, peptides, acids, diastereoisomers

Introduction: The chiral molecules frequently remain undistinguishable using ion mobility mass spectrometry (IM-MS), due to insufficient difference of their collision cross sections at an available mobility resolution of ion mobility drift tubes. The influence of the complexation with organic acids on the ion mobility separation of selected peptide diastereoisomers was evaluated.

Methods: IM-MS measurements were performed on a commercially available (Waters) quadrupole traveling-wave ion mobility time-of-flight spectrometer (Synapt G2-S HDMS). The initial structures of noncovalent complexes obtained with Metropolis Monte Carlo simulations were further optimized at the DFT level of theory. The theoretical cross sections of the optimized associates were calculated using the trajectory method (TM) in the open source software program MOBCAL.

Results: Peptide diastereoisomers containing arginine residue form stable associates with various organic acids in the gas phase. These associates are also stable in conditions of increased pressure of the ion mobility drift cell. Overall the increase of the diastereoisomeric peptide separation after complexation with selected acids was observed. The structures, selectivity, specificity, and the overall effect of complexation with acids on ion-mobility separation of the analyzed diastereoisomers are discussed. Additional relative gas-phase stability experiments were performed to define the association mode between examined peptides and selected organic acids.

Conclusions

The increase of the diastereoisomeric peptide separation after complexation with selected acids was observed. The gas-phase stability studies revealed that the presence of the arginine in a peptide sequence ensures the formation of stable complex in the gas phase. The presence of the available backbone hydrogens in peptide sequence additionally increases the stability of the complexes in the case of diacids.

Novel Aspect: Complexation with the selective acids induces improvement of chiral separation of peptides.

360 - DISSOCIATION OF HYDROGEN-ABUNDANT PEPTIDE RADICAL FORMED BY HYDROGEN ATTACHMENT IN GAS PHASE

Keywords: Hydrogen atom, N-C α bond cleavage, fragmentation dynamics. Ab initio molecular dynamics

Introduction

The novel fragmentation technique involving the interaction between peptide ion and hydrogen atom in gas phase, named HAD, has been recently developed. HAD is initiated by hydrogen radical attachment to the peptide ion in the ion trap, and the fragment ions due to N-C α bond cleavage were selectively observed. The fragmentation process of HAD is not yet fully understood. In this study, the detail processes of HAD were investigated by ab initio calculation.

Methods

HAD experiments were performed using a prototype MALDI QIT-TOF mass spectrometer based on the design of AXIMA Resonance equipped H \bullet source. H \bullet was generated by passing H₂ gas through a heated tungsten capillary and introduced into the ion trap. The pressure inside the ion trap chamber was maintained below 5x10⁻² Pa during the reaction. The fragmentation pathway and dynamics were calculated by Gaussian 16 and Car-Parrinello molecular dynamics (CPMD) programs.

Results

To identify the most probable dissociation mechanism of HAD processes, the peptides, AcLys, AcArg, and AcArg-Ala were used as the models. The protonated model peptide was produced by MALDI with CHCA, and then reacted with H \bullet in ion trap. The HAD-MS₂ spectrum of [M+H]⁺ showed fragment ions due to N-C α bond cleavage. The N-C α bond cleavage was initiated by H \bullet association to carbonyl oxygen in protonated peptide. The TS barrier for the H \bullet attachment was in the range of 0.45-0.6 eV. Since the temperature of H \bullet introduced to ion trap was estimated to 2300 K, 10% of H \bullet in ion trap have the kinetic energy higher than 0.6 eV, which can react with protonated peptides, leading to aminoketyl radical intermediate. To investigate the detail mechanism of aminoketyl radical fragmentation, we performed the simulation based on CPMD. According to the result, the aminoketyl radical immediately underwent homolytic N-C α bond cleavage. The homolytic cleavage resulted in the donation of an electron from the N-C α bond to the nitrogen atom, producing an c' fragment and z \bullet radical.

Conclusions

The use of hot H \bullet efficiently react with protonated peptide in gas phase, inducing N-C α bond cleavage. The dissociation rate on N-C α bond was strongly influenced the temperature of aminoketyl radical. When the temperature was set to be > 500 K, the N-C α bond occurred within 1 ps. Because the heading of ion trap enhanced yield of fragmentation, the computational results were in good agreement with the HAD-MS₂ result of protonated peptides.

Novel Aspect

H \bullet attachment to peptide leads to aminoketyl radical, which immediately underwent homolytic bond cleavage at N-C α bond

240 - A QUANTUM CHEMICAL TOOL FOR THE PREDICTION OF MASS SPECTRA AND THE IDENTIFICATION OF FRAGMENTATION PATHWAYS

Julie Cautereels (1) - Frank Blockhuys (2)

/, University of Antwerp/Departement of Chemistry, Antwerp (1) - /, Univeristy of Antwerp/Department of Chemistry, Antwerp (2)

Keywords: Quantum Chemical Mass Spectrometry (QCMS2), Density Functional Theory (DFT), inter-side-chain (ISC) interactions, Tandem Mass Spectrometry, Tripeptides

Introduction

A new computational tool for the prediction of mass spectra based on quantum chemical calculations is being developed, called Quantum Chemical Mass Spectrometry for Materials Science (QCMS2). It was benchmarked by predicting the EI fragmentation pathways of a number of organics with a variety of functionalities. The main features in the mass spectra were correctly reproduced and new fragmentation routes proposed by QCMS2 were confirmed by MS/MS experiments [1].

Methods

QCMS2 is based on DFT/B3LYP/6-311+G* calculations and selects fragmentation pathways based on the relative values of bond order, reaction energies (for bond cleavages) and transition state energies (for rearrangements). Known peptide-specific fragmentation mechanisms such as the Mobile Proton Model (MPM) for His, confirmed by quantum chemical calculations, have been implemented into the method and the code omits the breaking of irrelevant bonds [2].

Results

QCMS2 is being applied to predict the fragmentation patterns of tripeptides in ESI CID MS/MS focusing on the influence of inter-side-chain (ISC) interactions on the initial protonation and subsequent fragmentation. The fragmentations of a number of non-cyclic tripeptides consisting of His as the central amino acid (AA) and AAs which allow the formation of strong hydrogen bonds as the peripheral ones, have been studied. Observations such as (1) the fact that the (dis)appearance of ISC interactions in the Lys-His-X (X = Asn, Asp, Gln, Glu and Ser) and Trp-His-X combinations determines the most stable protonation site of the tripeptide, and (2) the fact that in Arg-His-Ser and Asn-His-Ser ISC interactions lead to specific fragmentations, illustrate the importance of strong interactions between AA side chains. The results obtained from QCMS2 are compared to those obtained from conventional methods to demonstrate how many of the peaks not predicted by these latter methods are due to fragmentations involving the side chains and are predicted by QCMS2.

Conclusions

QCMS2 correctly reproduces the main features in the mass spectra of tripeptides, i.e., the traditional backbone cleavages resulting in α -, β 2 and γ 1-ions. Furthermore, due to its taking the fragmentation of the side chain and ISC interactions into account, it also predicts fragments resulting from these and, as a result, convincingly outperforms common tools such as PEAKS, PeptideArt and Prospector.

Novel Aspect

QCMS2 assigns up to twice the number of signals in peptide mass spectra assigned by common mass spectral assignment software, and generates detailed fragmentation routes.

carbon-centered radicals, glycyglycyltryptophan, gas-phase

Dissociation of ligated copper(II)–peptide complexes, $[\text{Cu}(\text{L})\text{M}]^{\bullet 2+}$ (L, ligand; M, peptide), generates peptide radical cations ($\text{M}^{\bullet +}$) through single electron transfer. [1] Diversity is introduced into the ion chemistry of a peptide radical cation through the possibility of the radical migrating in a number of different ways to corresponding prerequisite radical sites prior to fragmentation; some of these competitive reactions are charge- and radical carrier-specific, and can be perturbed upon varying the nature or location of the radical/charge site, the basicity of the residue at that site, or the peptide sequence, all of which can substantially impact the isomerization barriers for radical or charge mobility and the subsequent reactions. [2–5] The major impetus of this study was to use a simple prototypical system, $[\text{Cu}(\text{L})\text{Y}\text{G}\text{W}]^{\bullet 2+}$, to track the location of the radical and charge sites, starting from the copper(II)–peptide complex to the predetermined radical sites of the peptide radical cations after a complex permutation of intramolecular hydrogen atom migrations—potentially allowing us to determine whether or not the individual isomerization, rearrangement, or fragmentation pathways would predominate. A wide variety of site-specific radical peptides can be produced efficiently with judicious choice of the metal–ligand–peptide system; [1–2] we used isomeric π -centered $[\text{G}\text{G}\text{W}\pi]^{\bullet +}$ (formed directly through dissociation of $[\text{Cu}(\text{amine})\text{G}\text{G}\text{W}]^{\bullet 2+}$ complexes) and α -centered $[\text{G}^{\bullet}\text{G}\text{W}]^+$ (generated through side-chain cleavage of the tyrosyl residue of the $\text{Y}\text{G}\text{W}^{\bullet +}$ radical cation) species for our initial infrared multiple photon dissociation (IRMPD) investigations, in conjunction with density functional theory calculations. The IRMPD spectrum of $\text{G}^{\bullet}\text{G}\text{W}^+$ displays a strikingly different set of product ions than those obtained from $[\text{G}\text{G}\text{W}\pi]^{\bullet +}$. It appears that the two isomeric radical cationic GGW structures did not interconvert on the time scale of our IRMPD experiments. Such isomeric π - and α -centered radical cationic peptides comprise a well-defined prototypical system for dissecting the fundamental parameters that govern the isomerization and dissociation of peptide radical cations, which undergo various rearrangement processes, including hydrogen atom, proton, and electron transfer, in the absence of solvation.

Keywords: ESI-FT-ICR, Cobalamin, nitric oxide, ion-molecule reactions

Introduction: Cobalamines (Cbls) are important cofactors in various enzymatic processes. Many studies indicate that the reduced form of cobalamin, Cbl(II), reacts reversibly with NO to form a nitrosylcobalamin adduct at a high rate. This evidence is supported by the NO-induced inactivation of Cbl-dependent enzymes and the inhibition of NO actions by Cbl supplementation.[1-2] Here, the intrinsic features for NO_x (x=1,2) binding to bare Cbl ions are assessed by ESI FT-ICR MS.

Methods: Experiments were carried out with a Bruker BioApex 4.7 FT-ICR mass spectrometer coupled with an ESI source. The reduced Cbl(II) and oxidized Cbl(III) forms were formed by ESI of a 10 μM aqueous hydroxycobalamin solution at physiological pH, mass-selected and exposed to NO_x (x = 1, 2) in the ICR cell at stationary pressures of 1.0-10 × 10⁻⁸ mbar. Pseudo-first order rate constants divided by the neutral concentration afford second-order rate constants.[3]

Results: In order to improve the current understanding of NO_x (x = 1, 2) scavenging by Cbls, the kinetics and mechanistic behavior of several Cbl species, either in the reduced or oxidized and protonated/sodiated or deprotonated forms, have been explored in the gas phase, lacking any perturbation by solvent or counterions. Some relevant/preliminary evidences may be outlined: i) both sampled neutrals undergo an addition process; ii) for NO₂ binding, an overall higher yield is observed with either Cbl(II) or Cbl(III), by a factor of ca. 3 and 10, respectively. The efficiency values span from 4.0 to 18% for Cbl(III) and doubly deprotonated Cbl(III), the only form which undergoes a double addition, whereas (de)protonated and monosodiated Cbl(II) show similar values (~ 8%); iii) the reactivity with NO shows a clear bias for Cbl(II) species; iv) Cbl(III) species undergo also hydrogen atom abstraction by NO_x (x = 1, 2).

Conclusions: Gas phase ion-molecule reactions provide mechanistic information relevant to biological functions void of environmental effects. Here, the binding properties of nitrogen oxides to various forms of cobalamin have been addressed, involving either deprotonated "base-on" or protonated "base-off" species. This study confirms preferential NO ligation to Cbl(II) and outlines the influence of the coordination environment of the cobalt ion.

Novel Aspect: Direct determination of reaction patterns and thermal rate constants are provided for NO_x (x = 1, 2) binding to naked Cbl(II) and Cbl(III) ions in a solvent free environment.

Keywords: metallo-supramolecular aggregates, supramolecular chemistry, ESI, ECD, ETD

Introduction:

Are the metal centres in metallo-supramolecular aggregates electronically isolated from each other? Is there an information transfer via ligands or space? How redox-innocent are the ligands? Gaining knowledge on the redox behaviour of metallo-supramolecular aggregates in solution is highly desirable, but rather difficult due to the inherent lability of the system: It is hard to oxidise or reduce only the aggregate of interest – and not affect one of the other compounds of the (desired) manifold of species present in equilibrium. Herein, a means is presented to study the reduction of isolated supramolecular aggregates under well-defined conditions using mass-spectrometry.

Methods:

High-resolution electrospray ionisation (ESI) mass spectra were recorded on a Bruker Apex IV FT-ICR or a Thermo Fisher Scientific LTQ Orbitrap XL mass spectrometer. A series of multiply charged cations typically is observed for metallo-supramolecular aggregates due to abstraction of several anions during the ESI process. After mass-selection of the species of interest, one-electron reduction is performed in the gas phase using the electron capture dissociation (ECD) technique in the FT-ICR or the electron transfer dissociation (ETD) method in the ion trap module of the Orbitrap XL instrument. Reduction products of interest were again mass-selected and fragmented by collision-induced dissociation (CID) or subjected to a second one-electron reduction step.

Results:

During ETD and ECD, a single electron is attached to the metallo-supramolecular aggregate. The resulting reduced species is either characterised by high resolution tandem mass-spectrometry or can even be subjected to another reducing step (ECD/ECD) prior to analysis. The presented examples include the stepwise reduction of a copper(II) helicate revealing otherwise unaccessible mechanistic details of its interconversion to the respective copper(I) congener with different stoichiometry.[1] Single-electron reduction of homoleptic metallosupramolecular squares shows the non-innocence of bipyridine ligands [2] whereas a similar experiment with bimetallic squares [3] enables the differentiation between different reduction sites. The effect of linker length is illustrated by reduction of dinuclear gold macrocycles of various ring sizes.[4]

Conclusions

Both ECD and ETD can be used to generate highly interesting partly-reduced open-shell metallo-supramolecular aggregates. The stability and further reactivity of the reduced species in dependence of type of metal building blocks, bridging and blockings and aggregate size and charge are addressed.

Novel Aspect:

ECD and ETD typically are applied to characterize peptide samples whereas they are used to generate and further study the chemistry of highly unusual reduced metallo-supramolecular aggregates herein.

Keywords: Bond dissociation energy, RRKM modelling, CID, tandem mass spectrometry, gold chemistry

Introduction:

Homogenous gold catalysis is a powerful approach to access high diversity and complexity of molecules.[1] Besides the metal, ligands play a major role to control and orientate the reactivity.[2] Many theoretical works have aimed and succeeded to interpret the particular behavior of ligands in cationic gold complex.[3] In contrast, experimental approaches to evaluate these effects and validate these theoretical models are scarce and would be highly desirable.

Methods:

A collection of gold carbonyl complexes was studied using a modified triple-quadrupole equipped with an ESI source. L-Au-CO⁺ ions were directly formed in the source and submitted to Collision Induced Dissociation (CID) experiments. From survival yield (SY) breakdown curves, critical energy values were obtained using a kinetic model based on transition state theory (RRKM theory). Results were analyzed using DFT calculations and energy decomposition analysis (EDA).

Results:

Au(I) complexes were successfully formed in the ESI source for 16 L ligands: expected, the greater the capacity of L to enrich gold, the higher the dissociation energy of Au-CO. The SY for this dissociation were recorded for different collision energies during CID experiments. Due to the variety of size and masses of the complexes, a semi-empirical calibration had to be established in order to get an evaluation of the mean internal energies of the complexes prior to decomposition. From there, critical energies were obtained using kinetic modelling. The variety of electronic effects of the studied ligands is reflected by these values: a range of 10.5 kcal/mol is observed between the weakest and the strongest Au-CO bond, as confirmed by DFT calculations. To gain insights into the Au-CO bond nature, an energy decomposition analysis was also performed. The contributions of the orbital and electrostatic interactions and the Pauli repulsion to the bonding were considered. Results are rationalized by considering the influence of each of these terms.

Conclusions:

Bond dissociation energies of 16 gold-carbonyl complexes were obtained using mass spectrometry and kinetic modelling. Depending on the nature of the ligand, a more or less large difference in the BDEs could be observed. These data were assessed as new probes for evaluating ligand effects in gold catalysis. With the help of energy decomposition analysis, a rationalization of the various electronic effects observed for the studied ligands could be achieved.

Novel Aspect:

A new experimental approach, based on mass spectrometry experiments and kinetic modelling, is proposed to evaluate the ligands effects in gold(I) complexes.

549 - ENERGY-RESOLVED COLLISION-INDUCED DISSOCIATION STUDY OF PROTON-BOUND HETRODIMERS OF GUANINE AND CYTOSINE

Sang Yun Han (1) - Jeong Ju Park (1) - Choong Sik Lee (2)

Gachon University, Department of Nanochemistry, Seongnam (1) - Ministry of National Defense, Scientific Investigation Lab., Seoul (2)

Keywords: Proton-bound base pairs; Guanine; Cytosine; ER-CID; DFT

Introduction:

To study the effect of protonation on DNA base pairing, we investigated energy-resolved collision-induced dissociation (ER-CID) of proton-bound heterodimers of guanine (G), guanosine (Gn), cytosine (C), and 1-methylcytosine (1-MeC), and cytidine (Cn), which are likely to be formed by Hoogsteen pairing including an ionic hydrogen bond. The structures, energies, and proton transfer reactions of dimeric conformers were also investigated theoretically.

Methods:

The protonated dimers of $[G:C:H]^+$, $[G:1-MeC:H]^+$, and $[Gn:Cn:H]^+$ were produced by electrospray ionization in the acidified conditions, which were interrogated by ER-CID experiments using LTQ XL (Thermo Fisher) and Xevo TQ (Waters) for multiple and single collision conditions, respectively. For quantum chemical calculations, density functional theory (DFT) at the B3LYP/6-311+G(2d,p) level using Gaussian09 program suite was utilized.

Results:

Recently, an extensive theoretical study [1] and an IR multiple photon dissociation (IRMPD) spectroscopy [2] suggested that the Hoogsteen basepair, i.e. $CH^+ \cdots G$, be the dominant conformation for $[G:C:H]^+$ in the gas phase. Based on the previous investigations, we modelled the proton-bound heterodimers of $[G:C:H]^+$, $[G:1-MeC:H]^+$, and $[Gn:Cn:H]^+$ as Hoogsteen base pairs using DFT calculations. ER-CID behaviours of the protonated heterodimers were explored both in multiple and single collision conditions. It was found that dissociation of $[G:C:H]^+$ led to preferential formation of $C:H^+$, while simple consideration of the kinetic method [3,4] predicts preferential protonation on more proton-loving moiety, G. However, CID of the other basepairs of $[G:1-MeC:H]^+$ and $[Gn:Cn:H]^+$ occurred with favored protonation on more proton-loving moieties, yielding $1-MeC:H^+$ and $Gn:H^+$ as the dominant fragments, respectively.

Conclusions:

DFT and CID study suggested Hoogsteen structures for $[G:C:H]^+$, $[G:1-MeC:H]^+$, and $[Gn:Cn:H]^+$. By varying substituents, alternation of energetics in base-pairing, dissociation, and intermolecular proton transfer reactions were introduced and examined. While the three heterodimers have similar energetic relations, CID of $[G:C:H]^+$ showed a unique behavior, where certain dynamic reasons are likely to be deeply involved.

Novel Aspect:

ER-CID of gas-phase Hoogsteen base pairs occurring by protonation of bases was examined for the first time, and an intriguing dissociation of $[G:C:H]^+$ was revealed.

461 - CORRELATION BETWEEN STRUCTURE AND STABILITY OF GAS PHASE OLIGONUCLEOTIDES PROBED BY TUNED COLLISION- AND VUV-MS/MS

Stefanie Ickert (1) - Jens Riedel (2) - Sebastian Beck (3) - Michael W. Linscheid (3)

Humboldt Universität zu Berlin/Federal Institute for Materials Research and Testing, Humboldt Universität zu Berlin/Federal Institute for Materials Research and Testing, Berlin (1) - Federal Institute for Materials Research and Testing, Federal Institute for Materials Research and Testing, Berlin (2) - Humboldt Universität zu Berlin, Humboldt Universität zu Berlin, Berlin (3)

Keywords:

DNA, Locked Nucleic Acids, VUV dissociation/postionization, CID fragmentation, Ion Mobility

Introduction:

Various MS/MS methods are commonly used to create comprehensive information for bioanalytical applications. However, only little data is available on gas phase and fragmentation behavior of important molecules like double stranded DNA and related clinically relevant analogs. Previously, CID was predominantly used to characterize these kind of samples, leaving other techniques underused.[1]

Methods:

A LTQ Orbitrap XL was used to generate CID and HCD spectra of single and double strand DNA and DNA-LNA hybrids. The Synapt G2-S was used for collisional cross section assessment. As an additional MS/MS method a continuous vacuum ultraviolet lamp with transmission maxima at 125 and 160 nm was used. This approach provided efficient fragmentation along atypical, orthogonal pathways in both ionization modes and sensitivity increase by postionization of neutral losses.

Results:

DNA folding in the gas phase is strongly dependent on the charge level. With the use of IMS and CID data, for this unfolding a clear correlation between the energetic dissociation onset and the reorganization could be determined.[1,2] LNA, as a more rigid structure in comparison to DNA, indicated a complete different behavior concerning unfolding and fragmentation pathways. This was not only found for single strand nucleic acids, but also for the respective DNA-DNA and DNA-LNA duplexes. While DNA dissociates along energy specific pathways, LNA was found to require higher energy for fragmentation and follow less specific dissociation channels.

Additionally, VUV fragmentation was tested for positive and negative ionization. [3] For multiply charged oligonucleotides and proteins a charge reduction following electron ejection followed by dissociation was found. Samples of other categories showed fragmentation into common and atypical fragments. Moreover, for some systems, a strong partition of radiation induced postionization was observed.

Conclusions

Double and single strands of DNA and LNA were selectively fragmented. While DNA showed clear pathways including reorganization, the rigidity of LNA caused multiple dissociation channels and different folding patterns. VUV as a new MS/MS method produced charge reduction of multiple charged ions as well as new fragment classes. Also an increase of intensity was observed by postionization of fragment ions.

Novel Aspect:

A comprehensive study of DNA and LNA concerning gas phase organization and dissociation in MS and IMS was achieved. VUV was introduced as a new MS/MS method.

457 - MEASUREMENT OF PROTONATED WATER CLUSTERS USING HIGH KINETIC ENERGY ION MOBILITY SPECTROMETRY (HIKE-IMS)

Ansgar T. Kirk (1) - Maria Allers (1) - Stefan Zimmermann (1)

Leibniz Universität Hannover, Department of Sensors and Measurement Technology, Hannover (1)

Keywords: protonated water cluster, hydronium ion, cluster distribution, ion mobility spectrometry

Introduction

Protonated water clusters $(\text{H}_2\text{O})_n\text{H}^+$ play an important role during many ionization processes, including atmospheric pressure chemical ionization (APCI), and in particular proton transfer reaction (PTR). The cluster size n influences ionization by changes in proton affinity and ion mobility. This is a major issue when calculating concentrations in PTR-MS [1, 2]. Furthermore, transfer into vacuum changes the water cluster distributions, rendering them unknown.

Methods

High Kinetic Energy Ion Mobility Spectrometry (HiKE-IMS) ionizes in a reaction tube operated at reduced pressures (20 mbar) and high reduced field strengths (up to 130 Td) [3], similar to PTR-MS. However, instead of a mass spectrometer, an ion mobility spectrometer operated at the same pressure as the reaction tube is used for ion separation and detection. This allows analyzing the ions under the ionization conditions with an ion mobility resolving power of $R_p=140$ [4].

Results

When monitoring the ion mobility spectrum while sweeping the reduced field strength in both the reaction and the drift region, a shift of the protonated water cluster peak position can be observed at the energies where a change in most prevalent cluster size is expected (30 Td, 60 Td, 90 Td). Significantly below each of these thresholds, a Gaussian peak was measured at the expected mobility of the respective larger water cluster. Near the threshold, the peak starts broadening and a changing ion distribution between the positions of the respective larger and smaller water cluster can be observed. Significantly above each threshold, again a Gaussian peak was observed, this time at the position of the smaller water cluster.

Conclusions

Using HiKE-IMS allows analyzing protonated water clusters under the conditions inside the ionization source. This way, both the prevalent cluster size and the ion mobility can be determined as for example needed for correct concentration calculation in PTR-MS.

Novel Aspect

For the first time, protonated water cluster distributions and ion mobilities have been directly measured under the conditions present during ionization.

Keywords: ion molecular kinetic, soft chemical ionization, glyoxal, SIFT-MS

Introduction:

Glyoxal (m.w. 58 g/mol) is a highly reactive molecule associated with some basic biological processes [1], photocatalysis of CO₂ into CH₄ on TiO₂ or photo-dissociation of anthropogenic and biogenic volatile organic compounds (VOC) [3]. Presence of glyoxal can be monitored using soft chemical ionization mass spectrometry (SCI-MS). Here we discuss the ion chemistry of glyoxal interacting with H₃O⁺, NO⁺ and O₂^{•+} reagent ions used in SCI-MS and possibility of detection.

Methods:

Selected ion flow tube mass spectrometry, SIFT-MS[4], was used to investigate ion-molecule reactions of H₃O⁺, NO⁺ and O₂^{•+} reagent ions with glyoxal at variable humidity. The ion chemistry under thermal conditions is theoretically described using B3LYP/6-311(p,d) calculations and using numerical modelling of the ion-molecule reaction kinetics.

Results:

NO⁺ reactions lead to formation of C₂H₂O₂(NO)⁺ and C₂H₂O₂^{•+} ions, in the humid environment the association reaction is dominant. Charge transfer was observed for O₂^{•+} reactions as well. Additional dissociation observed previously for O₂^{•+} reagent ion was not confirmed [5-6]. The H₃O⁺ reaction proceeds at dry conditions via proton transfer reaction forming C₂H₃O₂⁺. With increasing concentration of water molecules, formation of m/z 31 (CH₂OH⁺) is becoming dominant. Corresponding hydrated ions were observed as well. Using quantum chemistry calculations, we estimated PA(C₂H₂O₂) = 165.1 kcal/mol and characterised the energetics of reaction pathways forming CH₂OH⁺. Reaction kinetics modelling indicates formation of a stable intermediate C₂H₃O₂⁺.H₂O which dissociates to protonated formaldehyde CH₂OH⁺ after interaction with water.

Conclusions:

According to theory, protonated formaldehyde is formed from C₂H₃O₂⁺.H₂O by reaction with water resulting into CH₂OH⁺ + HCOOH + H₂O products or by a formation of excited C₂H₃O₂⁺.H₂O* after two body association which dissociates to CH₂OH⁺ directly. Finally, protonated formaldehyde hydrate is not the terminating ion at high humidities. Thus, we expect a catalytic effect of CH₂OH⁺.H₂O forming a proton bound water dimer as CH₂OH⁺.H₂O + H₂O → CH₂O + H₃O⁺.H₂O.

Novel Aspect:

Understanding of ion chemistry of glyoxal is important for its analysis in gas phase using SCI-MS techniques and its distinguishing from isobaric compounds.

108 - REACTION DYNAMICS OF IONIZED 1-METHYLPYRENE: WHY IS THE 1-METHYLENEPYRENE ION FORMED FROM H ATOM LOSS AND NOT A TROPYLIUM-CONTAINING ION?

Paul Mayer (1) - Brandi West (1) - Bethany Lowe (1)

University of Ottawa, University of Ottawa/Dept. of Chemistry and Biomolecular Sciences, Ottawa (1)

Keywords: polycyclic aromatic hydrocarbon ions, astrochemistry, iPEPICO, collision-induced dissociation

Introduction:

The chemical origins of the Diffuse Interstellar Bands have remained elusive. Polycyclic aromatic hydrocarbons, PAHs have been postulated to be sources of DIBs due to the similarity between the IR emissions of the cations of PAHs and the DIBs. One molecule that has been investigated for its potential role as a DIB source is 1-methylpyrene. Previous work has suggested that, unlike toluene ions, ionized methylpyrene dissociate by H loss from the methyl group [1-5]. This study aims to find out why.

Methods:

iPEPICO experiments were conducted on the VUV beamline at the Swiss Light Source (Paul Scherrer Institut, Villigen, Switzerland). The mass-selected TPES was acquired to establish the IE. RRKM theory was used to determine the 0 K activation energies (E_0) and entropies of activation ($\Delta^\ddagger S_{1000K}$) by modeling the experimental breakdown diagrams. Reaction pathways were calculated at the UCCSD/6-31G(d)//B3-LYP/6-31G(d) level of theory.

Results: (Limit 900 characters)

The energetics derived from modelling ($E_0 = 2.84 \pm 0.36$ eV) is the first experimental value reported for the dehydrogenation of ionized 1-methylpyrene. The loss of H could form either 1-methylenepyrene (A) or a tropylium-motif containing ion (B). The transition state of highest energy in the pathway to B lies ~ 3.20 eV, while that for A is only 2.54 eV, favoring simple H loss from the methyl group, in contrast to that observed for ionized toluene (2.12 eV compared to 2.17 eV [6]). The reason for this flip in relative energies for the two precursors is evident when the geometries for the key TS are compared. In the case of ionized toluene, the TS has equivalent bond angles consistent with a planar 7-membered ring (128.7°). The presence of the three additional rings in 1-methylpyrene prevents the ring from expanding, with the most constrained angle being $\angle 123$ with a value of 125.0° . The presence of geometric constraints prevents the ion from accessing routes of molecular relaxation which would lower the transition state energy.

Conclusions (Limit of 400 characters)

The derived energetics, combined with computationally determined reaction coordinates, allowed for the determination that the dehydrogenation product of 1-methylpyrene cations is the 1-methylenepyrene cation. The tropylium-motif containing fragment ion requires significantly more energy to be formed due to steric hindrance in key transition states caused by the constraints imposed by the three benzene rings. The $\Delta_f H_0$ (1-methylenepyrene cation) was derived to be 945 ± 31 kJ mol⁻¹.

Novel Aspect: (Limit of 150 characters)

The preferential formation of 1-methylenepyrene fragment ions is explained by calculations of the key transition states in the reaction pathway.

1245 - PROGRESS TOWARDS ENZYME-LIKE SPECIFICITY IN PROTEIN FRAGMENTATION

Scott A. McLuckey (1) - David J. Foreman (1)

Department of Chemistry, Purdue University, West Lafayette, IN, USA 47907-2084 (1)

Keywords: top-down protein characterization, selective fragmentation, ion/ion reactions, aspartic acid effect, ornithine effect, dehydroalanine effect

Introduction:

Strategies for top-down tandem mass spectrometry of protein ions have generally sought to maximize the number of structurally diagnostic product ions. We are interested in developing complementary approaches that tend to lead to a limited number of relatively abundant cleavages that arise from specific/predictable locations.

Methods:

Experiments were conducted using a quadrupole/time-of-flight tandem mass spectrometer (Sciex 5600) that has been modified to conduct ion/ion reaction experiments. Protein precursor ions were subjected to ion/ion proton transfer reactions to bring them into a mass-to-charge region in which aspartic acid and proline cleavages are favored upon ion trap CID.

Results:

Three strategies that provide enzyme-like specificity in protein ion fragmentation are described. These include taking advantage of the known tendencies for cleavages at aspartic acid and proline residues, as well as taking advantage of the ornithine and dehydroalanine effects. We describe an approach that concentrates precursor ion charge states derived from ESI under denaturing conditions into a single charge state via ion parking, ion isolation, proton transfer ion/ion reactions to generate precursor ions within a charge state range where aspartic acid and proline cleavages are most prominent, and use of a broad-band collisional activation technique to fragment all of the charge states simultaneously. This approach is demonstrated using four standard proteins commonly used to test/demonstrate top-down protein characterization approaches. The other two approaches rely on converting existing residues into either ornithine or dehydroalanine. These residues also give rise to highly favored cleavages.

Conclusions:

The ultimate goal is to develop a suite of strategies that provides the analyst with options for multiple selective approaches for deconstructing mass-selected protein ions as complementary approaches to the standard means for maximizing cleavage in non-specific fashion. The present work demonstrates approaches that are selective for aspartic acid residues, proline residues, arginine residues, and several other residues that can be used to generate dehydroalanine.

Novel Aspect:

Novel approaches are described that favor selective cleavages at a variety of residue types in protein ions.

306 - WALK-ON-SPHERE REARRANGEMENT AND RETRO-BINGEL REACTION OF GAS-PHASE FULLERENE MALONATE IONS

Johannes Oschwald (1) - Martin B. Minameyer (1) - Katerina L. Maxouti (1) - Andreas Hirsch (1) - Thomas Drewello (1)

Friedrich-Alexander-Universität Erlangen-Nürnberg, Department Chemie und Pharmazie, Erlangen (1)

Keywords: APCI, organic fullerene derivatives, retro-Bingel, fragmentation mechanism

Introduction:

C60LX (L=C(COOEt)₂; x=4-6) are investigated by APCI with a QIT- and a QTOF-MS to study their chemical stability as radical ions in the gas phase. For uncharged (neutral) fullerene adducts, the positions of the cyclopropane rings on the C60 surface are highly stable. In contrast, under electrochemically reducing conditions in solution an isomerization of the molecules via a walk-on-sphere rearrangement is observed.[1]

Methods:

APCI experiments were performed with a QIT- and a QTOF-MS. The samples were synthesized by a published procedure.[2] C60L6 and C60L5 are isomerically pure (determined by ¹³C NMR). C60L6 has an octahedral addition pattern with TH symmetry. C60L5 has a quadratic pyramidal addition pattern with C_{2v} symmetry. C60L4 consists of a mix of isomers with varying symmetries.

Results:

For all examined fullerene adducts, radical anion (C60LX^{•-}) and radical cation (C60LX^{•+}) formation is observed applying APCI. Fragmentation experiments with a QIT-MS show the repeated loss of L₂ as the main fragmentation pathway for C60LX^{•-} and C60LX^{•+} (x=4-6).[3] Energy-dependent fragmentation experiments using a QTOF-MS show a decreasing energy-demand for the fragmentation when the number of cyclopropane moieties increases. Furthermore, dissociation of radical anions is less energy demanding than of radical cations, this observation is in agreement with experiments by Kessinger et al. which show isomerization of C60L2 in solution under electrochemically reducing conditions by a walk-on-sphere rearrangement.[1]

Conclusions:

Both C60LX^{•-} and C60LX^{•+} (x=4-6) show a very selective fragmentation with the loss of L₂. This fragmentation can only occur when two diethyl ligands "walk" on the surface towards each other. The walk-on-sphere rearrangement is followed by the formation of a malonate dimer (L₂) which is then released from the fullerene.

Novel Aspect:

The charge-induced isomerization of C60LX (L=C(COOEt)₂; x=4-6) has been demonstrated unequivocally by observation of the loss of a malonate dimer (L₂).

Keywords: Platform molecules, Biomass, 5-HMF, proton affinity, gas phase ion chemistry

Introduction: 5-hydroxymethyl-2-furaldehyde (5-HMF) is produced in high yields from the acid catalyzed dehydration of carbohydrates. This reaction represents the key process of the cellulosic biomass conversion into furan-type platform chemicals.[1] Recently, we have employed mass spectrometric techniques to investigate the acid-catalyzed D-glucose and D-fructose dehydration highlighting the formation in the gas-phase of a protonated 5-HMF isomeric mixed population[2-3].

Methods: Full scan and MS_n mass spectra were acquired using a Bruker AmaZon SL ion trap (IT) and a Waters Ultima Q-TOF operating in the positive ion mode. Proton affinity (PA) and gas-phase basicity (GB) of 5-HMF were obtained by using the Wesdemiotis and Fenselau Cooks's "extended" kinetic method. The PA and GB values as well as the geometries of protonated isomeric structures were fully optimized in the gas-phase at the B3LYP/6-311++G** level of theory.

Results: In order to clarify the stability and structures of protonated 5-HMF isomers, the geometries of six different protomers were optimized at the B3LYP/6-311++G** level of theory and the energetics of their dissociation compared with the experimentally observed mass spectrometric fragmentation. Moreover, the unknown PA and GB of 5-HMF were measured by the extended Cooks's kinetic method along with theoretical calculations. The experimental PA value of 207.2 ± 3 kcal mol⁻¹ is in excellent agreement with the value of 207.5 kcal mol⁻¹ computed at the B3LYP/6-311++G** level of theory. The whole picture emerging from experimental and theoretical results allowed to attribute the structures of different protonated 5-HMF isomers to the m/z 127 ions generated by the acid catalyzed decomposition of hexose carbohydrates in the gas phase.

Conclusions

The unknown proton affinity and gas phase basicity of 5-HMF were determined by the joint application of Cook's kinetic method and quantum mechanical calculations. Theoretical calculations identify the oxygen atom of the aldehydic group as the most basic site. The formation of less stable protonated 5-HMF isomers as final product of the acid catalyzed decomposition of D-fructose and D-glucose was demonstrated on the basis of energetic considerations.

Novel Aspect: In this work the unexplored gas-phase ion chemistry of protonated 5-HMF, one of the top ten bio-based platform chemicals, was firstly investigated.

Keywords: fructose dehydration, Biomass, 5-HMF, gas phase ion chemistry, computational methods

Introduction: Understanding on a molecular level, the dehydration mechanism of sugar monomers from hemicellulose and cellulose, (e.g xylose, glucose, fructose) the main constituents of lignocellulosic biomass, to platform molecules such as 5-hydroxymethyl 2-furaldehyde (5- HMF) and 2-furaldehyde (2- FA), can offer the possibility of increasing selectivity and reaction yields in solution for the exploitation of this sustainable source.

Methods: A joined approach based on mass spectrometric techniques (Electrospray Triple Quadrupole Mass Spectrometry (ESI-TQ/MS) and Electrospray Ion Trap Mass Spectrometry (ESI-QIT/MS)) together with theoretical calculations at the B3LYP/6-31 + G(d,p) level of theory was used for the study of the gas phase selective conversion of protonated D-fructose to 5-HMF and to 2-FA

Results: Our mass spectrometric approach for the gas phase study of acid catalyzed dehydration of xylose, fructose and glucose [1-3] allowed us to structurally characterize reaction intermediates and final products and unequivocally ascertain reaction sequences. Molecular level evidences provided by our mass spectrometric approach highlighted a gas phase pathway for the selective conversion of fructose to 5-HMF through a nitrogen assisted dehydration process.

Conclusions .

Based on mass spectrometric evidences, theoretical calculations allowed a gas-phase mechanism for the selective conversion of protonated D-fructose to 5-HMF and 2-FA assisted by nitrogen-base, to be proposed.

Novel Aspect: In this work the gas phase selective fructose dehydration to 5-HMF and 2 FA assisted by nitrogen bases was firstly investigated.

Keywords: ion-molecule reactions, gas-phase chemistry, sulfur dioxide, carbon dioxide, intra-cluster reaction

Introduction:

Carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}) species are reactive inorganic components of the fine particulate matter (PM) implicated in several environmental and human health issues. Sulfate aerosols usually arise from the atmospheric oxidation of SO_2 , contributing to acid rain and climate change. [1] In this study the reactivity of $[(\text{Na}_2\text{CO}_3)_n\text{NaCO}_3]^-$ cluster ions ($n \geq 1$) was probed towards SO_2 and $^{13}\text{CO}_2$, as a model of processes occurring at the liquid/gas phase interface.

Methods:

The experiments were performed on a LTQ XL linear ion trap (Thermo Fisher Scientific) equipped with an electrospray ionization (ESI) source in negative ion mode. The instrument was in-house modified [2] to allow the introduction of neutral reagent gases (SO_2 , $^{13}\text{CO}_2$) into the ion trap and measure the kinetic rate constants of the observed ion-molecule reactions. $[(\text{Na}_2\text{CO}_3)_n\text{NaCO}_3]^-$ cluster ions were generated by spraying a 10^{-3} M solution of Na_2CO_3 in $\text{H}_2\text{O}/\text{CH}_3\text{CN}$ 1:3.

Results:

Cluster ions with the general formula $[(\text{Na}_2\text{CO}_3)_n\text{NaCO}_3]^-$ were observed in the gas-phase with $n \geq 1$. In the presence of SO_2 these carbonate species were quantitatively converted into the corresponding sulfite cluster ions $[(\text{Na}_2\text{SO}_3)_n\text{NaSO}_3]^-$ through a sequential replacement of each CO_2 moiety with a SO_2 molecule. The $\text{SO}_2 \rightarrow \text{CO}_2$ conversion may occur through the direct transfer of O_2^- from CO_3^{2-} to a SO_2 molecule, as reported in a previous study identifying the reactions of SO_2 at the surface of a molten carbonate eutectic. [3] The rate constants related to the SO_2 adsorption and CO_2 release were measured by monitoring the signal of the selected carbonate cluster ion as a function of SO_2 concentration. The obtained values were investigated on the basis of n . All the reactions are very fast and efficient. The same experiments were performed also in the presence of $^{13}\text{CO}_2$. As in the case of SO_2 , $^{13}\text{CO}_2$ is incorporated into the cluster ion structures by replacing CO_2 and leading to $[(\text{Na}_2^{13}\text{CO}_3)_n\text{Na}^{13}\text{CO}_3]^-$ ions with rate constants lower than those obtained for SO_2 .

Conclusions:

SO_2 molecules were converted into gaseous CO_2 via the reaction of carbonate cluster ions and the consequent formation of sulfite cluster species. Although varying the number n of (Na_2CO_3) moiety of the reactant ion, CO_2 is always efficiently replaced and SO_2 entrapped. The same reactions were observed also in the presence of labeled $^{13}\text{CO}_2$, but showing rate constants lower than those measured for SO_2 .

Novel Aspect:

A liquid/gas phase model has been reported to describe the processes involved in the maintenance of the atmospheric SO_2/CO_2 balance or in the SO_2 removal from flue gases.

354 - DEVELOPMENT OF TUNER INTEGRATED MICROWAVE DRIVEN RADICAL BEAM SOURCES FOR RADICAL INDUCED DISSOCIATION MOLECULAR STRUCTURAL ANALYSIS

Yuji Shimabukuro (1) - Hidenori Takahashi (2) - Shinichi Iwamoto (2) - Koichi Tanaka (2) - Motoi Wada (1)

Plasma Physics Laboratory, Doshisha University, Kyotanabe (1) - Koichi Tanaka Mass Spectrometry Research Laboratory, Shimadzu Corporation, Kyoto (2)

Keywords: Microwave Plasma, Radical Induced Dissociation, Tandem Mass Spectrometer, Post Translational Modification, Phospholipid

Introduction:

We have been developing a new mass analysis system by coupling a tandem mass spectrometer to a radical beam source. This research is an extension of our previous work: Hydrogen Attachment/Abstraction Dissociation (HAD) for peptide fragmentation[1]. A wide variety of radicals produced in the microwave plasma is introduced to a QIT confining peptide and phospholipid ions to investigate the possibilities of the gas phase reactions for biomolecular analyses.

Methods:

Two types of tuner integrated microwave driven radical sources (CCP [2] and ECR-ICP) have been developed to produce electrically neutral species from any reactive gases such as oxygen or water vapor. These radical sources directly deliver radical beams to a QIT chamber of MALDI QIT-TOF mass spectrometer to investigate the reaction between trapped analyte ions and injected species. In this report, substance P and phospholipids were used as analyte ions.

Results:

Both radical sources can commence hydrogen, nitrogen, oxygen, methane, and water discharges. The CCP source forms the plasma plume which realizes high transport efficiency under a higher gas pressure and high input power condition. Meanwhile the ICP source can ignite and sustain the discharge at a lower pressure and lower input power. The OES results of hydrogen ICP exhibits the high degree of dissociation: prominent atomic lines with faint molecular band spectra. The HAD reaction rates for substance P with hydrogen radicals generated by three types of radical sources are investigated to evaluate the radical source performance. Hydrogen radicals formed in the pure hydrogen and water vapor discharge of CCP source can realize the HAD cleavage similar to the one obtained by a thermal cracking source, while the ICP source did not cleave the precursor ions. On the other hand, when the target ions are phospholipids, the injection of reactive species from the water vapor discharge from both CCP and ICP can realize the double-bond specific fragmentations.

Conclusions:

Attachment pattern for QIT confined C60 ions are found different among thermal cracking, CCP and ICP sources. A series of experiments has shown that the CCP source produces a plasma of a higher effective temperature appropriate for peptide analysis that requires higher reaction energy. Meanwhile the ICP source that generates lower effective temperature plasma enables phospholipids analysis with the low energy radicals for double bond specific fragmentation.

Novel Aspect:

The versatile radical sources which have wide range of energy will open new approaches of radical attachment/abduction mass spectrometry.

727 - CONTROLLED REACTIONS OF METHYL CATION WITH OXYGEN COMPOUNDS AND HYDROCARBONS

Roland Thissen (1) - Claire Romanzin (2) - Christian Alcaraz (3)

Laboratoire Chimie Physique, Université Paris Saclay, Orsay (1) - Laboratoire Chimie Physique, Université Paris Saclay, Orsay (2) - Laboratoire Chimie Physique, Université Paris Saclay, Orsay (3)

Keywords:

Ion-molecule reaction, Photoionization, Planetary science, Absolute cross section, Physical Chemistry

Introduction:

The methyl carbocation is a reactive species whose presence has been detected in gaseous environments fed by high energy sources, such as the interstellar medium, planetary ionospheres and laboratory plasmas. Its reactivity is described only in its ground state while excited species are present and might affect the chemistry. Our established method of photoionization allows to study and quantify effects of internal and collision energy on reactivity.

Methods:

The CERISES setup (a Quad-Oct-Quad guided ion-beam experiment) allows studying the effects of internal energy (vibrational, electronic) on the reactivity of cations with neutral gaseous species. Ions with controlled degree of internal excitation are produced by photoionization at the DESIRS beamline of the SOLEIL synchrotron [2,3]. After mass selection, reaction occurs in calibrated pressure of target and products are then analysed in mass and counted.

Results:

The $\text{CH}_3\cdot$ radicals are formed by pyrolysis in a molecular beam of the nitromethane (CH_3NO_2) precursor molecule [1]. The CH_3^+ ion is produced via direct photoionization of the $\text{CH}_3\cdot$ radicals. This allows to define the average internal energy of the ion. Hence, we have studied the spectroscopy of the cation in order to derive the effective internal energy of the cation at all available photon energies (from 9.8 to 15.5 eV). In a second step, the reactivity of CH_3^+ with (i) formic acid HC(O)OH (ii) methanol CH_3OH , and (iii) 10 hydrocarbon molecules (ranging from C1 to C4 with isomers and different levels of unsaturation) has been studied. When necessary, isotopomers were used to clarify reaction channels. Branching ratios and absolute reaction cross-sections for each system and channel are obtained and the dependence on the vibrational and electronic excitation as well as kinetic energy (0-20 eV, lab) of the parent ion are described. Absolute reaction cross sections are obtained for all the systems allowing to derive a coherent image of the reaction dynamics.

Conclusions:

Strong effects of internal energy (vibrational as well as electronic) are observed in all the considered systems. New reaction channels appear and branching ratios are perturbed, allowing an improved description of the actual chemistry that occurs in terrestrial or astrophysical plasma. Results are analyzed for each system in terms of partition between charge transfer, dissociative charge transfer, and new bond formation.

Novel Aspect:

Access to direct photoionization of radicals, species which are important and difficult to handle, to probe effects of internal energy in ion molecule reactivity.

Keywords: Polyvanadate doubly-charged anions, sulfur dioxide, bond-forming reactions, hydrolysis, cooperative effects

Introduction:

Vanadium oxides are mostly used as catalysts in many oxidation reactions such as of SO₂ to SO₃, whereas hydrated vanadium oxides have potential application in Li-ion batteries [1, 2]. Following our interest in the chemistry of SO₂, we recently reported an unprecedented bond-forming and hydrolysis reactions of doubly-charged vanadium oxide and hydroxide cluster anions promoted by SO₂, leading to singly-charged ions, as a result of a charge separation process [3, 4].

Methods:

The reactions have been studied in the gas phase at room temperature by an in-house modified linear quadrupole ion trap mass spectrometer. NaV₃O₉²⁻ and H₂NaV₃O₁₀²⁻-dianions, prepared by electrospray ionization (ESI) of NaVO₃ aqueous solutions, were reacted in the gas-phase with SO₂. The rate constant, branching ratio and the efficiency of the reactions have been measured.

Results:

NaV₃O₉²⁻ reacts with sulfur dioxide giving a first stable association product [NaV₃O₉·SO₂]²⁻, that further reacts with a second molecule of SO₂ forming two singly charged products, NaV₂O₆·SO₂⁻ and VO₃SO₂⁻. The reaction involves formation of new V-O and S-O bonds, by breaking a V-O bond containing a bridging oxygen atom. By contrast, H₂NaV₃O₁₀²⁻, the hydrated form of NaV₃O₉²⁻, reacts with only one SO₂ also giving the hydrolysis products HOSO₂⁻ and HNaV₃O₉ in addition to those arising from the bond-forming process, H₂VO₄⁻ and NaV₂O₆·SO₂⁻. Both reactions proceed through the formation of long-lived intermediates, where the bonding to the neutral SO₂ is favoured with respect to the charge separation, that would arise from an electron transfer to SO₂. Instead, the charge separation is the consequence of a chemical reaction leading to the formation of two singly charged products. A common feature is the crucial role played by sulfur dioxide in promoting charge separation processes.

Conclusions:

The sequential addition of two molecules of sulfur dioxide to thermal doubly-charged vanadium oxide anions, NaV₃O₉²⁻, results in the breaking of the stable V₃O₉ core, whereas in the case of the hydroxide H₂NaV₃O₁₀²⁻ anions one SO₂ molecule is sufficient to promote also hydrolysis. These fast and efficient reactions are associated with charge separation processes that result in two singly charged ions by formation of new V-O and S-O bonds.

Novel Aspect:

Cooperativity of two SO₂ or SO₂/H₂O molecules in the bonding to polyvanadate dianions has proved fundamental in addressing bond-forming or hydrolysis reactions.

681 - GAS-PHASE FRAGMENTATION MECHANISMS STUDIES OF DOUBLY-PROTONATED PEPTIDE IONS CONTAINING BASIC AMINO ACID RESIDUES BY MASS SPECTROMETRY

Talat Yalcin (1) - Ahmet Emin Atik (2)

IzTech., Chemistry, Urla-Izmir (1) - Turgut Pharmaceuticals, Turgut Pharmaceuticals, Istanbul (2)

Gas-Phase Fragmentation Mechanisms Studies of Doubly-Protonated Peptide Ions Containing Basic Amino Acid Residues by Mass Spectrometry

A.E. Atik¹ and T. Yalcin²

1.Turgut Pharmaceuticals, Istanbul, Turkey

2. Izmir Institute of Technology, Dept. of Chem., Urla, Izmir, Turkey

Keywords: Basic Amino Acid Residues, Doubly-Protonated Peptide Ions, Gas Phase, Peptide Fragmentation

Introduction:

In recent years, many studies have been carried out for the gas-phase reaction mechanisms of the protonated peptides using mass spectrometry and many of these studies are related with singly- protonated peptides (1). However, there are a few studies related to multiply- protonated peptides in the literature (2,3). Most of these studies are not systematic studies, therefore they are not sufficient enough to better understand the gas-phase reaction mechanisms of peptides. Multiply-protonated peptides can be generated in ESI-MS studies if the peptides contain a basic amino acid residues.

In order to determine the amino acid sequence of the peptides correctly and reliable, the gas-phase reaction mechanism of peptides should be studied and understood very well. Multiply-protonated peptides can be easily formed if the peptide sequence consists of basic amino acid residue. As all know, when the proteins undergo enzymatic cleavage (especially with Trypsin), the C-terminal of truncated peptides always contain a basic amino acids such as lysine (K) or arginine (R). Especially, the gas-phase fragmentation mechanisms of multiply-protonated peptides should be investigated in details by MS to elucidate the sequence as well as the function of proteins.

Methods Mass spectrometry experiments were conducted on a LTQ XL linear ion-trap mass spectrometer (Thermo Finnigan, San Jose, CA, USA) equipped with an electrospray ionization (ESI) source. A 100 pmol L⁻¹ peptide solutions were introduced into the ion source at a flow rate of 5 L/min. The peptide working solutions were prepared in MeOH/dH₂O/HCOOH (50:50:1, v/v/v) containing mixture. Full scan MS spectra were acquired in the m/z range 150–1000.

Results During the study, XXXXXH-NH₂ (X = A, C, F, G, L, M, S, T, V, Y) and XYAGFLV-NH₂, YXAGFLV-NH₂, YAXGFLV-NH₂, YAGXFLV-NH₂, YAGFXLV-NH₂, YAGFLXV-NH₂, YAGFLVX-NH₂ peptide derivatives were studied. In literature, it has been reported that peptide chain length can effect the fragmentation mechanisms of doubly-protonated peptides using AlaxH (X= 5,6,7,8 and 10).

In this work, the peptide chain length is kept constant and the position of basic residues, lysine (K), arginine (R), and histidine (H), is changed within the peptide sequence to probe the effects of position as well as the identity of these amino acid residues on the fragmentation pathways. The effects of location of basic residues (close to the C-terminal and N-terminal) was also studied.

Conclusions This work presents a detailed investigation of multiply charge ions produced different peptide series. It was shown that,

All the peptide series were showed the class 1 ions (b₂/y₅) considering basic amino acid position starting from N-position (3,4,5,6,and 7)

b2 and y5 ion intensities were changed with respect to position of basic amino acid

The formation of b2 and y5 ion was observed at 4th position at the peptide series of XYAGFLV-NH₂, YXAGFLV-NH₂, YAXGFLV-NH₂, YAGXFLV-NH₂, YAGFXLV-NH₂, and YAGFLVX-NH₂ (where X= K, H and R) not the 3rd position like the peptide series of XAAAAAA-NH₂, AXAAAAA-NH₂, AAXAAAA-NH₂, AAAAXAA-NH₂, AAAAAXA-NH₂, and AAAAAAX-NH₂ (where X= K, H, and R)

b2/y5 (class 1) ion formation was affected by peptide sequences. Especially, the ions (b2/y5) produced from SSSSSH-NH₂

Novel Aspect:

The purpose of the current study is the investigation of the gas-phase fragmentation mechanisms of multiply-protonated peptides to gain peptide sequence correct and reliable.

Keywords: Supercharging, ion-molecule reactions, protein sequencing, Electrospray ionisation, Gas-phase reactions

Introduction:

In electrospray ionisation (ESI), highly charged protein ions (HCPI) can be formed that fragment readily to result in higher sequence coverage than ions with less charge. Recently, we discovered that HCPIs can be formed in such high charge states [1] that they protonate N₂, O₂ and Ar at room temperature. [2] Here, we report a low pressure ESI source that can be used to form HCPIs in even higher charge states that protonate He; i.e. HCPIs are the most acidic entities known.

Methods:

Ion molecule reactions of HCPI's with atmospheric gases were conducted on a linear quadrupole ion trap mass spectrometer (LTQ-MS; Thermo Scientific) equipped with an external ESI source. A low-pressure electrospray ionisation source (LP-ESI) was developed using computer aided design and machined using a CNC-mill. Calculated gas-phase values were determined by software written in Python and can be obtained at <https://github.com/mgleeming/PredictPrPlus>.

Results:

The extent of protein ion charging in ESI is limited by proton-transfer reactions with atmospheric gases (e.g., N₂ and O₂) surrounding the ESI source. [2] ESI at low pressures should improve protein ion charging by reducing the number of proton-transfer reactions that can occur between protein ions and N₂ and O₂. Based on the data, it suggests that HCPIs are formed via the ion evaporation model, and not the charge residue model as HCPIs are more than 6 eV less basic than the least basic solution additives.

Using the LP-ESI source, protein ion charge states can be increased by over 40%. For carbonic anhydrase, the charge state improved from 44+ to 58+. Highly charged protein ions formed by low pressure ESI are sufficiently acidic that He can be protonated in room-temperature ion-molecule reactions; i.e., these ions are the most acidic entities that have been isolated to date.

Conclusions:

Using the LP-ESI for the formation of extremely high charge states should allow for improvements in top-down mass spectrometry because protein ions in high charge states are highly reactive and fragment readily. Thus, it is anticipated that the formation of HCPIs by low pressure ESI and chemical supercharging will significantly improve top-down protein sequence analysis by tandem mass spectrometry.

Novel Aspect:

The limit to protein charging was found to be due to ion molecule reactions between HCPIs and atmospheric gases. Using LP-ESI, protein ions can be formed in higher charge states.

618 - PIRENEA 2: A NEW SETUP TO STUDY COSMIC DUST IN THE LABORATORY

Anthony BONNAMY (1) - Pavol JUSKO (1) - Ming-Chao JI (1) - Patrick MORETTO-CAPELLE (2) - Sebastien ZAMITH (2) - Jean-Marc L'HERMITE (2) - Michel PELLARIN (3) - Christine JOBLIN (1)

Institut de Recherche en Astrophysique et Planétologie, Université de Toulouse, CNRS, CNES, TOULOUSE (1) - Laboratoire Collisions Agrégats Réactivité, Université de Toulouse, CNRS, TOULOUSE (2) - Institut Lumière Matière, Université Lyon 1, CNRS, LYON (3)

Keywords: Laboratory astrophysics, clusters, molecular aggregates, cryogenic ion trap, FTICR mass spectrometry

Introduction

The ERC Synergy Nanocosmos project aims to understand the physical and chemical processes leading to the formation of cosmic dust. In the framework of Nanocosmos, the PIRENEA 2 setup, an upgrade of the PIRENEA setup[1], is currently under construction in our laboratory. It combines sources of cosmic dust analogues with cryogenic trapping to study the interaction of relevant species with photons and gas under interstellar conditions.

Methods

The species that are generated from either a molecular aggregation source [2] or a laser vaporization cluster source [3], can be mass-selected and stored in a cryogenic radio-frequency (RF) quadrupole trap to be thermalized at tunable temperatures (~4-300 K). They can then be transferred to a cryogenic ion cyclotron resonance (ICR) cell (~20 K) for high-resolution mass analysis. Interaction with photons and gas can be studied in the quadrupole trap and in the ICR cell.

Results

The different parts of the setup (sources, RF trap and ICR cell) are still in the commissioning phase. In this poster, we will report on the achieved progress. Since polycyclic aromatic hydrocarbons (PAHs) are considered as the smallest in size dust particles, we will show how derivatives of these PAHs, which can be of astrophysical interest, can be produced with our sources including PAH clusters [4] and organometallic complexes made of PAHs and heavy atoms (Fe, Si) [5].

On the other hand, first tests of the performances of the new Fourier Transform ICR mass spectrometer (FTICR-MS) were performed. In particular this setup is equipped with a cryogenic pre-amplifier that was installed in order to significantly increase the sensitivity of ion detection [6].

Conclusions

Ion sources and the FTICR-MS part of PIRENEA 2 were tested. Next step will be to commission the cryogenic RF ion trap and interface all the modules together to get PIRENEA 2 fully operational.

Novel Aspect

The new PIRENEA2 setup opens new perspectives for the study in the laboratory of large molecular species and clusters under interstellar conditions.

1039 - MASS SPECTROMETRY A NEW APPROACH TO STUDY THUNDERSTORMS

Luan Felipe C Oliveira (1) - David Ulisses Tega (1) - Fernando Galembeck (1) - Marcos Nogueira Eberlin (1)

UNICAMP, Chemistry Institute, Campinas (1)

Mass Spectrometry a New Approach to Study Thunderstorms

Keywords: Mass Spectrometry, Thunderstorms, Separation of Charge, V-EASI

Introduction

Until now in the study of thunderstorms techniques to measure voltage, charge, current, electromagnetic field and visible radiation were employed to understand about their electric aspects[1-5]. Alternatively, herein we present a precursor work in the use of mass spectrometry to understand the molecular aspects involved in thunderstorms. Therefore, physical changes in water were studied simulating some changes in clouds.

Methods

A quadrupole-mass spectrometer (LCMS shimadzu 2010) with Ventury Easy Ambient Sonic-Spray ionization (V-EASI) was used in positive and negative mode with a range of m/z 10-1000 Da to analyze Milli Q water during melting process and warming in the range of 25 °C – 80 °C. Vapor of Milli Q water also measured without any source of ionization during warming in the range of 25 °C – 80 °C and after its boiling point.

Results

During the melting process different rates of variation in ionic current (IC) were observed between 10-50%. In the study of the vapor were observed an increase of the IC directly proportional of the amount of water vapor, the IC was ten times higher in this process. In the study of water warming a rise of two times in the IC only between 25 °C – 60 °C was present in the positive mode, between 60°C – 80°C the IC was constant. On the other hand, in the negative a rise in the whole interval studied was observed and an increase of four times. In all cases, we noted that the species responsible for the rise of IC were water clusters. The rise of charge during the melting is in agreement with other works[6-8], while the charge increase during the range of temperature and liquid-vapor transition is new among the processes of formation of clouds and thunderstorms.

Conclusions

This work presents a new application of Mass Spectrometry, the study of thunderstorms, showing to be efficient to study processes of electrification already studied and also new ones. The most important aspect of this work is that the technique provides information about molecular aspects involved in thunderstorms such as the suggestion that the atmospheric discharge could be a discharge of water clusters.

Novel Aspect

The use of mass spectrometry to study process related to thunderstorms.

295 - RELAXATION AND FRAGMENTATION DYNAMICS OF POLYCYCLIC AROMATIC HYDROCARBONS EXCITED BY AN ULTRASHORT XUV PULSE

Marius HERVE (1) - Pablo CASTELLANOS (2) - Gabriel KARRAS (1) - Victor DESPRE (1) - Alexandre MARCINIAK (1) - Eric CONSTANT (1) - Vincent LORIOT (1) - Alexander KULEFF (3) - Alexander TIELENS (2) - Franck LEPINE (1)

Institut Lumière Matière (ILM), Université Lyon 1, Lyon (1) - Leiden Observatory, Leiden University, Leiden (2) - Physikalisch-Chemisches Institut, Universität Heidelberg, Heidelberg (3)

Keywords: PAHs; XUV excitation; femto-astrochemistry; cation fragmentation dynamics; many-body quantum effects

Introduction:

Sources of ultrafast XUV pulses have brought new possibilities of exploring relaxation dynamics of gas phase molecules following high-energy absorption. We used XUV excitation to produce highly excited states in Polycyclic Aromatic Hydrocarbons (PAHs) cations, thought as important components of interstellar media, and probed their subsequent femtosecond dynamics. This reveals that many-body quantum effects could have consequences in astrochemistry models.

Methods:

We used an XUV pump-IR probe scheme coupled to a time-of-flight setup [1]. Femtosecond XUV pump pulses centered around 23 eV were generated by High-order Harmonics Generation (HHG), and recombined with delayed 800 nm probe pulses to interact with gas phase neutral PAHs of various size (from Naphtalene C₁₀H₈ to Hexabenzocoronene C₄₂H₁₈), creating XUV excited cations probed by IR photons. Fragments and dication yields were then measured as a function of the XUV-IR delay.

Results:

In all the studied PAHs, dication yield reveals an instantaneous population of cationic states, followed by an ultrafast decay, ranging from 29 fs for Naphtalene to 59 fs for Hexabenzocoronene. XUV-induced shake-up ionization indeed forms highly correlated cationic states lying just below the second ionization potential, whose relaxation dynamics to lower states is governed by coupled electron and nuclear motion [2]. Addition of a delayed IR photon thus probes this dynamics by second ionization. Increase of this timescale with PAH size is explained by the higher density of shake-up states through which initial population has to decay.

We further observed population of fragmentation channels on the 100 fs timescale (e.g. 119 fs for H loss of Pyrene) in the fragment yields. This longer timescale corresponds to the vibrational energy redistribution in the molecule following the non-adiabatic shake-up states relaxation, leading finally to fragmentation. It reveals the energy spread to nuclear degrees of freedom.

Conclusions

We reported dynamics occurring in small and large PAHs after XUV absorption. Relaxation dynamics of highly excited cations occurs on a similar timescale for all the PAHs, increasing with PAHs size, followed by energy redistribution to vibrations. It demonstrates that relaxation of these highly correlated states through many-body quantum effects is a general mechanism for PAHs. These general trends could be incorporated in the description of interstellar media [3].

Novel Aspect:

Femtosecond XUV sources were used to measure ultrafast relaxation dynamics of astro-relevant PAHs, where electron and nuclei are fully coupled.

draft

Christine Joblin (1)

University Toulouse/CNRS (1)

Keywords: Laboratory astrophysics, polycyclic aromatic hydrocarbons, ion traps, UV processing, gas-phase formation

Introduction:

Polycyclic aromatic hydrocarbons (PAHs) play a key role in the physical and chemical evolution of UV-irradiated astrophysical environments from protoplanetary disks to galaxies. In order to progress on our knowledge of these species, laboratory astrophysics activities have both to address the interaction of PAHs with UV photons, which is key to their stability, and investigate possible formation routes for these large molecules in cosmic environments.

Methods:

The study of the photophysics of isolated PAHs, including ionisation, dissociation and radiative cooling benefits from different setups (molecular jets, ion traps, storage rings) and their coupling with VUV synchrotron radiation [1-5]. PAH formation mechanisms are investigated using gas-phase chemical reactors, in order to identify key reactions [6] or evaluate the impact of various experimental parameters on the production of carbon dust and PAHs [7-10].

Results:

In the recent years, we have been able to better quantify the photophysics of isolated PAHs, including the dynamics of ionisation [11], as well as the rates of radiative cooling [5] and fragmentation [1]. The contribution of PAHs to the formation of H₂ has gained further support [12-14]. The detection of the fullerene C₆₀ in cosmic environments has led to considerations on the formation of this species by VUV photoprocessing of large PAHs [15].

On the other hand, activities are on going within the Nanocosmos ERC Synergy project [16] to study the formation of carbon dust in conditions that prevail in evolved stars, where this dust is likely formed. More specifically, the Stardust machine [10] aims at mimicking the key steps involved in dust formation around evolved stars. The AROMA setup was designed to support these experiments by analysing the molecular content of the synthesised dust [17]. This analysis, combined with that of meteorite samples, is expected to provide new insights into chemical pathways leading to the formation of cosmic PAHs.

Conclusions:

Based on their photophysical properties, only large PAHs containing ~100 atoms are predicted to survive in the harsh conditions of UV-irradiated regions. On the other hand, these large PAHs do not appear to be formed in gas-phase reactors neither be present in meteorite samples.

Understanding this point requires a multidisciplinary approach at the frontier between astronomy, molecular physics, and chemistry. Mass spectrometry remains a key tool in these studies.

Novel Aspect:

In order to identify relevant cosmic PAHs, dedicated laboratory setups are now available to study their photophysics and tackle the chemistry involved in their formation.

Charles University in Prague, Faculty of Science, Prague (1) - J. Heyrovsky Institute of Physical Chemistry of the CAS, Department of Chemistry of Ions in Gaseous Phase, Prague (2)

Keywords: ion/molecule interactions, high-energy interactions, ion-induced processes, planetary atmospheres

Introduction:

Atmospheres of Titan and Jupiter have already been investigated by several probes in the past. Atmosphere of Titan is composed of nitrogen and methane and other minor constituents [1], while Jupiter's atmosphere comprises mainly hydrogen and helium in addition to other less abundant compounds [2]. Constituents of both atmospheres undergo ionization by energetic heavy ions present in magnetospheres of Saturn [3] and Jupiter [4] respectively.

Methods:

The experiments were performed on a modified sector-type mass spectrometer having a quadrupole analyzer attached to a collision chamber located between magnetic and electrostatic sector. The incident ions were formed in EI source, accelerated to 5 – 10 keV, mass-selected by the magnetic sector and directed through the collision chamber. The secondary ions stemming from the neutrals admitted to the collision chamber were analyzed by the quadrupole mass analyzer.

Results:

In this study we focused on projectiles and neutral targets relevant to ionospheres of Titan and Jupiter. When projectiles interact with a neutral target, two processes can occur: ionization and electron transfer. Occurrence of one or the other depends on thermochemistry of the reaction. Objective of this study is to investigate the amount of internal energy deposited in nascent secondary ions which is reflected by the extent of fragmentation of the ionized neutral. It was found out that in the case of atomic projectiles, fragmentation of the ionized neutral strongly depends on the ionization energy of the projectile but depends very little on the center-of-mass collision energy in the collision energy range used. However in the case of molecular projectiles, the extent of fragmentation is generally very low, i.e. only molecular ions are formed, and no apparent dependencies of ionization energies, sizes or chemical structures of ionic projectiles were found.

Conclusions:

For atomic projectiles, it was found that the extent of fragmentation depends on thermochemistry of electron transfer: the higher difference in ionization energies, the higher the extent of fragmentation is. For molecular projectiles the extent of fragmentation seems to be inversely proportional to the size of the projectile.

Novel Aspect:

To our knowledge, processes investigated in this study with the particular sets of projectiles and neutrals have not yet been investigated experimentally.

Acknowledgment:

The study was supported by the Charles University, project GA UK No. 928417.

109 - REACTION DYNAMICS OF SUBSTITUTED PAH IONS

Paul Mayer (1) - Brandi West (1) - Lukas Lesniak (1) - Jake Burner (1)

University of Ottawa, University of Ottawa/Dept. of Chemistry and Biomolecular Sciences, Ottawa (1)

Keywords: polycyclic aromatic hydrocarbon ions, astrochemistry, iPEPICO, collision-induced dissociation

Introduction:

The chemical origins of the Diffuse Interstellar Bands have remained elusive. Polycyclic aromatic hydrocarbons, PAHs have been postulated to be sources of DIBs due to the similarity between the IR emissions of the cations of PAHs and the DIBs. One molecule that has been investigated for its potential role as a DIB source is 1-methylpyrene. In this study we examine the dissociation of this ion and two other substituted PAH ions, 1-nitropyrene and 9-cyanophenanthrene.

Methods:

iPEPICO experiments were conducted on the VUV beamline at the Swiss Light Source (Paul Scherrer Institut, Villigen, Switzerland). The mass-selected TPES were acquired to establish the IEs of each compound. RRKM theory was used to determine the 0 K activation energies (E_0) and entropies of activation ($\Delta^\ddagger S_{1000K}$) by modeling the experimental breakdown diagrams. Reaction pathways were calculated at the UCCSD/6-31G(d)//B3-LYP/6-31G(d) level of theory.

Results: (Limit 900 characters)

For ionized 1-methylpyrene, the loss of H could form either 1-methylenepyrene (A) or a tropylium-motif containing ion (B). The transition state of highest energy in the pathway to B lies ~ 3.20 eV, while that for A is only 2.54 eV, favoring simple H loss from the methyl group, in contrast to that observed for ionized toluene. The presence of the three additional rings in 1-methylpyrene prevents the 7-member ring from expanding to relax the structure and lower the TS energy.

For ionized 1-nitropyrene, competition was observed between NO loss (resulting from a nitro-nitroso isomerization in the precursor ion), the loss of NO₂ to form a triplet state product ion, and a sequential loss of CO, which was confirmed by D-labelling experiments.

Unlike the previous 2 ions, the -CN group in 9-cyanophenanthrene appears to act only to destabilize the PAH product ions. The -CN group itself is not directly involved in the dissociation, shown to be H and C₂H₂ loss. The energies required for these reactions (~ 5.5 eV) are higher than observed for unsubstituted PAHs (~ 4.5 eV, regardless of PAH size)[1], an effect traceable to the impact of the electron-withdrawing -CN group on the product ion stability.

Conclusions (Limit of 400 characters)

The substituent on a large PAH like pyrene has been shown to play a variety of roles in the unimolecular dissociation of the ions. It can either drive the reaction mechanism (nitropyrene) or have a predominantly electronic effect (cyanophenanthrene). The larger ring system of pericondensed PAHs can also push the chemistry away from extensive isomerization (methylpyrene).

Novel Aspect: (Limit of 150 characters)

Presented are the first detailed investigations of the unimolecular ion chemistry of 3 substituted PAHs.

213 - A MULTI-VENDOR APPLICABLE TARGET SYSTEM FOR (MA)LDI INSTRUMENTS WITH DISTINCT PERFORMANCE CHARACTERISTICS FOR THE ANALYSIS OF SMALL ORGANIC MOLECULES RELATED TO C CHONDRITES

Edita Rados (1) - Ernst Pittenauer (1) - Johannes Frank (2) - Kurt Varmuza (3) - Günter Allmaier (1)

TU Wien, TU Wien/Institute of Chemical Technologies and Analytics, Vienna (1) - TU Wien, TU Wien/ Joint Workshop of the Faculty of Technical Chemistry, Vienna (2) - TU Wien, TU Wien/Institute of Statistics and Mathematical Methods in Economics, Vienna (3)

Keywords: small organic molecules, LDI, target adapter, gold target

Introduction:

A serious comparison of one and the same sample preparation on different LDI-MS instruments is usually not possible because each device requires the use of its own, specific target. Therefore, we developed a target system, which enables the use of only one target for different devices. The work was focused on the analysis of small organic molecules selected due to their different desorption/ionization behavior and their potential presence in carbonaceous chondrites.

Methods:

The selected organic molecules (e.g. tryptophan, 2-deoxy-D-ribose and triphenylene) were prepared and spotted onto the target plate (stainless steel or gold) and analysed on three devices with different performance characteristics, namely an Axima TOF2 (LinTOF/curved field RTOF), an ultrafleXtreme (LinTOF/dual stage RTOF) and a Synapt G2 (Qq/dual stage RTOF). The samples were also analysed on the TOF-SIMS 5 mass spectrometer equipped with gridless RTOF.

Results:

The developed target system consisting of modified Bruker target adapter, a standard SS Waters target plate and an Au target plate allowed comparison of data acquired on four MS instruments with different performance characteristics (e.g. different lasers, different laser repetition rates, different ion source vacuum regimes). The data were obtained for all analytes from plain SS and Au target. In positive-ion mode, we were able to detect different types of molecular ions (M^+ , radical cations, $[M+H]^+$, $[M+Na]^+$, and $[M+2Na-H]^+$ ions) depending on the type of analyte. All sample molecules showed similar desorption/ionization behavior on all instruments in the positive-ion mode independently of the target applied. A deprotonated molecule of tryptophan was also detectable on all instruments with the use of SS and Au target. The use of the Synapt G2 instrument allowed accurate mass determination (± 4 ppm) at a resolution of up to RFWHM 20.000 for all types of molecular ion. Additionally, low- and high-energy CID-spectra were acquired for tryptophan.

Conclusions:

We showed that an in-depth comparison of the data obtained with devices from different vendors with distinct performance characteristics is possible when the presented target system is being used. The possibility to obtain accurate masses can be useful in identifying unknown compounds in C chondrite meteorite samples.

Novel Aspect:

The developed target system allows the use of only one target on multiple LDI/MALDI-devices. Small organic molecules can be measured with LDI and accurate mass can be obtained.

33 - INVESTIGATING THE POSSIBILITY OF FORMING PREBIOTIC MOLECULES BY GAS PHASE ION-MOLECULE REACTIONS. APPLICATION TO GLYCINE.

Riccardo Spezia (1) - Yannick Jeanvoine (2) - Antonio Largo (3) - William L. Hase (4) - Joel Lemaire (5) - Debora Scuderi (6)

CNRS, Sorbonne Université, Laboratoire de Chimie Théorique, Paris (1) - Université d'Evry, Laboratoire Analyse et Modélisation pour la Biologie et l'Environnement, Evry (2) - Universidad de Valladolid, Departamento de Química Física, Valladolid (3) - Texas Tech University, Department of Chemistry and Biochemistry, Lubbock (4) - CNRS, Université Paris Sud, Laboratoire de Chimie Physique, Orsay (5) - Université Paris Sud, Laboratoire de Chimie Physique, Orsay (6)

Keywords: Ion-molecule reactions; prebiotic chemistry; chemical dynamics simulations; Infra-red multi photon dissociation (IRMPD)

Introduction: (Limit of 400 characters)

In last years, progresses in astrophysics have revealed the presence in the interstellar medium (ISM) and in comets of many organic molecules, like glycine [1], urea [2] and formamide [3]. Due to the extreme conditions in space, it is not clear how such prebiotic molecules can be synthesized. Gas-phase ion chemistry, combining simulations and experiments, can propose some synthetic routes.

Methods: (Limit of 400 characters)

Chemical dynamics simulations and quantum chemistry were used to theoretically investigate ion-molecule reactions [4]. Simulations were done at different collision energies. Experimentally, we have used a Paul ion trap where we have introduced the ions and the neutrals. IR laser was used to characterize the products [5] and to induce the reactivity of the stabilized complexes [6].

Results: (Limit 900 characters)

To form glycine, we have considered the reaction: $\text{NH}_3\text{OH}^+ + \text{CH}_3\text{COOH}$. Bohme and co-workers reported that it produces protonated glycine in a flow-tube [7].

Chemical dynamics simulations, tuning collision energy, form an ion with m/z 76 and water. However, the ions formed do not have the structure of protonated glycine [8].

Experimentally, the same reaction done in the ion trap conditions does not form the ion m/z 76, but the ion m/z 94, corresponding to the complex made by NH_3OH^+ and CH_3COOH . It was irradiated by IR and characterized comparing IRMPD and theoretical spectra.

When doing IRMPD on the m/z 94, one of the photo-fragment is the ion m/z 76, corresponding to protonated glycine, suggesting a possible role of IR radiation in the synthesis of such prebiotic molecule.

Preliminary calculations [9] and experiments on urea formation suggests that a similar picture can occur also in this case.

Conclusions (Limit of 400 characters)

We have shown that glycine can be formed by ion molecule collisions between protonated hydroxylamine and methanol. This reaction can occur if some translational energy is given or if the formed complex is irradiated by an IR laser.

The species observed in simulations have the same m/z of protonated glycine but different structures, suggesting that radio-astronomy should consider this possibility.

Novel Aspect: (Limit of 150 characters)

Simulations and experiments of ion-molecule reactions suggest new synthetic route to form prebiotic molecules under astrophysical conditions.

759 - THE THRESHOLD DISPLACEMENT ENERGY OF BUCKMINSTERFULLERENE C₆₀ AND FORMATION OF THE ENDOHEDRAL DEFECT FULLERENE HE@C₅₉

Mark Stockett (1) - Michael Wolf (1) - Michael Gatchell (2) - Henning Schmidt (1) - Henning Zettergren (1) - Henrik Cederquist (1)

Stockholm University, Department of Physics, Stockholm (1) - Universität Innsbruck, Institut für Ionenphysik und Angewandte Physik, Innsbruck (2)

Keywords: fullerenes, collisions, knockout, endohedrals, supernovae

Introduction:

The observation of fullerenes in various astronomical environments, and the identification of C₆₀⁺ as the carrier of several Diffuse Interstellar Bands, has led to a surge in interest in the formation and destruction mechanisms of fullerenes under different astrophysical conditions. Non-statistical fragmentation of fullerenes and other large molecules following collisions with energetic H and He atoms in supernova shocks is considered a key mechanism [1].

Methods:

C₆₀⁻ ions are produced by electrospray, selected with a quadrupole mass filter, and accelerated to 1-15 keV. Collisions with He at center-of-mass energies of 20-80 eV mimic supernova processing. Negatively and positively charged product distributions are measured with an electrostatic energy analyzer. Classical molecular dynamics (MD) simulations enable detailed analysis of collisions.

Results:

As the electron affinity of C₆₀ is much lower than any of its dissociation energies, collisions depositing enough energy to induce statistical unimolecular dissociation most likely lead to electron loss and thus do not contribute to the negative ion product spectrum. Non-statistical fragmentation ie single carbon knockout is observed directly by detecting C₅₉⁻. We observe for the first time the endohedral defect fullerene complex He@C₅₉⁻. Secondary decay products of these ions, C₅₈⁻ and He@C₅₈⁻, are also observed. We measure the threshold center-of-mass energy for knocking out a single carbon atom from C₆₀ in collisions with He. Combining this with our MD simulations, we determine a semi-empirical value for the (projectile-independent) threshold displacement energy, the minimum energy needed to remove a single carbon atom from the C₆₀ cage [2]. Our value, 24.1(5) eV, is much higher than generally assumed previously for fullerenes (around 15 eV), and is similar to that determined for graphene [3] and Polycyclic Aromatic Hydrocarbons [4].

Conclusions

Non-statistical fragmentation of fullerenes and other large carbonaceous molecules is an important destruction mechanism in collisions like those taking place in supernova shocks. The products of these collisions are surprisingly robust, and may serve as reactive seeds for bottom-up growth of larger molecules in the Interstellar Medium. The observation of He@C₅₉⁻ is a testament to the complexity of fullerene reactions.

Novel Aspect:

We report the first observation of endohedral defect fullerene ions and the first measurement of the threshold displacement energy of a fullerene.

D.05 FUNDAMENTAL MASS SPECTROMETRY - NONCOVALENT INTERACTIONS

826 - THE ASSEMBLY OF ISLET AMYLOID POLYPEPTIDE (IAPP) AND THE ROLE OF THE DISULFIDE BOND

Michael Bowers (1) - Alexandre Ilitchev (1) - Dezmond Bishop (1) - Steven Buratto (1)

UCSB, Chemistry and Biochemistry, Santa Barbara (1)

Keywords: Ion Mobility, Atomic Force Microscopy, IAPP, Amyloid

INTRODUCTION

Islet Amyloid Polypeptide (IAPP), a 37 residue hormone, has been identified as a primary agent in the etiology of Type 2 Diabetes and the driving force for pancreatic cell death. There has been a substantial amount of research on the mechanism of the cytotoxic process but it is still not well understood. It is known that assembly of IAPP is involved and the oligomer states not the fibrils are the toxic agents. Here we provide new evidence bearing on the molecular details of the IAPP assembly process.

METHODS

Ion Mobility Based Mass Spectrometry (IMS-MS) will be used to characterize the assembly of IAPP and a number of N-terminal mutants designed to shed light on the importance of the disulfide bond in this process. These results will be complimented with data from Atomic Force Microscopy (AFM) using the same solutions utilized in the IMS-MS studies.

RESULTS

There is a disulfide bond linking cysteine residues at positions 2 and 7 in wild type IAPP. The stability of this loop appears to limit the participation of the N-terminal regions in the amyloid assembly of IAPP. However recent studies have shown that the N-terminal region is capable of self-assembly. Further, wt IAPP has an inhibitory affect on insulin secretion in beta cells but truncating the N-terminus reduces this effect. Here we look at a series of modified IAPP molecules and compare their assembly with wt: These include reduced IAPP, IAPP(8-37, and cysteine side chain Carbamidomethylation (CAM). We find reduction of the disulfide bond results in significant acceleration of the aggregation process while the CAM mutant greatly inhibits aggregation. The truncated form behaves similar to wild type in formation of oligomers but accelerates fibril formation. The implication of these results will be discussed.

CONCLUSIONS

The N-terminus has been shown to have a dramatic effect on the assembly of IAPP contrary to expectations. The results presented here contribute to clarifying the assembly mechanism of IAPP which is crucial to developing therapeutic agents to ameliorate its cytotoxic effect in Type 2 Diabetes

NOVEL ASPECT

New data on the importance of the N-terminal region of IAPP is presented and the complimentary nature of IMS-MS and AFM emphasized.

586 - GAS-PHASE COMPLEXATION OF α -/ β -CYCLODEXTRIN WITH AMINO ACIDS STUDIED BY ION MOBILITY-MASS SPECTROMETRY AND MOLECULAR DYNAMICS SIMULATIONS

Yinjuan Chen (1) - Zhicheng Zuo (1) - Wenning Wang (1) - Chuanfan Ding (1)

Fudan University, Department of Chemistry, Shanghai (1)

Keywords: Non-covalent Complexes; cyclodextrin; amino acids; ion mobility-mass spectrometry; molecular dynamics simulation

Introduction:

Cyclodextrins (CDs) have the hydrophilic surface and hydrophobic cavity and enable CDs to form non-covalent complexes with other molecules. Electrospray ionization-mass spectrometry (ESI-MS), and ion mobility-mass spectrometry (IMMS) are suitable technology for the gas phase conformational study. Herein, non-covalent complexes involving amino acids and α -/ β -CD are investigated using IMMS combined with molecular dynamics simulations.

Methods:

The gas-phase complexation of non-covalent complexes involving α -/ β -cyclodextrin (α -/ β -CD) and amino acids (AA) (AA=Gly, Leu and Phe) are investigated by ion mobility-mass spectrometry in negative mode. The complex ions are further identified by tandem mass spectrometry. The complex gas-phase conformations are clarified by IMS in combination with molecular dynamics simulations.

Results:

The 1:1 [α -/ β -CD+AA]⁻ adducts are observed when equimolar α -/ β -CD:Gly:Leu:Phe solutions are electrosprayed. The complex ions are further identified by tandem mass spectrometry, in which complex ions are fragmented into [CD]⁻ via losing one neutral AA molecule. Their gas-phase stability order of [α -/ β -CD+Gly]⁻ < [α -/ β -CD+Leu]⁻ < [α -/ β -CD+Phe]⁻, revealed by survival yield curves, can be explained by gas-phase basicity difference. The anion is kinetically more stable with much smaller gas-phase basicity difference of [CD]⁻ and [AA]⁻. The complex gas-phase conformations are clarified by IMS in combination with molecular dynamics simulations. The nearly equal collision cross sections of [β -CD+Gly/Leu/Phe]⁻ anions were obtained by ion mobility analysis, while various cross sections were observed for the [α -CD+Gly/Leu/Phe]⁻ anions.

Conclusions

The structure of [α -CD+Leu/phe]⁻ which obtained by IMS represented the exclusion structure in which the hydrophobic side chain remains outside the hydrophobic cavity of α -CD, and inclusion structure was proposed for other complex anions with the AA molecule being trapped inside the hydrophobic cavity of CD. The conformations are consistent with the most stable configurations obtained by molecular dynamics simulations.

Novel Aspect:

The gas phase inclusion or exclusion structure of non-covalent complexes of α -/ β -cyclodextrin and amino acids can be identified by IMS and molecular dynamics simulations.

1004 - INVESTIGATING THE INTERLOCKED NATURE OF CATENANES AND KNOTS WITH MASS SPECTROMETRY AND ION MOBILITY SPECTROMETRY

Anneli Kruve-Viil (1) - Schalley Christoph (1)

Freie Univeversität Berlin, Institut für Chemie und Biochemie, Berlin (1)

Keywords: mechanical bond, ion mobility, catenanes, knots

Introduction

Mechanically interlocked molecular architectures are exclusively used to convert energy into directed molecular motion on molecular level. Catenanes [1-3] and other mechanically interlocked systems are often hard to unambiguously characterize; the NMR studies need isolation and purification of the MIM as well as control experiments. On the other hand, in mass spectrometry (MS) unspecific binding often cannot be ruled out.

Methods

We are proposing a fast, selective, and simple approach based on collision induced dissociation combined with ion mobility spectroscopy (CID/IMS) to unambiguously characterize the topology for catenanes and knots.

Results

CID is used to induce the cleavage of the covalent bonds and IMS to separate the formed species based on their size in gas phase. Therefore, applying CID on catenanes results on two species an open macrocycle and a closed macrocycle, which can be easily separated with IMS and detected with mass spectrometry. The method automatically involves a quantitative control experiment: the amount of formed open and closed macrocycle sum up to the amount of catenane that has under gone cleavage. Similarly, this technique helps distinguishing knots from simple macrocycles. We have tested CID/IMS based method to characterize several libraries with already well known architectures including imine-bond based catenanes in water, oligolactame based structures, metal templated catenanes, etc. Thereafter, we applied CID/IMS method to probe the libraries with previously unidentified topology. Both catenanes and knots were identified; however, also libraries without mechanically interlocked bonds could be identified as true negatives. For the unknown libraries, the structures were later separated and confirmed also with other techniques.

Conclusions

We demonstrate that CID/IMS based method is rapid, conclusive, straightforward, and can be applicable to various types of catenane, including both for symmetrical and unsymmetrical catenanes, mixtures, or even crude products. Additionally, in case of dynamic libraries it can also be used to effectively probe the kinetic and thermodynamic properties of the mechanical bond.

Novel Aspect

MS, combined with IMS and IMS/MS/MS can be effectively used to characterize the structure of interlocked supramolecular structures.

196 - EXPLORING THE INHIBITION MECHANISMS OF AMYLOID PROTOFIBRILS USING FOURIER TRANSFORM ION CYCLOTRON RESONANCE-MASS SPECTROMETRY (FTICR-MS)

Yuko P. Y. Lam (1) - Cookson K.C. Chiu (1) - Christopher A. Wootton (1) - Ji-Inn Song (1) - Meng Li (1) - Ian Hands-Portman (2) - Mark P. Barrow (1) - Peter B. O'Connor (1)

University of Warwick, Department of Chemistry, Coventry (1) - University of Warwick, Department of Life Science, Coventry (2)

Keywords: Amyloid protein, Inhibition mechanism, Deamidation, Non-covalent interaction, Aggregation

Introduction:

Human Islet Amyloid Polypeptide (hIAPP) is an amyloidogenic protein that aggregates rapidly in humans. [1-5] Classic structure-based design for therapeutics cannot apply to amyloid protein drug development as most amyloid proteins are inherently disordered.[6-7] Herein, Fourier Transform Ion Cyclotron Resonance (FTICR) MS was used to study the potential inhibitors, identify binding regions through top-down MS/MS, and correlate with fluorescence and transmission electron microscopy (TEM) measurements to understand target regions for aggregation inhibition mechanisms.

Methods:

Collisionally activated dissociation (CAD) MS/MS and electron capture dissociation (ECD) MS/MS in a 12T FTICR MS were used to show the interaction strengths and regions between hIAPP/ deamidated hIAPP and the potential inhibitors respectively.

The performance of the aggregation inhibitors on preventing hIAPP/ deamidated hIAPP aggregation was quantified by a fluorescence spectrometer and relative MS quantification to determine the amount of fibrils formed in the incubated solutions. The overall fibrils structures were observed by TEM.

Results: (900 characters only)

Insulin, 3-APS, BISA, EGCG are all reported inhibitors of hIAPP aggregation. Insulin was found to specifically bind to the critical aggregation region of hIAPP (Ser-29 to Asn-35) which inhibited the formation of the early oligomers and the mature fibrils. The hIAPP in the heterodimer complex was easily converted back to soluble hIAPP in an aqueous solution, thus, 100% recovery of the soluble hIAPP was observed in an incubated solution.

On the contrary, EGCG bound non-specifically to hIAPP and the interaction pattern of EGCG was very similar to the potential drugs which were found to be ineffective at inhibiting hIAPP aggregation (3-APS and BISA). Instead, EGCG was found to aggregate rapidly with hIAPP in a non-fibrillary complex to inhibit the aggregation.

For deamidated hIAPP, CAD MS/MS results showed insulin had a weaker interaction with the deamidated hIAPP compared to the wild-type and mature amorphous aggregates were formed during the experiment.

Conclusions: (400 characters only)

The results demonstrated there are two potential inhibition mechanisms adopted by the potential inhibitors to prevent hIAPP aggregation. Insulin directly inhibits hIAPP fibrillization by specific interaction with target sequence regions, and EGCG rapidly redirects hIAPP into non-toxic amorphous aggregates which prevents the amyloid fibrils formation. Only EGCG inhibitors with redirecting the protein into non-toxic amorphous aggregates was found to be applicable in inhibiting the deamidated hIAPP aggregation.

Novel Aspect: (150 characters only)

Understanding underlying mechanisms that prevent amyloid aggregation are the key to amyloid drug development

draft

591 - DIFFERENT MEANS OF SOLUBILIZATION OF MEMBRANE PROTEINS FOR NATIVE MS

Nina Morgner (1) - Oliver Peetz (1)

Frankfurt University, Frankfurt University / Physical Chemistry, Frankfurt (1)

Keywords: membrane proteins, nanodiscs, SMALPs, native MS, LILBID

Introduction:

Membrane proteins are of high interest, but still underrepresented in research due to the inherent difficulties for many investigation methods, arising from their hydrophobic nature. Depending on the feature of the membrane protein complex the researcher is interested in (protein stoichiometry, lipid affinity, annular lipids...), different means of solubilisation can enable MS analysis.

Methods:

LILBID (Laser Induced Liquid Bead Ion Desorption) is an ionization method which employs a droplet generator to produce analyte droplets of 30-50µm diameter at a frequency of 10Hz [1]. These droplets are irradiated by a mid-IR laser leading to the explosive expansion of the droplet. The solvated ions are set free and are mass analyzed.

Results:

We investigated the usability of artificial membranes for the study of membrane protein complexes with LILBID-MS. Lipid bilayer mimics as nanodiscs and liposomes allow the analysis of the oligomerization state of a protein complex. Cell-free expressed membrane proteins can be solvated by lipid bilayer mimics without ever being in contact with detergents. This allows for example the study of lipid dependent oligomerization [2]. Even SMALPs, which allow to cut protein complexes out of living cells preserving their annular lipid belt, can be used to determine the constituting proteins of a complex, in dependence of growth conditions of the cells.

Conclusions:

LILBID-MS is well suited for the analysis of membrane proteins complexes solubilized by detergent or different lipid bilayer mimics, such as nanodiscs, liposomes or SMALPs. This allows analysis of the complexes' constituting proteins, as well as their dependence on specific lipids or ligands.

Novel Aspect:

Analysis of membrane protein complexes directly out of lipid bilayer mimics

Keywords:

Membrane proteins, detergent micelles, G protein coupled receptors

Introduction:

Mass spectrometry (MS) has the potential to monitor different modes of lipid binding to membrane protein complexes. Initial studies monitored the addition of lipids and deduced the kinetic and thermodynamic effects of lipid binding to proteins. Recently we have identified lipids already present, explicitly in plugs, annular rings or cavities. These lipids have higher residence times and consequently can be quantified and characterized by mass spectrometry.

Methods:

We have used native MS of membrane proteins liberated from micelles to study protein lipid interactions. Using an Orbitrap MS platform developed for membrane proteins (1) we show that it is possible to distinguish lipids, cofactors and drugs while in direct contact with the membrane protein target.

Results:

While most steps of lipid II transfer across the cytoplasmic membrane are understood, identifying the lipid II flippase has yielded conflicting results. We used native mass spectrometry to characterise lipid II binding to two candidate proteins MurJ and FtsW. We showed that lipid II binding competes with cardiolipin to reduce lipid II binding to MurJ (2). We also showed how drug binding mediates phosphorylation in a class A GPCR (P2Y1R) (3) and that purification of three further class A GPCRs results in binding of specific lipids. These lipids in turn affect downstream coupling to certain types of G-proteins and consequently appear to enhance selective coupling primarily to class A GPCRs.

Conclusion:

The ability to detect lipid binding which have both structural and functional effects, for example on lipid flippase activity or G-protein coupling, is a powerful and important attribute of the study of membrane proteins by mass spectrometry.

Novel Aspect:

First mass spectra of folded GPCR complexes and demonstration of competition between lipids affecting function.

Katharina Root, Konstantin Barylyuk, Anatol Schwab, Jonas Thelemann,, Boris Illarionov,Markus Fischer, François Diederich, Renato Zenobi

Introduction:

Characterizing the mode of action of non-covalent inhibitors in multisubunit enzymes often presents a great challenge. Most of the conventional used techniques often fail because they do not reveal how the distribution of individual ligand-bound states changes with ligand concentration but instead describe an average property of the ensemble as a function of ligand concentration. Thus, mixed models comprising both competitive and noncompetitive binding are often used that proved very little insight into the mechanisms of ligand binding and recognition.

Methods:

Native electrospray ionization mass spectrometry (ESI-MS) has recently emerged as a powerful technique for direct, label-free analysis of intact protein complexes. Native ESI-MS has been increasingly recognized for its ability to directly probe such properties of intact macromolecular assemblies as the protein-ligand complex stoichiometry, binding affinities, and allosteric effects.

Results:

Here we apply native ESI-MS to comprehensively characterize an isoprenoid biosynthesis enzyme IspF from *Arabidopsis thaliana*, an example of homomeric protein complex with multiple binding sites for several types of ligands, including a metal cofactor and a synthetic inhibitor. Based on these combined with computational modeling, we propose a mechanism of AtIspF inhibition by aryl bis-sulfonamides that involves both the competition with the substrate for the ligand-binding pocket and the extraction of Zn²⁺ from the enzyme active site. This inhibition mode is therefore mixed competitive and non-competitive, the latter exerting a key inhibitory effect on the enzyme activity.

Conclusions

The results of our study deliver a profound insight into the mechanisms of AtIspF action and inhibition, open new perspectives for designing inhibitors of this important drug target, and demonstrate the applicability and value of the native ESI-MS approach for deep analysis of complex biomolecular binding equilibria.

Novel Aspect:

While standard biophysical techniques failed to reveal the mode of action of aryl-sulfonamide-based inhibitors of AtIspF, direct native ESI-MS titrations of the protein with the ligands and ligand competition assays allowed us to accurately capture the solution-phase protein-ligand binding equilibria in full complexity and detail.

Keywords: clusters, charge separation, non-covalent complexes, peptides, tandem mass spectrometry

Introduction:

Self-association and interactions of amino acids and peptides is in the focus of intensive research since a long time. In this work, clustering properties and gas-phase dissociation pathways of multiply charged peptide clusters were studied. We have analyzed the cluster formation of tripeptides as well as the collision induced dissociation of their clusters in an ion trap mass spectrometer.

Methods:

Mass spectrometric experiments were performed using two tyrosine-containing tripeptides: H-Tyr-Ala-Gly-OH and H-Tyr-Gly-Phe-OH, on a Bruker Esquire 3000+ ion trap mass spectrometer equipped with ESI source. Optimized ion source parameters were: nebulizer gas pressure: 80 psi, dry gas flow: 0.5 l/min, dry temperature: 250 °C, skimmer voltage: 40V, capillary exit voltage: 106 V.

Results:

The relatively high peptide concentrations were found to enhance the formation of peptide aggregates. Ion source parameters were optimized to achieve high signal intensity for larger peptide aggregates. We observed, that high nebulizer gas pressure and low dry gas flow rate facilitate the detection of large, multiply charged clusters. Both peptides exhibit a characteristic cluster distribution profile in ESI-MS. Beside the protonated monomer, dimer and trimer species, peptides produce larger clusters in the 1200-2400 m/z. Most intensive peaks correspond to 5 and 6 peptide units with one charge. MS/MS experiments revealed that multiply charged metaclusters of peptides appear at the same mass-to-charge ratios as peptide aggregates with lower charge states. Peptide clusters of interest were isolated in the ion trap and fragmented to identify their fragmentation pathways.

Conclusions

The dominant fission products for the tripeptide clusters were the losses of the proton-bound dimers, presumably due to the high gas-phase stability of this species. Charge separation by cluster fission was proved to be a major dissociation pathway of these peptide clusters. Beside the formation of singly charged ion population, triply charged species were preferred products as well.

Novel Aspect:

Characteristic cluster distribution was detected for tripeptides, together with typical charge separation-based fragmentation pathways.

Keywords: fluorous flying salts, fluorous clusters, ambient ionization, non-covalent complexes, energy-dependent tandem mass spectrometry

Introduction:

Cluster formation is an important research topic in fundamental mass spectrometry. Formation of alkali metal halide clusters using electrospray ionization has long been known. These salts can form very large cluster structures such as $\text{Na}_{124}\text{Cl}_{1222}^+$ [1]. Here we report the discovery of novel, bilateral fluorous alkoxide-based clusters by ESI, showing unique structural properties.

Methods:

Experiments were performed using a Bruker Esquire 3000+ ion trap MS with ESI ion source and a Bruker microQTOF with DART ion source. MM/QM computational studies were carried out with Schrödinger Maestro 11.1 and Gaussian16 software packages. We optimized the structures with OPLS2005 force field and B3LYP/Def2SVP (GD3BJ) and calculated single point energy with B3LYP/Def2TZVPP level of theory.

Results:

Nonafluoro-tert-butyl alkoxides, $\text{MOC}(\text{CF}_3)_3$ [$\text{M} = \text{Li}, \text{Na}, \text{K}, \text{Rb}, \text{Cs}$], were synthesized to investigate their clusters using mass spectrometry. Solutions prepared in dry acetonitrile were directly injected into the ESI ion source. The salts show complexes of outstanding stability and high intensities both in positive and negative ionization modes, such as $[\text{M}_4\text{A}_3^+; \text{M}_5\text{A}_6^-]$; where $\text{A} = (\text{OC}(\text{CF}_3)_3)^-$.

Computational chemistry methods, MM/QM modelling, were used to calculate the stable gas phase structures. Energy-dependent MS/MS fragmentation experiments were also performed to quantitatively describe affinity and stability parameters of clusters. Experimental data were in good correlation with calculated values.

Conclusions:

Formation of fluorous alkoxide clusters are described here for the first time. These special compounds, referred to "fluorous flying salts", represents a new cluster type, in which the anion has fluorous-ionic bilateral properties, which prevents the limitless polymer cluster formation, and support the outstanding stability of defined structures.

Novel Aspect:

Bilateral fluorous alkoxide-based clusters discovered by ESI-MS give novel opportunity for the study of electron pair acceptor compounds by MS.

177 - NONCOVALENT COMPLEXES IN NATURAL EXTRACTS

Pietro Traldi (1) - Sara D'Aronco (2) - Sara Crotti (1) - Marco Agostini (2) - Luisa Mattoli (3) - Michela Burico (3) - Sara Tamimi (3)

Fondazione Istituto di Ricerca Pediatrica Città della Speranza, Città della Speranza, Padova (1) - Dipartimento di Scienze Chirurgiche, Oncologiche e Gastroenterologiche, Università di Padova, Padova (2) - Aboca, Ricerca Fitochimica, Sansepolcro (3)

Keywords: noncovalent complexes in natural extracts

Introduction: Chemical evolution includes capture, mutation and propagation of molecular information via covalent and noncovalent associations [1]. Considering the high complexity of natural substrates, for the presence of molecular species of different chemical nature, the formation of noncovalent complexes has to be expected. They could play a role in the activity of the extract, leading to structures of active compounds different to that of the synthetic analogous products.

Methods: The presence of noncovalent complexes in different natural extracts (green tea, Ceylon tea, green coffee, mate) has been investigated by precursor ion scan on ions generated by ESI and neutral loss scans. In order to exclude that the complexes so detected were artifact due to ESI conditions, LC MS measurement were performed, and reconstructed chromatograms based on accurate mass values confirmed the presence of noncovalent complexes in the natural extracts.

Results: Some investigations were performed to establish unequivocally the presence of catechin/caffeine complexes in green tea (GTE), Ceylon tea, green coffee, mate extracts. By ESI-MS experiments performed on GTE by means of precursor ion scan and neutral loss scan methods, the presence of caffeine:catechin complexes was proved [2]. The same approach showed that in the case of Ceylon tea the abundance of these complexes is strongly reduced, while for green coffee and mate complexes of caffeine with chlorogenic acid present in the extracts were undetectable. Further experiments were performed on GTE by LC/MS method operating in high resolution conditions. The reconstructed ion chromatograms of the exact mass ions corresponding to the caffeine/catechin complexes have been obtained, showing the presence of the complexes of caffeine with gallate-type catechins [2]. This approach was able to put in evidence the presence of the same complex with different structures, exhibiting different retention times, in agreement with the data of Ujihara and Hayashi [3].

Conclusions The complexes between caffeine and catechins already observed in solid state and in solution by NMR in ad hoc prepared solution are detectable also by mass spectrometry, once specific methods are employed. These complexes are detected in green tea and, in minor extent, in Ceylon tea. In mate and in green coffee the complexes possibly originating by interaction of caffeine with chlorogenic acid are undetectable, reasonably due to the low affinity of the two molecular species.

Novel Aspect: For the first time the presence of caffeine/catechin complexes in green tea and in Ceylon tea extracts has been proved by mass spectrometric experiments.

1114 - NATIVE MS OF NONCOVALENT RNA:PROTEIN COMPLEXES

Vicki Wysocki (1)

Dept of Chemistry and Biochemistry, Ohio State University (1)

Keywords: Native MS; protein complex; nucleoprotein; surface-induced dissociation; structural biology

Introduction:

Characterization of the overall topology and inter-subunit contacts of non-covalent protein complexes, and their assembly/disassembly and unfolding pathways, is critical because protein complexes regulate key biological processes, including those important in understanding and controlling disease. Native mass spectrometry is an approach that provides critical structural information at high throughput on low sample amounts.

Methods:

The power of native MS increases when coupled to ion mobility (IM-MS), a technique that measures rotationally averaged collisional cross sections and thus information on conformational changes, or to high resolution mass spectrometry (HRMS). This presentation illustrates CID, SID/IM, and SID HRMS for characterization of topology, intersubunit connectivity, and other structural features of multimeric nucleoprotein complexes.

Results:

Native MS is being used in our lab for characterization of soluble, membrane, and nucleoprotein complexes. Native MS results for multiple systems will be presented in this talk, with a primary focus on RNA:protein complexes. The first nucleoprotein system under investigation (with Venkat Gopalan of OSU) is RNase P, an endonuclease that catalyzes 5' maturation of t-RNAs. While we've been able to bind four RNase P proteins to the RNA or a fifth protein to kink turns in the RNA, we are still optimizing conditions to simultaneously bind all five proteins. A second system under investigation (with Karin Musier-Forsyth of OSU) involves the retroviral Gag protein involved in HIV-1 genome packaging and viral assembly, a system for which we've measured 3:1 Gag:Psi complexes. A third nucleoprotein project (with Sarah Woodson of Johns Hopkins) involves the hexameric RNA chaperone Hfq bound to RNA and recruiting messenger RNA, a system for which surface-induced dissociation of the hexameric ring is altered by the presence and absence of the bound RNA.

Conclusions:

Native MS coupled to HCD, SID, ion mobility, or high resolution mass spectrometry, along with complementary tools such as covalent labeling MS, provides information on conditions needed for optimal formation of the protein:RNA complexes (ionic strength, Mg²⁺ concentration, protein:RNA ratios) and on the protein-RNA connectivity and structure. Experiments are underway to determine the best ways to calibrate the CCSs of the RNAs and RNA:protein complexes.

Novel Aspect:

Native MS and SID of nucleoprotein complexes provides structural information unavailable or difficult to obtain by other structural biology tools.

1403 - STERIC STRUCTURE AND STABILITY OF THE GAS-PHASE COMPLEXES OF MACROCYCLIC RECEPTORS WITH ANIONS

Magdalena Zimnicka (1) - Alicja Wasilewska (1) - Kajetan Dabrowa (1) - Witold Danikiewicz (1)

Polish Academy of Sciences, Institute of Organic Chemistry, Warsaw, Poland (1)

Keywords: ion mobility mass spectrometry, macrocycles, anions, noncovalent complex

Introduction: One of the most intensively developed topics of supramolecular chemistry is design, synthesis and studies of neutral molecular receptors capable of strong and selective binding of anions because of their crucial role in many chemical and biochemical processes. The ion mobility mass spectrometry (IM-MS) supported by theoretical calculations and CID methods are evaluated as fast screening methods in the development of new receptors.

Methods: IM-MS measurements were performed on Synapt G2-S HDMS. Collision-induced dissociation (CID) measurements were performed on the triple quadrupole 4000 Q Trap (MD SCIEX). Starting models of the molecules and ions were generated using Spartan software and were further optimized with DFT Methods: The theoretical collision cross sections for model structures were calculated using Mobcal program.

Results: The complexes of macrocyclic receptors with selected anions are stable enough in the gas-phase to survive the conditions of the IM-MS experiments. The experimentally measured collisional cross sections were used for establishing the steric structures of the studied ions by comparing them with the cross section values obtained from molecular modelling. **Methods:** The type of calibrant ions significantly affects the accordance between theoretical and experimental values of collision cross sections. The effects of the deformation of macrocyclic receptors upon complexation with anions are recognized in IM-MS experiments.

Conclusions

The results confirm the usefulness of the IM-MS technique for studying the structures of complexes of the macrocyclic receptors with anions. They also prove that the IM-MS method is very sensitive to even small differences in the structures of the studied complex ions. The IM-MS and CID techniques are potentially very efficient and cost-effective methods to study supramolecular recognition of anions.

Novel Aspect: IM-MS and CID techniques evaluated as fast screening methods in the development of new receptors.

824 - FT-ICR MS STUDIES OF THIOMOLYBDATE CLUSTERS AS MODEL CATALYSTS FOR HYDROGEN EVOLUTION

Aristeidis Baloglou (1) - Milan Ončák (1) - Christian van der Linde (1) - Marie-Luise Grutza (2) - Philipp Kurz (2) - Martin K. Beyer (1)

Universität Innsbruck, Institut für Ionenphysik und Angewandte Physik, Innsbruck (1) - Albert-Ludwigs-Universität Freiburg, Institut für Anorganische und Analytische Chemie, Freiburg (2)

Keywords: molybdenum sulfide; catalysis; hydrogen evolution; action spectroscopy; dissociation

Introduction:

Molybdenum sulfide-based catalysts have the potential to replace platinum as a hydrogen evolution reaction (HER) catalyst in electrochemical water splitting [1]. A better understanding of the reaction mechanisms contributes to the targeted optimization of the catalysts. In this contribution, individual reaction steps are investigated quantitatively employing precisely defined gas-phase models, like $\text{Mo}_3\text{S}_{13}(2-)$ and $\text{Mo}_2\text{S}_{12}(2-)$.

Methods:

Fourier transform ion cyclotron mass spectrometry (FT-ICR MS) is used, as it is an excellent tool to examine ion-molecule reactions in the gas phase [2], including catalytic cycles. By combining FT-ICR MS with IR and UV/VIS laser spectroscopy, the reactants, products and reactive intermediates can be further characterized.

Results:

IR-spectroscopy experiments with the protonated species $\text{HMo}_3\text{S}_{13}-$ show a distinct H-S stretching vibration. Comparing this result with density functional theory (DFT) calculations suggests that the proton is bound to an edge disulfide unit of the cluster. In gas phase, the cluster $\text{Mo}_3\text{S}_{13}(2-)$ unfolds from the highly symmetric Mo_3 -ring structure, found in the solid state, to form irregular structures with a variety of mono- and disulfide ligands. Structural changes are also expected for molybdenum sulfide clusters deposited on electrodes. Investigation of the structural flexibility and chemical properties of the different sulfur moieties contributes to an understanding of the catalytic activity of molybdenum sulfide surfaces.

Conclusions:

Structural features evolve in the gas phase that elucidate the conformational flexibility and relative stability of reactive molybdenum sulfide species. Hydrogen is bound at sulfur centers, as revealed by the infrared signature of the S-H bond. Electronic excitation spectra indicate the availability of low-lying excited states for some species generated by mild collisional activation.

Novel Aspect:

Molybdenum sulfide clusters are synthesized with isotopically enriched molybdenum and characterized by mass spectrometry in combination with optical excitation.

1198 - TANDEM CRYO ION TRAP MASS SPECTROMETRY FOR KINETICS AND SPECTROSCOPY OF TRANSITION METAL CLUSTERS

Gereon Niedner-Schatteburq (1)

Fachbereich Chemie and Forschungszentrum OPTIMAS, TU Kaiserslautern, Kaiserslautern, Germany (1)

We have implemented cryo ion trap FT-ICR instrumentation with temperature control to as low as 11 Kelvin. With two such instruments we investigate the magnetism and the adsorption kinetics of transition metal clusters and complexes. We have upgraded one of these instruments by a cryo RF trap for tandem cryo operation. Spectroscopy comes into play through application of Infrared Photon Dissociation (IR-PD) by optical parametric oscillator/amplifier (OPO/OPA) photon sources. This enables one and two colour investigations of metal organic complexes[1] and of transition metal cluster adsorbate complexes[2-3].

Stepwise cryo adsorption kinetics of N₂ on Ni_n⁺ clusters reveal clearly discernible mono layer like adsorbate shells which interpret in the light of IR-PD spectra of the product complexes Ni_n(N₂)_m⁺. It emerges a characterization of the cluster surface morphology and its adsorbate induced reorganization[4-5]. The according data on Fe_n⁺ cluster N₂ adsorption are subject of current interpretation.

Case studies on various metallophthalocyanine complexes found interpretation in terms of adsorbate induced spin quenching[6], and recent findings of non classical blue shifts of N₂ stretching modes of adsorbates to Fe₃O(OAc)₆⁺ complexes received interpretation in terms of orbital interactions[7].

The tandem cryo trap option comes to live by studying consecutive co-adsorptions of N₂ and H₂ to selected Ru₈⁺ clusters – as compared to the reverse order co-adsorption. Our findings allowed to elucidate the mutual interdependencies amongst the adsorption kinetics, their activation and migration[8].

This work was supported by the Deutsche Forschungsgemeinschaft DFG in the framework of the transregional collaborative research center SFB/TRR 88 3MET.de.

1115 - ESI IN THE STUDY OF THE INTERACTIONS BETWEEN PHOSPHINO-CU(I) COMPLEXES AND CU(II) SALTS WITH MODEL PEPTIDES RELEVANT TO HUMAN COPPER TRANSPORTERS (HCTR)

Francesco Tisato (1) - Karolina Bossak-Ahmed (2) - Marina Porchia (1) - Wojciec Bal (2) - Arkadiusz Bonna (3)

ICMATE – CNR, Corso Stati Uniti, 4 – 35127 Padova, Italy (1) - Institute of Biochemistry and Biophysics, Polish Academy of Sciences, Pawińskiego 5a, 02-106 Warsaw, Poland (2) - Department of Biochemistry, University of Cambridge, Tennis Court Road, Downing Site, Cambridge CB2 1QW, United Kingdom (3)

Keywords: Copper anticancer drugs, internalization of copper in cancer cells, Cu(I) and Cu(II), model tripeptides, human Copper Transporter1 (hCtr1)

Introduction: Human Copper Transporter 1 (hCtr1) is a 190 amino-acids trans-membrane protein mainly devoted to the recruitment of metal ions from the extra-cellular fluids [1]. The extracellular domain of hCtr1 contains histidine-rich and methionine-rich sequences likely responsible of metal ions recruitment. The terminal portion of the protein extruding from the cell membrane contains the characteristic Met-Asp-His peptide sequence.

Methods: The interaction of Cu(I), Ag(I) and Cu(II) ions comprised in appropriate precursors (i.e. $[\text{Cu}(\text{P})_4]^+$, $[\text{Ag}(\text{P})_4]^+$ and CuCl_2 (P = tertiary phosphine)) with selected model tripeptides XYHis (X = Gly, Met; Y = Gly, Asn, Asp) and some polypeptides relevant to hCtr1 has been investigated by electrospray ionization mass spectrometry, and the interaction products have been characterized by multiple collisional experiments, using an ion trap mass instrument.

Results: Model XYHis tripeptides starting from the designed GlyGlyHis derivative of the ATCUN family [2] are able to mine Cu(I) and Ag(I) from $[\text{M}(\text{I})(\text{P})_4]^+$ inorganic precursors through the formation of the $[\text{M}(\text{I})(\text{XYHis})]^+$ adducts under ESI(+)MS conditions [3]. Also Cu(II) is wrapped by XYHis tripeptides via $[\text{Cu}(\text{II})(\text{XYHis}) - \text{H}]^+$ adducts. MSn of these metal-tripeptide complexes indicate that His is bound strongly to the metal in all cases. While CID pathways of $[\text{M}(\text{I})(\text{XYHis})]^+$ ions proceeded through losses of neutral fragments, MSn fragmentation of $[\text{Cu}(\text{II})(\text{XYHis}) - \text{H}]^+$ ions instead took place mainly through intramolecular electron transfer reactions including the reduction of Cu(II) to Cu(I) and the formation of fragment radical cations. The interaction of $[\text{M}(\text{I})(\text{P})_4]^+$ precursors with polypeptide sequences representing the terminal extra-cellular portion of hCtr1 (MetAspHis, MetAspHisSerHisHis and MetAspHisSerHisHisMetGlyMetSer) confirms the ability of these peptides to mine and recruit M(I) ions from inorganic precursors.

Conclusions: Model tripeptides having a free-amino group at N-terminus and either a free carboxylic or an amidated group at the C-terminus of His in third position, and polypeptide sequences relevant to hCtr1 are able to mine Cu(I), Ag(I) and Cu(II) from inorganic precursors via formation of $[\text{M}(\text{tri/polypeptide})]^+$ adducts. This experimental evidence is significant to shed light in the cell internalization process of anticancer phosphino-Cu(I) drugs.

Novel Aspect: The observation that Cu(II) comprised in the $[\text{Cu}(\text{II})(\text{XYHis}) - \text{H}]^+$ ions undergoes redox reaction under ESI(+)MSn conditions might be relevant in the claimed reduction processes of physiological Cu(II).

675 - UV-VIS SPECTROSCOPY AND PHOTOCHEMISTRY OF TRAPPED IONS USING FT-ICR-MS

Christian van der Linde (1) - Milan Ončák (1) - Nina K. Bersenkovitsch (1) - Andreas Herburger (1) - Thomas Taxer (1) - Martin K. Beyer (1)

Universität Innsbruck, Institut für Ionenphysik und Angewandte Physik, Innsbruck (1)

Keywords: spectroscopy, photochemistry, FT-ICR-MS, atmosphere, magnesium cluster

Introduction:

While infrared spectroscopy of ions is a well-established field, the potential of UV-VIS spectroscopy of ions is barely touched. The field was pioneered by Ben Freiser in the 1980s, using lamps and monochromators as light source.[1] Nowadays tunable optical parametric oscillators cover a wide range of wavelengths from UV to infrared which can be used for spectroscopy, e.g. the photodissociation of peptides.[2]

Methods:

Two FT-ICR-MS setups are used: A modified CMSX47 instrument equipped with a 4.7T magnet, APEX II data station and a laser vaporization ion source and a Bruker Apex Qe, equipped with a nanobay console, electrospray ion source and a 9.4T magnet. Light from tunable OPO (EKSPLA NT342B) is guided into the FT-ICR cell for studying spectroscopy and photochemistry. Experiments are supported by theoretical calculations.

Results:

FT-ICR-MS is, compared to time of flight techniques or quadrupole mass filters, inherently slow, with a duty cycle in the range of seconds. High-resolution spectroscopy over a wide wavelength range, which requires the recording of 103-104 mass spectra, is not the prime application of FT-MS instruments. However, FT-MS offers a combination of high mass resolution, long trapping times, flexible mass selection capabilities in a collision-free environment and simultaneous detection of all fragments with high fidelity of absolute intensities. These features give FT-MS significant advantages over other techniques for specific problems.

Selected examples which illustrate these advantages include photochemical hydrogen formation in the $\text{Mg}+(\text{H}_2\text{O})_n$, $n = 1-5$, system, or the spectroscopy of the atmospherically relevant $\text{CO}_3-(\text{H}_2\text{O})_{1,2}$ ion in combination with a nitrogen cooled FT-ICR cell.

Conclusions:

The results show that FT-ICR-MS is a powerful tool in combination with theory for investigation of the photochemistry of cluster systems.

Novel Aspect:

Interplay between single and two photon processes play an important role in photodissociation of hydrated positively charged magnesium clusters.

Keywords: Antimonato polyoxovanadates, solution and gas phase reactivity, isotope exchange experiments, CID, mechanistic studies

Introduction:

Polyoxometalates cover a broad spectrum of interesting properties related to the nature and number of incorporated metals, their size and shape, their redox behavior, magnetic and photochemical characteristics. Possible applications are manifold. Yet to harness a certain functionality, comprehensive insights into their structure and reactivity are crucial.

Methods:

We are presenting the investigation of structure and reactivity in solution and in the gas phase of different antimonato polyoxovanadates by electrospray ionization mass spectrometry (ESI-MS), isotope exchange experiments in solution, collision-induced dissociation tandem MS and ion mobility MS experiments conducted at a SYNAPT G2-Si (Waters, Manchester).

Results:

The first water-soluble antimonato polyoxovanadate cluster was demonstrated to be present in solution as two distinct species, which both possess an intact, closed cage-like $\{V_{15}Sb_6\}$ structure: a water-encapsulating and a water-free cluster core. Its chemical behavior is greatly dependent on the encapsulated water molecule, since a transduction of inner-phase reactivity of the guest results in changes in the outer-phase reactivity of the cluster cage.[1] Moreover, the surrounding cationic metal-complexes and the ligand environment, as well as additives influence the reactivity of the $\{V_{15}Sb_6\}$ cluster in solution.[2] In this regard, a $\{Sb_6V_{15}\} \rightarrow \{Sb_8V_{14}\}$ cluster transition was discovered by ESI-MS. This reaction enables in combination with a change in the ligand sphere the formation of an unusual, meta-stable $\alpha^1\text{-}\{V_{14}Sb_8\}$ isomer which forms dimeric super structures. These were investigated in the solid state, in solution and in the gas phase.[3]

Conclusions:

ESI-MS and IMS could serve as a probe for the elucidation of solution and gas-phase reactivity of metal-oxo clusters, as well as the identification and structural analysis of new products. These methods can provide the rational guideline for the synthesis of new compounds and for the assembly of resulting complex supramolecular architectures.

Novel Aspect:

We present the first comprehensive study on the structure as well as solution and gas-phase reactivity of antimonato polyoxovanadate clusters.

622 - ANALYSIS FOR REFORMING PROCESSES FOR GASOLINE SURROGATE FUEL-AIR PRE-MIXTURES BY NON-THERMAL PLASMAS USING ION ATTACHMENT MASS SPECTROMETRY

Daiki Asakawa (1) - Eiichi Takahashi (2) - Naoaki Saito (1)

AIST, Research Institute for Measurement and Analytical Instrumentation, Tsukuba (1) - AIST, Research Institute for Energy Conservation, Tsukuba (2)

Keywords: Oxygen atom, Ozone, Ketone, Aldehyde, Ab initio calculation

Introduction

Non-thermal plasma induced reforming of fuel-air mixtures can improve the thermal efficiency of internal combustion engines by achieving its super-lean-burn operation. To address the general mechanisms of non-thermal plasma induced gasoline reforming in air, we used iso-octane, n-heptane, toluene, trimethyl pentene and methyl cyclohexane, which are components of gasoline surrogate fuel, as the models.

Methods

A mixture of air with liquid hydrocarbons was reformed by non-thermal plasma in a flow reactor, generated by a dielectric barrier discharge (DBD), and then directly analyzed using ion attachment mass spectrometry (IAMS). The reactor temperature was kept at 393 K and the equivalence ratio of the pre-mixture was set to 0.5. The simulation of the fuel reforming was performed by DFT calculation with Gaussian 16 program.

Results

The IAMS mass spectra of the alkane/air mixture with DBD irradiation showed intense signals corresponding to ketone and aldehyde. The DBD irradiation of the alkane/air mixture produced oxygen atoms, which abstract a hydrogen atom from alkanes. As a result, alkanes were converted to alkyl hydroperoxide through alkyl radicals. The ketone and aldehyde were generated by fragmentation of alkyl hydroperoxide. As in the case of oxygen atom generation, DBD produced ozone, which selectively reacts with alkenes to produce molozonide. The trimethyl pentene undergoes the cleavage of double bond by DBD irradiation, leading to ketones. The DBD irradiation to toluene/air mixture provided the signal corresponding to benzaldehyde. A hydrogen atom in toluene was abstracted by oxygen atoms. The produced benzyl radical was immediately converted to benzyl hydroperoxide by the reaction with oxygen molecules and subsequent fragmentation would produce benzaldehyde. The proposed fuel reforming processes are supported by the ab initio DFT calculations.

Conclusions

DBD irradiation of the fuel/air mixture produced oxygen atoms and ozone, which react with fuel molecules. Hydrocarbons were converted to ketones and aldehydes by DBD induced fuel reforming. The presence of products due to DBD plasma irradiation, such as ketones, aldehydes, and intermediates e.g., alkyl hydroperoxide and molozonide, would contribute to the combustion enhancement resulting in the thermal efficiency and stability of lean internal combustion engines.

Novel Aspect

DBD induced fuel reforming of hydrocarbons provides ketones and aldehydes, which would contribute to improve the performance of lean combustion in internal combustion engines.

1195 - ELUCIDATING THE CHEMISTRY OF ELUSIVE GAS PHASE RADICALS USING DISTONIC RADICAL IONS: TRYING TO GET A GOOD DEAL FROM A FAUSTIAN BARGAIN

Stephen Blanksby (1) - David L. Marshall (1) - Berwyck L. J. Poad (1) - Adam J. Trevitt (1)

Central Analytical Research Facility (CARF), Institute for Future Environments, Queensland University of Technology (1)

Keywords: ion-trap mass spectrometry; distonic radical ions; ion spectroscopy; thermochemistry

Introduction:

Distonic radical ions can be used to explore the chemistry of transient radicals in the gas phase. While this approach facilitates the experimental observation of elusive radicals, it also perturbs their native reactivity. Direct thermodynamic and spectroscopic measurements of the influence of charge on radical stability within distonic radical ions have been undertaken and highlight perturbations over significant intramolecular separations.

Methods:

Radical ions have been synthesized in the gas phase using regioselective approaches based on collision-induced dissociation and photodissociation on modified ion trap mass spectrometers. The kinetics of ion-molecule reactions have been measured by seeding low concentrations of reagent gas in the helium buffer gas supplied to the ion trap.

Results:

Pioneering research by Kenttämää has demonstrated the power of the distonic ion approach but has also highlighted the Faustian bargain that is entered into with the introduction of the charged moiety to the radical [1]. That is, while the presence of the charge facilitates the experimental observation and characterization of elusive radicals it can also perturb their native energetics. In our laboratory a homologous series of distonic ions incorporating nitroxyl and peroxy radicals have been regioselectively prepared as both positively and negatively charged ions. The influence of the charge polarity and the distance between the charge and radical sites were systematically explored using a combination of ion spectroscopy; thermochemical measurements (using the kinetic method); and ion-molecule reactions. Key findings from these investigations reveal that radical moieties are stabilised in distonic anions and destabilised in analogous cations, with respect to their corresponding neutrals. Significantly, these effects could be measured over intramolecular distances of up to 10 Å.

Conclusions: The thermodynamic impact of charged groups on radical stability provides the critical insight required to extrapolate distonic ion behaviours to their neutral archetypes. Moreover, the long range nature of charge-radical effects suggests that these phenomena are likely playing a significant role in the dissociation chemistries of the radical ion intermediates formed in contemporary ion dissociation technologies (e.g., ETD, ECD and RDD).

Novel Aspect:

Direct measurement of charge-radical interaction energetics in distonic ions

Keywords: IRMPD kinetics, isomerism, conformer discrimination, cisplatin, aminoacids

Introduction:

Relevant intermediate species in the reaction path of cisplatin with aminoacids can be difficult to characterize due to the high reactivity of square planar complexes of Pt(II) with nucleophiles. However, ESI-MS proved to be valuable in allowing to detect for the first time the primary complexes generated from direct substitution of one of the labile chloro ligands of cisplatin with aminoacids like His and Met, modeling cisplatin interaction with peptides and proteins.

Methods:

The complexes of interest were brought to the gas-phase using ESI and mass-analyzed using a Paul ion trap instrument (Bruker Esquire 6000) or a FT-ICR mass spectrometer (Bruker APEX-Qe and 7T Solarix). Vibrational features of the mass-selected ions were assayed using IRMPD spectroscopy in both XH (X = C, N, O) stretching and fingerprint regions using an OPO/OPA benchtop laser system and the free electron laser (FEL) at the Centre Laser Infrarouge d'Orsay, respectively.

Results:

The primary complexes of cisplatin with histidine and methionine, $\text{cis-[PtCl(NH}_3\text{)}_2\text{(L)]}^+$ (L = His, Met), have been characterized using high-resolution MS and IRMPD spectroscopy. The IR spectrum of bare ions can be directly compared with calculated spectra, thus allowing the attribution of the assayed species to a particular conformer or a set of them. In the case of the cisplatin-histidine adduct, a complex mixture of isomers and conformers was hypothesized and finally resolved using IRMPD kinetics on conformer-specific vibrational modes.[1] Regarding the adduct with methionine, the comparison of the IRMPD spectrum with theoretical ones confirmed the preferred interaction of Pt with the thioether functionality of the aminoacid. However, when the complex of a structural isomer of the drug, transplatin, with Met was assayed, differences in the photofragmentation kinetics on a same, selected vibrational mode permitted to unveil the presence of a mixture of isomers presenting platinum coordination at either the amino or the thioether group.[2]

Conclusions

We show the ability of mass spectrometry to extract and isolate from solution species difficult to characterize using condensed-phase based techniques. Also, the coupling with IRMPD permitted to obtain spectroscopic information on the mass-isolated ions, proving the presence of complex isomeric mixtures. In this regard, the use of fixed-wavelength IRMPD kinetics permitted to discriminate and quantify isomers and conformers forming the gas-phase populations.

Novel Aspect:

Monofunctional adducts of cisplatin with His and Met have been characterized for the first time. IRMPD kinetics were used to discriminate and quantify isomers and conformers.

Characterization of a Nitrogen Dielectric Barrier Discharge Ionization

Keywords: ambient ionization techniques, nitrogen dielectric barrier discharge, fundamental, reactive species

Introduction:

In the last decade, ambient ionization coupled to mass spectrometry generated enormous attention due to the fast and sensitive analysis with nearly no sample preparation. [1] However, the development of new sources dominated over the understanding of the ionization mechanism of already existing Methods: In this work, the active capillary plasma ionization source was characterized to get a better understanding of the behavior of the reactive species.

Methods:

The active capillary plasma ionization source contains a stainless steel capillary (ground electrode) which is separated by a glass capillary from a copper ring (sine-modulated high voltage). [2] Nitrogen or air was used as discharge gas. The plasma source is directly connected to the mass spectrometer. All optical measurements were performed AT the cross section of the plasma source using either UV-VIS spectrometer in the range of 200-850 nm or a ns-gated iCCD camera.

Results:

The active capillary plasma ionization source based on nitrogen dielectric barrier discharge was characterized by optical emission spectroscopy. The two most abundant signals were the transitions of NO (γ system) and N₂ (2nd positive system) and in low abundance the transition of N₂⁺ (1st negative system) and O₂⁺ (Schumann band) was obtained. It is known that N₂⁺ is the reactive species for producing (H₂O)H₃O⁺ or SH⁺, which are mostly responsible for the protonation of the analytes (MH⁺). However, the lower abundance of N₂⁺ was obtained in nitrogen plasma than in helium, which is due to the different ionization pathway. Nevertheless, the sensitivity of the ionization was similar for both discharges, since different geometries to the MS and sample introduction into the plasma was used. The nitrogen plasma ignites as irregular filaments between the inner electrode and the glass, which was confirmed by using an iCCD camera. Analytes can therefore travel through the plasma-free regions inside the capillary without fragmentation.

Conclusions

The properties of the filaments were studied by monitoring the transitions of NO (γ system) and N₂ (2nd positive system) when applying different plasma parameters (voltage, frequency, humidity, etc.). Characterization of the plasma not only helps to improve the understanding of the ionization mechanism but also allows to optimize the performance of the plasma source when coupled with the mass spectrometer.

Novel Aspect:

This is the first report on spectroscopic characterization of the active capillary plasma ionization source which is used as a soft ionization source coupled to MS.

Introduction:

Metabolome, the end product of the genome, can be studied through identification and quantification of small molecules. The global metabolome influences the individual phenotype through clinical and environmental interventions.^(1, 2) Metabolomics has become an integral part of clinical research and allowed for another dimension of better understanding of disease pathophysiology. The clinical biochemistry laboratory routine workload (>95%) is based on small molecular identification, which can potentially be analyzed and discovered through metabolomics.^(3, 4) However, multiple challenges in clinical metabolomics impact the entire workflow and data quality, thus the biological interpretation needs to be standardized for a reproducible outcome. The existing Mass spectrometry-based Newborn Screening assay has false discovery rate (FDR) that can be minimized once linearly integrated with other markers.

Methods:

Herein, we introduce the establishment of a comprehensive targeted metabolomics method for a panel of 225 clinically relevant metabolites using Liquid chromatography-tandem mass spectrometry (LC-MS/MS) standardized for clinical research. The sensitivity, reproducibility and molecular stability of each targeted metabolite (amino acids, organic acids, acylcarnitines, sugars, bile acids, neurotransmitters, polyamines, and hormones) were assessed under multiple experimental conditions. The metabolic tissue distribution was determined in various rat organs. Furthermore, the method was validated in dry blood spot (DBS), the standard sample type for newborn screening, collected from patients known to have various inborn errors of metabolism (IEMs).

Results:

The targeted LC-MSMS-based metabolomics method was developed for quantitation purpose, and the validity of this method was studied by following the United States Food and Drug Administration (USFDA) guideline.⁽⁵⁾ This approach appears to be sensitive (LLOQ for 2-Ketobutyric acid is 1 nM) and robust (CV% ranges from 80-120%). The metabolic chemical stability and extraction recovery were evaluated in this approach using several biological matrices to control the method robustness in the routine analysis. The sensitivity of the method demonstrated differential and unique expression profiles in various rat tissues, where the overall metabolic expression varied, but was highest in the kidney tissue (35%) compared to the liver (25%), brain (17%), heart (15%) and muscle tissue (8%) for the same amount of tissue. Several optimizations and studies have been done on DBS samples such as relative

metabolic expression compared to whole blood and serum, the normal cutoff for each expressed metabolite in this panel, and the differential expression compared to patient samples. 56 patient samples with known diagnosis were analyzed using this platform for clinical validation. This method was capable to produce the same diagnosis as in the routine NBS platform using the same key markers, for instance, it gives the Phenylalanine/tyrosine ratio high in PKU patients compared to the others. Additionally, several other metabolites were found to be differentially expressed in these patients compared to control samples such as betaine, succinic acid, niacinamide, fructose 1, 6-bisphosphate. Several sugars (i.e. arabinose, ribulose) were overexpressed mainly in the disorders of mitochondrial metabolism (VLCAD and GA2 deficiency) compared to controls. In MMA (n=6) and PA (n=2) patients displayed distinct metabolomics profiles with minimal overlap including hyperglycinemia and related elevated glutamine levels. Interestingly, spermine appears to be markedly reduced in MMA compared to PA suggesting a preferential toxicity to the synthetic polyamine pathway in such patients.

Conclusions:

There is a strong clinical need to develop and validate quantitative methods capable of measuring the largest number of metabolites subject to wide and rapid dynamic changes present in a biological system. In the present study, we demonstrated the effect of sample matrix on the expression of profiles of a large set of clinically oriented metabolites which may help to guide the choice of the optimal sample type and matrix in which it is collected. We have also shown the capability of this assay to detect common inborn errors of metabolism. In addition to its role as a second tier assay, this targeted panel is also potentially useful as a screening tool for a large group of inborn errors of metabolism

Novel Aspect:

This panel has the ability to identify patients with IEMs and discover novel markers that minimize the assay FDR.

Keywords: steroid bisconjugate, molecular di-anion, stable isotope label, MS fragmentation, ion loss,

Introduction:

Doubly or bisconjugated steroid metabolites have been known for decades and typically studied by indirect GC-MS Methods: Recently, the direct detection of steroid bis(sulfates) by LC-MS has been applied to doping in sport [1] and the prenatal diagnosis of inborn errors of steroid biosynthesis [2]. Access to labelled compounds for MS would increase our understanding of these fascinating compounds.

Methods:

General methods of chemical synthesis were developed to prepare stable isotope ^{18}O -labelled sulfate esters and ^{13}C -labelled glucuronides, including selectively labelled steroid bis(sulfate) and bisglucuronide compounds for use as MS probes or internal standards. The ionisation and fragmentation of these reference materials have been studied in detail on a triple quadrupole mass spectrometer.

Results:

Stable isotope ^{18}O -labelled sulfate esters and ^{13}C -labelled glucuronides were prepared from commercially available $\{^{18}\text{O}_4\}$ -sulfuric acid (96 atom %) and $\{^{13}\text{C}_6\}$ -D-glucose (>99 atom %). High levels of incorporation were observed with the conjugates suitable for use as MS probes or stable isotope labelled internal standards. Selectively labelled steroid bis(sulfate) and bisglucuronide compounds were used to study MS fragmentation pathways. Steroid bis(sulfate) compounds preferentially ionized as the doubly deprotonated molecule ($[\text{M}-2\text{H}]^{2-}$) and this precursor typically underwent ion loss of the HSO_4^- ion (m/z 97) to afford fragment ions of higher m/z ($[\text{M}-2\text{H}-\text{HSO}_4]^-$). Other fragmentation processes including ion loss of $\bullet\text{SO}_3^-$ (m/z 80) and HSO_3^- (m/z 81), neutral loss of SO_3 (40 Da) and ion molecule "roaming" were observed and correlated with analyte structure.

Conclusions:

Access to stable isotope labeled sulfate and glucuronide conjugates has unveiled the rich MS fragmentation behaviors of steroid bisconjugates. This knowledge paves the way for the development of new LC-MS approaches for the direct and untargeted detection and identification of these metabolites.

Novel Aspect:

Synthesis of stable isotope labelled sulfate and glucuronide conjugates, selectively labelled bisconjugates and their use in MS fragmentation studies.

Keywords: Reaction monitoring, density functional theory, microreactor, online, reaction mechanism

Introduction:

Understanding reaction mechanisms is crucial in studies of chemical reactions. When knowing the mechanism, reaction conditions can be designed to maximize the yield of desired product(s). Microreactors coupled online to mass spectrometry are ideal for experimental reaction mechanism studies[1],[2], while density functional theory calculations are well-established for theoretical studies.

Methods:

A 3D printed polypropylene microreactor with an integrated ESI needle[3] was interfaced with an ion trap mass spectrometer for online analysis of the oxidation of heptafulvenes to tropones. Density functional theory calculations were done with the software Gaussian 09, using the M06-2X functional and a 6-311++G(d,p) basis set to identify the most favored reaction pathway.

Results:

Online mass spectrometry allowed observation of the heptafulvene starting material, two key intermediates of the oxidation reaction and the tropone product as protonated molecules in positive mode ESI. MS_n analysis of these species, as well as how their intensity change in relation to each other depending on the reaction time, support the proposed identifications. Based on the mass spectrometric results six competing reaction pathways were studied with density functional theory. The lowest energy reaction pathway, which thus is the most likely one, proceeds via initial formation of an epoxide, which is opened upon the addition of a second equivalent of the oxidizing species meta-chloroperoxybenzoic acid. The adduct then undergoes a Criegee-like rearrangement to produce a positively charged hemiketal, which upon deprotonation dissociates into acetone and the tropone.

Conclusions:

The most likely reaction mechanism for oxidizing heptafulvenes to tropones has been identified by experimental and theoretical investigations. These results are a good basis for optimizing reaction conditions to improve yields of the promising anti-cancer compound tropone[4]. Furthermore, these results highlight the usefulness of combining experiments and theory for studying reaction mechanisms.

Novel Aspect:

The synergy of combining results from a microreactor coupled to mass spectrometry and computational chemistry to find a plausible reaction mechanism.

646 - HOW TO MODIFY THE ACIDITY OF CHARGED DROPLETS?

Mari Ojakivi (1) - Jaanus Liigand (1) - Anneli Kruve (2)

The University of Tartu, Institute of Chemistry, Tartu (1) - Freie Universität Berlin, Institut für Chemie und Biochemie, Berlin (2)

Keywords: aerosols, electrospray, ionization efficiency, protonation, surface chemistry

Introduction:

The concept of acidity in confined spaces has been poorly understood, especially in media violating electroneutrality. Here [1] we present a study on the acidity of charged droplets to fill the gap in knowledge. We studied the effect of pH and different additives on the acidity of charged water and methanol droplets via protonation of nitrogen bases in electrospray. As a result, the work gives insight into how to modify the acidity of charged droplets.

Methods:

The protonation of 10 nitrogen bases was studied using ESI/MS. The extent of protonation (which is related to the acidity of charged droplets) was calculated using ionization efficiency values. To alter the acidity of charged droplets produced in ESI, 28 solvent compositions were used in water ($pH_{H_2O}=1.42-10.29$) and 14 in methanol ($pH_{MeOH}=3.63-12.24$). The solvent composition was varied using 10 additives in different concentrations and combinations.

Results:

Generally, we observed that the ionization efficiencies of most analytes are pH dependent in specific pH range in both water and methanol. However, wrong-way-round ionization occurs in both solutions. Also, the extent of protonation decreases sharply in the pH_{H_2O} range from 2 to 4 for all compounds, even though pK_{aH_2O} values of these compounds range from 2.7 to 9.0. Close investigation of the pH range of 2 to 4 revealed that additive type affects the acidity of the droplets more than pH in aqueous solutions, enhancing the extent of protonation of the compounds when only acidic additives are present compared to droplets of the same pH containing also ammonium salts. Thus, we propose that in case of acidic additives, the excess charge on the droplet surface is a result of protonated acid and water molecules and, therefore, enhances ionization efficiency of compounds significantly. The effect of additives is less influential in case of methanol droplets, as the excess charge is situated in the interior of the droplets.

Conclusions:

The results show that the concept of acidity in solution phase cannot be transferred to charged droplets. We demonstrated that the acidity of charged water droplets depends on the additive; which means that the extent of protonation can effectively be modified by changing additive type even if the pH is kept constant. The opposite is true for charged methanol droplets where the extent of protonation can be adjusted with the conventional approach of changing the pH.

Novel Aspect:

While the protonation in charged methanol droplets depends on the solution-phase acidity, the protonation in charged water droplets can easily be modified with additives.

Studies of a L-proline catalyzed inverse electron demand Diels-Alder reaction by ESI-MS

Schnell, J. A. Willms, M. Engeser

Kekulé-Institute of Organic Chemistry and Biochemistry, University of Bonn

Keywords:

Charge-tagging; electrospray ionization mass spectrometry; L-proline; organocatalysis; reaction mechanism

Introduction:

The synthetic scope of the L-proline catalyzed inverse electron demand Diels-Alder reaction between tetrazines and ketones has been published by Xie et al.[1] in 2008 alongside a postulated catalytic cycle. The postulated catalytic cycle includes three intermediates. First an enamine I derived from L-Proline and a ketone, which undergoes the Diels Alder reaction with the tetrazine forming II which loses nitrogen in a retro Diels-Alder reaction forming III. [1]

Methods:

Samples of the reaction solution were analyzed by ESI-MS and CID experiments. A charge-tagged substrate and a catalyst were utilized in different experiment setups as to enhance the ESI response factors of the respective intermediates.

Results:

While studying the reaction without implementing a charge tag into any of the participating species the third intermediate III could be detected and kinetic studies could be obtained. The charge tagged tetrazine was synthesized in hopes of detecting the second intermediate II as well, but to no avail; however again kinetic studies could be obtained. By using the charge tagged L-proline derivative from our group[2] as a catalyst all three intermediates could be detected and characterized by CID experiments. Within the CID experiments it was possible to mimic the reaction steps of the catalytic cycle.

Conclusions:

It was possible to thoroughly verify the catalytic cycle for the L-proline catalyzed inverse electron demand Diels-Alder reaction between acetone and 3,6-di-2-pyridyl-1,2,4,5-tetrazine.

Novel Aspect:

The superior effectiveness of utilizing a charge-tagged catalyst in ESI-MS studies of catalytic reactions could be demonstrated.

50 - AMINO-ACIDS OXIDATION: A COMBINED STUDY OF CYSTEINE OXO-FORMS BY MASS SPECTROMETRY, IRMPD SPECTROSCOPY AND SIMULATIONS

Debora Scuderi (1) - Enrico Bodo (2) - Simonetta Fornarini (3) - Barbara Chiavarino (3) - Maria Elisa Crestoni (3) - Veronica Macaluo (4) - Riccardo Spezia (5)

Laboratoire de Chimie Physique, UMR 8000, Université Paris Sud, Orsay (1) - Dipartimento di Chimica, Università degli Studi di Roma La Sapienza, Rome (2) - Dipartimento di Chimica e Tecnologie del Farmaco, Università degli Studi di Roma La Sapienza, Rome (3) - LAMBE, Université d'Evry, CNRS, CEA, Université Paris-Saclay, Evry (4) - Laboratoire de Chimie Théorique, UMR 7616 CNRS, Sorbonne Université,, Paris (5)

Keywords:

IRMPD spectroscopy; cysteine oxo-forms; collisional induced dissociation; ab initio molecular dynamics simulations; chemical dynamics simulations;

Introduction: (Limit of 400 characters)

Cysteine residues in sulfenic (-SOH), sulfinic (-SO₂H) and sulfonic (-SO₃H) forms are key intermediates in the redox-switch chemistry of proteins [1]. Although sulfenic acids have been identified in several biochemical frameworks, they are transient and not isolable in small molecular systems. Low-energy collision-induced dissociation of L-Cysteine sulfate affords L-cysteine sulfenic acid.

Methods: (Limit of 400 characters)

Chemical dynamics simulations [2] have been employed to shed light on fragmentation mechanisms of L-Cysteine sulfate. A combined approach based on infrared multiple photon dissociation spectroscopy, calculations of IR frequencies and finite temperature ab initio molecular dynamics simulations has been employed to characterize the gas-phase structures of deprotonated cysteine oxo-forms.

Results: (Limit 900 characters)

IRMPD spectra of cysteine oxo-forms have been recorded in the highly informative mid-IR spectral range employing a Paul ion-trap mass spectrometer coupled to the IR beamline of the tunable free-electron laser at the CLIO facility in Orsay [3]. These ions show different structural motifs owing to the preferential binding of the proton to either the carboxylate or the sulfur-containing group. Due to the decreasing basicity of the sulfenic, sulfinic and sulfonic terminals, the proton is bound to SO- in [cysSO]⁻, migrates on the carboxylate in [cysSO₃]⁻, while it turns out to be shared in [cysSO₂]⁻. Evidence is gathered that a mixture of close-lying low-energy conformers is sampled for each cysteine oxo-form in a Paul ion-trap at room temperature [4]. An exotic roaming mechanism has been evidenced in the formation of L-cysteine sulfenic acid with other competing pathways.

Conclusions (Limit of 400 characters)

The spectroscopic signatures of the oxidative modifications enable the assignment of the deprotonation site and conformational landscape of the sampled [CysSO_x] (x= 1,2,3) oxo-forms and may provide diagnostic probes to reveal critical intermediates in protein redox regulation.

Novel Aspect: (Limit of 150 characters)

The type of mass spectrometry instrument employed for collisional activation of L-Cysteine sulfate resulted to be "pathway" selective.

311 - LOSS OF WATER FROM POLYGLYCINES AND THEIR [BN]⁺ IONS; IMIDAZOLONES AND OXAZOLONES

K. H. Brian Lam (1) - Justin Kai-Chi Lau (1) - Cheuk-Kuen Lai (1) - Ivan K. Chu (2) - Jos Oomens (3) - Alan C. Hopkinson (1) - K. W. Michael Siu (4)

York University, Department of Chemistry and Centre for Research in Mass Spectrometry, Toronto (1) - University of Hong Kong, Department of Chemistry, Hong Kong (2) - Radboud University, Institute for Molecules and Materials, FELIX Laboratory, Toernooiveld (3) - University of Windsor, Department of Chemistry and Biochemistry, Windsor (4)

Keywords: Loss of water; imidazolone; oxazolone; [bn]⁺ ions; interconversion between isomers

Introduction:

Loss of water in the fragmentation of protonated tetraglycine is mainly from the peptide backbone, resulting in [b4]⁺ ions with imidazolone structures. These [b4]⁺ ions have identical CID spectra indicating isomerization prior to dissociation. Here, the fragmentations of larger protonated polyglycines [Gly_n + H]⁺ and their [bn]⁺ ions (n=5–10) are examined. Isomerization of the [bn]⁺ ions and their fragmentation mechanisms are studied.

Methods:

All experiments were carried out using an Orbitrap Elite Hybrid Ion Trap-Orbitrap mass spectrometer. Isotopically labeled peptides were synthesized and used to determine the structures of the fragment ions. DFT calculations at B3LYP/6-311++G(d,p) level provided reaction energetics and insight into the dissociation mechanisms.

Results:

18O-labeling experiment shows that loss of water in the fragmentation of protonated pentaglycines are predominantly from the first and second amide groups. Unlike the [b4]⁺ ion derived from tetraglycines, the [b5]⁺ ions show similar CID spectra but with different relative abundances. This suggests that the [b5]⁺ ions undergo fragmentations more easily than isomerize. This conclusion is supported by DFT calculations that give the energy barrier for the isomerization to be higher than that to fragmentation. Hexaglycine loses water from the first three amide groups. The [b6]⁺ ions derived from the water loss from the first and second amide oxygens shows similar fragmentation patterns to the corresponding [b5]⁺ ions. However, further water loss from the peptide backbone is found from the [b6]⁺ ion that was formed when water was lost initially from the third amide group.

Conclusions

The [b4]⁺ ions from tetraglycine possess imidazolone structures and undergo isomerization prior to fragmentation. However, the larger [bn]⁺ ions have different fragmentation patterns indicating that the barrier to isomerization is high. These [bn]⁺ ions still feature imidazolone structures, and there is no evidence for oxazolone structures.

Novel Aspect:

Loss of water from protonated polyglycines are mainly from the backbone. With the increase of the peptide chain length, multiple water loss is observed. (164/150 characters)

Keywords: organoarsenic chemicals, fragmentation pathways, rearrangements

Introduction

Arsenic-containing chemical warfare agents were used in World War I and World War II. Large part of the Axis stockpiles were destroyed after the World War II by burying in soil and dumping in sea. The environmental effect of these actions are still seen around the world. Mass spectrometry is widely used to analyze these chemicals and their degradation products. Arsenic atom induces a large number of rearrangement reactions.

Methods

The fragmentation pathways of selected organoarsenic chemicals were studied using gas chromatography-electron ionization/high resolution mass spectrometry (GC–EI/HRMS) and liquid chromatography-electrospray ionization/high resolution mass spectrometry (LC–ESI/HRMS). The latter instrument can produce also MSⁿ/HRMS data using quadrupole, ion trap and Orbitrap analyzers. The spectra were carefully analyzed to identify fragmentation pathways.

Results

Some characteristic fragmentation pathways were identified based on the mass spectra. Arsenic atom induces rearrangement reactions, which lead to formation of a large number of cyclic fragmentation products.

The chemicals discussed in this paper will include intact warfare agents, which are typically chlorine-containing chemicals, their degradation and oxidation products as well as some alkylthiol derivatives required for GC-based analyses.

For most of the chemicals there are several fragments, where neutral arsenic species are lost from the ionized molecule. One of the most exotic rearrangements is the formation of a phenyl cation from tris(2-chlorovinyl)arsine ("Lewisite I"). It is worth noting that in LC–ESI/MS, diphenylarsenic chemicals are producing highly characteristic radical cations, e.g. C₁₂H₁₀⁺•, C₁₂H₈⁺• and C₆H₅As⁺•.

The current paper will present the suggested fragmentation pathways and highlight common ions formed from phenyl and diphenylarsenic chemicals.

Conclusions

Organoarsenic chemicals are an interesting group of chemicals, which fragment in unconventional ways to produce characteristic fragments. These fragment ions can be identified and then used for search of novel chemicals possibly forming in the environment. Several novel chemicals have been tentatively identified using these fragments in sediment samples taken in CHEMSEA, MODUM and DAIMON projects from dump sites in the Baltic Sea.

Novel Aspect

Novel chemicals have been detected in environmental samples. Their spectra have been analyzed using data obtained from other phenyl and diphenyl arsenic chemicals.

40 - KINETICS OF A CLICK REACTION IN CHARGED MICRODROPLETS WITH TIME RESOLVED REACTIVE LASER ABLATION ELECTROSPRAY IONIZATION MASS SPECTROMETRY

Kinetics of a Click Reaction in Charged Microdroplets with Time Resolved Reactive Laser Ablation Electrospray Ionization Mass Spectrometry

Keywords: cycloaddition • kinetics • laser ablation electrospray ionization • reactive intermediates • time resolved mass spectrometry

Introduction:

Time resolved mass spectrometry (TRMS) provides insights into fundamental processes in (bio)molecular reactions, such as the direct detection of short-lived intermediates and the acquisition of kinetic data. Laser ablation based injection coupled to electrospray ionization (LAESI) can be used as a novel TRMS method to perform reactions in charged microdroplets, e.g., to accelerate synthesis or to study the chemistry of life.

Methods:

A Protea Biosciences LAESI DP-1000 system was electronically connected to a Waters Synapt G2-S time of flight mass spectrometer (MS). The distance between LAESI ion source and MS inlet was variable between 1 and 100 cm. Transport of ions from the ionization source to the MS inlet was assisted by a nebulizer gas via a grounded metal tube. Temporal resolution was obtained by the difference in time between the pulsed laser pulse (injection) and MS detection of product.

Results:

We demonstrate a reactive LAESI-TRMS method with the study of a cycloaddition reaction between dipyriddy-tetrazine and an amine derivative of bicyclononyne (BCN-amine) in charged microdroplets. In this reaction, a highly strained bicyclic reaction intermediate is formed before release of molecular nitrogen to obtain the final reaction product. For the first time, this short-lived intermediate was detected by a direct physical method. In addition, the ratio intermediate to product could be regulated by controlling the temperature of the MS source (thermal energy to overcome the low, intermediate to product, activation barrier). Kinetic data was obtained with the use of temporal resolution, which was demonstrated in the 1 to 500 ms time range. Interestingly, no drop was detected in product absolute intensity over a distance up to 100 cm (0.5s). Finally, reactive LAESI mass spectrometry imaging (MSI) experiments were conducted on an image containing dipyriddy-tetrazine solution.

Conclusions:

We have developed a novel method for the determination of reaction kinetics and the analysis of short-lived intermediates in charged microdroplets. We detected the reaction intermediate of a cycloaddition reaction and were able to obtain the pseudo-first order rate constant. Additionally, we demonstrated our methodology in a reactive LAESI-MSI experiment.

Novel Aspects:

Coupling of laser ablation injection with ESI-MS to study reactions in microdroplets with temporal resolution, and demonstrating reactive LAESI-MS(I) for the first time.

544 - ACETONE AS PHOTO-INITIATOR FOR DISULFIDE REDUCTION – APPLICATION TO STRUCTURAL ANALYSIS OF DISULFIDE RICH PEPTIDES AND PROTEINS

Yu Xia (1) - Sarju Adhikari (2) - Xiaoyue Yang (1)

None, Tsinghua University/Chemistry, Beijing (1) - None, Purdue University/Chemistry, West Lafayette (2)

Keywords: Photo-Initiator, Radical Reaction, Disulfide Peptide, Tandem Mass Spectrometry, Proteomics

Introduction:

Pinpointing disulfide linkage pattern is necessary for characterizing proteins containing disulfide bonds. Often carefully controlled enzymatic digestion and multi-step partial disulfide reduction are needed before MS analysis to achieve confident assignment. Herein, we describe a new method based on coupling radical initiated disulfide bond cleavage with tandem mass spectrometry for rapid and detailed structural analysis of disulfide-rich peptides.

Methods:

A flow microreactor consisted of a 254 nm low-pressure mercury lamp (BHK, Inc., Ontario, CA) in parallel to UV-transparent fused silica capillary (100 μm i.d., 375 μm o.d) at 0.5 cm distance. The peptide/protein solution was infused to the reactor by a syringe pump and subjected to photochemical reactions before online electrospray ionization (ESI)-MS analysis. All data were collected on QTRAP 4500 and X500R QTOF mass spectrometers (SCIEX, Concord, ON, Canada).

Results:

Acetone (1% volume ratio) was used as photo-initiator (PI) to induce subsequent radical reactions. Upon 254 nm UV irradiation, acetone underwent Norrish type I cleavage, producing acetyl radical and methyl radical [1]. The presence of alkyl alcohol as co-solvent in the peptide solution converted the primary radicals into hydroxyalkyl radicals, which subsequently cleaved disulfide bond via substitution [2]. Disulfide reduction was the dominant reaction channel when using isopropyl alcohol, which completed in less than 5 s with >95% yield. More importantly, partial reduction of disulfide bonds could be achieved simply by shortening the reaction time. For structural characterization of disulfide-rich peptides/proteins, sequence information and disulfide bond connecting pattern could be obtained from coupling complete or partial disulfide reduction with MS/MS. The analytical utility of this method was demonstrated with peptides/proteins containing 2 to 4 disulfide bonds.

Conclusions :

Disulfides are highly reactive toward radical attack; however, uncontrolled radical reactions often lead to disulfide bond scrambling, which is undesirable for disulfide linkage pattern determination. In this work we demonstrated that controlled disulfide cleavage via hydroxyalkyl radical could be achieved. Furthermore, this reaction can be directly coupled with ESI-MS/MS analysis, allowing characterization of disulfide rich peptides.

Novel Aspect:

Photochemical reduction of disulfide bond in peptides and proteins and its online coupling with ESI-MS/MS for disulfide linkage pattern determination.

232 - IDENTIFICATION AND INTERCONVERSION OF ISOMERIC 4,5-FUNCTIONALIZED 1,2,3-THIADIAZOLES AND 1,2,3-TRIAZOLES IN CONDITIONS OF ELECTROSPRAY IONIZATION

Marina Zimens (1) - Dmitrii Mazur (2) - Vasiliy Bakulev (3) - Albert Lebedev (2)

Lomonosov Moscow State University, Organic Chemistry Department, Lomonosov Moscow State University, Organic Chemistry Department, Moscow (1) - Lomonosov Moscow State University, Organic Chemistry Department; Lomonosov Northern (Arctic) Federal University, Core Facility Center "Arktika", Lomonosov Moscow State University, Organic Chemistry Department; Lomonosov Northern (Arctic) Federal University, Core Facility Center "Arktika", Moscow, Arkhangelsk (2) - Ural Federal University, Technology of Organic Synthesis Department, Ural Federal University, Technology of Organic Synthesis Department, Yekaterinburg (3)

Keywords:

HRMS, electrospray ionization, 1,2,3-thiadiazoles, 1,2,3-triazoles, isomer identification, Orbitrap

Introduction:

Investigation of 1,2,3-triazoles and 1,2,3-thiadiazoles has a great biological potential. However the problem of isomerisation of 4,5-functionalized 1,2,3-thiadiazoles and 1,2,3-triazoles in the presence of an acid or a base at room temperature makes it difficult to identify each isomer. The present study deals with ESI-MS application in positive and negative modes to identify each isomer by CID and HCD mass spectra and reproduce the rearrangement processes.

Methods:

All experiments were performed with Orbitrap Elite mass-spectrometer (Thermo Fisher Scientific, USA) with electrospray ionization source. The acetonitrile solution of each compound was introduced through syringe pump directly into the ion source at 5 μ l/min. High resolution mass spectra were acquired both in positive and negative modes. MS/MS experiments were carried out using both CID and HCD fragmentation techniques at different energies.

Results:

The monomolecular transformations under (\pm)ESI-MS conditions of 4,5-functionalized 1,2,3-thiadiazoles and 1,2,3-triazoles in the gas phase were investigated varying the amino- and sulfanyl moieties. Fragmentation pattern of each isomer was carefully studied by scanning CID and HCD energies in positive and negative modes. It was demonstrated that basic fragmentation process in case of protonated 1,2,3-thiadiazoles involves the loss of N₂ molecule. All other fragment ions in MS₂ spectra originate from the primary [MH-N₂]⁺ ion. Unlike 1,2,3-thiadiazoles, MH⁺ ions of 1,2,3-triazoles demonstrate a richer fragmentation pathway without losing N₂ molecule. The main fragmentation process of MH⁺ ion involves the loss of sulfinylaryl/sulfinylalkyl or sulfonylaryl/sulfonylalkyl radical. Appearance of [MH-N₂]⁺ ion in the spectra of 1,2,3-triazoles was proved to form due to the gas phase rearrangement during the ESI-MS analysis. The connection of all precursor and product ions was established in MS₃ experiments.

Conclusions

Analysis of (\pm)ESI-MS/MS mass spectra of the isomeric 4,5-functionalized 1,2,3-triazoles and 1,2,3-thiadiazoles with HRMS allowed identifying each isomer. Moreover, only 1,2,3-triazoles undergo transformation into the corresponding 1,2,3-thiadiazoles under (+)ESI-MS conditions, thus mimicking the reaction in the condensed phase. Alkyl substituent next to the sulfone group in both isomers leads to new fragmentation pathways.

Novel Aspect:

1,2,3-Triazoles and 1,2,3-thiadiazoles have been differentiated using (\pm)ESI-MS/MS method. 1,2,3-Triazoles were shown to rearrange during the (+)ESI-MS analysis.

Keywords: histone tail, ion mobility mass spectrometry, theoretical structural calculation

Introduction:

Nucleosome core particle (NCP) is the basic structural unit of nucleosomes and composed of four histone proteins and ca. 150 bp DNA strand. The behavior of histone tails in nucleosomes with a variety of lengths of DNA was investigated using nanoESI-MS and nanoESI-IM-MS. The MS data were evaluated by comparing the structures generated by computational calculation in solution and gas phases.

Methods:

Positive-mode nanoESI-MS and nanoESI-IM-MS data were obtained using a Waters Synapt G2 HDMS mass spectrometer. Nucleosomes were prepared with different lengths of DNA strands, 147, 250, or 342 bp DNA. Samples for MS experiments were prepared with ammonium acetate solutions. Possible structures of NCP were investigated by theoretical calculation.

Results:

We found that the charge-state distributions of the nucleosomes were classified into two groups, narrow and wide, which was supported by IM-MS. By systematic analysis with ESI-MS in the positive-ion mode, it was suggested that the range of charge state of nucleosomes is related to the length of free DNA region. When the DNA strand has a region that is not involved in the NCP core structural formation, charge-state distributions of nucleosomes are narrow. In contrast, when the extra region of DNA does not exist, the charge-state distribution is widely spread. This suggests that histone tail regions contribute to generate structural diversity of nucleosomes in the absence of free DNA region. This was also supported by theoretical structural calculation of NCP.

Conclusions:

When eukaryotic chromatin is viewed under an electron microscope, NCPs are linked via histone-free DNA strands. Although further study is required, our findings that the free DNA regions affects the histone tails' behavior may provide biological insight into the regulation mechanism of eukaryotic transcription initiation.

Novel Aspect:

It was suggested that flexibility of histone tail regions is affected by the existence of free DNA regions. [1]

Keywords: Variable temperature ion mobility mass spectrometry; disordered proteins

Introduction:

Mass spectrometry (MS) coupled with electrospray ionisation (ESI) has been extensively applied to identify proteins and elucidate stoichiometry of protein complexes. Since desolvated species are affected by solvent conditions such as pH, buffer strength and concentration, ESI-MS is an appropriate method by which to consider the range of conformational states that proteins may occupy including natively folded, disordered, denatured and amyloid.

Methods:

Rotationally averaged collision cross sections of the ionised forms of proteins, provided by the combination of mass spectrometry and ion mobility (IM-MS), are measured and used to explore conformational landscapes in the absence of solvent. Measurements are made at a range of temperatures, on two model proteins as well as on permutants of the highly disordered protein p27.

Results: We present a novel method of monitoring the effect of charge location on structures, on unfolding transitions and the stability of transient intermediates using a variable temperature ion mobility mass spectrometer (VT IM-MS)[1] capable of measurements from 150-500K. We show with VT IM-MS, that for both ubiquitin and fully oxidised lysozyme, transient intermediate structures can be detected upon activation followed by trapping and ion mobility separation at cryogenic temperatures. We show that for permutants of p27 the location of charged groups has a dramatic influence on the structures adopted in the gas phase, and how this compares with solution phase measurements and predictions. We have obtained data providing direct evidence that restructuring of the compact states of ubiquitin and lysozyme proceeds through extremely diverse intermediate forms. In addition, our results indicate that intermediates are initially highly elongated and subsequently converge to compacted structures.

Conclusions

The processes of elongation and subsequent compaction indicates quasi-reversible folding transitions. The influence of charge location on protein structure is strong with implications for gas phase measurements. The presented novel data obtained on well studied “model” systems highlights the potential of utilizing this methodology in studying protein folding in the gas phase.

Novel Aspect:

VT-IM-MS on model proteins; consideration of the effects of sequence on stability.

Keywords: HDx-MS; membrane proteins; OmpF; outer-membrane vesicles; structural mass spectrometry

Introduction: (Limit of 400 characters without spaces)

Hydrogen-deuterium exchange (HDX) associated with mass spectrometry (MS) is emerging as a powerful tool to provide conformational information about membrane proteins [1]. Unfortunately, as for X-ray and NMR, HDX performed on reconstituted in vitro systems might not reflect the in vivo environment. We took advantage of the outer-membrane vesicles (OMVs) naturally released by *E. coli* to carry out conformational and dynamic analysis of native OmpF through HDX-MS.

Methods: (Limit of 400 characters without spaces)

A new protocol compatible with HDX analysis that avoids hindrance from the lipid contents was setup. Briefly OMVs purified from *E. coli* Δ ompA were precipitated with TCA and washed with ice-cold acetone. In order to minimize the back exchange, all sample preparation steps have been shortened as much as possible. Each step required less than 5 s and was followed by centrifugation for 4 min at 4 °C.

Results: (Limit of 600 characters without spaces)

The extent of deuterium incorporation was in good agreement with the X-ray diffraction data of OmpF [2] as the buried β -barrels incorporated a low amount of deuterium, whereas the internal loop L3 and the external loops incorporated a higher amount of deuterium. Moreover, the kinetics of incorporation clearly highlights that peptides segregate well in two distinct groups based exclusively on a trimeric organization of OmpF in the membrane: peptides presenting fast kinetics of labeling are facing the complex surrounding environment, whereas those presenting slow kinetics are located in the buried core of the trimer.

Conclusions: (Limit of 400 characters without spaces)

The work presented here clearly demonstrates that HDX-MS is a versatile technique that can provide information on solvent accessibility and spatial arrangement of major bacterial outer-membrane proteins. This study was possible by taking advantage of the OMVs and by developing a protocol that allows the removal of most of the lipid content while limiting the back exchange.

Novel Aspect:

Gaining information on accessibility and dynamics of antigens in native conditions will be of pivotal importance for the future rational design of efficient vaccines.

Keywords: Interleukin IL-23, HDX-MS, computational approaches, binding interactions, phage display peptides

Introduction:

Interleukin IL-23 is a pro-inflammatory cytokine that contributes to the pathogenesis of autoimmune inflammatory diseases. The inhibition of the activity of IL-23 has promising therapeutic effects for psoriasis, psoriatic arthritis, inflammatory bowel disease, rheumatoid arthritis and multiple sclerosis.[1] IL-23 is a heterodimer composed of the cytokine subunits p19 and p40 that bind to the receptor complex IL-23R and IL-12R β 1 respectively. The discovery of monoclonal antibodies designed to target IL-23 (either p19 and /or p40) have shown significant efficacy in human studies for some of these diseases. Here we present the application of HDX-MS [2] and computational approaches to interrogate the binding interactions of IL-23 with its receptors and the binding epitope of new IL-23 inhibitors such as phage display peptides [3].

Methods:

The exchange reaction was performed with a Tecan liquid handler modified to allow for freezing of samples into Millitubes arrayed in a 96 well plate format. Thus, samples were prepared triplicate of the following time course; Dmin, 10s, 30s, 90s, 270s, 810s, 2430s, 7290s and Dmax. The injection and sample thawing was performed in a robotic module equipped with an universal robotics UR5 arm designed to present samples in series to a LEAP CTC-PAL system in a refrigerated cabinet. Samples were thawed and injected into the injection port following digestion. The resulting proteolytic peptide mixtures were desalted and separated on a C18 analytical column and detected by mass spectrometry. HDX-MS data treatments were performed with HDX-Workbench software. [4-5]

Results:

Computational studies permitted the generation of a canonical model of the IL-23 receptor complex. To validate such model and to gain deeper insights of the interactions (dynamic view of conformational changes) between a protein and its corresponding protein partner in solution, HDX-MS experiments were performed. Thus, the proteins were exposed to D2O buffer for different periods of time to measure the deuterium incorporation in IL-23, IL-23/IL-23R, IL-23/IL-12R β 1 and IL-23/IL-23R/IL12R β 1 complexes. The HDX analysis of the Apo protein revealed that both subunits (p19 and p40) were dynamic in solution. Helices A and C and the A-B, B-C and C-D loops exhibited the highest deuterium uptake while helices B and D were identified as the less flexible regions (solvent protected) in this subunit. While some parts of domains D1-D3 in p40 exhibited faster and higher deuterium uptake, other regions in these domains showed less deuterium exchange, consequently suggesting more rigid structures. The HDX data of the IL-23/IL-23R complex indicated protection across helices A-D which allowed confirmation of the contact interactions of IL-23p19 when mixed with IL-23R. In a similar way, differential HDX analysis of IL-23 in the presence and absence of IL-12R β 1 revealed protection from exchange in mainly some parts of domains D1 and D3 of IL-23p40. The interactions of the cytokine with its partner receptors were confirmed with the HDX results in the full trimeric complex IL-23/IL-23R/IL-12R β 1.

Our results revealed that HDX-MS was also able to identify the binding epitope of phage display peptides previously identified as inhibitors of IL-23. The characterization of the interactions of these chemotypes by HDX-MS will also be presented.

Conclusions

In conclusion, Our HDX-MS and computational analyses revealed valuable information about the interactions of IL-23 and its cognate receptors IL-23R and IL-12R β 1. These studies provide new insights into the quaternary structure of this protein-protein interaction in solution and allowed us to discover novel anti-IL-23 peptides from phage display approach. The binding activity of these peptides was confirmed by biophysical techniques meanwhile the binding epitope against IL-23 was measured by HDX-MS.

To our knowledge, this is the first structural evidence of the interactions of the full trimeric complex IL-23/IL-23R/IL-12R β 1. In addition, we confirmed by HDX-MS the characterization of the binding mode of macrocyclic small molecule to IL-23 for the first time. Indeed, this new chemotype can be used as foundation for discovery and characterization of small molecules targeting this cytokine and its receptors.

Novel Aspect:

HDX-MS and computational approaches to probe the binding interactions of IL-23 with its receptors and phage display peptides.

136 - A COARSE-GRAINED COMPUTATIONAL WORKFLOW FOR THE ELUCIDATION OF BIOMOLECULAR STRUCTURE AND DYNAMICS BY ION MOBILITY SPECTROMETRY-MASS SPECTROMETRY

Rebecca D'Esposito (1) - Daniele Fabris (2)

University at Albany, Chemistry, Albany, NY (1) - University at Albany, Chemistry and Biological Sciences, Albany, NY (2)

Keywords:coarse-graining modeling; molecular dynamics simulations; IMS-MS; collisional cross section; global dynamics.

Introduction

The interpretation of ion mobility spectrometry-mass spectrometry (IMS-MS) data from large biomolecules relies on molecular dynamics (MD) simulations to model their putative structures. With the goal of enabling millisecond simulations approaching typical IMS-MS timescales, we explored possible coarse-grained (CG) schemes to replace overly expensive all-atom frameworks, while still meeting the level of detail necessary for proper structural elucidation.

Methods

Selected nucleic acid structures were modeled by using 2-, 5-, and 7-bead representations, and then submitted to MD simulations in GROMACS by using the Martini force-field. The collisional cross section (CCS) algorithms contained in MOBCAL were reparametrized according to a previously reported procedure to accommodate the pseudoatoms included in our CG frameworks, thus enabling the seamless calculation of theoretical CCS values directly from CG models [1].

Results

This report evaluated the merits of employing CG models to capture the global dynamics of large biomolecules, which involve the conformational rearrangement of entire domains completed in the ms range typical of IMS-MS determinations. The advantages of this approach were demonstrated by performing test MD simulations that provided a 0.009 s/ns wall time for a CG model versus 680 s/ns for the corresponding all-atom version, equivalent to 0.00025 hr versus 18 hr of computing time per 100 ns of simulation. Reparametrizing the MOBCAL algorithms provided the means for obtaining a full-fledge CG workflow to enable model building, MD simulations, and CCS calculations with no need for all-atom representations. This approach allowed us to test the possibility of employing the reparametrization process to correct for gas-phase effects on biomolecular structure, which are not adequately addressed in the leading force-fields, such as the apparent compaction of structures forced to establish self-solvating interactions in a solvent-free environment.

Conclusions

For large biomolecules, the resolution and timescale of IMS-MS analysis thwart the dissection of local dynamics involving side-chain/nucleobase displacement occurring in the ns timescale, whereas they enable the recognition of global dynamics in the ms range, which may produce distinguishable conformers. Therefore, CG approaches provide an excellent solution for completing MD simulations in the proper IMS-MS scale to enable their experimental observation.

Novel Aspect

Direct application of coarse-graining computational approaches to support the analysis of the structure/dynamics of large biomolecules by IMS-MS.

Keywords: intrinsically disordered protein, alpha-synuclein, in-cell, H/D exchange, protein structural dynamics

Introduction:

It is well established that purified monomeric α -synuclein is an intrinsically disordered protein, but its structure in the cellular environment has been a matter of intense scientific controversy [1-3] fueled by reports that α -synuclein adopts a stable folded tetramer in cells, but only when they are intact.[4-7] This controversy is mainly due to the inherent difficulties associated with probing protein structures inside the cell.

Methods:

We here present a novel approach to probe the intracellular structure of endogenous proteins and we address the question whether the cellular structure of endogenous α -synuclein is folded or disordered. Our approach is based on in-cell hydrogen/deuterium exchange where α -synuclein is labeled in its cellular environment with D₂O followed by immunoaffinity purification at acidic conditions (in-cell-HDX-IPAC) where the isotopic exchange is quenched.

Results:

Recombinant ¹⁵N-labeled monomeric α -synuclein was added to human erythrocytes prior to isotopic exchange as an intrinsically disordered extracellular reference protein. This allows for sensitive detection of protection of intracellular endogenous α -synuclein caused by any putative folded stable structure. To ensure that the equilibration of D₂O across the plasma membrane of erythrocytes occurs sufficiently rapid, we determined the deuterium uptake of intracellular and extracellular hemoglobin and it was found to be identical. To enable in-cell HDX-MS analysis of endogenous α -synuclein, an effective enrichment of the protein at quench conditions is required. For this purpose, we developed a novel immunoaffinity approach (in-cell-HDX-IPAC) that maintains strong capture efficiency at acidic conditions (pH 3.5) to limit the amount of back exchange. The enriched α -synuclein was eluted at pH 2.0. Our results show that the deuterium uptake of intracellular and extracellular α -synuclein is identical.

Conclusions

The identical deuterium uptake of intracellular and extracellular α -synuclein suggests that the vast majority of endogenous α -synuclein in erythrocytes is intrinsically disordered. Furthermore, we have also shown that our in-cell-HDX-IPAC approach is able to detect the protection pattern of the presence of nonnative α -synuclein oligomers.[8,9] In addition, we have investigated the stability and dynamics of nonnative α -synuclein oligomers.

Novel Aspect:

In-cell H/D exchange followed by immunoaffinity purification at acidic conditions (in-cell-HDX-IPAC) is utilized to probe the intracellular structure of α -synuclein.

ATTN: Division of Mass Spectrometry Awards Committee

I am a third year graduate (Ph.D.) student in the Chemistry lab of Dr. Derek Wilson at York University. I am writing to you to request your monetary assistance to facilitate my travel to Florence, Italy to present my work at the International Mass Spectrometry Conference. To date in my graduate studies, I have submitted a paper to the Journal of the American Chemical Society (2018), published in Photochemical and Photobiological Sciences (2017) and coauthored a JoVE report (2017). In May 2017, I presented a poster in Sweden for the International Conference on Hydrogen Deuterium Exchange (IC HDX) for which I received the award for best mini presentation. More recently, last August I presented my work at the Trent (Lake Couchiching) Conference on Mass Spectrometry on a national travel award. Below, I provide an expanded abstract of my research Mapping Conformational Dynamics to Binding Modes in TEM-1 β -lactamase Using Millisecond Scale ESI-MS that I hope will interest you and lead you to granting my request for a travel award to attend the 2018 IMSC this August.

Keywords: catalysis, antimicrobial resistance, enzymes, HDX, beta-lactamase

Introduction:

Current studies contribute to the work on antibiotic resistance by studying the enzymatic digestion of antibiotic drug families and mapping drug potency based on dynamic differences in drug binding modes. The induced fit model of enzyme function highlights the critical role of dynamics in substrate binding. However, there has been little evidence to support the notion that individual dynamic modes are required for catalytic processes after initial binding.

Methods:

Tandem mass spectrometry (MS/MS) is utilized to identify peptides after proteolytic digest within a chip. Without MS/MS, column chromatography would be used to identify the eluted peptides, leaving the experiment vulnerable to back exchange and unreliable dynamic information. Experiments are performed on a Synapt G2 Time-of-Flight instrument with Ion Mobility Separation (IMS). Microfluidic devices are constructed in house using a VersaLaser and machine drill.

Results:

By enabling deuterium uptake to be monitored on a millisecond timescale, we greatly enhance the manner that catalytic activity can be observed under native conditions(1). We use HDX-MS to identify dynamic modes linked to catalytic processes in the antibiotic resistant enzyme TEM-1 β -lactamase(2-4). Using a very active substrate (ampicillin), a poorly deacylated substrate (cephalexin) and an off-pathway inhibitor (clavulanate), we isolate dynamics that are linked to 3 processes: substrate binding; lactam ring hydrolysis; and, deacylation. These separations translate to leads for dynamics-targeted antibiotic development, such as at the allosteric binding site at the C-terminal helix, H11 (5,6) and the link between known mutational sites and increased conformational dynamics upon drug binding(7-9). We propose that an inner β -strand, residues 245-257, is directly responsible for increased resistance to cephalosporin drugs(10) and should be conserved through a co-inhibitor to increase the potency of current on the market drugs.

Conclusions:

Our results identify dynamic modes that are uniquely linked to specific processes in the catalytic (or inhibitory) mechanism. In each case, these links could be rationalized in terms of what was known about the role of particular residues or structural elements within the identified region, supporting the reliability of the approach as a means to isolate catalytically important dynamics and to reveal new submolecular targets for drug design.

Novel Aspect:

Microfluidics HDX on the millisecond timescale is unlike traditional HDX that utilizes chromatography and operates on a minute to hours timescale.

Thank you very much for your consideration of my request for your financial support to present my research and to attend the conference to further my own development as a scientist.

Sincerely,
Ruth Knox

874 - EFFECTS OF OXIDATIVE STRESS ON THE CONFORMATIONAL STABILITY OF HEMOGLOBIN MEASURED BY VARIABLE TEMPERATURE NESI-IMS-MS

Daniel Woodall (1) - Tarick El-Baba (1) - Christopher Brown (1) - Daniel Fuller (1) - Shannon Raab (1) - David Clemmer (1)

Indiana University, Indiana University, Bloomington (1)

Keywords: protein stability, oxidative stress, ion mobility, PTMs, native MS

Introduction: 400/400

Structural stability plays an integral role in regulating protein function and activity. Stability and protein-protein binding interactions can be regulated by post-translational modifications that affect subunit binding affinities of protein complexes. Here, we use ion mobility spectrometry-mass spectrometry (IMS-MS) to explore how oxidative modifications affect subunit binding affinity and conformational stability of the hemoglobin tetramer complex.

Methods: 397/400

IMS-MS experiments were performed using a Waters SYNAPT G2 mass spectrometer. Hemoglobin solution was dialyzed against 150 mM NH₄OAc (pH 7.4), and diluted to 15 μ M [tetramer] for analysis. Protein solution temperature was controlled using a custom-fabricated heated nanoelectrospray device, in which the temperature of analyte solution and nESI emitter can be heated. Collision cross sections (CCS) were estimated using the protocol described by Ruotolo et al.[1]

Results: 900/900

Unfolding and dissociation of the native hemoglobin tetramer is induced by incrementally increasing the solution temperature in the nESI source. Shifts in the average charge state, and CCS of the $\alpha_2\beta_2$ tetramer arise with increasing solution temperature, leading to dissociation into $\alpha\beta$ dimers, as well as populations of both holo and apo monomers. Stabilities of each oligomeric state and conformer are determined based on their midpoint dissociation temperature (Td). The $\alpha_2\beta_2$ holotetramer has a Td = 58 °C, while the $\alpha\beta$ holodimer has a Td = 62 °C, indicating the dimer is more stable at elevated temperatures relative to the tetramer. A subpopulation of $\alpha\beta$ dimers exists where one of the monomer units is in the apo state ($\alpha\eta\beta\alpha$). A significant portion of this subpopulation shows evidence of an oxidation PTM at β Cys93. β Cys93 has been identified as a "hotspot" for oxidation, as well as having implications on β -subunit heme loss due to its proximity to the heme binding pocket.[2] The oxidized species has a midpoint Td = 57 °C, while the unmodified species has a Td = 61 °C.

Conclusions 393/400

The Td of the oxidized $\alpha\eta\beta\alpha$ dimer species is 5 °C lower than the holodimer, indicating that β Cys93 oxidation has a considerable destabilizing effect on the α/β subunit interface, even more so than the loss of the heme group. In addition to decreasing the subunit binding affinity, the oxidized species favor structures with more compact CCS at increased temperature, suggesting a structural collapse or compaction may be involved in destabilizing the dimeric units.

Novel Aspect: 120/150

Thermal stability analysis by IMS-MS reveals conformational destabilization induced by oxidative stress in hemoglobin tetramer complex.

498 - STRATEGY TO IDENTIFY INDUSTRIAL PEAK EMISSIONS BASED ON LONG-TERM HRMS DATA TIME SERIES

Sabine Anliker (1) - Martin Loos (2) - Matthias Ruff (1) - Rahel Comte (1) - Kathrin Fenner (1) - Heinz Singer (1)

Eawag, Environmental Chemistry, Dübendorf (1) - looscomputing, R&D, Zürich (2)

Keywords: High resolution mass spectrometry, non-target screening, short-term peak emissions, industrial wastewater, time profiles

Introduction

Micropollutant emissions from industrial wastewater are poorly understood. Challenges arise from missing substance information due to confidentiality of production data. Moreover, short-term emissions from industrial batch processes are unlikely captured by conventional grab sampling. Hence, we developed a strategy for comprehensive identification of potential industrial peak emissions from treated wastewater to surface water.

Methods

Daily effluent samples (24-h composite) were collected for three months at two wastewater treatment plants (WWTPs) receiving different proportions of industrial wastewater. The samples were then analyzed by large volume direct injection LC-HRMS (orbitrap technology) in positive and negative ESI mode. Data processing followed a non-target approach using the freely available enviMass workflow [1] to extract time profiles of all detected signals from full scan spectra.

Results

After data cleaning and cross-sample componentization (isotopologue and adduct grouping), more than 20'000 and 60'000 time profiles of a priori unknown compounds were detected at the two WWTPs. More profiles were detected at the WWTP treating larger amounts of industrial wastewater. Based on observed time profile characteristics of compounds with known origin we developed a workflow to differentiate between continuous domestic emission and potential industrial peak emission profiles. Of the considered descriptors, profile intensity spread was the most conclusive, i.e. values for peak emissions were twice as high as for domestic emissions. The percentage of profiles finally classified as potential industrial peak emissions differed substantially between the two investigated WWTPs, being 3-fold higher for the plant receiving more industrial wastewater. For several of the observed peak emissions the underlying compound was identified and the emission was further assigned to a pharmaceutical production site in the catchment of the WWTP.

Conclusions

Our strategy of source attribution based on time profile characteristics proved to correctly identify industrial peak emissions and accurately predicted a higher share of peak emission profiles for the WWTP treating larger volumes of industrial wastewater. This approach is currently being applied to a national field study to estimate the contribution of industrial discharges on the overall micropollutant contamination of Swiss surface waters via WWTPs.

Novel Aspect

This study presents a non-target approach for systematic inspection of entire HRMS full scan time series datasets to identify potential industrial peak emissions.

844 - TRANSFORMATION PRODUCT FORMATION IN DRINKING WATER TREATMENT

Andrea M Brunner (1) - Dennis Vughs (1) - Wolter Siegers (2) - Cheryl Bertylkamp (2) - Annemieke Kolkman (3) - Thomas ter Laak (1)

KWR Watercycle Research Institute, Water Quality and Health, Nieuwegein (1) - KWR Watercycle Research Institute, Drinking Water Treatment, Nieuwegein (2) - KWR Watercycle Research Institute, Water Quality and Health, Nieuwegein (3)

Keywords: Non-target screening, transformation products, mass spectrometry, drinking water, water technology

Introduction:

Transformation products (TPs) are formed in the water cycle through biological and technological processes. Despite their potentially altered toxicity compared to parent compounds, TPs formed by drinking water treatment are not routinely monitored and remain elusive. This is mainly due to the technical challenges in analyzing the often unknown, low concentration compounds. Their analysis requires non-target HRMS/MS methods and novel data analysis approaches.

Methods:

Here, we performed lab scale experiments to monitor TP formation of the three organic micropollutants carbamazepine, clofibric acid and metolachlor during rapid sand filtration and ozonation, two readily applied biotic and abiotic drinking water treatments, respectively. TP identification from non-target data was facilitated through prediction of potential TPs based on literature and models, halogenated and/or isotopically labeled parent compounds.

Results:

The experimental results showed that the degradation of parent compounds did not per se lead to mineralization of the compound, but rather to an abundance of TPs, in often low concentrations. Some of these TPs were bigger and less polar than their parent compounds, which was somewhat unexpected. The identification of peaks representing TPs was straightforward and semi-automatic with the developed workflow, based on statistical testing and peak area filters. The suspect screening based on TP suspect lists manually curated from literature mining and prediction tools was efficient for TPs in the lists. However, the majority of TPs identified did not match suspect list entries. Furthermore, the structural identification of these features, as well as of isobaric suspects remained labor and time intensive.

Conclusions

The majority of TPs remained structurally unidentified, and for the majority of identified TPs toxicological risk assessment was missing. Follow-up work should target and hopefully alleviate these issues. Finally, the developed workflow can be applied to pilot-scale experiments to allow TP monitoring in actual drinking water production.

Novel Aspect:

develop and test an efficient workflow to monitor TP formation and identify drinking water treatment specific TPs on a lab-scale

577 - MOLECULAR LEVEL INVESTIGATION OF OIL CONTAMINATED SOILS GENERATED DURING THE GULF WAR WITH TWO-DIMENSIONAL GAS CHROMATOGRAPHY(GCXGC) AND ULTRA-HIGH RESOLUTION MASS SPECTROMETRY

Eunji Cho (1) - Moonhee Park (2) - Young Hwan Kim (2) - Guyoung Kang (3) - Yunju Cho (4) - Sunghwan Kim (1)

Kyungpook National University, Department of Chemistry, Daegu (1) - Korea Basic Science Institute, Biomedical Omics Group, Cheongju (2) - Hankuk University of Foreign Studies, Department of Environmental Sciences, Cheoin gu (3) - Green-Nano Materials Research Center, Department of Chemistry, Daegu (4)

Keywords: Gulf War, Oil Spill, Contaminated Soil analysis, Two dimensional GC, FT-ICR MS

Introduction:

The oil spills occurred at the end of the Gulf War is one of the serious environmental problem in history. Although 30 years have gone after the gulf war, the world is still concerned about the environmental impact of spilled oil. It is important to characterize and understand the chemical compositions of oil spills for effective cleaning of the oil spill area. In this study, extracts from contaminated soil in oil spill area were analyzed using 2DGC and FT-ICR MS.

Methods:

Two soil samples were collected each between 15~20cm below the surface (top soil) and about 1m below the surface (bottom soil). The soil samples were extracted using sonication in hexane and acetone. Soil extracts were filtered and dried. The extract and oil samples were further diluted with solvent for FT-ICR MS. For 2DGC analysis, Rtx-5MS (30m x 0.25mm, 0.25 μ m) is used as the first non-polar column and Rxi-17sil-MS (1.3m x 0.15mm, 0.15 μ m) as the second polar column.

Results:

Class distributions obtained by (+) APPI, ESI and LDI MS did not show significant difference between the soil extracts and non-degraded crude oils. On the other hand, (-) ESI showed a noticeable difference. Increased abundance of O₂ class was observed from the top soil extract. Relative abundance of O₂ class compounds with DBE 2 or 3 were most abundant in the top soil extracts. And the A/C ratio (acyclic/ Σ (2-4 ring cyclic) O₂ species) of topsoil extract was the lowest.[1] In addition, when the soil samples were extracted with water, a significant number of polar components were detected only in the topsoil extract. About 300 peaks were observed from 2DGC MS data obtained from soil extracts and oil. Volatile alkane peaks were disappeared and only aromatic compounds were observed from soil extracts.

Conclusions:

Comprehensive analyses of soil extracts and oil were done by use of 2D GC and FT-ICR MS. The most of the light compounds in the soil were evaporated because of hot weather in Kuwait. And the top soil extract showed significant abundance of oxidized peaks. However, it was surprising to find that extensive oxidation has not occurred in the bottom soil. This study shows that chemical compositions are different in contaminated soils located at different depth from the surface.

Novel Aspect:

This is the first study to analyze contaminated soils from spilled oil during the Gulf War using 2DGC and Ultra-High resolution MS.

888 - OCCURRENCE OF ORGANOPHOSPHATE FLAME RETARDANTS IN SWIMMING POOLS AND THEIR ENDOCRINE DISRUPTING POTENTIAL

Pei-Hsin Chou (1) - Wen-Ting Shih (1)

National Cheng Kung University, Department of Environmental Engineering, Tainan City (1)

Keywords: Organophosphate flame retardants, Endocrine disrupting activity, In vitro bioassays

Introduction:

The use of organophosphate flame retardants (OPFRs) has been increasing because of the restriction and phase out of brominated flame retardants. Environmental contamination of OPFRs is of growing concern since they have been reported to show various toxic effects, such as carcinogenicity, neurotoxicity, and endocrine disrupting activity [1-4]. The aim of this study was to investigate the occurrence of OPFRs in swimming pools and their potential health effects.

Methods:

Swimming pool water samples were separated into dissolved phase (W) and suspended solids phase (SS) by filtration. W and SS samples were extracted by solid phase extraction and Soxhlet extraction, respectively. Concentrations of selected OPFRs were quantified using an isotope-dilution liquid chromatography-tandem mass spectrometry (LC-MS/MS) method. Endocrine disrupting activities of OPFRs and pool samples were investigated using in vitro bioassays [5].

Results:

LC-MS/MS results revealed that 7 and 6 OPFRs selected for analysis were detected in W and SS samples, respectively, and the detection frequencies ranged from 65 to 100%. Tris(1-chloro-2-propyl) phosphate was the dominant OPFR in W samples, which was the major OPFR found in Australian public swimming pools as well [6]. Tri-n-butyl phosphate was the dominant OPFR in SS samples, and its concentrations were about 3 orders higher than other OPFRs. Bioassay results showed that selected OPFRs exhibited antagonist activities for androgen receptor (AR), glucocorticoid receptor (GR), and progesterone receptor (PR). AR and GR antagonist activities were also frequently found in W samples collected from southern Taiwan. By contrast, no AR antagonist activities were found in SS samples, and PR agonist/antagonist activities were not detected in W or SS samples as well.

Conclusions:

The present study demonstrated that OPFRs were ubiquitously present in W and SS samples collected from Taiwanese swimming pools. Also, OPFRs exhibited AR, GR, and PR antagonist activities, suggesting potential health risks of OPFR exposure from swimming pool water. Further investigation will be undertaken to evaluate the contribution of OPFRs to the receptor antagonist activities detected in pool samples.

Novel Aspect:

Trace concentrations of OPFRs in Taiwanese swimming pools were successfully analyzed for the first time by using the isotope-dilution LC-MS/MS method.

Introduction

BPA and DEHP are endocrine disruptors (ED) widely used as plasticizers and associated with the development of endocrine and metabolic diseases. In the LIFE PERSUADED project we developed UHPLC/MS-QTOF and GCMS methods to monitor exposure to BPA and DEHP (by the evaluation of metabolites MEHP, MEHHP, MEOHP) in 900 healthy pairs mother-child living in rural and urban areas from North to South Italy. Questionnaires on lifestyle and nutrition were recorded [1-3].

Methods

Urine samples (500 µl) were treated with enzymatic deconjugation to hydrolyze the glucuronide and separate free phthalates and BPA. Compounds with ¹³C standard were purified with C18SPE. DEHP metabolites were quantified by UHPLC/MS-QTOF (ZORBAX SB Phenyl 2.1x100mm 1.8 µm); the sample was then derivatized with BSTFA 1%TMS and acetonitrile and BPA was quantified by GCMS in selective ion monitoring (J&WDB-5MS30m, 0.25mm, 0.25µm) and normalized by creatinine.

Results

We were able to quantify DEHP metabolites in all urine samples. Preliminary data in 350 children (4-14 years, males, M and females, F) and mothers (Mo) showed that ranges were: MEHP 1.3-187.5, 1.49-117.26 and 1.9-51.8; MEHHP 0.74-1502.68, 0.0052-953.75 and 2.69-165.3; MEOHP 0.82-303.82, 1.27-827.03 and 0.024-51.96 µg/g of creatinine (respectively in F, M vs Mo).

BPA analyses by UHPLC/MS-QTOF were affected by a matrix effect that was evident only in deconjugated samples. For this reason, after UHPLC/MS-QTOF analysis samples were dried and derivatized with BSTFA to be analyzed in GCMS. Total BPA range was 0.69-1036.55 µg/g of creatinine (F) and 0.951-1146.786 µg/g of creatinine (M) in children and 0.84-43.78 µg/g of creatinine in their mothers.

Internal exposure was different according to living area, age (young children showed higher values), with gender differences. Data evaluation of questionnaires and food diaries is in progress and will be integrated with ED exposure data to provide the determinants to be used in risk assessment.

Conclusions

Although not persistent, BPA and DEHP metabolites have been detected in all enrolled children, with different exposure was different according to living area, age (lower range), with gender differences.

Novel Aspect

We set up a method to quantify DEHP metabolites by UHPLC/MS-QTOF and BPA concentration by GCMS starting from 500 µl of urine.

1170 - DULOXETINE: DEGRADATION PROCESSES, TRANSFORMATION PRODUCTS ELUCIDATION BY MASS SPECTROMETRY AND IN SILICO ANALYSIS

Rodrigo Osawa (1) - Maria da Conceição Conceição (2) - Olinda Monteiro (1) - Maria Helena Florêncio (3)

Faculdade de Ciências, Universidade de Lisboa, Lisboa (1) - Instituto Superior Técnico, Universidade de Lisboa, Lisboa (2) - Faculdade de Ciências, Universidade de Lisboa, LISBOA (3)

Keywords: Time-of-flight mass spectrometry; duloxetine; transformation products, in silico toxicity prediction.

Introduction

This study aimed to elucidate the transformation products (TPs) of duloxetine (DUL), a serotonin–norepinephrine reuptake inhibitor, under controlled experimental conditions, to simulate processes that can occur in the environment and WWTP: photodegradation under UV irradiation and chlorination. Moreover, the ecotoxicity of the transformation products was predicted based on in silico tools [1]

Methods

The experiments were carried out on spiked distilled water. The chlorination consisted of adding sodium hypochlorite in the solution and for the photodegradation an UV irradiation source was used (450 W medium-pressure mercury-vapor lamp). The time profiles of formation/degradation of the transformation products were analyzed. Samples were directly injected in the LC-QTOF/MS system in full-scan and MRM mode.

Results

The parent compound completely degraded in the photodegradation experiments after 30 minutes of UV irradiation whereas the chlorination process accounted for about 90% of its removal. On the whole, eleven TPs were formed, nine from the contact with UV light and two from the chlorine reactions. These TPs were identified and their structures elucidated by analysis of their fragmentation patterns. Their formation has been attributed to, namely, oxidation, hydrolysis and dehydrogenation reactions. All TPs formed were totally degraded in both experiments: photodegradation in 4 hours and chlorination in 1 day. In comparison with DUL all TPs presented low ecotoxicity with the endpoints LC50 F. minnow, *D. magna* and *T. pyriformis* from ECOSAR tool, and the quantitative structure–activity relationship (QSAR-TEST) analysis for mutagenicity resulted in five TPs with Ames-positive prediction.

Conclusions

Our experiments showed that duloxetine reacts with chlorine and under UV irradiation, producing transformation products, the structures of which were elucidated by analysis of their fragmentation patterns obtained using a LC-QTOF/MS equipment. These experiments also showed that the TPs and the parent compound degraded in both processes. Moreover the in silico analysis enabled to conclude that some TPs presented mutagenic potential.

Novel Aspect

Duloxetine is frequently detected in effluents, but little is known about its TPs. This study enables to throw some light on the behavior of this compound in the environment.

217 - MULTI-MODE IONIZATION TECHNIQUES FOR EFFICIENT MS/MS ANALYSIS OF PESTICIDES

Heather Gamble (1) - Charles Jolliffe (1) - Avinash Dalmia (2)

Perkin Elmer, R&D, Woodbridge (1) - Perkin Elmer, R&D, Shelton (2)

Keywords: MS/MS, multiple ionization modes

Introduction:

Triple quadrupole mass spectrometry is well suited for targeted quantitative analysis of large numbers of compounds including pesticides, which can belong to a wide range of chemical classes and span a wide range of volatilities. Different pesticides tend to respond to a variety of ionization and separation techniques, such as LC-ESI, LC-APCI, GC-EI, etc. It is advantageous to support analysis of as many of these compounds as possible on one hardware platform.

Methods:

A test suite of pesticides spanning different chemical classes and volatilities was selected for analysis using a single hardware platform consisting of a QSight 300 triple quadrupole mass spectrometer fitted with a versatile dual ion source capable of analyzing LC and GC amenable compounds using a variety of ambient ionization techniques. Methods were developed to demonstrate highly sensitive analysis of diverse pesticides using a common hardware platform.

Results:

Using a highly sensitive QSight 300 triple quadrupole mass spectrometer equipped with a versatile dual ion source it was possible to efficiently and quantitatively analyze both LC and GC amenable pesticides, including difficult to ionize compounds such as chlordane or pentachloronitrobenzene. Multiple strategies are possible. One approach is to use HPLC to separate all compounds. The output of the LC was connected by T or switching valve to both probes on the dual ion source which was fitted with one LC-ESI and one LC-APCI probe. Traditionally difficult to ionize compounds, often analyzed by GC, can respond to APCI. Fast mode switching between the ESI and APCI probes was used to analyze both LC and GC amenable compounds using a single method, and within a single injection. The dual probe ion source can also be coupled to two separation devices, e.g. two LC's, or one LC, one GC, allowing for additional versatility.

Conclusions

A QSight 300 triple quadrupole mass spectrometer equipped with a versatile dual probe source was used to demonstrate efficient, highly sensitive, quantitative analysis of both LC and GC amenable pesticides using a single hardware platform.

Novel Aspect:

Simultaneous analysis of both LC and GC amenable pesticides using a single hardware platform.

912 - DEVELOPMENT AND OPTIMIZATION OF A MEMBRANE-INLET-PHOTOIONIZATION MASS SPECTROMETER FOR REAL-TIME ANALYSIS OF (POLY)AROMATIC COMPOUNDS IN AQUATIC SYSTEMS

Christian Gehm (1) - Thorsten Streibel (1) - Johannes Passig (1) - Detlef Schulz-Bull (2) - Ralf Zimmermann (3)

Joint Mass Spectrometry Center, University of Rostock / Chair of Analytical Chemistry, Rostock (1) - Leibniz-Institute for Baltic Sea Research Warnemünde, Section of Marine Chemistry, Rostock - Warnemünde (2) - Helmholtz Zentrum München – German Research Center for Environmental Health, Cooperation Group Comprehensive Molecular Analytics, Neuherberg (3)

Keywords: resonance enhanced multiphoton ionization, membrane introduction, mass spectrometry, (poly)aromatic hydrocarbons, marine environment

Introduction:

Fast and sensitive analysis of (poly)aromatic hydrocarbons (PAH) is of high importance due to their impact on human health and the environment. However, very low concentrations of PAHs in marine environments complicate their detection and monitoring. A promising approach, regarding to direct determination of PAHs in marine systems, is resonance-enhanced multiphoton ionization (REMPI) coupled to membrane introduction mass spectrometry (MIMS).

Methods:

In MIMS analytes are extracted from the water phase into the vacuum of the MS by using semipermeable membranes. No laborious enrichment techniques are needed. With REMPI ions are formed by the subsequent absorption of two photons via an excited molecular state. The unique ionization scheme of REMPI provides selective and sensitive detection of PAHs. For the analysis of water samples, a REMPI-MIMS system with external inlets for sheet or hollow fiber membranes was built.

Results:

In this proof of principle study we present measurements of selected small (poly)aromatic species in different simulated (tap water, artificial sea water) and real world water samples. Both inlet designs show promising results with respect to the fast and sensitive determination of small PAHs. For a hollow fiber membrane setup, the trap-and-release technique can be utilized for direct determination of small (poly)aromatic species in water samples down to ppb range in less than 5 minutes. Here, the pervaporating compounds are trapped inside of the membrane tube for a certain time and are released by fast heating of the membrane as a sharp peak into the MS. By using a sheet membrane assembly fast response times and low limits of detection were obtained for toluene, p-xylene and naphthalene. Hereby, the membrane is heated indirectly by tempering the inflowing water. With increasing water temperature improvement of response time and signal heights can be achieved. For both inlet designs limits of detection can be improved by using high repetition lasers.

Conclusion:

REMPI-MIMS is a powerful technique for the direct measurements of PAHs in aquatic environments. With this early-stage system concentrations down to the mid-ppb range for selected small (poly)aromatic compounds are easily accessible in minutes without any sample preparation.

Novel Aspect:

Hyphenating external inlets with REMPI-MS is utilized for the first time. Additionally, we present the first measurements of real world water samples with REMPI-MIMS.

183 - MULTICLASS ANALYSIS OF ANTIBIOTICS IN SEDIMENTS BY LC-Q-ORBITRAP HRMS. APPLICATION TO THE NERA RIVER.

Danilo Giusepponi (1) - Fausto Scoppetta (2) - Marta Sargenti (2) - Giorgio Saluti (1) - Simone Moretti (1) - Rosanna Rossi (1) - Marinella Capuccella (2) - Roberta Galarini (1)

Istituto Zooprofilattico Sperimentale dell'Umbria e delle Marche "Togo Rosati", Centre for Development and Validation of Methods, Perugia (1) - Istituto Zooprofilattico Sperimentale dell'Umbria e delle Marche "Togo Rosati", Umbria Regional Center of Veterinary Pharmacovigilance, Perugia (2)

Keywords: veterinary drugs, sediments, liquid chromatography-high resolution mass spectrometry, Nera River

Introduction: (Limit of 400 characters)

Environmental research showed that pharmaceuticals from wastewater treatment plants, industries and hospitals can contaminate waters, sediments, aquatic flora and fauna [1]. Aquaculture plants also play an important role in this contamination. This study focused on the analysis of 58 antibiotics in sediments of Nera river (Umbria, Italy), an area in which several trout farms are present.

Methods: (Limit of 400 characters)

Sample preparation protocol consisted in three consecutive extraction steps followed by a tandem SPE clean-up (Oasis HLB + Strata-X-C). The LC-Q-Orbitrap conditions were the same described in our previous work [2]. The validation study has been performed at 1 and 10 µg/kg dry weight (dw). Samples from Nera River were collected monthly at three sites from March to December 2017.

Results: (Limit 900 characters)

The optimized sample treatment involved three extractions with mixtures at different pHs (7, 3 and 10, respectively) to take out the wide range of substances included in the method scope: 58 analytes belonging to ten different antibiotic classes widely used in veterinary practices. After validation, the sediments collected from Nera River were analyzed (30 samples). Two tetracyclines (oxytetracycline and tetracycline), three quinolones (ciprofloxacin, flumequine and oxolinic acid) and trimethoprim were measured. In particular, oxytetracycline (and its epimer) was detected in the 100% of the samples with concentrations from 2 to 159 µg/kg dw. The other drugs were always lower than 10 µg/kg dw and their detection frequencies ranging from 3% (tetracycline) to 73 % (ciprofloxacin).

Conclusions (Limit of 400 characters)

The results revealed the presence of drugs used in trout farming, but other antibiotics were from other sources (ciprofloxacin and oxolinic acid). Nera River collected at the same time [3]. On the other hand, it is well known that the sediment composition favors the adsorption of only certain drugs.

Novel Aspect: (Limit of 150 characters)

This is the first survey on the presence of antibiotics in the Nera River sediments.

571 - DETERMINATION OF 16 POLYCYCLIC AROMATIC HYDROCARBONS BY CORE-SHELL MOLECULARLY IMPRINTED POLYMERS PREPARED BY REVERSIBLE ADDITION FRAGMENTATION CHAIN TRANSFER POLYMERIZATION WITH APGC-MS/MS

Ali-Asghar Golbabanezhad-Azizi (1) - Fereshteh Shahhoseini (1) - Christina Bottaro (1)

Memorial University of Newfoundland, Department of Chemistry, St. John's (1)

Keywords: Magnetic molecularly imprinted polymers; dispersive solid phase extraction; atmospheric pressure chemical ionization gas chromatography; reversible addition fragmentation chain transfer polymerization

Introduction:

Polycyclic aromatic hydrocarbons (PAHs) with carcinogenic and mutagenic properties are considered priority pollutants by regulatory agencies world-wide. Liquid-liquid extraction and solid phase extraction (SPE) are non-selective techniques influencing the sensitivity, accuracy and precision of MS analysis [1]. Molecularly imprinted polymers (MIPs) as selective sorbents can improve the efficiency, and reproducibility, and reduce matrix effects [2].

Methods:

MIP particles were prepared by surface polymerization on magnetic Fe₃O₄@SiO₂ nanoparticles through reversible addition fragmentation chain transfer (RAFT) [3]. The RAFT-MIPs were used for dispersive SPE (dSPE) of 16 PAHs from aqueous matrices, then isolated by magnetic collection. The analytes were desorbed into organic solvent prior to quantitation with atmospheric pressure chemical ionization gas chromatography tandem mass spectrometry (APGC-MS/MS).

Results:

To obtain maximum performance by the RAFT-MIPs, the composition of polymeric coating as well as the parameters influencing extraction efficiency for enrichment of PAHs were assessed and optimized. The synthesized particles were also analyzed using XRD and IR measurements to confirm formation of selective binding sites through surface polymerization onto core-shell nanoparticles. Under optimized conditions (15 mg RAFT-MIPs, 40-mL sample volume, 1 min ultrasonic dispersion extraction time, 1 mL desorption solvent and 10 min desorption time), RAFT-MIPs were used for selective extraction of 16 PAHs from water samples. Good recognition properties (IF between 1.7 and 2.7) for extraction of PAHs in water samples were obtained without matrix manipulation, such as filtration or removal of interferences. The developed method with good detection limits (ng/L levels) and high precision (RSD < 8%) provides a sensitive and reliable procedure for analysis of PAHs in any complex matrix.

Conclusions:

RAFT polymerization, as a controllable technique relying on living radical initiators, was used to create cavities with accessible and homogenous binding sites for the target molecules. The RAFT-MIPs yielded a rapid, selective and efficient procedure for extraction of PAHs from water samples. Indeed, application of a hydrophilic comonomer enhancing the water compatibility of magnetic MIP makes the sorbent suitable for the analysis in aqueous matrices.

Novel Aspect:

Water compatible magnetic RAFT-MIPs were produced for rapid, selective and simultaneous extraction of 16 PAHs with reduced interferences for instrumental analysis.

Keywords:

Double bond equivalent

Naphthenic acids

Constructed wetland

Kinetic analysis

Orbitrap-MS

Introduction:

Oil sand process-affected water (OSPW) is a complex mixture containing naphthenic acids (NAs) as the primary acid component [1, 2]. High-resolution Orbitrap mass spectrometer is well suited for the characterization of complex samples and is useful for monitoring the changes in distribution of OSPW-NAs during treatment. In this work, the effectiveness of constructed wetland treatment (CWT) in the transformation of naphthenic acid fraction components (NAFCs) was evaluated in a non-aerated wetland design using high-resolution Orbitrap-MS.

Methods:

NAs transformation in non-aerated CWT was assessed using high-resolution Orbitrap-MS technique. The NAs from aqueous wetland outflow samples were extracted using WAX SPE method described previously [3]. Class distributions were established with acquired accurate mass data and Composer version 1.5.3 with mass accuracies of less than 2 ppm. In addition, kinetic and statistical analysis was performed with SigmaPlot software.

Results:

The distributions of NAs in the untreated and CWT were examined for selectivity based on the changes in carbon number numbers and double bond equivalents (DBE). The results demonstrated that the non-aerated CWT preferentially transformed O2-NAs with larger carbon numbers than small carbon number NAs. The oxidized NAFCs (O3-NAFCs and O4-NAFCs) were more recalcitrant towards transformation relative to O2-NAs in the wetland system. Furthermore, kinetic data indicated that rate of transformation of O2-NAs with larger carbon numbers was faster than small carbon number NA species and there was no direct correlation between the increased transformation rate and size of the DBE observed in the treatment system.

Conclusions

The non-aerated wetland treatment system was effective for treatment of OSPW-NAFCs and favors the transformation of higher carbon number over small carbon number species. This suggests that preferential removal of NA species may be related to design of the system. Work is ongoing to compare with other wetland designs such as aerated wetlands to determine whether these designs have impacts on their selective transformation.

Novel Aspect:

The present study reported herein is the first study to evaluate the feasibility of OSPW-NAFCs transformation in constructed wetland treatment (CWT) using high-resolution negative-ion electrospray Orbitrap-MS for detailed understanding of their fates and behavior in the CWT.

draft

Diego Holanda Pereira de Souza (1) - Thiago Carita Correra (1) - Vitor de Moraes Zamarion (1)

Universidade de São Paulo, Institute of Chemistry, São Paulo (1)

Keywords: Photocatalysis; Titania; Visible light; Organic Pollutants; Electrospray.

Introduction:

Some metal oxides, such as titanium dioxide (TiO₂), can be employed as photocatalysts because of their ability to promote oxidation of organic molecules when activated by UV-light [1] due to its wide band gap. In this work, we showed via ESI(-)-MS that thin mesoporous films of TiO₂ nanoparticles can degrade hazardous environmental pollutants, as 2-naphtol [2], under visible light incidence.

Methods:

Three identical aqueous solutions of 2-naphtol (photosensitive substance) and ammonium hexafluorophosphate (internal standard) were prepared. To one of them, a glass plate was immersed (control), and into the others two plates of TiO₂ films were dived. One of the tubes containing titania was kept in the dark, and the other two tubes were maintained under incidence of blue LED light.

Results:

To conduct a quantitative experiment, NH₄PF₆ was employed as an internal standard for the analysis. This compound was chosen because it easily ionizes in aqueous solution generating anions that are stable and inert under these experimental conditions.

The photodegradation rate was carried by periodically sampling a small aliquot of the solutions in contact with the glass plates every 60 minutes for 6 hours. The decay rate of 2-naphtol was controlled by the ratio of the intensities of the [2-naphtol-H]⁻ to the PF₆⁻ over time.

It was observed that TiO₂ films can easily promote photooxidation of 2-naphtol under incidence of visible light and in the presence of oxygen gas by showing an almost complete photodegradation after about 6 hours of reaction. The systems that were set up with TiO₂ film in the dark and with the bare glass under blue light did not demonstrate any kind of degradation.

Conclusions:

TiO₂ films can photodegrade organic pollutants, as 2-naphtol, in the absence of UV radiation and under incidence of visible light. A quantitative MS technique was developed and NH₄PF₆ was used as internal standard. This procedure worked well for evaluating photodegradation and allows the degradation products to be detected.

Novel Aspect:

The use of ammonium hexafluorophosphate as an internal standard and the determination that visible light can induce photocatalysis in TiO₂ films.

1Department of Environmental Science and Engineering, School of Architecture and Environment, Sichuan University, Chengdu, China; 2Perkinelmer Management (Shanghai) Co., Ltd., Shanghai, China; 3PerkinElmer Inc., Woodbridge, ON

Keywords: degradation mechanism, atrazine removal, nanoparticles, electrochemical reaction, UHPLC-MS/MS

Introduction:

CuFe₂O₄ (CFO) magnetic nanoparticles, worked as both particle electrode and catalyst for persulfate (PS), are applied to the three-dimensional electrochemical processes for atrazine removal. In this study, the effects of several key parameters, such as the content of Na₂SO₄ electrolyte, CuFe₂O₄, persulfate, other inorganic anions, the initial pH and current density on atrazine removal were investigated. In addition, the degradation intermediates were determined by UHPLC-MS/MS. Based on the identified intermediates, the degradation pathway or mechanisms for atrazine in the CFO/PS system were confirmed. Finally, the possible electrochemical reaction mechanism of the CFO/PS system was proposed according to the comprehensive study.

Methods:

The degradation intermediates of atrazine were determined by coupling PerkinElmer UHPLC to a QSightTM 220 mass spectrometer. A C18 column was used for separation with gradient elution at a flow rate of 0.3 mL/min, with mobile phases consisted of acetonitrile (A) and pure water containing 0.1% formic acid (B). The mass spectra with electrospray ionization (ESI) source were recorded across the range of 50-300 m/z with the positive scan mode and MRM mode. The operation parameters were as follows: drying gas of 100, HSID temperature of 250 °C, nebulizer gas of 200, electrospray voltage of +5500V, and source temperature of 450 °C.

Results: (Limit 900 characters without spaces)

In this electrochemical reaction process, CFO magnetic nanoparticles have been successfully applied as a catalyst for the activation of persulfate, exhibiting excellent performance for atrazine removal in CFO/PS system after 35 min treatment. The optimal operating conditions (i.e., CFO dosage of 3.0 g/L, PS dosage of 4.0 mM, initial pH of 6.3 and treatment time of 35 min) were obtained by investigating the effects of key parameters on the atrazine removal. The high-efficiency of the CFO/PS for atrazine removal was confirmed through seven control experiments. It was found that CFO particles retained high activity after four excessive cycles, demonstrating the stability and recyclability of CFO in the studied system. The comparative study of the freshly prepared and reacted CFO also confirmed the stability of CFO. In this study, the sulfate radical was identified as the main reactive radical in the atrazine degradation process. In addition, the degradation mechanism of atrazine was ascertained according to the 12

degradation intermediates detected by UHPLC-MSMS. Finally, the possible electrochemical reaction mechanism of CFO/PS system was proposed according to the aforementioned analysis.

Conclusions (Limit of 400 characters without spaces)

In this study, CFO magnetic nanoparticles have been successfully applied as a catalyst for the activation of persulfate, exhibiting excellent performance for atrazine removal in CFO/PS system. The high-efficiency of the CFO/PS for atrazine removal was confirmed. It was found that CFO particles retained high activity after four excessive cycles, demonstrating the stability and recyclability of CFO in the studied system. The sulfate radical was identified as the main reactive radical in the atrazine degradation process and the degradation mechanism of atrazine was ascertained according to the 12 degradation intermediates detected by UHPLC-MSMS.

Novel Aspect: (Limit of 150 characters without spaces)

The degradation mechanism of atrazine was ascertained according to the 12 degradation intermediates determined by UHPLC-MSMS.

316 - NEW PESTICIDE METABOLITES IN GROUNDWATER DETECTED USING HIGH RESOLUTION MASS SPECTROMETRY

Karin Kiefer (1) - Adrian Müller (1) - Heinz Singer (1) - Juliane Hollender (1)

Eawag, Environmental Chemistry, Dübendorf (1)

Keywords: suspect screening, high resolution mass spectrometry, pesticide metabolites, groundwater

Introduction:

Groundwater contributes to 80% of drinking water supply in Switzerland [1]. However, various contaminant sources such as pesticide application in agriculture pose risks to groundwater quality. Only for few pesticide metabolites reference standards are commercially available so that groundwater quality is partly unknown. Thus, high resolution mass spectrometry combined with a screening of exact masses of potential metabolites is a possibility to detect new contaminants.

Methods:

31 groundwater samples were enriched via water evaporation, and analyzed with liquid chromatography coupled with electrospray ionization to high resolution tandem mass spectrometry (LC-ESI-HRMS/MS). The HRMS data were searched for the exact masses of more than 1000 pesticide metabolites, most of them observed within the European pesticide registration process [2, 3], using Compound Discoverer (Thermo Scientific).

Results:

After background and target removal 8400 compounds were annotated as suspects in positive and negative ionization mode. Despite optimization of the parameter settings in Compound Discoverer using target compounds, a high number of compounds were grouped insufficiently across samples and noise peaks were not fully removed. Therefore, visual inspection was required. The remaining 590 compounds, which showed a signal/noise >10, were checked for plausibility based on isotope pattern, retention time and in silico fragmentation with MetFrag [4]. The pesticide producers provided reference standards for 28 metabolites originating from 16 pesticides. So far, 11 compounds have been confirmed; 4 out of the 11 compounds were already detected in a target screening study by Reemtsma et al. [5].

Conclusions:

Due to the high-quality suspect list, the optimized workflow and the HRMS data the suspect screening successfully identified several new pesticide metabolites which have not been measured before in groundwater. However, despite advances in the evaluation softwares during recent years, suspect screening is still related to a large manual effort, a combination of computational tools and expert knowledge.

Novel Aspect:

Groundwater samples were screened for >1000 pesticide metabolites. Water evaporation allowed to minimize losses of polar compounds during enrichment.

365 - COMPARISON OF ORGANIC MIXTURES FROM PARTICULATE MATTERS COLLECTED IN KOREA AND CHINA BY USING GCXGC/HIGH RESOLUTION MASS SPECTROMETRY

Moon-Hee Park (1) - Geul Bang (1) - Kyung-Soon Jang (1) - Kihong Park (2) - Sunghwan Kim (3) - Young Hwan Kim (1)

Korea Basic Science Institute, Biomedical Omics Group, Cheongju (1) - Gwangju Institute of Science and Technology, School of Earth Science and Environmental Engineering, Gwangju (2) - Kyungpook National University, Department of Chemistry, Daegu (3)

Keywords: particulate matter, PM2.5, GCxGC/HRMS, PAHs, atmosphere air

Introduction:

In Korea and neighboring China, airborne particulate matter (PM2.5) is very serious environment problems, having primary organic pollutants directly released from emission sources and secondary organic pollutants generated from atmosphere chemical reaction. Thus, the complex organic compounds extracted from PM2.5 collected day after day during one month in each country were analyzed to compare their identifications, relative quantities and emission sources.

Methods:

Samples of PM2.5 were simultaneously collected day after day for 28 days (4-31 January 2018) in Gwangju and Beijing using a high volume air sampler. The 90 cm² filter was extracted with dichloromethane through sonication twice. The two days of extracts were combined, filtered and concentrated under N₂ gas. Comprehensive two-dimensional gas chromatography/high resolution time-of-flight mass spectrometry (LECOGC-HRT) was utilized to analyze the organic extracts. [1]

Results:

Approximately, 460 compounds were separated on the polar and sequential nonpolar GC columns and identified based on the mass spectral data from NIST and Wiley libraries, and exact mass accuracy (<1 ppm) of molecular ion from high resolution data, including alkanes, carboxylic acids, hopanes, PAHs, substituted aromatics and steranes, so on. A variety of PAHs were identified in Beijing samples such as 11H-benzo[b]fluorine, benzo[ghi]fluoranthene, benzo[a]anthracene, acepyrene, pyrene and benzo[A]yrene. Their concentrations in Beijing were more 49 to 3 times according to PAH compounds than those in Gwangju for 16/17 days PM2.5. On the contrary to this, natural resin such as dehydroabiatic acid was much more in Korea sample. The organic compound markers which can make a distinction between the emission sources of PM2.5 in Korea and China are present. Among them, naphthalic anhydride found in this analysis may become a candidate marker. The study about what this compound in PM2.5 is originated from is currently ongoing. [2]

Conclusions

The complex organic mixtures from PM2.5 were analyzed by using GCxGC/HRMS. The identified organic compounds were different qualitatively and quantitatively between Korea and China. The PM2.5 generated in China has been sometimes transferred into Korea by atmosphere air. Thus, there is anticipated that the issues between two countries related about the emission sources will be discussed, based on these objective results obtained for PM2.5 collected in Korea and China.

Novel Aspect:

The organic compounds extracted from PM2.5 collected in Korea and China were different qualitatively and quantitatively due to their different emission sources.

467 - BIOCIDES SPRAY PRODUCT EXPOSURE: MEASURED GAS, PARTICLE AND SURFACE CONCENTRATIONS COMPARED WITH SPRAY MODEL PREDICTIONS

Vivi Kofoed-Sørensen (1) - Asger Nørgaard (2) - Marie Frederiksen (1) - Peder Wolkoff (1) - Per Axel Clausen (1)

National Research Center for the Working Environment, Chemical working environment, Copenhagen (1) - Novo Nordisk, Development, Copenhagen (2)

Keywords: Spray products, Biocides, Modelling, Exposure, MS

Introduction:

Spray product emissions may be inhaled and some of the chemical ingredients may be respiratory irritants which may cause development of asthma or have other health effects. The aim of this project was to compare experimental exposure of 3 biocidal spray products (#1, #2, #3) applied in an exposure chamber with computed exposure calculations in existing models. The results were used to validate the models to contribute to a better risk assessment of spray products.

Methods:

Three biocidal spray products with different active compounds and spray nozzles were selected. They were applied in a 20.3 m³ controlled exposure chamber in accordance with the description provided by the manufacturers. Airborne organic compounds were sampled on Tenax and XAD and surface deposited by wiping with swabs. Samples were analyzed by (TD)-GC-MS/MS and LC-(QTOF)MS. Mass and number concentrations and size distributions of particles were measured on-line.

Results:

#1 had permethrin, piperonyl butoxide, and pyrethrum extract as active compounds, which along with alkanes were found in the air after spraying. Like the particles these followed a 1st order decay, however, the removal rates were higher than the air exchange rate (AER) indicating they were associated with the depositing particles. The alkane decay followed the AER indicating they were in the gas-phase.

#2 contained λ -cyhalothrin as the active compounds but it was not found in the air samples. Large particles (>0.5 μ m) were found in very low concentrations (<0.1 mg/m³), while smaller particles (<0.3 μ m) stayed at background levels. λ -cyhalothrin was found in wipe samples from surfaces.

#3 had benzalkonium chlorides as the active compounds, which were measurable in air up to 36 min after spraying following a 1st order decay. The particle pattern was the same as for #2. The wipe samples showed that the benzalkonium chlorides were mainly on surfaces near the spray area.

Preliminary results showed discrepancy between models and experiments.

Conclusions

The sprayed aerosols had shorter residence time in air than explained by the AER. Concentrations of the active compounds and low vapor pressure organic compounds decayed faster than explained by AER since they were associated with the aerosols, while more volatile compounds followed the AER. Aerosols of benzalkonium chlorides could be measured in the air more than ½ hour after application. The active compounds deposited mainly at the floor near the spraying position.

Novel Aspect:

Modelling is used extensively in risk assessment; however there is a research gap on the compliance between modelling and actual exposure data using standardized conditions.

1251 - HILIC-MS (NON-)TARGET SCREENING, MONITORING AND TOXICOLOGICAL EVALUATION OF HIGHLY POLAR COMPOUNDS IN DRINKING WATER AND SOURCES

Annemieke Kolkman (1) - Rosa Sjerps (2) - Pascal Kooij (1) - Kirsten Baken (2) - Pim de Voogt (2)

KWR Watercycle Research Institute, Laboratory for Materials Research and Chemical Analysis, Nieuwegein, Netherlands (1) - KWR Watercycle Research Institute, Chemical Water Quality and Health, Nieuwegein, Netherlands (2)

Keywords: very polar compounds, non-target screening, hydrophilic interaction liquid chromatography, Orbitrap Fusion

Introduction:

Highly polar organic compounds are of special interest for drinking water utilities, since these substances are likely to end up in drinking water. Currently there is an analytical gap, a monitoring gap, and a lack of toxicity data for persistent and mobile organic compounds [2]. We aimed to close these gaps by applying a target and non-target screening using hydrophilic interaction liquid chromatography (HILIC) coupled to high resolution mass spectrometry in a monitoring study [3], followed by a toxicological risk assessment.

Methods:

HILIC-MS target and non-target screening approach including a pre-treatment was developed. The method was validated for the determination of 38 highly polar compounds in surface water and in drinking water.

29 samples from surface water, river bank filtrate, groundwater and drinking water in The Netherlands and Flanders were analysed.

A toxicological risk assessment was performed for the observed highly polar compounds.

Results:

More than half of the 38 highly polar target compounds were present in surface-, ground and/or drinking water at levels between LOD and LOQ or above the LOQ. Traces of several highly polar compounds were observed in drinking water. One compound, dichloroacetic acid, was introduced during disinfection treatment.

Non-target HILIC-MS screening detected 145 features: compounds with a unique combination of accurate mass and retention time. The identity of eleven compounds could be confirmed by reference standards, the remaining compounds are yet to be identified. Due to threshold settings for detection not all target compounds that were observed with target HILIC analysis were observed with non-target HILIC-MS screening.

A pGLV could be derived for 8 chemicals. For the remaining compounds present in the evaluated samples, insufficient information was available to derive a provisional drinking water guideline value (pGLV).

Conclusions

A HILIC-MS non-target screening approach was developed and validated for the determination of highly polar compounds.

The HILIC target analysis and non-target screening were proven useful for the detection of highly polar compounds in source waters and in drinking water.

Further identification of chemicals observed and toxicological risk assessment are imperative to evaluate the relevance of highly polar chemicals in (sources of) drinking water.

Novel Aspect:

An novel non-target screening approach using HILIC was developed for highly polar compounds revealed the presence of known and unknown polar compounds in the water cycle.

1228 - OCCURRENCE AND HUMAN EXPOSURE TO BROMINATED AND ORGANOPHOSPHATE FLAME RETARDANTS FROM FINNISH HOUSEHOLD DUST

Eva Kumar (1) - Panu Rantakokko (1) - Joris Braber (1) - Jani Koponen (1) - Taya Huang (1) - Hannu Kiviranta (1)

National Institute for Health and Welfare (THL), Health Security, Kuopio, Finland (1)

Keywords: brominated flame retardants, organophosphate flame retardants, household dust, human exposure, exposure model

Introduction:

Flame retardants (FRs) are chemicals that are used to decrease flammability of consumer products. They are incorporated as additives or reactive ingredients in materials including plastics and textiles. Brominated (BFRs) and organophosphate flame retardants (PFRs) are the two main classes of FRs that are extensively used wherein the latter are considered as potential replacements to conventional BFRs but also part of those exhibit potential health risk to consumers.

Methods:

BFRs and PFRs were measured in Finnish household dust (n=40) by GC-HRMS. Children and adults exposure assessment (ingestion, inhalation, dermal) was based on measured dust concentrations, and it was made according to models published by Little et al. [1]. Exposure assessment needed calculation of dust-air distribution of FRs, the validity of which was evaluated using measured dust and indoor air concentrations of FRs from Norway [2].

Results:

The certified dust SRM2585 was used as the quality control of the analytical method: recoveries were 91-121% for BFRs and 65-120% for PFRs. In case of BFRs, BDE-209 (410 ng/g) had the highest median concentration followed by DBDPE (Decabromodiphenyl ethane) (120 ng/g), and BEH-TEBP (Bis(2-ethylhexyl) tetrabromophthalate) (110 ng/g) in household dust. TBOEP (Tris(2-butoxyethyl) phosphate) (11000 ng/g) was the most abundant PFR followed by TCIPP (Tris(2-chloroisopropyl) phosphate) (1870 ng/g) and TPHP (Triphenyl phosphate) (770 ng/g). From modelled exposure assessment, it was determined that exposure via dust ingestion contributes most for BFRs and also for less-volatile PFRs for children who are also more susceptible to FRs exposure than adults. But dermal adsorption governs the exposure pathway for more-volatile PFRs. However, the model used for determining air concentrations underestimated some low volatile BFRs and over-estimated some volatile PFRs, that results in the respective under/over estimation of exposure.

Conclusions

Measured dust and calculated air concentrations of FRs in Finland were found to be similar with those measured in Norway. Total daily FR intakes were some orders of magnitude lower than the oral reference doses from literature. This study presents simple analytical and exposure assessment methods which enable effective screening of exposure. However, further studies are required to develop cost-effective methods to study the distribution and exposure of FRs.

Novel Aspect:

We present a simple analytical-calculation method to assess total exposure from indoor environment to FRs that is based solely on the measured FR concentrations in dust.

121 - NOVEL DRINKING WATER DISINFECTION BY-PRODUCTS

Albert Lebedev (1) - Dmitry Kosyakov (2) - Nikolay Ul'yanovskii (2) - Mark Popov (2) - Tomas Latkin (2)

Lomonosov Moscow State University, Chemistry Department, Moscow (1) - Northern Federal University, Chemistry, Arkhangelsk (2)

Novel drinking water disinfection by-products

Albert T Lebedev^{1, 2}; Dmitry Kosyakov²; Nikolay Ul'yanovskii²; Mark Popov²; Tomas Latkin²
¹Moscow State University, Moscow, Russian Federation; ²Northern (Arctic) Federal University, Arkhangelsk, Russia

Keywords: disinfection by-products, HPLC-HRMS, tap water, organochlorines, organobromines

Introduction:

Drinking water chlorination is used over 100 years. Destroying microbes chlorination however leads to formation of toxic disinfection by-products (DBPs), appearing due to reaction of active chlorine with natural and anthropogenic compounds dissolved in water. The list of DBP, contains over 700 compounds. However they cover only 50% of organic halogens in drinking water. In the present study over 30 new halogenated organic compounds were identified by HPLC-HRMS.

Methods:

Water samples from the Severnaya Dvina river at the water intake of Arkhangelsk (Russia), after purification and coagulation, and after chlorination were collected in March-June 2017. Two liters of water at pH 3 were made pass through SPE Bond Elute PPL cartridges (Agilent) cartridges. High resolution QTOF mass spectrometer TripleTOF 5600, (AB Sciex) with ion source Duospray connected to the HPLC system LC-30 Nexera (Shimadzu) was used.

Results:

Non targeted screening of pollutants in the Arkhangelsk tap water with HPLC- HRMS allowed detecting over 50 organohalogenes. Among phenols pentachlorophenol is usually considered as an independent priority pollutant. However it was not present in the samples before chlorination.

MS/MS allowed referring the largest group to halohydrines and dihalogenated fatty amides, the products of conjugated electrophilic addition of halogens to unsaturated fatty amides. The proposed structures were confirmed by oleamide chlorination in water. These compounds are a brand new class of DBPs, while their toxicities require special study. Five oxygenated species were 3,5-dichloro-4-hydroxybenzoic, dimethylbromobenzoic, and dimethyldibromobenzoic acids, trichlorophenylacetate, and 2,4-trichloro-1,3,5-benzotrialdehyde. ChemSpider search and spectra interpretation of N-containing compounds allowed identifying 3,4-dichloro-2-methoxy-5-oxo-2,5-dihydro-1H-pyrrol-1-yl)-acetic acid and highly substituted halogenated pyridines.

Conclusions:

Several groups of new disinfection by-products were identified in the tap water of Arkhangelsk (Russia). Mass spectral conclusions were confirmed by independent synthesis with standard compounds. Chlorinated and brominated compounds are formed at the stage of disinfection of the Severnaya Dvina river water rich with humic matter. Unfortunately there is no any available information on the toxicities of the novel DBPs.

Novel Aspect:

Several groups of novel disinfection by-products were established with HPLC-HRMS in the drinking water in Arkhangelsk, Russia

921 - A COMPARATIVE STUDY OF ULTRA-TRACE-LEVEL URANIUM BY THERMAL IONIZATION MASS SPECTROMETRY WITH CONTINUOUS HEATING: STATIC AND PEAK-JUMPING MODES

Chi Gyu LEE (1) - Jinkyu PARK (1) - Sang Ho LIM (1) - Sun Ho HAN (1)

Korea Atomic Energy Research Institute, Nuclear Chemistry Research Division, Daejeon (1)

Keywords: Ultra-trace-level Uranium, Isotope Ratio, TIMS, Detection mode, Nuclear Safeguards

Introduction:

For ensuring nuclear safeguards, we report the analytical signal-detection performance of thermal ionization mass spectrometry (TIMS) with continuous heating for the measurement of isotopic ratios in samples containing ultra-trace amounts of uranium.

Methods:

The isotope ratio measurements were performed using a thermal ionization mass spectrometer (TRITON Plus, Thermo Fisher Scientific, Germany). As methods for detecting uranium signals, peak-jumping mode using a single detector and static mode using multiple detectors were examined with U100 (10% ^{235}U -enriched) uranium standard samples in the femtogram-to-picogram range.

Results:

Uranium isotope ratios, $n(^{235}\text{U})/n(^{238}\text{U})$, were measured down to levels of 1 fg and 3 fg in static and peak-jumping modes, respectively, while $n(^{234}\text{U})/n(^{238}\text{U})$ and $n(^{236}\text{U})/n(^{238}\text{U})$ values were measured down levels of 100 fg in both modes. In addition, the dependency of the ^{238}U signal intensity on sample quantity exhibited similar tendencies in both modes. The precisions of the isotope ratios obtained in the static mode over all sample ranges used in this study were overall slightly higher than those obtained in peak-jumping mode.

Conclusions:

These results indicate that the analytical performance by TIMS with continuous heating are almost independent of the detection method, i.e., peak-jumping mode or static mode, which is characteristic of isotope-ratio measurements using the TIMS method with continuous heating.

Novel Aspect:

The results suggest that similar analytical performance can be obtained in the two detection of TIMS with continuous heating.

654 - ANALYSIS OF NATURAL RADIONUCLIDES CONCENTRATIONS IN MONAZITE USING ACID DIGESTION BY QUADRUPOLE ICP-MS

JUHYUN LEE (1) - SUNG YI (2)

KOREA INSTITUTE OF NUCLEAR SAFETY, HANYANG UNIVERSITY/DEPARTMENT OF CHEMICAL ENGINEERING, DAEJEON (1) - HANYANG UNIVERSITY, HANYANG UNIVERSITY/DEPARTMENT OF CHEMICAL ENGINEERING, SEOUL (2)

Keywords: Acid digestion, uranium, thorium, ICP-QMS

Introduction: (Limit of 400 characters)

According to the Act on Protective Action Guideline Against Radiation in the Natural Environment in South Korea has been planned and conducted the field investigation to monitor the radioactivity concentration surrounding usage facilities of raw materials and residues and protect from radiation in the natural environment. Anyone who handles raw materials or residues contained uranium or thorium whose activity concentration exceeds 1Bq/g should be registered the material informations (radioactivity concentrations, total amount, etc.). The objective was to monitor of potential pollution materials in naturally environment and offer some useful information for policy decision. Then it was important to pretreat the samples in order to accurately analyze the concentrations. There are various digestion procedures: open vessel digestions, closed vessel digestions, microwave digestions, alkali fusion. The digestion of monazite is an important aspect of thorium and uranium elements analysis using by quadrupole inductively coupled plasma mass spectrometry (ICP-MS). This paper describes comparison of two digestion methods for thorium and uranium elements analysis in monazite.

Methods: (Limit of 400 characters)

In this study, the monazite was dissolved by the conventional acid digestion and electric fusion system. Prior to the pretreatment, it was using a XRD in order to analyze the components of the suspicious materials, detected matter whose radioactive concentration exceeds or is suspected to exceed limits determined by NSSC in monitors at harbors. After homogenous sample preparation through milling or mixing, the sample were dried in a temperature controlled oven up to 450 °C for about 5hrs. The samples were dissolved by fusion with lithium metaborate and acid digestion with HF, HNO₃, and HClO₄ to break refractory complex. The dissolved solutions were precipitated at pH 7 using Fe co-precipitation and dilution HNO₃ for analysis by ICP-QMS. In addition, the samples were completely sealed in D6H4 bottle to secure the confinement of radon gases. It spends time for 1 month to attain the secular equilibrium between radium and radon isotopes in decay series. Thorium and uranium series that represented ²²⁸Ac and ²¹⁴Bi gamma nuclides measured by HPGe and ²³²Th and ²³⁸U atomic analyzed by ICP-QMS.

Results: (Limit 900 characters)

The reference sample with certificate values (zircon by ALML) was analyzed for the different digestions. The alkali fusion method showed great thorium and uranium yield up to 98% and the closed vessel acid digestion method was similar thorium and uranium yield. The results of ²³²Th and ²³⁸U using HPGe and ICP-QMS showed a similar distribution. However, the monazite showed different values between fusion method and acid digestion. The higher concentration of the samples, the bigger the difference values.

In addition, the radioactivity of the ²³²Th and ²³⁸U indicator decreased in the monazite and showed a different concentration of thorium and uranium between ICP-QMS and HPGe.

Conclusions (Limit of 400 characters)

It is the most important to monitor environmental radiation, raw materials, residues and products for protect from radiation exposure. NSSC enforced "Act on Protective Action Guidelines Against Radiation in the Natural

Environment” since 2012. Thus, this study establishes the procedures of radiation measurement or radioactivity analysis about NORM samples. In particular, it was necessary to analyze the thorium and uranium concentrations of monazite using acid digestion and evaluate the assessment of radiation risk for the Korean population and protect the health of the workers involved and the environment.

Novel Aspect: (Limit of 150 characters)

Comparison between alkali fusion and acid digestion for thorium and uranium analysis in monazite or products suspected as contaminant materials in the field survey based on NORM regulation in South Korea

137 - DETERMINATION OF GLOBAL DNA METHYLATION AND OXIDATION OF DNA AND LIPID BIOMARKERS IN METAL OXIDE NANOMATERIAL-HANDLING WORKERS BY LIQUID CHROMATOGRAPHY-TANDEM MASS SPECTROMETRY

Hui-Ling Lee (1) - Saou-Hsing Liou (2)

Fu Jen Catholic University, Fu Jen Catholic University/Chemistry, New Taipei City (1) - National Health Research Institutes, National Institute of Environmental Health Sciences, Zhunan, Miaoli County (2)

Determination of global DNA methylation and oxidation of DNA and Lipid biomarkers in metal oxide nanomaterial-handling workers by liquid chromatography-tandem mass spectrometry

Keywords: metal oxide nanomaterials; 8-hydroxydeoxyguanosine; biomarkers; LC-MS/MS

Introduction

The nanotechnology industry is a rapidly growing. The most commonly used nanomaterials (NMs) are, titanium dioxide (TiO₂), silica (SiO₂) and zinc oxide. To assess whether oxidative stress markers of nucleic acids (8-OHdG), DNA methylation levels in urine and white blood cell (WBC), and EBC 8-isoprostane were associated with nanomaterial exposure. Moreover, the relationship between oxidative damage biomarkers and global DNA methylation was investigated.

Methods

In the present study, urinary and white blood cell (WBC) 8-hydroxydeoxyguanosine (8-OHdG), and exhaled breath condensate (EBC) 8-isoprostane were measured as oxidative stress biomarkers. WBC global methylation was measured as an epigenetic alteration. To examine global methylation, oxidative DNA damage, and lipid peroxidation in workers with occupational exposure to metal oxide nanomaterials using LC-MS/MS.

Results: (Limit 900 characters)

Exposure to TiO₂, SiO₂, and indium tin oxide (ITO) resulted in significantly higher oxidative biomarkers such as urinary 8-OHdG and EBC 8-isoprostane. However, significantly higher WBC 8-OHdG and lower global methylation were only observed in ITO handling workers. Significant positive correlations were noted between WBC and urinary 8-OHdG (Spearman correlation $r = 0.256$, $p = 0.003$). Furthermore, a significant negative correlation was found between WBC 8-OHdG and global methylation ($r = -0.272$, $p = 0.002$). These results suggest that exposure to metal oxide NMs may lead to global methylation, DNA oxidative damage, and lipid peroxidation.

Conclusions

Global DNA methylation levels, and levels of oxidative stress markers 8-OHdG and 8-isoprostane were assessed in metal oxide nanomaterial handling workers. The results show that exposure to metal oxide nanomaterials may lead to global hypomethylation, DNA oxidative damages, and lipid peroxidation. Furthermore, we identified a negative correlation between WBC 8-OHdG and global methylation.

Novel Aspect

Exposure to metal oxide nanoparticles may lead to global methylation and DNA oxidative damage and lipid peroxidation.

42 - MASS SPECTROMETRY STUDY: WHEN AND HOW GREEN SOLVENTS IONIC LIQUIDS TURN INTO TOXIC COMPOUNDS

Xing-Fang Li (1) - Ping Jiang (2) - Ian Vander Meulen (1)

University of Alberta, Division of Analytical and Environmental Toxicology, Edmonton (1) - University of Alberta, Division of Analytical and Environmental Toxicology, edmonton (2)

Mass Spectrometry Study: When and How Green Solvents Ionic Liquids Turn into Toxic Compounds

Ping Jiang, Ian Vander Meulen and Xing-Fang Li

Introduction

Ionic liquids (ILs) are increasingly used in industrial processes as “green chemicals” because of unique properties of low volatility and customizability. ILs can be used to enable novel processes and/or replace conventional organic solvents in a wide variety of applications. Widespread use may increase the risk of accidental release of IL-containing industrial wastes into environmental waters. Most ILs are highly water soluble, and have estimated environmental half-lives of several days to a month. IL cations often consist of aromatic or alkyl quaternary amines that resemble previously confirmed N-nitrosamine (NAs) precursors. NAs are confirmed animal carcinogens and classified as probable human carcinogens. NAs are also potent, estimated to have negative health effects at ng/L concentrations. Therefore, this study is to investigate the formation of ILs of various structures to form nitrosamines under the conditions of water chloramination.

Methods

Laboratory reactions of ILs consisting alkyl and aromatic tertiary amines with chloramine will be performed. HPLC-MS and HPLC-MS/MS methods are developed and used to identify and quantify the nitrosamines produced in the reactions.

Preliminary Results

We have studied two ILs, 1-ethyl-1-methylpyrrolidinium bromide (EMPyr) and 1-ethyl-3-methylimidazolium bromide (EMIm), for their nitrosamine formation potential. Each IL species was reacted with pre-formed monochloramine under various conditions. After 24h, samples were extracted from water using dichloromethane. The extracts were analyzed for nitrosamines formed in the reactions. HPLC-high resolution MS analysis of the extracts identified the produced nitrosamines, while HPLC-MS/MS with multiple reaction monitoring mode quantified the concentrations of the NAs using a deuterated internal standard. Both EMIm and EMPyr can produce NAs: EMIm generating N-nitrosomethylethylamine, while EMPyr producing N-nitrosopyrrolidine. The formation yield of NAs is dependent on the structures of the ILs. EMPyr produced higher amount of NA than EMIm under all conditions evaluated. EMPyr can produce NA with a yield on the same order of magnitude as polydiallyldimethylammonium chloride, a confirmed nitrosodimethylamine precursor. We are investigating a variety of ILs for the formation potential of NAs. In addition, we will further investigate how to use UV/H₂O₂ to reduce the formation of nitrosamines from ILs. This study is the first report demonstrating the formation of NAs from ILs under water chloramination conditions. This study emphasizes the importance of prevention of environmental discharge of ILs to water bodies, and highlights a need for further evaluation of potential lifecycle impacts of ILs prior to their wide ranging applications.

Novelty: MS studies of Ionic liquids forming toxic nitrosamines under common water treatment conditions.

Wei Liu (1) - Jundong Hu (1)

Chinese Academy of Geological Sciences, National Research Center for Geoanalysis, Beijing (1)

Keywords: iodine, speciation, stability, distribution, soil

Introduction

Soil plays an important role in the environmental geochemistry circulation and transformation process of iodine. In this study, the primary interest was to understand the iodine species that were potentially mobilizable and bioavailable, rather than the total iodine species present in the soil. Investigation has been conducted on the status of iodine distribution in Fenyang, in order to elucidate the distribution characteristics of iodine in the environment.

Methods

Soil profile samples were mainly collected from farmland in Fenyang. The total iodine concentration was detected by inductively coupled plasma mass spectrometry (ICP-MS) using ammonium hydroxide digestion. The speciation analysis of iodine was determined by high performance liquid chromatography (HPLC) coupled with ICP-MS. Two methods that water extracting and phosphate extracting were used to investigate the bioavailability of iodine in soil samples.

Results

Good results were achieved using 10 % ammonium hydroxide (v/v) and 0.5 mM EDTA where the transformation between IO_3^- and I^- was clearly minimized. Inorganic iodine was the main iodine species in the extraction solution. Iodine in soil exists as organic iodine has been reported elsewhere [1,2,3]. Our results indicated that the transformation of organically bound iodine to inorganic iodine must be occurred because the sums of inorganic iodine were agreed with the certified values of reference soils. But the transformation between IO_3^- and I^- was not observed.

Water extraction and phosphate extraction were used to investigate the bioavailability of iodine in 6 soil samples. The results showed that I^- was the main iodine species. It confirmed that iodine in soils was mainly transported into plants in the form of inorganic iodine. The iodine concentrations of all the soil profile samples ranged from 0.56~5.69 $\mu\text{g-I g}^{-1}$. The maximum iodine concentration was at the depth of 0~20 cm. And the soil iodine content decreased with increasing sampling depth.

Conclusions

Efforts were made to preserve the oxidation of IO_3^- to I^- by using EDTA. Although this method should be further tested for its application for a broad range of soil samples, the results obtained in this study are promising. The main species of iodine uptake from soil was iodide. The content of iodine in the surface soil was higher than that in the depth. It was not only related to iodine content in groundwater, but also related to geological structure and properties of soil.

Novel Aspect

The stability of inorganic iodine was achieved by adding EDTA into the extraction solution. The distribution and bioavailability of iodine in soil profile samples was discussed.

90 - DETERMINATION OF AG NANOPARTICLES IN VLTAVA RIVER (PRAGUE, CZECH REPUBLIC) BY SINGLE PARTICLE ICP-MS

Martin Loula (1) - Antonin Kana (1) - Oto Mestek (1)

University of Chemistry and Technology Prague, Department of Analytical Chemistry, Prague (1)

Keywords: single particle ICP-MS; silver nanoparticles; Vltava river;

Introduction:

Nanoparticles are used in many areas of industry and everyday life and they are released in great quantities into the environment. Despite this, little is known about their (eco)toxicity and the risks they might pose. To be able to evaluate these risks and take appropriate precautions, it is necessary to understand their behavior and fate in the environment.

Methods:

The single particle ICP-MS was used to determine and characterize Ag nanoparticles in samples of river water taken at several places from Vltava and a few smaller streams in Prague and its neighborhood. NexION 350D (Perkin Elmer, Concord, Canada) spectrometer was used for all measurements. Samples were stabilized by addition of gelatin immediately after sampling and were analyzed the same day.

Results:

The developed method exhibited good characteristics and only minor matrix effects of the river water were observed: limit of detection (LOD) of particle size ca. 25 nm (depends on dissolved Ag concentration), LOD of particle number concentration 100 mL⁻¹, 1.3% repeatability and 98% recovery. Small distortion of nanoparticle diameter was observed: mean diameter 92 nm was found for particles with diameter 96 ± 8 nm.

Ag nanoparticles were present in samples of water from Vltava river. The found Ag nanoparticles covered a wide range of diameters, ca. 30-120 nm. Their number concentrations were extremely low, ca. 300-2000 mL⁻¹, however well above the LOD. The Ag nanoparticles number concentrations increased as the river flowed through the urban agglomeration.

Conclusions:

Single particle ICP-MS proved to be capable of determining Ag nanoparticles in surface waters. Ag nanoparticles with wide range of diameters were successfully determined in the Vltava river and an increase of number concentrations, likely due to human activity, was observed downstream of Prague. It should be evaluated whether these number concentrations can be harmful to the environment.

Novel Aspect:

To the best of our knowledge this is the first study of Ag nanoparticles in surface waters in the Czech Republic.

Financial support from specific university research (MSMT No 21-SVV/2018) and Grant Agency of Czech Republic (project no. 17-00291S) is gratefully acknowledged.

543 - ANTIBIOTICS IN WATERS ALONG THE GRAND CANAL, CHINA

Guohui Lu (1) - Haitao Piao (1) - Shu Chen (1) - Xingchun Jiao (1) - Yongliang Yang (1)

Chinese Academy of Geological Sciences, National Research center for Geoanalysis, Beijing (1)

Keywords: Antibiotics; river water; the Grand Canal; spatial distribution

Introduction

The Grand Canal passes through some industrial cities (e.g. Hangzhou, Suzhou, Wuxi, and Tianjin), and also vast rural areas. The aim of this work is to reveal the differences in contamination levels and composition profiles of antibiotics in waters of different sections of the Canal with comparisons of population density and economic scale in each section.

Methods

HLB column (500mg, 6cc, Waters, USA) was used as the solid phase extraction for extraction and enrichment of the target antibiotics. Analysis of antibiotics was performed using a high-performance liquid chromatograph tandem mass spectrometer. Separation of the analytes was performed by an Agilent HP1200 liquid chromatograph interfaced with API 4000 tandem quadrupole mass spectrometer operated in the electrospray ionization mode.

Results

Among the 20 target antibiotics, 14 antibiotics were detected. The predominant types of antibiotics were sulfonamides and macrolides. The spatial distribution pattern of antibiotics shows that the concentration levels at the sampling sites in the north end of the canal (average: 117.1 ng/L) and the south end sections (average: 96.5 ng/L) of the canal were obviously higher than those in the middle sections (average: 48.8 ng/L). At the north end of the canal there are two metropolitan cities Beijing and Tianjin, and at the south end of the canal there are cities with dense population and industries such as Suzhou and Hangzhou. Municipal sewage could be the main sources for sulfonamides and macrolides in these cities [1-2]. Most of the sampling sites in the middle part of the canal are in rural areas, especially in the northern Jiangsu Province, and Shandong and Hebei Provinces where animal husbandry and fish farming could be the main sources for sulfonamides and macrolides.

Conclusions

High concentrations of sulfadiazine, sulfamethoxazole and ampicillin were observed. Antibiotics showed large geographical variations from the North to the South, with high concentrations occurring at the sampling sites in the Yangtze River Delta area and Tianjin-Beijing urban and suburban areas, while low levels were generally found in the middle sections of the canal with vast agricultural areas, showing a V-shape geographic distribution along the river.

Novel Aspect

The impacts of urbanization and economic development on concentrations and compositions of antibiotics in waters of different sections of the Grand Canal are discussed.

Keywords: GC×GC-MS, environmental mass spectrometry, retention index, semivolatiles compounds

Introduction: (Limit of 400 characters)

Gas chromatography-mass spectrometry (GC-MS) is one of the most precise, well developed, and reliable analytical tools for the analysis of small volatile and semivolatiles compounds. This method has been extensively improved and tested by enhancing the separation technique via comprehensive two-dimensional gas chromatography (GC×GC-MS). Application of GC×GC-MS is especially useful for analysis of complex mixtures, which environmental objects usually are.

Methods: (Limit of 400 characters)

Various organic compounds as well as dichloromethane extracts of different water samples were analyzed using Pegasus® GC×GC HRT 4D instrument (LECO Corp., USA). Compounds from SV Internal Standard Mix (Restek, USA) were used as internal standards (IS) for retention index calculations (perdeuterated 1,4-dichlorobenzene and some PAH). Chromatographic separation was performed using Rxi-5MS and Rxi-17SilMS columns (Restek, USA) for both dimensions respectively.

Results: (Limit 900 characters)

Several examples revealing insufficiency of GC-MS and GC-HRMS methods in precise identification of some organic compounds put forward GC×GC-MS as one of the most powerful tools for non-target analysis. To improve the identification certainty a simple method for calculation of retention indices attributed to the secondary dimension column (2I) using single injection and PAH as internal standards commonly used in US EPA methods for the analysis of semivolatiles organic compounds was proposed. Using the linear combination of both retention time (tR) and retention temperature (TR): $2I = a(TR+ktR) + b$, a series of 2I values for various organic compounds were calculated with good reproducibility under different separation conditions. a and b are proportional to enthalpy and entropy of interaction between analytes and stationary phases, k – non-linearity compensation coefficient. Time constituent of the 2I function by itself was found useful for identification of homological series of some classes of compounds (alkanes, fatty acids).

Conclusions (Limit of 400 characters)

GC×GC-MS was demonstrated to be crucial for non-target analysis of complex environmental mixtures. A simple and reliable approach is proposed for the calculation of retention indices in GC×GC experiments. The proposed method uses the Lee indices based on PAH, that may be used as a reference under certain conditions, and doesn't require any additional runs. The method is applicable for both target and non-target analyses for a wide range of compounds.

Novel Aspect: (Limit of 150 characters)

A simple and reliable approach is proposed for the calculation of retention indices in GC×GC analyses as one more analytical parameter to increase the identification certainty.

830 - THE ANALYSIS OF ENVIRONMENTAL SAMPLES USING HIGH RESOLUTION MASS SPECTROMETRY TO IDENTIFY NOVEL PFAS COMPOUNDS

Daniel McMillan (1) - Simon Roberts (2) - Craig Butt (2) - Chris Borton (2)

SCIEX, Business Development, Warrington (1) - SCIEX, Application Development, Framingham (2)

Keywords: PFAS, EPA, Non-target, Identification, Q-TOF

Introduction:

There are a very wide number of PFAS compounds that are actually present in environmental samples that are not part of the current EPA methods for PFAS analysis. The goal of this work was to use a QTOF mass spectrometer with Non Target Screening workflow to locate and identify unique PFAS compounds that were not known to be in the sample.

Methods:

Water samples were analyzed using a Sciex X500R QTOF system set up to acquire data in a Non Target Screening workflow. The instrument first performed a TOF scan from 100-1500. This scan was followed by a data dependent scan where ions above a set threshold were selected for fragmentation and acquisition of a full scan MS/MS spectrum. The resulting MS/MS spectra were searched against a high resolution library to identify potential PFAS of compounds present in the samples.

Results:

Perfluoroalkyl substances (PFASs) encompass a range of fully fluorinated alkyl compounds and are prevalent in Aqueous Film Fire Foam (AFFF). In addition, PFASs are ubiquitous as they are used in many household goods and have been found in various environmental and biological samples. Here, we demonstrate the use of QTOF technology to exploit the power of high resolution mass spectrometry and the use of product ion spectra to identify novel compounds in AFFF contaminated samples.

Novel Aspect:

Novel PFAS compounds are identified using high resolution mass spectrometry

147 - CHARACTERIZATION OF ORGANIC COMPOUNDS IN AQUATIC SEDIMENT BY ION PROFILES OBTAINED USING GC/MS SYSTEM

Zaharie Moldovan (1)

National Institute of Research and Development for Isotopic and Molecular Technology, Mass Spectrometry, Cluj-Napoca (1)

Characterization of organic compounds in aquatic sediment by ion profiles obtained using GC/MS system

Zaharie Moldovan, National Institute of Research and Development for Isotopic and Molecular Technology, INCDTIM, Cluj-Napoca, Str. Donat 67-103, Romania, zaha@itim-cj.ro

Keywords: GC/MS, river sediments, ion profiles

Introduction: The analysis of sediments is an efficient way of re-constructing the depositional history of organic compounds and environmental changes in aquatic environment [1-3]. The organic compounds are released to the environment through anthropogenic (industrial releases) and natural sources (aquatic organisms and terrestrial plants). Some compounds in sediments are widely used as a sensitive indicator for source identification. In respect to this, one of priority tasks is to determine the environmental distribution of organic compounds in the aquatic sediments. The present paper purpose is the characterization of main families of compounds by characteristic ion obtained by Ion Impact Mass Spectrometry using GC/MS system.

Methods: Sediment sample were prepared by Ultrasonic Solvent Extraction (USE). An aliquot (2g) of freeze-dried sediment was extracted successively with 10 ml CH₂Cl₂+methanol (2:1). The extract was fractioned on Al₂O₃ with following organic phases: n-hexane, n-hexane+CH₂Cl₂ (1:2), CH₂Cl₂+methanol (1:1) and methanol respectively. The final extracted was dried to 1ml in n-hexane. The analyses were performed using a GC/MS system with mass spectrometer operated in EI mode to 70 eV. The gas chromatograph was equipped with a capillary column HP-5MS (30x0.25mm) with 0.25µm thickness with programmed temperature from 90°C to 315°C.

Results: The families of compounds are visualized by chromatograms on diagnostic ions. The main group of compounds is: 1) n-Alkanes which show compounds with the number of carbon atom ranging from 12 to 30. 2) Acyclic isoprenoids compounds with a large number of methyl branching points in their structure. This group of compounds include pristane (C₁₉) and phytane (C₂₀) often used as an indicator of depositional environments. 3) Pentacyclic triterpanes (Hopanes) a class of compounds that has a great impact on petroleum geochemistry, they being useful as source indicators. 4) An important group of compounds found in the sediment samples is the Linear Alkylbenzenes (LABs), with number of carbon from 10 to 13. 5) An abundant class of compounds consists from Polyaromatic Hydrocarbons (PAHs) of environmental concern due to their carcinogenic proprieties. 8) Sulphonated Polyaromatic Hydrocarbons (SPAHS), other important group of pollutants used very often as biomarkers for the source information.

Conclusions: Are obtained characteristic profiles of organic compound families present in sediments. Their profile shapes is a function of their sources and reflect the natural, industrial and domestic activities at regional level.

Novel aspect: An efficient method based on GC/MS technique is developed for detection of eight families of organic compounds in sediment. Every family is presented as characteristic ion profile having a large number of compounds.

103 - STUDY OF PHARMACEUTICALS REMOVAL RATES IN WASTEWATER TREATMENT PLANT USING GC/MS ANALYTICAL TECHNIQUE

Zaharie Moldovan (1) - Olivian Marincas (1) - Ioana Feher (1)

National Institute of Research and Development for Isotopic and Molecular Technology, Mass Spectrometry, Cluj-Napoca (1)

Study of pharmaceuticals removal rates in Wastewater Treatment Plant using GC/MS analytical technique

Zaharie Moldovan, Olivian Marincas and Ioana Feher

National Institute of Research and Development for Isotopic and Molecular Technology, INCDTIM, Cluj-Napoca, Str. Donat 67-103, Romania, zaha@itim-cj.ro

Keywords: GC/MS, PPCPs, WWTP, isotopic dilution, removal rate,

Introduction: Many xenobiotics including Pharmaceuticals and Personal Care Products (PPCPs) are released into the environment from Wastewater Treatment Plants (WWTPs) [1]. The pharmaceuticals persist in the environment, remaining active and affecting aquatic life [2-4]. The PPCPs could act as persistent compounds, because of their continual discharge into aquatic sustaining a multigenerational exposure for the resident organisms [3]. In recent years, reliable methods have been established for analysis of these pollutants down to low ng/L levels in water environment, based on HPLC-MS and GC-MS. The purpose of this work was to quantify some pharmaceutical compounds in the aqueous phase at different stages of a conventional WWTP situated in Cluj-Napoca (Romania) with aim to determination of removal rate.

Methods: The compounds were extracted by SPE procedures and derivatised with N-methyl-N-trimethylsilyltrifluoroacetamide (MSTFA) and than analyzed by Gas Chromatography-Electron Ionization Ion Trap Mass Spectrometry (GC/EI-ITMS), in full scan mode. For quantification isotopic dilution was applied.

Results: An effective analytical method for the simultaneous determination of pharmaceuticals from various therapeutic classes in aqueous samples has been developed. The optimized GC separation was obtained for 38 PPCPs. The complete mass spectra were registered for natural, derivatised and isotopic labeled compounds. Are detected also compounds originating from thermal decomposition of pharmaceutics during GC separation. Were analyzed sample collected from different places of WWTP leading to removal rate for different treatment units.

Conclusions: Were obtained: 1) GC/MS separation of 38 compounds from family PPCPs; 2) Mass spectra for natural, silylated and isotopic labeled compounds; 3) Mechanism of thermal decomposition for cyclophosphamide and carbamazepine; 4) The removal rate for every compound in WWTP in the range 19.5-92 %, depending of chemical structure.

Novel aspect: a) Detection and quantification of PPCPs in an efficient analysis by SPE extraction, derivation by MSTFA and GC/MS analyses; b) Registration of mass spectra of the natural, silylated and isotopic labeled for the same compounds; c) Determination of the removal rate for different units of WWTP.

1169 - CITALOPRAM PHOTODEGRADATION: IDENTIFICATION OF TRANSFORMATION PRODUCTS BY MASS SPECTROMETRY

Rodrigo Osawa (1) - Maria da Conceição Oliveira (2) - Olinda Monteiro (1) - Maria Helena Florêncio (3)

Faculdade de Ciências, Universidade de Lisboa, Lisboa (1) - Instituto Superior de Lisboa, Universidade de Lisboa, Lisboa (2) - Faculdade de Ciências, Universidade de Lisboa, Lisboa (3)

Keywords: Transformation products; time-of-flight mass spectrometry; citalopram; wastewater samples.

Introduction

Citalopram (CIT), an antidepressant drug, is an emerging contaminant frequently detected in environmental matrices, but there are few data on its transformation products (TPs) formed in sewage treatment processes [1,2]. The objective in this study was to elucidate the formation in real matrices of CIT TPs by photodegradation under UV irradiation using LC-QTOF/MS for identification purposes.

Methods

Photodegradation experiments were conducted using a photoreactor with 100 mL of spiked distilled water (4 mg L⁻¹) cooled by water circulation. The UV irradiation source was a 450 W medium-pressure mercury-vapor lamp. The experiments consisted of 0.1 mL aliquots withdrawn in certain times. The QTOF Impact II mass spectrometer (Bruker Daltonics, German) was operated in the ESI positive mode in full scan and multiple reaction monitoring (MRM) mode.

Results

The photodegradation experiments almost completely removed CIT (C₂₀H₂₁N₂O) in 4 hours and it was possible to identify 12 probable TPs with different kinetics of formation and degradation behavior. Analyses were based on accurate mass and on the fragmentation patterns observed in the MS/MS spectra and the mass errors were less than 5 ppm. Reactions of oxidation (neutral loss of CO), hydroxylation (neutral loss of H₂O), formation of amide (neutral loss of NHCO) and dehalogenation (neutral loss of HF) were observed. The most abundant TP, namely TP4 (C₂₀H₂₂N₂O₂), was formed by the dehalogenation of fluorine and hydroxylation on the furan ring. Desmethylcitalopram (TP2, C₁₉H₁₉N₂O₂) and citalopram amide (TP11, C₂₀H₂₃N₂O₂F), human metabolites, were also detected in these experiments and showed that the compounds can be formed under UV-light. A pathway for the formation of TPs was proposed. Two TPs (TP2 and TP3, C₂₀H₂₁N₂O₂F) were detected in effluent samples, where the tertiary treatment is UV disinfection.

Conclusions

LC-QTOF/MS proved to be a useful tool for elucidating TPs formed under laboratory conditions. UV irradiation showed good efficiency in the removal of CIT and all TPs formed completely or partially degraded until the end of the experiment (4 hours), most of them having the maximum intensity between 1 and 2 hours. Analysis of wastewater samples showed that only TP2 and TP3 were detected, presumably because in sewage treatment plant complex interactions may occur.

Novel Aspect

The results obtained are relevant to elucidate the identity of TPs formed in photodegradation and also which ones may exhibit greater toxicity than the parent compound.

225 - A NOVEL ANALYTICAL INTEGRATED APPROACH BASED ON MASS SPECTROMETRY FOR THE EVALUATION OF IMIDACLOPRID EXPOSURE DURING CNS DEVELOPMENT

Alice Passoni (1) - Renzo Bagnati (1) - Massimiliano De Paola (1) - Enrico Davoli (1) - Alessandro Mariani (1)

IRCCS - Istituto di Ricerche Farmacologiche Mario Negri, Environmental Health Sciences Department, Milan (1)

Keywords: neonicotinoid, high-resolution mass spectrometry, neurotoxic effects, multiple reaction monitoring

Introduction:

The neonicotinoid pesticide imidacloprid (IMI) has been developed to act selectively as agonists of nicotinic acetylcholine receptors (nAChRs) in insects. However, recent evidences show that it is able to bind mammalian nAChRs, leading to toxic responses in cultured neurons [1]. To properly assess the risk in humans, we developed an integrated analytical strategy combined to the analysis of biological effects in a mouse model of prenatal exposure.

Methods:

The passage of blood-brain barrier (BBB) and placenta was verified analysing IMI concentrations in mouse dam brains and embryos by a multiple reaction monitoring (MRM) method. Different metabolites of IMI were identified in biological samples by high-resolution mass spectrometry (HRMS). Biological effects were evaluated in brains from newborn mice in utero-exposed to IMI by immunochemical techniques.

Results:

Results of MRM analysis showed quantifiable IMI levels in both plasma and brain (about 0.3% of the total administered amount of IMI) of treated dams, suggesting a passage of mammalian BBB. HRMS analysis allowed the identification of eight main metabolites, mainly due to phase I metabolic reactions in both plasma and brain, including desnitro-IMI that has a binding affinity to nAChRs similar to nicotine. Analysis of embryos showed detectable levels of IMI (0.03%) and its metabolites, suggesting a passage through placenta. The measured concentration of IMI in biological samples has been correlated with neurodevelopmental impairments in newborn mice (verified as expression of synaptic protein and marker of immature neurofilaments in brains) and immune system alterations (reduction of microglial cells in different brain areas).

Conclusions:

The newly developed analytical methods, including both MRM and HRMS, allowed an accurate quantitation of IMI in biological samples and the evaluation of relative distribution of its main metabolites. The results highlighted the passage of IMI and its main metabolites through the biological barriers (BBB and placenta) after oral exposure in a mouse model and neuro/immune system development impairments in newborn mice exposed in utero to IMI.

Novel Aspect:

Combining an accurate and sensitive analytical strategy to neurological investigations at human exposure levels, our approach paves the way for a proper risk assessment.

629 - NON-TARGETED APPROACH FOR THE STUDY OF LABILE DISSOLVED ORGANIC MATTER

Claudia Patriarca (1) - Per J.R. Sjöberg (1) - Jonas Bergquist (1) - Lars J. Tranvik (2) - Jeffrey A. Hawkes (1)

-, Uppsala University/ Department of Chemistry, Uppsala (1) - -, Uppsala University/ Department of Ecology and Genetics, Uppsala (2)

Keywords: labile dissolved organic matter, non-targeted analysis, high resolution mass spectrometry, HILIC

Introduction

Dissolved organic matter (DOM) is a complex and ubiquitous organic mixture involved in a multitude of biogeochemical processes. In order to better understand its role in the global carbon cycle, the investigation on the most elusive DOM fraction is of critical importance. The goal of this study is the development of a non-targeted method for the analysis of the labile (biologically reactive) DOM, in order to monitor its depletion and transformation on short timescales.

Methods

Labile DOM, mainly characterized by hydrophilic compounds, was produced by cold water extraction of Norway maple leaves. This material was incubated with native bacteria over four weeks. Samples were pre-concentrated and analyzed by hydrophilic interaction chromatography (HILIC) coupled to high resolution mass spectrometry (Orbitrap-MS). Data analysis and interpretation were performed by R and Matlab statistical software.

Results

The analysis of leaf-derived DOM showed a consistent transformation over the incubation period. Compounds found in the leaves exudates, characterized by high oxygen-to-carbon and hydrogen-to-carbon ratios (typically identified as sugars) were gradually removed from the solutions. Preliminary data revealed that from the transformation and depletion of the labile DOM fraction, a molecular signature typically found in the aquatic environments emerged. This suggests that recalcitrant DOM can be derived from the fast degradation of the elusive labile DOM by rapid microbial activity. Contrarily, a large part of the organic material showed no reactivity in the tested time scale suggesting that many species are not easily accessible for bacterial degradation.

Conclusions

The preliminary data show promise for the development of mechanistic studies involving the investigation of labile DOM material. The method allows the monitoring of natural compounds in the complex mixture and might be applied to find biomarker useful in environmental metabolomics analysis. Such experiments can also be used to gain insight into the global carbon cycle.

Novel Aspect

Easy and flexible non-targeted method for determination of labile DOM compounds.

67 - SCREENING OF PHARMACEUTICAL AND THEIR METABOLITES IN FISH BY HRMS USING DATA-BASE SUPPORT

Juan Manuel Peña-Herrera (1) - Nicola Montemurro (1) - Sandra Pérez (1) - Damià Barceló (1)

IDAEA-CSIC, Environmental Chemistry, Barcelona (1)

Screening of pharmaceutical and their metabolites in fish by HRMS using data-base support

Juan Manuel Peña-Herrera^{1*}, Nicola Montemurro¹, Sandra Pérez¹, Damià Barceló^{1,2}

Water and Soil Quality Research Group, Department of Environmental Chemistry, IDAEA-CSIC, Barcelona, Spain

*juan.pena@idaea.csic.es

Catalan Institute for Water Research (ICRA), Girona, Spain

Keywords: Organic pollutants, HRMS, Data-base support, Fish

Introduction: (Limit of 400 characters)

Occurrence of pharmaceuticals in the aquatic environment has raised concerns about adverse effects on exposed wildlife. Little is currently known on exposure levels of drugs in fish [1], but studies already reported detection of pharmaceuticals in fish samples [1-4]. Pharmaceuticals could be much more concentrated in fish than in polluted living waters. Additionally, fish are known to possess a hepatic detoxification system which are likely capable of metabolizing pharmaceuticals taken up from polluted waters.

Methods: (Limit of 400 characters)

Riverine fish from were collected between 2014-2017 from different regions of Spain. Bile samples were analyzed after a protein precipitation and isolation by UPLC-HRMS. Muscle were treated with organic solvents and analyzed similarly. UPLC-HRMS system present great value in establishing the fragmentation pathways to identify pharmaceuticals and elucidate the structure of fish metabolites.

Results: (Limit 900 characters)

The HRMS data allowed screening for suspected pharmaceuticals and their metabolites and provided plausible chemical formulae. The comparison of MS/MS spectra of the parent compounds and their metabolites allowed to propose chemical structures for possible metabolites in fish bile. With this analytical methodology some metabolites, corresponding to different reactions that includes products of hidroxylation, glucuronide conjugates were identified, similar to the metabolites reported previously in our group in a similar study for carbamazepine. The suspect analysis of bile samples allowed the detection of several pharmaceuticals. Psycho-active drugs were one of the most commonly detected drugs. Their identities were proposed by matching their accurate MS and MS/MS data against different libraries.

Conclusions (Limit of 400 characters)

The UPLC-HRMS analysis of fish bile and muscle extracts allowed the detection of pharmaceuticals and metabolite. We are presently identifying more metabolites which they still require confirmation. Psycho-active drugs have been the most commonly detected drugs in fish. Thus, this analytical methodology highlights that UPLC-HRMS is a powerful tool for qualitative analysis, allowing the search for suspected metabolites, their identification and possible quantitation of target compounds.

Novel Aspect: (Limit of 150 characters)

we propose the evaluation of the metabolism of frequently detected drugs in fish, performing a rapid screening of bile and muscle extract by HR-MS for the presence of stable intermediates.

679 - SUSPECTED SCREENING OF NATURAL TOXINS IN SURFACE WATER BY LIQUID CHROMATOGRAPHY HIGH RESOLUTION MASS SPECTROMETRY.

Massimo Picardo (1) - Daria Filatova (1) - Oscar Nuñez (2) - Marinella Farré (3)

Spanish Council for Scientific Research (IDAEA-CSIC), University of Barcelona/Analytical chemistry, Barcelona (1) - University of Barcelona, University of Barcelona/Analytical chemistry, Barcelona (2) - Spanish Council for Scientific Research (IDAEA-CSIC), Environmental chemistry (IDAEA-CSIC), Barcelona (3)

eywords: Q-exactive Orbitrap, natural toxins, surface water, non-target screening, HPLC-ESI/HRMS

Introduction:

Natural toxins are the prevalent contaminants in surface water reservoirs that may cause several health effects to humans [1]. Only microcystin-LR was regulated by the EU legislation [2]. High-resolution mass spectrometry (HRMS) is a powerful approach used for the non-targeted screening of natural toxins in surface water [3]. In this context, a HRMS non-targeted analysis was carried out using an in-silico approach for the identification of a wide group of biotoxins.

Methods:

A mix of natural toxins representative compounds has been used as standards. After solid phase extraction (SPE) enrichment and elution, compounds were separated by a C18 HPLC column and analyzed with a ESI-QExactive-MS. Data acquisition was based on full scan in positive ionization mode from 100 to 1500 Da with a resolution of 70000 FWHM. A homemade dataset was used as a library with Compound discoverer 2.1 software, in order to obtain a biotoxin tentative list.

Results:

A double layer solid phase for SPE enrichment has been optimized for the widest range of natural toxins. The method allows good recoveries ranging from 60 to 70% and LOD below 1 ug/L. To the authors knowledge' no previous works reported an approach intended to retain such a large class of compounds. No cleanup was applied since loss of polar analytes was observed. The method was applied to perform a natural toxins suspect screening in water samples obtained from several rivers in Catalonia (NE Spain). The spectral data have been processed by Compound Discoverer 2.1 revealing the possible presence of several natural toxins in the "Riera de Rubí" river (Catalonia). Several suspected toxic compounds have been found, most of them being plant toxins and mycotoxins (but no cyanotoxins), with a level 3 of confirmation[4].

Conclusions:

A novel approach able to carry out a screening of suspected natural toxins in water samples has been developed and validated. To the authors knowledge' this is the first method able to detect various groups of natural toxins simultaneously in one analysis.

Novel Aspect:

This is a novel method to analyze a large group of biotoxins. A home-made dataset coupled with an in-silico approach coupled to HRMS enhanced the screening performances.

Keywords: PTR-MS, CHARON, VOC, Organic aerosol, Airborne measurement

Introduction

Organic gases and particles are important trace constituents of the Earth's atmosphere. They affect climate and human health, and play an important role in atmospheric chemistry. Aircraft measurements of organics are analytically challenging because of the high sampling frequency requirement (> 1 Hz), low analyte concentrations in the remote atmosphere (ppt levels), and the chemical complexity of the sample.

Methods

Proton Transfer Reaction – Mass Spectrometry (PTR-MS) is an online chemical ionization mass spectrometry technique for detection of VOCs [1]. The recently developed CHARON ("Chemical analysis of aeRosolONline") inlet enables PTR-MS instruments to measure the organic composition of submicrometer particles [2]. Significant sensitivity improvements have been recently achieved by the inclusion of radio frequency ion lenses.

Results

Our PTR-MS instruments are nowadays routinely flown on NASA's airborne science laboratories for measuring trace organics in the Earth's atmosphere. During the three most recent deployments, we i) measured a set of organic trace gases (methanol, acetone, dimethyl sulfide) that are emitted from or taken up by the North Atlantic Ocean, ii) chased another research aircraft that was fueled with a biofuel blend to measure its emissions both on the ground (during taxiing) and in the air, and iii) test flew the new CHARON inlet to characterize particulate organic matter emitted from wildfires and anthropogenic sources. We will show selected data examples to illustrate how the latest generation of PTR-MS instruments has been successfully used on NASA's airborne platforms for characterizing the organic composition of gases and particles in the Earth's atmosphere.

Conclusions

A PTR-MS instrument has been successfully used for airborne measurements of selected organic trace gases (e.g., methanol, acetone, dimethyl sulfide) at high measurement frequency (1-10 Hz) and low detection limits (single-to-double-digit ppt at 1 second signal integration time). First test flights have been performed with the new CHARON particle inlet.

Novel Aspect

Airborne VOC measurements have been performed with unprecedented instrument sensitivity and detection limit. The CHARON particle inlet has been flown for the first time.

1224 - EMERGING CONTAMINANTS: STATE OF THE ART AND NEW DISCOVERIES

Susan D. Richardson (1)

Department of Chemistry & Biochemistry, University of South Carolina, Columbia, SC 29205, USA (1)

Environmental research continues to expand beyond traditional, regulated contaminants to emerging contaminants, such as sucralose and other artificial sweeteners, nanomaterials, perfluorinated compounds, pharmaceuticals, hormones, drinking water and swimming pool disinfection by-products (DBPs), 1,4-dioxane, sunscreens/UV filters, flame retardants, benzotriazoles, naphthenic acids, algal toxins, and new contaminants on the horizon: ionic liquids and microplastics. These are now frequently being found in water samples, including rivers, lakes, ground water, and drinking water. Moreover, understanding their fate and transport in the environment and in wastewater/drinking water treatment is vitally important, and as such, one of the major trends continues to be in identifying their transformation products. Because environmental samples are inherently complex mixtures with trace-level contaminants, mass spectrometry has been key for their identification and measurement. This presentation will provide an overview of the state of the science for emerging contaminants, their formation and transformation in the environment, and the modern tools used to measure them.

176 - DISSIPATION STUDIES OF DIMETHACHLOR AND METABOLITES IN SOIL AND WATER BY UHPLC-ORBITRAP-MS

Keywords: Dimethachlor, LC-Orbitrap-MS, degradation, soil, water

Introduction:

Dimethachlor, which belongs to the class of chloroacetanilide, is a selective herbicide. It has a variety of metabolites, detected in soils, surface water or air [1] but they have not been included in the maximum residue level of dimethachlor yet. This herbicide was not authorized in Spain, but it was used in several countries as France, and there are scarce studies focused on the degradation pathway of this herbicide.

Methods:

Extraction methods based on QuEChERS approach, using acetonitrile and magnesium sulfate and sodium chloride as well as solid phase extraction, using Oasis HLB cartridges have been developed in order to determine dimethachlor and related metabolites in soil and water, respectively. Then, ultra high performance liquid chromatography (UHPLC) coupled to high-resolution mass spectrometry, applying Exactive-Orbitrap as analyzer, has been used.

Results:

In relation to the degradation studies of dimethachlor, it has been carried out in two types of soils, sandy loam and loam, at normal and double dose and in water under sunny and darkness conditions at normal and fivefold dose. It can be concluded that it degrades slowly in both matrices. For instance, when spiked soils were monitored, the initial concentration was 35 mg/kg and in seven days, the concentration is 31 mg/kg. In relation to metabolites, a targeted analysis determines that metabolites like dimethachlor CGA, dimethachlor SYN, dimethachlor SYN Na salt and dimethachlor oxalamic acid are detected 15 days after application in soils and after 30 days in water. On the other hand, untargeted analysis can allow us to discover other metabolites like CGA 39981, CGA 369873, CGA 72649, CGA 42443 and CGA 102935.

Conclusions

A new analytical method has been developed and validated for the determination of dimethachlor and related compounds by UHPLC-Orbitrap-MS. Due to the importance of the appearance of metabolites, UHPLC-Orbitrap-MS was used in targeted mode to monitor all the compounds generated in the process and untargeted mode to look for new compounds. Degradation of the parent compound occurred slowly in soils and water.

Novel Aspect:

Evaluation of the degradation of dimethachlor in soil and water applying UHPLC-Orbitrap-MS for the identification of metabolites by targeted and non-targeted approaches.

838 - PAVING THE WAY FOR THE ANALYSIS OF TRACE COMPOUNDS IN METALLURGICAL GASES BY PROTON-TRANSFER-REACTION TIME-OF-FLIGHT MASS SPECTROMETRY. IMPORTANCE OF BACKGROUND

Jorge Iván Salazar Gómez (1) - Christian Klucken (1) - Martha Sojka (1) - Thomas Lunkenbein (2) - Robert Schlögl (3)

Max-Planck-Institute CEC, Heterogeneous Reactions, Mülheim a.d. Ruhr (1) - Fritz-Haber-Institute of the Max-Planck-Society, Inorganic chemistry, Berlin (2) - Max-Planck-Institute CEC / Fritz-Haber-Institute of the Max-Planck-Society, Heterogeneous Reactions / Inorganic chemistry, Mülheim a.d. Ruhr / Berlin (3)

Keywords: Proton-transfer-reaction time-of-flight mass spectrometry (PTR-TOF-MS), Volatile organic compounds (VOCs), coke oven gas, blast furnace gas, catalyst poisoning

Introduction:

In the detailed traceanalyses of industrial gases and catalytic processes the background level of carrier gases is of paramount importance. Wrong estimation may result in the underestimation of purification units [1]. Here, we focus on the analysis of the background of inert gases with different qualities at various humidity levels by proton transfer reaction (PTR) using PTR-QiTOF-MS.

Methods:

Measurements were performed with a Proton-Transfer-Reaction Quadrupole interface Time-Of-Flight Mass Spectrometer (PTR-QiTOF-MS) [2]. Prior to the measurements of the background, the measurement parameters for the substances of interest were optimized, which focuses on the minimization of the intensities of parasitic ions like $N_2.H^+$, NO^+ , O_2^+ and fragmentation products. By means of a commercial gas calibrator, toluene was used for the optimization process.

Results:

With regard to the typical parasitic ions ($N_2.H^+$, NO^+ , O_2^+ , N_3^+), our results revealed that the most important effect was the change of humidity in the system. It was observed that some of these parasitic ions, such as N_2^+ and $N_2.H^+$ showed a significant signal reduction in the presence of humidity, whereas ions like $NH_3.H^+$ and NO^+ remained unchanged. To date only the parasitic ions NO^+ , O_2^+ and water cluster $H_3O^+(H_2O)_n$ have been considered in the literature as most dominant. In our study, the most dominant parasitic ion is $N_2.H^+$ even after the optimization process. Our developed methodology is straightforward and allowed for assigning the origin of individual parasitic ions. Parasitic ions that are independent of the gas quality are exclusively produced in the ion source, whereas some parasitic ions which depend on humidity may be produced in the quadrupole interface. For most VOCs humidity showed an increase in sensitivity. For toluene no significant change was observed, which is in disagreement with previous results [3].

Conclusions

The characterization of VOCs in inert gases of different qualities with a PTR-QiTOF-MS and their humidity dependency in background measurements, were beneficial for the identification of instrument specific peaks. By changing the humidity it was possible to sense substances, which in dry conditions due to fragmentation were not measurable. Humidity is necessary in order to reduce the presence of parasitic ions generated in the quadrupole ion guide.

Novel Aspect:

A comprehensive determination of trace contaminants present in the background of typical inert gases by means of the prototype PTR-QiTOF-MS has not been reported before. A straightforward method to identify instrument specific substances is shown.

568 - NOVEL APPLICATION OF MOLECULARLY IMPRINTED POLYMERS WITH GAS CHROMATOGRAPHY-ATMOSPHERIC PRESSURE IONIZATION-MASS SPECTROMETRY FOR HIGH THROUGH-PUT DETERMINATION OF 16 PAHS

Fereshteh Shahhoseini (1) - Ali-Asghar Golbabanezhad-Azizi (1) - Stefana Egli (1) - Christina Bottaro (1)

Memorial university of Newfoundland, Department of Chemistry, St. John's (1)

Keywords: APGC-MS/MS, PAHs, Thin film extraction, water sample, Porous material

Introduction

Polycyclic aromatic hydrocarbons (PAHs) are common contaminants in marine and freshwaters. Identified as toxic, carcinogenic, and teratogenic, limits on the content of PAHs in water, air, and food are set by national and international regulatory agencies, e.g. the United States Environmental Agency (US-EPA). Traditional methods for extraction of PAHs from water are LLE and SPE [1,2] with excessive organic solvent use, and poor recoveries for certain species.

Methods

A thin film of molecularly imprinted polymer (MIP), designed to be selective for PAHs in water, was prepared on a glass substrate using a drop-casting method and UV-initiated radical polymerization. PAHs were extracted from 20 mL of aqueous sample into a MIP film over a fixed interval. Sorbed PAHs were extracted into a small quantity of solvent and analyzed using gas chromatography-atmospheric pressure ionization (APGC) coupled to a Xevo-TQ-S. (Waters).

Results

APGC parameters can be optimized for soft ionization ideal for MS/MS measurements, e.g., dry source conditions were used here to produce molecular ions (rather than protonated molecules), to give the highest PAH signal-to-noise. Our PAH-specific MIP films are used much like solid phase microextraction and share common approaches to method optimization. For example, sample salinity, stirring rate and extraction time, desorption solvent, and desorption time, were optimized for the 16 PAHs. The best limits of detection (LODs) were achieved when sorption to the MIP reached equilibrium at ~3 h, but since there is little sample handling simultaneous extraction of many samples allows for high throughput. Since these MIP films are intended for single-use to eliminate any carry-over and cross contamination, inter-film reproducibility was evaluated and found to be <10%. The optimized MIP-APGC-MS/MS method was applied to real samples, e.g., produced water from oil and gas operations, to give fast, reproducible results at sub-ng/mL LOD.

Conclusions

A high throughput method is reported using porous thin MIP films with APGC-MS for detection of 16 PAHs from water. The methodology offers simplicity, reproducibility and speed, while minimizing consumption of organic solvents and waste generation. Results showed high extraction efficiency with good LOD which meet the maximum allowable concentrations set by the USEPA.

Novel Aspect

Single use MIP thin films designed for compatibility with APGC-MS/MS are developed as adsorption material for a high throughput sample preparation for regulated PAHs in water.

369 - NEW ANALYSIS METHOD FOR ORGANOTIN COMPOUNDS BY TANDEM-LC/MS WITHOUT THE DERIVATIZATION STEP

Yoon Chae SONG (1)

Korea Apparel Testing and Research Institute, Environment analysis center, Anyang city (1)

Keywords: Organotin compounds, LC/MS, Derivatization, Direct analysis

Introduction:

The analysis of organotin compounds which are endocrine disrupter is important in consumer product. The derivatization step with NaBEt₄ for the analysis, however the derivatization reagent NaBEt₄ is hard to obtain because it's highly expensive, flammable and only air delivery except Europe countries. In this study, we have developed a method for direct analysis method for organotin compounds by Tandem-LC/MS without the derivatization step.

Methods:

According to international environment regulatory trends, 8 kinds of organic tin compounds with one, two, or three alkyl substituents were analyzed. MBT, DBT, TBT, TPhT, MOT, DOT, TOT, and TCyT were obtained from Accustandard and Chiron. Analytical instrumentation was developed using a Tandem-LC / MS system consisting of Agilent Technologies' 1200 series HPLC and 6460 Triple Quad Mass Spectrometer.

Results:

Determination of optimum extraction solvent using Design of Experiment(DoE)

Different polarity of organotin compounds should be considered when determining the best extraction solvent for simultaneous extraction of various types of organotin compounds. For example, tri-alkylated organotin with a relatively large number of alkyl groups can be regarded as a nonpolar compound compared to mono, di-alkylated organotin, and non-polar compounds such as hexane may be more suitable as the extraction solvent. Therefore, in this study, Tropolone, a complexing agent, was added to methanol used as an extraction solvent in EN ISO 17353 and ISO / TS 16179, which is a conventional organic tin compound analysis method, and used as an extraction solvent.

Determination of Tandem-LC/MS analysis condition for direct method development

Tandem-LC/MS generates ion fragments from the ion source of injected analytes using the MRM mode and transfers only the precursor ion to the collision cell in the primary mass filter (Q1) It is a system that detects only the most characteristic ions by passing through secondary mass filter (Q2) by shipping. Direct analysis of organotin compounds using Tandem-LC/MS has developed in this study does not need a derivatization process through complicated pre-treatment steps.

Conclusions

A GC/MS analysis for organotin compounds in food and consumer products are popular method, but it needs a difficult derivatization step. The new method without derivatization by LC/MS is much simpler and safe and not time consuming. The direct method is using methanol solvent containing complexing agent, tropolone. The optimum

condition of extraction solvent was confirmed then the peak of each compound was obtained in chromatogram. Also international round test showed the validation of direct method by LC/MS.

Novel Aspect:

Direct analysis of organotin compounds using Tandem-LC/MS does not need complicated derivatization step. Therefore the extraction step is very short, much simpler and safer operators

Keywords: SIFT-MS, SIFDT-MS, VOCs, TD, FastGC, quantification

Introduction:

The main objective is to develop a new analytical method for selective and rapid quantification of individual monoterpene isomers. This is especially relevant for atmospheric chemistry because different isomers exhibit highly variable reactivity with the OH• radical [1] and their role in formation of pollutants may be different for individual isomers. Thus, the precise measurements of their fluxes and concentrations will refine input data for numerical models.

Methods:

Soft chemical ionization technique of SIFT-MS [2] and its drift tube variant [3] have been used for absolute quantification of monoterpene isomers. Because SIFT-MS can quantify only the total concentration of monoterpene isomers, we employed more traditional separation method of fast gas chromatography, GC, [4] and thermal desorption, TD, and coupled them with Profile 3 instrument.

Results:

Separation by the fast GC was carried out on an electrically heated 5 m long non-polar MXT capillary column. Elution times of the isomeric compounds through short, rapidly heated column were characterised and optimised. Using the fast GC coupled to a Profile 3 SIFT-MS instrument we successfully separated eight of the most abundant plant monoterpene isomers (α -pinene, β -pinene, Camphene, Myrcene, 3-carene, R-limonene, α -terpinene and γ -terpinene). A combination of TD with SIFT-MS showed the ability for partial separation of isomers achieved by a slow temperature desorption profiles in contrast to the common approach of rapid desorption from TD tubes. The characterization of several sorbents was experimentally researched and tested. The optimal conditions for the TD approach such as the amount of sorbent, sampling flow rate, or sampling volume were defined.

Conclusions

The combination of fast GC or TD with SIFT-MS represents a promising and robust analytical method for selective and rapid quantification of monoterpene isomers. The advantage of fast GC is better separation in time of a minute, can be used in-situ, but does not allow the use of eddy covariance method. TD based method is very useful for long term monitoring of atmosphere and sample storage on TD tubes.

Novel Aspect:

Separation by TD profiles of the isomeric compounds trapped on sorbent was researched. Separation by fast GC using short capillary column was characterised and optimised.

542 - CONTINUOUS-INTRODUCTION AEROSOL-TO-LIQUID SAMPLER AND ITS COUPLED USE WITH ICP-MS FOR ON-LINE SENSITIVE ANALYSIS OF ATMOSPHERIC AEROSOL

Yong-yang Su (1) - Zhi-ming Li (1) - Wei Wang (1) - Sui Fang (1)

Continuous-Introduction Aerosol-to-Liquid Sampler and its coupled use with ICP-MS for on-line Sensitive Analysis of Atmospheric Aerosol

Keywords: Continuous-Introduction Aerosol-to-Liquid Sampler; ICP-MS; on-line Analysis; Atmospheric Aerosol.

Introduction:

With the use of sampling pump[1], self-aspiration assembly[2] or aerosol introduction interface[3], ICP-MS is capable of on-line monitoring of atmospheric aerosol. However, parameters matching and conditions optimization are required prior to analysis. Moreover, concentration enrichment or matrix removal are necessary to overcome the matrix effect and sensitivity deterioration. Many types of aerosol-to-liquid samplers have been developed for efficient collection of aerosol into the liquid flow for subsequent analysis, i.e., ion chromatography[4], flow cytometry[5], GC-MS[6], LC-MS[7], ESI-MS[8], novel sensor[9,10].

In order to make full use of the advantages of the aerosol sampler and ICP-MS while avoid the possible interfere, a Continuous-Introduction Aerosol-to-Liquid Sampler (CIALS) was proposed and used in couple with ICP-MS for on-line, sensitive analysis of atmospheric aerosol. This paper presents a preliminary study conducted in the laboratory.

Theory and Methods:

Taking into account the arrangement of the three nozzles in the commercial BioSampler (SKC Inc.), a new collector matching the top part of BioSampler was proposed. One inlet for makeup liquid and one outlet for hydrosol are placed in the tangential but opposite position at the bottom of the collector. When CIALS is used in couple with ICP-MS, the makeup liquid flow rate (Q_1) is controlled precisely by the peristaltic pump, the hydrosol flow rate (Q_2) equals the nebulization flow rate of the ICP-MS, and the liquid loss rate (Q_3) in the collector is dependent on the sampling gas flow rate mainly due to evaporation. The sampling mechanism of this sampler is identical to the BioSampler. Because the relative position of the nozzle and the collector wall is not changed, the size-dependent collection efficient should be very close to that of BioSampler[11].

By adjusting the speed of the peristaltic pump, the liquid mass in the collector could be kept nearly constant, which is crucial for efficient sampling of aerosol into the liquid. Assuming that individual droplet is fully dissolved as soon as it's collected in the liquid, the sample concentration in the collector liquid would decay exponentially with time. The time constant equals the initial liquid mass (M_0) divided by Q_2 .

Experimental and Results:

The above model was verified preliminarily through experiment in the laboratory. Firstly, ICP-MS (Model 8800, Agilent Inc.) was tuned by introducing 2% HNO_3 through the sample tube and multi-elements standard solution (with concentration of around 1×10^{-9} g/g) through the "IS" tube simultaneously. The multi-elements standard solution was introduced throughout the experiment to calibrate the sensitivity of the total system. Secondly, the CIALS was connected to the nebulization system of ICP-MS through a PTFE tube. The liquid flow was continuously extracted for sequent nebulization and analysis. Meanwhile, the makeup 2% HNO_3 was introduced to compensate the liquid mass variation in the collector. The inlet of CIALS was placed downstream of a HEPA filter to sample filtered air. The background of target elements in the total system were monitored by ICP-MS when the vacuum pump was running. Thirdly, 10 microliters of standard solution containing natural Ce, Tb and Ho (214.5×10^{-6} g/g) was transferred through pipette and dropped into the collector liquid when the vacuum pump was turned off. Finally, the signals of ^{205}Tl (only from "IS" solution), ^{140}Ce (from "IS" solution and sample), ^{159}Tb and ^{165}Ho (both only from sample) were monitored by ICP-MS.

The relative variation of 205Tl intensity is ~7%, much higher than the typical value (~2%) when CIALS was not coupled with ICP-MS. Hence, intensity correction using internal standard is necessary. It's clearly observed that 140Ce signal is a sum of stable signal from IS solution and variable signal from sample liquid. The signal profiles of 159Tb and 165Ho after adding of individual droplet both satisfy exponential decay law very well. The fitted values (magnitude and time constant) of the two elements math well with each other, indicating that they synchronously disperse, diffuse, and transport in the system. By using signal integration method and internal standard correction, it is possible to obtain the total amount of element in the individual particle. The fitted value of the time constant is ~1000s, which roughly agrees with the value (814 s) predicted by the model. This suggests that the current system is able to monitor atmospheric aerosol with time resolution of ~15min.

Conclusions and Novel Aspect:

a Continuous-Introduction Aerosol-to-Liquid Sampler (CIALS) capable of on-line sampling, efficient collection of particle into liquid and continuous introduction to ICP-MS was proposed. A theoretical model for predicting the sample concentration in the collector liquid was derived. The CIALS was used in couple with ICP-MS and preliminary experiments was conducted in the laboratory. Results show that the total amount of element in individual soluble particles could be determined by using the current system. The combination use of CIALS and ICP-MS has a time resolution of ~15 min for on-line monitoring of atmospheric aerosol.

Keywords: CIMS, volatile organic compound, FTICR, PTRMS, pollutant removal

Introduction:

Acetone is one of the major pollutants in the Earth's atmosphere [1]. So that it is becoming more and more necessary to reduce acetone anthropogenic emission. The new non-thermal plasma technique for pollution control has received increasing attention [2]. While there has been recent progress in acetone removal, clear identification of the reaction products, eventually toxic, to be done.

Methods:

We used a photo-triggered low-temperature plasma discharge [3] to study the mechanisms of acetone decomposition at different concentrations in N₂ and N₂/O₂ mixtures. Degradation by-products are detected in-situ by a compact FTICR mass spectrometer BTrap [4], that uses chemical ionisation by proton transfer reaction from H₃O⁺ [5] or by charge transfer from O₂⁺. Identification and direct quantification of the molecules is conducted in real-time in the instrument.

Results:

Presence of oxygen in the gas mixture reduces the discharge efficiency, even for a small O₂ amount, up to 5%. The decomposition of the molecule entails the formation of many by-products. For acetone diluted in N₂, at least 20 different compounds were detected. The major detected by-products include nitrile compounds (hydrocyanic acid and acetonitrile), formaldehyde and acetaldehyde, alcohols (mainly methanol and ethanol). Some products, such as hydrogen cyanide, appear at the first discharge and increase rapidly. These products are then reprocessed but not completely. These results are compared with those of acetone decomposition in N₂/O₂, which leads to oxygenated compounds such as nitro-alkanes.

Conclusions

The large number of by-products leads to better understanding of the mechanisms involved in plasma degradation. Our work shows that the non-thermal plasma technique degrades efficiently acetone in N₂ and N₂/O₂ gas mixtures. We plan to extend these analysis methods to others discharge conditions with or without associating catalysts.

Novel Aspect:

Coupling of a high resolution compact FTICR to a VOC degradation plasma reactor and real-time monitoring of by-products.

180 - COMPREHENSIVE DEPTH PROFILING OF STATEN ISLAND SOIL BY GC AND PETROLEOMICS

Mary Thomas (1) - Emma Collinge (2) - Matthias Witt (3) - Christopher Vane (4) - Mark Barrow (2)

MAS CDT, University of Warwick, Coventry (1) - Department of Chemistry, University of Warwick, Coventry (2) - Bruker Daltonik GmbH, Bruker Corporation, Bremen (3) - Organic Geochemistry, British Geological Survey, Keyworth (4)

Keywords: Contaminated soil, petroleomics, GC, FTICR MS

Introduction: (Limit of 400 characters)

Staten Island is located in the New York/New Jersey (NY/NJ) Estuary, a region with one of the highest population densities in the United States. Surface sediment concentrations showed the NY/NJ Estuary to be among the most chemically contaminated waterways in the United States. Analysis of the extent of environmental contamination by complex petroleum-related pollutants is of rising importance.

Methods: (Limit of 400 characters)

Sediment cores were collected in a marsh region of Staten Island, NY and freeze-dried. Samples taken at intervals to 1 m depth were spiked with PAH standard mixture and subjected to solid phase extraction (SPE) before bulk analysis by GC MS. Sediment samples from 5 selected depths underwent Soxhlet extraction prior to compositional analysis by direct infusion APPI-FTICR MS and GC-APCI-FTICR MS.

Results: (Limit 900 characters)

Saturate, aromatic and resins (SAR) GC MS analysis at each sampling depth showed a sharp increase in concentration at two depths that may correlate with the timing of major spills in the area, including the 1990 Exxon pipeline spill. Direct infusion APPI-FTICR MS measurements showed a corresponding spike in the relative contributions to spectral intensity from radical hydrocarbon as well as oxygen and sulfur-containing compound classes at these depths. However, background sampling depths were also found to have strong contributions from petroleum-related contaminants, indicating continuously poor water and soil quality in the NY/NJ Estuary resulting from regular oil spills in the region. Using GC-APCI-FTICR MS additional compound classes were observed, revealing the impact of leaks of industrial chemicals and agricultural effluent on the estuary system.

Conclusions (Limit of 400 characters)

Several trends in the compositional profiles obtained by direct infusion APPI-FTICR MS and GC-APCI-FTICR MS were found to correlate with the bulk analysis obtained by GC-MS, including relatively strong contributions from OxSy[H] compound classes. Samples originally obtained for background study were found to contain significant contamination from anthropogenic sources.

Novel Aspect: (Limit of 150 characters)

Comprehensive study of petroleum-contaminated soil by GC-MS, direct infusion APPI-FTICR MS and GC-APCI-FTICR MS.

77 - UPTAKE OF DIOCTYL PHTHALATE BY POPULUS ALBA VILAFRANCA

Keywords: DOP, micro-pollutants, phthalates, poplar, xenobiotics

Introduction: Phthalates are micro-pollutants detected in aqueous systems and their removal through wastewater treatment plants results ineffective [1,2]. The accumulation and metabolism of organic pollutants (caffeine, erythromycin, sodium dodecyl sulfate) in poplar has been demonstrated [3,4,5,6] and in this study we evaluated the poplar capability to uptake and translocate dioctyl phthalate inside the plant.

Methods: Plants of Populus alba Villafranca clone, growing in a hydroponics condition, were treated for 21 days with 0, 40 and 400 $\mu\text{g L}^{-1}$ of dioctyl phthalate (d4-DOP). The health status of the plants was monitored through the plant growth, relative chlorophyll content and fluorescence analyses. The d4-DOP concentrations in roots, stem and leaves were evaluated through LC-MS/MS analysis.

Results: Treatments did not affect significantly poplar health at none concentrations tested: plants maintained a good photosynthetic performance and no variation amongst relative chlorophyll contents were observed between control and treated d4-DOP plants. After 21 of treatments, 400 $\mu\text{g L}^{-1}$ d4-DOP induced an increase in root dry biomass. On the contrary, leaves number and leaf dry weight were reduced. Poplar revealed the ability to uptake the d4-DOP with the highest accumulation observed in roots. Indeed, the d4-DOP concentration in roots reached $7.1 \pm 3.29 \mu\text{g g}^{-1}$ FW and 3.4 ± 2.28 , after 1 day and 21 days of treatments respectively. In leaves d4-DOP concentration values were lower than $0.02 \mu\text{g g}^{-1}$ FW.

Conclusions: P. alba Villafranca showed a good tolerance to d4-DOP at both concentrations tested and the accumulation of d4-DOP occurred mainly in roots after one day of treatment.

Novel Aspect: For the first time tree removal of DOP from aqueous solutions was explored. Our findings can contribute to the development of green technologies for the remediation of phthalates.

Keywords: mass spectrometry, pharmaceuticals, degradation products, soils

Introduction

Pharmaceuticals are frequently detected in different matrices, including soils, in the last decade [1, 2]. Different degradation/transformation products can be formed by interaction of soil bacteria with pharmaceuticals [3]. Only limited information on this topic is available, we aimed to study the fate of the selected pharmaceuticals and their possible metabolites in the different soils.

Methods

Fortified soils samples were incubated under controlled conditions, extracted and analysed with LC-ESI-full scan HRMS (QExactive, Thermo Fisher Scientific) at a resolution of 70,000 FWHM. Compound Discoverer 2.0 software was used for data processing. The high resolution product scan (HRPS) at 17 500 FWHM resolution was applied to list of suspect metabolites to obtain the MS² fragmentation.

Results

The degradation of 6 pharmaceuticals (carbamazepine, citalopram, clindamycin, fexofenadine, irbesartan and sulfamethoxazole) was investigated in 4 different soil types. The parent compounds degraded in all of the soils. Dissipation curves for the parent compounds of interest were constructed to evaluate a degradation rate by means of slope values. We obtained list of suspect transformation products from two different workflows in CD software for each compounds. The list was further evaluated using HRPS data to confirm or disprove proposed compounds. Tentatively identified TPs were semiquantified with method described by Koba [4]. Time trends of TPs concentration could further help in both degradation mechanism and kinetics clarification

Conclusions

Using sequence of full scan HRMS, advanced data processing, HRPS structure confirmation and back semi quantification from HRMS we were able to identify degradation products of selected pharmaceuticals and obtained important information on transformation of pharmaceuticals in soil.

Acknowledgements

This study was supported by the by the Grant Agency of Czech Republic (No. 17-8937S)

Novel Aspect

Identification and semi quantification of degradation products of pharmaceuticals in soils significantly increase information value of analysis.

45 - THE STUDY OF SAMPLING PIPELINE EFFECT FOR GASES PARTIAL PRESSURE MEASURE WITH MASS SPECTROMETER

Rongxin Yan (1)

Beijing Institute of Spacecraft Environment Engineering, CAST, Beijing (1)

Abstract Title: The Study of Sampling Pipeline Effect for Gases Partial Pressure Measure with Mass Spectrometer

Keywords: Mass spectrometer, Gases partial pressure measurement, Sampling pipeline, Stability time

Introduction: In some gases analysis or partial pressure measure with mass spectrometer, The gases are far from the mass spectrometer because mass spectrometer is not portable or the gases environment is toxic. The sampling pipeline connecting gases and mass spectrometer has to be used. But the sampling pipe how to affect measure results such as stable time, ingredient aberration, which are worthwhile to study.

Methods: Based on the study of unsteady-state gas flow with the effect of pipeline adsorption, the physical mechanism of gases at molecular regime in pipeline flowing into mass spectrometer chamber and pumped out by vacuum system has been studied. The gases transportation equation in sample pipeline and gases partial pressure distributing equation in mass spectrometer chamber are set up. The effect of sample pipeline for some gases partial pressure in air are calculated.

Result: The relation equation of sample pipeline gases pressure, the mass spectrometer chamber gases pressure, analysis time, pumping rate to the chamber, gas molecular mass, pipeline length has been got.

The pressures in sampling pipeline gas are a complex exponential equation with sampling time and sampling pipeline distance;

The gases balance pressures in mass spectrometer chamber are direct proportion to the gases pressure of the sampling place;

The sampling pipeline change the ration of gases ingredient. After sampling equilibrium, the ratio of partial pressure is inverse to the square root of the ratio of gas mass. The pressure in mass spectrometer chamber is inverse to the length of pipeline.

(4) The minimum pressure stable time in chamber is proportion to the square of pipeline length and inverse to gas molecule thermal motion speeds.

Novel aspects: The mass spectrometer gas pressure equation with sample pipeline length and sample time was deduced. The stable time and ingredient aberration of gases partial pressure measure with mass spectrometer can be calculated.

Direct Analysis of
17 Perfluorinated Compounds in Water at Low Parts-Per-Trillion Levels by LC-MS/MS Workflow

Sha Josh Ye, Jingcun Wu, Marko Gori, Luca Piatti, Derek Mattern, Stefan Edler, Frank Kero, Feng Qin,
501 Rowntree Dairy Road, Unit 6, Woodbridge, ON, L4L 8H1, Canada
Keywords: Direct Analysis, LC-MS/MS, perfluorinated compounds

Introduction: (Limit of 400 characters)

Perfluorinated compounds (PFCs) are used as surfactants, fire-retardants, nonstick cookware coatings, and coatings for paper packaging for over a half century[1,2]. PFCs have recently received attention as emerging persistent organic pollutants [3-14]. Presently, a LC-MS/MS direct sample injection method was developed for analysis of PFCs in water samples. The results indicate that a good sensitivity, robustness were achieved with LOQ below the proposal by EU.

Methods: (Limit of 400 characters)

The PFCs native and internal standards were obtained from Wellington Laboratories (Guelph, Ontario). 100 µL of lake or tap water samples were first filtered then injected onto a PerkinElmer Brownlee SPP C18 (100x2.1mm, 2.7µm) column for separation at 0.5 mL/min with total run time of 15 minutes. The mobile phases were A) water and B) methanol, both containing 5mM ammonium formate. Detection was via a QSight triple quadrupole LC-MS/MS system.

Results: (Limit 900 characters)

The calibration standards were prepared with different levels of PFCs to determine instrument detection limits and set up calibration curves. Detection limits for most analytes were ≤ 1 ng/L except for PFBA, PFTA, PFHxDA, and PFODA which were ≤ 5 ng/L. The calibration curves for all analytes were linear over three orders of magnitude with a R^2 value of > 0.995 . Identification and confirmation of the analytes in investigated samples was achieved by comparing their respective retention times and peak area ratios between the quantifier and qualifier MRM transitions with those from the standards. Ten (10) samples were screened for PFOA and PFOS with the developed method. Five of them were detected with PFOA at a concentration of larger than 2 ng/L and six of the samples were detected with PFOS at a concentration of larger than 5 ng/L.

Future work would include further development of shorter LC separation time, robustness evaluation, and the analysis of other brands of bottle water and water from rivers or lakes using the workflow developed in this study.

Conclusions (Limit of 400 characters)

The fast and simple LC-MS/MS method for 17 perfluorinated compounds analysis in water samples was developed by coupling a UHPLC system to a QSight 220 triple quadrupole mass spectrometer. This method can be employed to the direct determination of PFCs in drinking and surface water samples, with LOQs well below the limits set by regulatory boards from many countries.

Novel Aspect: (Limit of 150 characters)

Direct analysis of perfluorinated compounds in water at low ppt levels with improved sensitivity and robustness by a simple LC-MS/MS workflow.

Francisco Javier Yuste Córdoba (1) - Belén Godoy Cancho (1)

CICYTEX, ICMC, Mérida, Spain (1)

Keywords: cork, phenolic compounds, HPLC, QTOF

1. Introduction:

Cork is the outer surface of the cork oak tree and it is a versatile material that can be used for a variety of products, mainly stoppers. Industrial preparation of cork requires the immersion of cork planks for approximately one hour in boiling water. Cork boiling wastewaters (CBWs) are waste streams with high loads of phenolic compounds (1). This work studies the direct analysis of CBWs with HPLC/QTOF in order to identify useful by-products for their recovery.

2. Methods:

The samples were analysed by HPLC on a reversed-phase column RP-18 (250 nm x 4 mm x 5 µm). and detection was carried out using a diode array detector. Other sub-samples were analysed by HPLC-QTOF in order to confirm the target compounds.

3. Results:

Several low-weight phenols were detected with HPLC-DAD by comparing UV-vis absorption maxima in mass spectral analysis and the retention times of standards. Mass spectra of these phenolic compounds were compared with the corresponding standards by QTOF. 18 target compounds were studied: gallic, protocatechuic, ellagic, p-hydroxyphenyl acetic, p-hydroxybenzoic, vanillic and syringic acids; esculetin, vanillin, syringaldehyde, ferulic, caffeic, p-coumaric and salicylic acids; coniferyl aldehyde, sinapaldehyde, eriodictyol and naringenin. From these phenolic compounds, significant concentrations of vanillin and gallic, ellagic, vanillic, protocatechuic, ferulic and syringic acids were detected, confirmed and quantified. Besides, some characteristic ellagitannins were also analyzed but they were not detected.

4. Conclusions:

The direct analysis of CBWS by HPLC/QTOF confirmed several low weight phenolic compounds highlighting the presence of vanillin and gallic, ellagic, vanillic, protocatechuic, ferulic and syringic acids. This kind of compounds and their concentrations coincides in general terms with other studies (1). Regarding extractable compounds from cork such as ellagitannins didn't appear, maybe due to the higher temperature of the boiling process.

5. Novel Aspect:

This work shows that the direct analysis of phenolic compounds in CBWs without pre-concentration achieved good results and made the tests simpler.

276 - MOLECULAR COMPOSITION OF DISSOLVED ORGANIC MATTER IN THE TALDICE ICE CORE.

Roberta Zangrando (1) - Veronica Zanella (2) - Ornela Karroca (2) - Elena Barbaro (1) - Natalie M. Kehrwald (3) - Dario Battistel (2) - Andrea Gambaro (2) - Carlo Barbante (1)

Consiglio Nazionale delle Ricerche, Institute for the Dynamics of Environmental Processes, Mestre-Venezia (1) - Ca' Foscari University of Venice, Department of Environmental Sciences, Informatics and Statistics, Mestre-Venezia (2) - U.S. Geological Survey, Geosciences and Environmental Change Science Center, Denver (3)

Keywords: Untargeted analysis, ice cores.

Introduction:

Deep polar ice cores are archives that collect information on paleoclimatic and paleoenvironmental conditions during glacial-interglacial swings. This information is then obtained by detailed analyses of the ice to obtain past temperature, greenhouse gas concentrations, and sea ice extent etc. The presence of trace chemicals in ice, reflect changes in their sources, transport, deposition, preservation.

Methods:

An untargeted analysis of dissolved organic matter (DOM) provides a general overview of molecular species in the ice samples giving information on their sources and processes. For this kind of analysis typically 100 - 900 mL are required, this is not possible when dealing with deep ice cores. Using a nano-UPLC-nano-ESI-HRMS technique we have detected the major molecular species using only 4 μ L of melted ice.

Results:

This work allowed us to tentatively identify generally aliphatic species, that were attributable mainly to the presence of saturated and unsaturated fatty acids, hydroxyl fatty acids and their degradation products, along with species from the oxidation of isoprene and monoterpenes and other compounds more difficult to interpret. Interglacial had more species while their number decreased in glacial samples. The reduction in oxidation products of isoprenes and monoterpenes is probably due temperature changes that affected terrestrial vegetation and the sea ice extent. Passing from interglacial to glacial times, unsaturated FAs almost disappeared because they are exposed for longer to oxidative processes.

Conclusions

Until now untargeted analyses have been limited to surface snow and shallow ice cores covering a short time span. To the best of our knowledge these are the first indications of the behavior of fatty acids and their oxidation products and the oxidation products of isoprene and monoterpenes in a deep ice core.

Novel Aspect:

The innovative aspect of this work was the creation of a micro-volume analytical method that allowed the molecular characterization of DOM in a deep ice core.

560 - INVESTIGATIONS ON THE ADSORPTION OF REES BY GO WITH DIFFERENT SIZES: MECHANISM AND APPLICATION

Wenbo Zhao (1)

Chinese Academy of Geological Sciences, National Research Center for Geoanalysis, Beijing (1)

Keywords: Rare earth elements (REEs); (Inductively coupled plasma mass spectrometry) ICP-MS; Graphene oxide (GO); Adsorption;

Introduction:

Rare earth elements (REEs) are major resources for modern society but have the risk of environmental pollution. With a high surface area, carbon nanomaterial shows the good adsorption character and has the bright future to become a novel REEs separation material [1]. Herein, we demonstrate the special adsorption behavior on REEs by graphene oxide. The mechanism is also investigated and has the chance of being applied in the comprehensive ecological improvement.

Methods:

GO nanosheets were synthesized from natural flaky or expanded graphites using the modified Hummer Methods: The physicochemical properties of GO nanosheets were characterized by SEM, FTIR and Raman respectively. We tested the adsorption behavior of GO nanosheets on Rare earth elements with different concentrations. After centrifugation and filtration, the solution was transferred into ICP-MS to obtain residual content of REEs.

Results:

We obtained GO with 5 different meshes from natural flaky graphites and 3 giant GO with pre-expanding process. The SEM results exhibited that GO surface morphology was well nanoscale thin layer. FTIR spectra indicated that GO had similar O-containing functional groups as mentioned [2]. It was worth mentioning that GO of 500 and 200 meshes had higher carboxyl, aromatic, sharp C=O and -OH, whereas the giant GO of 100 mesh had higher -OH. Raman spectroscopy showed that GO of 300 and 100 meshes had more defects/edges. Through the key ICP-MS detection, we found GO had superior adsorption ratio on REEs to other inorganic elements even including heavy metals. Then, we compared the adsorption behavior on 17 REEs with 5 different concentrations. When at proper concentration of REE, GO with 500, 200 and 100 meshes exhibited more excellent adsorption ratio. Surprisingly, neither a lower nor a higher concentration of REEs could display adsorption difference. The accordance of adsorption and characterization made us to illuminate the adsorption mechanism properly.

Conclusions

Comparing with other inorganic elements, we verified the superior adsorption on REEs by GO which was fabricated by modified Hummer's Methods: The corresponding adsorption mechanism was illuminated that aromatic, carboxyl, sharp C=O and -OH contribute to the whole special adsorption behavior. The proper GO meshes should have to be selected to separate or enrich REEs in the future environmental pollution.

Novel Aspect:

GO has special adsorption behavior on REEs superior to other inorganic elements and the mechanism is also been illuminated.

667 - DEVELOPMENT OF LC-MS/MS ANALYTICAL PROTOCOL FOR ARTEMISININ AND ITS DERIVATIVE COMPOUNDS QUANTIFICATION IN THE ARTEMISIA ANNUA L. EXTRACTS FOR COSMETIC APPLICATIONS

Rosana M. Alberici (1) - Elaine C. Cabral (1) - Gislaire C. Nogueira (2) - Renata Vardanega (2) - Maria Angela A. Meireles (2) - Marcos N. Eberlin (1)

Thomson Mass Spectrometry Laboratory, University of Campinas, Campinas (1) - LASEFI-School of Food Engineering, University of Campinas, Campinas (2)

Keywords: Artemisia annua, artemisinin, supercritical extraction, LC-MS/MS

Introduction:

Artemisia annua L., a plant used as traditional Chinese herb medicines, is rich in sesquiterpene lactones that present a wide range of biological activities, exhibiting therapeutic potential as anti-inflammatory and antimicrobial. Here, an improved liquid chromatography-tandem mass spectrometry (LC-MS/MS) protocol was developed to quantify artemisinin and its derivative compounds in A. Annua extracts obtained by supercritical CO₂ fractional extraction.

Methods:

A. annua extracts, including essential oil, fraction rich in artemisinin and a residual fraction were obtained using supercritical CO₂ fractional extraction, under optimized temperature and pressure experimental conditions. Thin layer chromatography (TLC) and liquid chromatography-tandem mass spectrometry (LC-MS/MS) were used, respectively, for qualifying and quantifying, artemisinin and its derivative compounds in the extracts.

Results:

The developed LC-MS/MS method covers both the unambiguous identification and simultaneous quantification of artemisinin and its derivative compounds, while TLC protocol was effective for artemisinin semi-quantification during the optimization of the supercritical extraction process, as a rapid screening method. Using multiple reaction monitoring (MRM) method, artemisinin, deoxyartemisinin and dihydroartemisinin were detected as ammoniated adducts. For validation purposes, an A. annua extract, denominated E4, obtained by supercritical extraction, was used. Calibration curves were prepared in the concentration range of 50-500 ng/mL. Analytical parameters such as linearity, precision, accuracy, limit of detection (LD) and limit of quantitation (LQ) were established. The data indicated that the linearities resulting from the three analytes of interest showed correlation coefficient (r) ≥ 0.99 . LD and LQ were 25 and 50 ng/mL, respectively. The relative inter and intraday standard deviation (RSD) was $< 5\%$.

Conclusions:

The developed analytical methodology can be used for quality control of A. annua extracts due to be able to quantify simultaneously artemisinin, deoxyartemisinin and dihydroartemisinin. The standardized extracts could be used in cosmetic formulations.

Novel Aspect:

Standardized and certified extracts from A. annua using LC-MS/MS protocol could be used more safely in new and effective natural cosmetic products.

Keywords: metabolomics, pharmacognosy, contextualization approaches, molecular networks, bioinformatics

Introduction

Bioinformatic approaches are shaping multiple scientific fields and such tools have particularly impacted natural products chemistry in the latest years. The ever improving capabilities of mass spectrometry analytical platforms now allow to acquire signals of quality for the hundreds to thousands analytes constituting complex biological matrices. At the moment, such metabolomics approaches are the most appropriate to characterize natural products extracts in a comprehensive way.

Methods

In our sense, two main challenges emerge when implementing and developing such approaches. On one side, and this defies what is well identified within the community, important progresses are to be done regarding metabolite identification tools and strategies.[1] On the other hand, we propose that what we define as contextualization approaches will be crucial to fully grasp the complexity of natural products and establish the discipline of pharmacognosy in the digital era.[2]

Results, Conclusions and Novel Aspects

Here we will present some of these contextualization strategies developed in our lab. After explaining the role of central tools such as molecular networking and in-silico fragmentation approaches,[3] we will present the establishment of a bioactive natural products prioritization pipeline based on the establishment of multi-informative molecular maps.[4] We will discuss application examples, evaluation methods and possible further developments.

523 - METABOLOMIC UHPLC-QTOF METHOD TO ANALYZE TANNINS IN NATURAL COMPLEX PRODUCTS USING ALL-IONS FRAGMENTATION ACQUISITION

Michela Burico (1) - Luisa Mattoli (2) - Pietro Traldi (3)

Aboca Spa società agricola, Area Ricerca Fitochimica, Sansepolcro (1) - Aboca SpA Società Agricola, Area Ricerca Fitochimica, Sansepolcro (2) - Città della Speranza, Istituto di Ricerca Pediatrica, Padova (3)

Keywords: Tannins, Mass Spectrometry, All-Ions, Metabolomic

Introduction

Tannins are a class of compounds naturally occurring in some plants. They can be classified into condensed tannins (or proanthocyanidins, PAs) and hydrolysable tannins (HTs), further sub-classified in galloyltannins (GTs) and ellagitannins (ETs). Structurally, they are the most complex class of polyphenols as they are polymeric molecules. Here is described a metabolomic LC-HRMS method using All-Ions Fragmentation acquisition (AIF)[1] [2] to increase natural tannins identification.

Methods

Green tea leaves dried-extract (GTE) has been analyzed by means of UHPLC-qToF using a reverse phase chromatographic column, in high resolution (2GHz) and using AIF. In negative ion mode, AIF has been acquired at four different energies: 0, 20, 30, 40 eV. The EICs of fragment ions, from the high energy scan data, have been correlated to the precursor ion, from the low energy scan data. The EICs of each tannin subclass typical-fragments has been used to get tannin semi-quantitative data.

Results

Tannins are polymers characterized by certain degree of polydispersity, so that actually it is not possible to find on the market reference standards for all the possible molecular structures. In this context, the analysis in AIF shows its potential to study natural complex products containing tannins, as using this algorithm the fragment ion of UHPLC eluted compounds is correlated to its precursor. Combining the MS/MS information with retention time, high resolution accurate mass and product/precursor ion intensity ratios, it has been possible the identification and annotation of various tannins in GTE. After the creation of a specific tannins in-house database and the study of the tannins fragmentation behavior, the following fragments common to each tannin subclasses have been identified: ions at m/z 125.0236 and m/z 169.0140 for GTs, m/z 300.9980 for ETs, m/z 289.0719 and m/z 577.1358 for PAs. The annotated GTE tannins have been semi-quantified by external regression curves of Gallic acid (ions at m/z 169.0140) for GTs, Ellagic acid (ions at m/z 300.9980) for ETs and Procyanidin B1 (ions at m/z 577.1358) for PAs.

Conclusions

If reference standards are available, tannins can be analyzed by comparison with the corresponding compounds. In case this is not possible, metabolomic screening by AIF is an effective alternative! The approach presented here has allowed us to identify more than twenty GTE tannins, increasing the quality of the information on tannins, opening new perspectives in routine quality control of tannins as well in understanding their fate in biological studies.

Novel Aspect

A new metabolomic method for analyzing tannins in natural complex products while reference standards are unavailable on the market is now available.

438 - NEW APPROACH FOR THE STRUCTURE ELUCIDATION OF (ACYL)POLYAMINES IN SPIDER VENOMS BY UHPLC-HR-ESI-MS/MS

Yvonne Forster (1) - Stefan Bienz (1) - Laurent Bigler (1)

University of Zurich, Department of Chemistry, Zurich (1)

Keywords: acylpolyamine, spider venom, H/D exchange, database, in-silico fragmentation

Introduction: Acylpolyamines, often found in spider venom, are promising lead compounds to treat cancer or neurodegenerative diseases like Alzheimer's disease, epilepsy or stroke. [1,2] Polyamines follow characteristic fragmentation rules; therefore MS/MS is ideal for their structure elucidation. [3] However, low available sample amounts, co-eluting isomers and diverse nomenclature strategies in literature make the structure elucidation demanding.

Methods: The fragmentation rules for linear polyamines were used to develop a new database with in-silico fragmentation for known and unknown acylpolyamines. The spider venom was analyzed by UHPLC-HR-ESI-MS and MS/MS on a QExactive. The method was optimized for small, basic molecules. In addition, the number of acidic protons was determined in an on-line H/D exchange experiment (HDX).

Results: The database of spider venom acylpolyamines provides fast access to the related literature and acquired MS/MS spectra. Therefore, already known acylpolyamines are identified easily and time can be used to focus on the structure elucidation of unknown lead compounds. Database entries for new acylpolyamines can easily be generated by assembling the structure from simple building blocks. The separation of co-eluting isomers could be improved. The HDX experiment clarified the presence of N-methylated amines and supports the structure elucidation in general. The optimized method allowed the identification of more than 90 polyamines from just one microgram lyophilized venom of the spider *Agelenopsis aperta*. More than half of the structures were not described before.

Conclusions: The improved analytical method in combination with the developed acylpolyamine database enables the routine identification of linear polyamine amides even from sources of limited sample amounts like spider venoms. The in-silico fragmentation enables the identification of polyamine structures without the analysis of expensive reference material.

Novel Aspect: The database with in-silico fragmentation supports the annotation of known and the structure elucidation of new acylpolyamines based on HR-MS/MS and HDX.

Keywords: phytochemistry, beta amino acids, isoflavonoids, fragmentation, quantitative

Introduction:

The non-protein amino acids are widespread in the flora as important molecules against insect herbivores. Based on our previous results, *Ononis* species contain beta amino acids mainly in the form of isoflavonoid glucoside esters. The beta amino acid structural motif is common in CNS drugs. As *Ononis* species are used in traditional medicine, we aimed to characterize these structures as well as to define their quantity.

Methods:

For the structural identification HPLC-HR-MS/MS, authentic standards, isolation and NMR experiments were used. HPLC-MS was applied to screen for these molecules in various Leguminosae plants. Since the quantitation of the beta amino acid was performed for its free form, a prior hydrolysis method has been developed. To minimize the matrix effect during the quantitative HPLC-MS experiments, a further SPE method was applied for purification purposes.

Results:

Based on the MS/MS fragmentation of the investigated molecules, six isoflavonoid glucosides and two beta amino acids could be assumed, resulting in altogether 12 compounds. The structures of isoflavonoid moieties were identified as formononetin, pseudobaptigenin, medicarpin, maackiain, onogenin and sativanone because of their specific MS fragmentation pattern [1]. The HR-MS/MS results combined with NMR data and comparison with authentic standards proved that homopiperic acid and homoproline esterify the isoflavonoid glucosides. The presence of the esters was investigated in various Leguminosae plants (*O. spinosa* and *arvensis*, *Trifolium repens*, *Glycine max*, *Medicago sativa*), however, those were only characteristic for *Ononis* species. The roots of *M. sativa* also contained trace quantities while none of the other plants contained these molecules at all. Homopiperic acid content of *Ononis* species ranged from 1 mg to 35 mg/100 g dried plant, while homoproline levels were between 0.1 mg and 16 mg/100g.

Conclusions:

The structures of 12 isoflavonoid beta amino acid esters were elucidated. Screening various Leguminosae plants, only *Ononis* species contained them in significant amount, thus, these molecules could serve as chemotaxonomic markers. Levels of the beta amino acids were also quantified in these plants. Comparing these values with the ones required to induce CNS effects [2], [3] one can conclude that the rational use of *Ononis* species as traditional remedy, is safe.

Novel Aspect:

This work presents the structure of 12 new isoflavonoid beta amino acid esters and firstly describes the quantity of cyclic beta amino acids in *Ononis* species.

1239 - AN UNUSUAL TMS ARTIFACT IN EI MASS SPECTROMETRY - PERRHENIC ACID TMS

W Gary Mallard (1) - Yufang Zheng (1) - Sanford P Markey (1) - James L. Little (1)

NIST, MSDC, Gaithersburg, United States (1)

Keywords: TMS derivatization artifacts, surface reaction

Introduction:

Trimethyl silyl derivatives (TMS) are one of the most common methods for extending the range of compounds for which GC/MS methods can be used, however as with most methods where reactions are involved there are often undesirable by-products [1]. Here we report an unusual artifact that appears to be caused by the mass spectrometer filament – specifically Perrhenic acid-TMS ($\text{Re}(\text{O}_3)\text{-O-TMS}$) appears to be formed during the ionization process.

Methods:

Pure samples of compounds were analyzed both as the native and TMS derivatized compounds. The derivatization was carried out with BSTFA and the analysis was done with an Agilent 5977 MS with an Agilent 8939 GC. Chromatography used 15M Agilent VF-5MS column, 40:1 split ratio, 270C inlet temperature, program 50C start, ramp 15C/min to 300, ion source temperature 250K. All data were analyzed using AMDIS.

Results:

Several TMS spectra had low intensity ions at m/z 307,309. In some spectra these ions were above the expected MW and in some they were unreasonable losses from the molecular ion. The AMDIS deconvolution showed that these ions did not have the same time history as the main ions in the spectrum – they always appeared slightly delayed. However, the ions could not be arising from a distinct compound formed in the derivatization process since the ion maxima were always nearly coincident with the derivatized compound regardless of the elution time. Some of the data files had separations in time between the 307/309 maxima and that of other ions was sufficient that AMDIS could extract a distinct spectrum. Comparing this spectrum with the NIST library gave a match factor of over 900 to Perrhenic acid-TMS ($\text{Re}(\text{O}_4)\text{Si}(\text{CH}_3)_3$). Careful examination of the smaller peaks in the spectra when the Perrhenic acid spectrum could not be deconvolved showed that the other expected peaks (294/292, 279/277, and 263/261) were seen with the isotope ratios expected for Re.

Conclusions:

TMS derivatives reacted with the rhenium filament in the ion source to produce Perrhenic acid-TMS. The reaction product was typically slightly delayed in time from the derivative, but in some cases the temporal separation was not sufficient to allow for deconvolution of the pure derivative spectrum. Aging of the filament over a 2 month period removed the active sites on the filament and the perhenic acid TMS was no longer observed.

Novel Aspect:

Perrhenic acid-TMS from reaction of the rhenium filament and TMS derivatives is reported. The time history was used to determine the identity using AMDIS.

Keywords: natural product extraction, HPLC, GC/MS, LC/MS, MSn

Introduction

Nowadays the study of chemical compounds from natural sources is an established method to obtain new active substances. This strategy is used for the treatment of many different diseases and natural products show anti-inflammatory, antidiabetic, analgetic and anticancer activity.[1] We engage ourselves with the extraction, separation and characterization of various natural materials to contribute to the treatment and prevention of intractable diseases.

Methods

We use a two step method for the extraction which includes the use of ultrasound and microwave radiation. The polar extracts are then separated via HPLC to obtain fractions containing multiple substances and pure compounds. The complex mixtures are analyzed with LC/MS and GC/MS. Full scan experiments with two scan modes give us a good overview of the extract composition. For further information we apply target molecule scans and tandem mass spectrometry (MSn).

Results

Following our two step extraction method we were able to produce different plant extracts. We extracted various natural sources like sea buckthorn, chokeberry, cornelian cherry and Chinese medical plants using mainly ethanol and ultra pure water as extraction solvents. With the help of our LC/MS and GC/MS devices the identification of many compounds from different substance classes was possible. Especially vitamins, organic acids, isoflavones, anthocyanins and other flavonoids were often found. Different glycosilated forms of those structures were also present within the extracts. We managed to obtain different fractions of our plant extracts after method developing with our HPLC system. Both full extracts as well as defined substance mixtures have been applied in cell culture studies. Some of them showed promising results in reducing cellular injury.[2] Our ion trap MS device enabled us to perform some MSn experiments. That way we collected structural information on several unknown compounds within the extracts.

Conclusions

We were able to prepare plant extracts which then were separated into fractions containing defined substances mixtures. The cell biological studies showed promising results for some of the tested compounds and we will continue to further separate the mixtures. The question remains if the biological activity is a synergistic effect of multiple natural products or only one active substance. We also need to obtain the pure unknown compounds for a full characterization.

Novel Aspect

The natural materials we extract in the PePPP-project are applied in the study of hereditary liver and pancreas disease, namely Wilson's disease, pancreatitis and Johanson-Blizzard syndrome.

Native-MS, natural products, protein interactions, multienzyme complex

Introduction:

Polyketides are a large class of biologically active and structurally diverse compounds. They are synthesized by polyketide synthases (PKSs), classified as type I, II and III enzymes. The Aryl-polyene ester (APE) system is a PKS type II-like system, where ten unbound proteins are involved, but the exact process of the biosynthesis of APEs is mostly unknown [1,2]. Here we report our current results of protein interactions in the synthesis of APE.

Methods:

To reconstitute the APE biosynthesis, all proteins that are involved in this process were purified from *X. doucetiae*. Components were mixed in vitro, and samples were desalted with Micro Spin Columns (Thermo scientific) into ammonium acetate or Tris buffer directly before MS analysis. ESI mass spectra of the enzymes were obtained in positive ion mode using a Synapt G2S (Waters) mass spectrometer.

Results:

The acyl carrier protein (ACP) is a small protein in PKS systems, which is responsible for carrying substrates cargo between active sites [3]. We see binding of ACP to different proteins showing protein-specific differences in binding strength. Acyl-acyl carrier protein synthetase (AasS) is a monomer and forms dimers in presence of ACP, it binds one ACP in monomeric and two ACPs in dimeric form. Ketosynthase 2 (KS2) can oligomerize up to a tetramer, but the dominant species are the monomer and dimer; it binds ACP in the monomeric and dimeric states. We can show the regulating effect of ACP on the oligomerization states of the proteins. The thioesterase (TE) forms tetramers and is able to bind up to four ACPs. The ketoreductase (KR) forms tetramers, where the dimer is the building block for the tetramer. Surprisingly we find that in this system the ketosynthase 1 (KS1) and the chain length factor (CLF) as well as the two dehydratases (DH1/DH2) build heterodimeric complexes, and only in their heterodimeric form, they can interact with ACP.

Conclusions:

Incubation of all the proteins of the PKS and MS analysis supports the hypothesis that the APE system is a PKS II-like system. ACP has a regulating effect on the oligomerization of the proteins. We could determine the oligomeric states and binding behavior of the proteins that are involved in the APE process. These results are the first step in reconstructing the process of the APE biosynthesis.

Novel Aspect:

Native MS analysis of protein interactions in PKS II system with separate proteins that act together in a multienzyme complex, which are used iteratively to form polyketides.

Introduction:

Our study aims to exploit the Yellow-legged hornet venom (*Vespa velutinigrithorax*) in the cosmetic. It is known that environmental factors could induce morphological and behavior modification of insect to adapt to climatic changes. Our hypothesis is that seasonal variation can have a qualitative and quantitative impact on venom. In general, insect venoms contain a complex mixture of molecules, including proteins, peptides and low molecular weight compounds.

Methods:

V. velutina venoms from winter or summer hornets were separated into two fractions using 10 kDa filter (Sartorius). Protein profiles were achieved from >10 kDa fraction by gel electrophoresis, their density was measured by TLC Visualizer (CAMAG). In parallel, <10 kDa fractions were analyzed by two techniques on UHPLC-qToF (MS or MS/MS) and MALDI-TOF MS to obtain peptide profiles. Their differences of seasonal samples were accessed by statistical analysis (PCA, PLSDA).

Results:

The protein profiles obtained in gel present a mass distribution from 10-95 kDa, in which the most abundant bands were observed from 20-50 kDa. Density profiles achieved from TLC Visualizer at white light, however, do not reveal the significant difference between winter and summer samples in this mass range.

Besides, a separation method by UHPLC-qToF (MS and MS/MS) was developed that allowed us to analyze peptides and low molecular weight compounds in *V. velutina* venom. The rich peptide profile was observed in each sample. In parallel, to develop an analytical method for investigating the peptide profile on MALDI-TOF, four matrices were screened with venom. The peptide profiles obtained from MALDI-TOF correspond to one from LC-MS and in addition, they provide more information in the high mass range. For global comparison, the statistical analysis results for each analytical method are in process.

Conclusions:

There is no significant discrimination between winter and summer protein profiles on gel electrophoresis. The methodology for analyzing the profile variation of venom samples issued from different periods was established. The PCA and PLSDA approaches are essential for evaluating the difference and the results are in process.

Novel Aspect:

The intraspecific comparison of venom compositions will be carried out to achieve a completed view of Yellow-legged hornet venom.

744 - EVALUATION OF COSMETIC INTEREST OF THE YELLOW-LEGGED HORNET VENOM (VESPA VELUTINA NIGRITHORAX)

Keywords: venom, antioxidant, peptidome, LC-MS/MS

Introduction:

Our study aims to explore novel bioactive molecules from the Yellow-legged hornet venom for preventing or reducing skin aging in the cosmetic.

In this study two challenges are set: i) evaluate the antioxidant potency venom and then identify the bioactive structure responsible for it ii) establish and compare the peptidome expression pattern between the winter and summer venoms to assess if seasonal sampling impact qualitatively and quantitatively venom compounds.

Methods:

We develop a technical investigation platform that includes DPPH (for radical scavenging capacity), FRAP (for ferric reducing antioxidant power) chemical assays as well as ROS (reactive oxygen species) production in HaCaT keratinocyte cells in order to determine the antioxidant capacity of hornet venom. To identify the active molecules responsible for this remarkable property, the crude venom was fractionated by HPLC and then identified by UHPLC-ESI-qToF MS/MS.

Results:

Our results revealed a significant antioxidant activity of the venom in three activity assays. Nine fractions were obtained from HPLC and again evaluated. Only one fraction revealed an antioxidant activity. Although the fraction is rich, the identification of the compound responsible for the activity could be achieved and validated by an antioxidant test directly on Thin Layer Chromatography (TLC). From the analysis in mass spectrometry, we identified one major compound responsible for almost the whole antioxidant activity of the crude venom.

In parallel, the venom peptidomes of winter and summer hornet workers were investigated with UHPLC-qToF-HRMS or MS/MS and their differences were evaluated by statistical analysis (PCA, PLSDA).

Conclusions:

We have successfully identified the compound responsible for antioxidant activity in Yellow-legged hornet venom and compared the profile variation of venom samples issued from different periods.

Novel Aspect:

The other cosmetic applications will be carried out to obtain a complete view of Yellow-legged hornet potency.

Keywords: plant metabolites, OrbitrapTM, liquid chromatography

Introduction:

Alkaloids (alks) are widespread in nature. These nitrogen-containing organic constituents occur mainly in plants as secondary derivatives of the amino acid metabolism, or arising from amination of other substrates, which may be, for example, terpenes or steroids [1]. The biosynthesis often involves a further glycosylation of the alks (aglycones) as glycoalkaloids (glyalks) [2]. One of the best-known glyalks is the steroidal Solanine, a poisonous compound present in the Solanaceae plant family, but, to date, only a few studies on glyalks belonging to other chemical categories have been reported.

Methods:

The chromatographic separation was performed using a UHPLC equipped with an SPE on-line system and a biphenyl column. The binary mobile phase was composed of 0.1% formic acid (FA) with 5 mM ammonium acetate (AAc) and MeOH/ACN 95:5 v/v with 0.1% FA and 5 mM AAc. A Full MS/AIF/NL dd-MS² experiment was performed in positive ion mode with the resolution set at 140,000 FWHM (m/z 200; 1.5 Hz) for full MS spectra, at 70,000 FWHM (3 Hz) for AIF and at 17,500 FWHM (12 Hz) for dd-MS².

Results:

Neutral losses of pentose (m/z 132.0423), deoxyhexose (146.0579), and hexose (162.0528), and of all the combinations of up to four of these sugar units were considered. Full MS and AIF spectra were processed comparing the possible glyalk masses with the corresponding aglycone mass of about 100 alks already reported in literature as characteristic of the examined herbs [3,4]. If both the glycoside (in full MS) and the aglycone (in AIF spectra) peaks were present at the same retention time, a manual interpretation of spectra was performed. The compound identification was assessed considering the matching of glycosidic experimental dd-MS² spectra with the fragmentation patterns of previously studied alks. The study allowed us to describe the profiles of glyalks belonging to the most important chemical classes (indole, piperidine, protoalkaloid, pyridine, pyrrolidine, pyrrolizidine, quinoline, steroidal, terpenoid, and tropane alks) in a selection of 21 plants.

Conclusions

This high resolution mass/neutral loss experiment permitted us to describe the presence of the glycosidic forms of a large selection of alks, permitting higher awareness of the possible risks and benefits relating to the consumption of popular plant-based medicines with new attention to both the free and bound alk forms.

Novel Aspect:

To our knowledge, this is the first high-resolution mass - neutral loss approach proposed for a broad identification of plant glyalks belonging to the main chemical classes.

Keywords: *Ophiopogon japonicus*, LC-MS/MS, Authentication, secure supply

Introduction:

Ophiopogon japonicus tubers are used in Traditional Chinese Medicine and are currently traded for the treatment of pathological skins. Their supply has to be traced and secured to ensure safety and efficacy of the resulting dermo-cosmetic ingredient. They share botanical and morphological characteristics with other plant species, particularly *Liriope spicata*. To avoid falsifications, analytical authentication of these plants tubers is thus an essential step.

Methods:

In this context, we performed a comparative analytical study of various samples of *Ophiopogon japonicus* tubers, from different supply regions. Phytochemical profiles obtained by ultra performance liquid chromatography coupled with tandem high resolution mass spectrometry (UPLC-MS/MS) were then directly compared with those of *Ophiopogon japonicus* and *Liriope spicata* specimens from referent collections.

Results:

Chromatograms obtained from referent samples revealed specific markers of *Ophiopogon japonicus* and *Liriope spicata*, in particular the range of homoisoflavonoids [1-5] and alkaloids. Identification of the species could be performed thanks to comparison of parent and fragment ions to components described in the literature.

Based on these data, our results demonstrated that one of the samples contains alkaloids not present in *Asparagaceae* (i.e. the family of *Ophiopogon japonicus* and *Liriope spicata*), thus suggesting falsification of this sample. Two other samples display trace amounts of homoisoflavonoids, a variation probably due to the cultivation region which does not totally refute *Ophiopogon japonicus*. The other samples have the specific markers of authentic specimen of *Ophiopogon japonicus*.

Conclusions:

This analytical analysis of samples from different regions allowed us to authenticate samples of *Ophiopogon japonicus* comparatively to certified specimens. This approach will allow to secure future supplies of this starting raw material and to detect early some falsifications. This work is essential to guarantee safety and efficacy of the resulting dermo-cosmetic ingredient.

Novel Aspect:

This study shows that an analytical approach is complementary to botanics to authenticate a plant species, avoid falsifications and secure its supply.

Maftuna Shamshiddinova (1) - Yong-Moon Lee (1)

Chungbuk National University, Chungbuk National University/ College of Pharmacy, Cheongju, Korea, Republic Of (1)

Keywords: short chain peptides, anti-aging, cosmetic formulations, LC-ESI-MS/MS analysis

Introduction: Skin aging is a natural event characterized by progressive structural and physiological changes in the skin. The main outcomes are the atrophy of the skin followed by loss of elasticity and a slowed metabolic activity [1]. Peptides like GHK, pal-KTTKS, and pal-GHK stimulate collagen renovation and shows anti-aging activity [2,3,4,5]. Thus, cosmetic producers interested in the introduction of peptides in cosmetic formulations is greatly increased in last years.

Methods: 4 modified peptides: 2,5-dihydroxybenzoic acid-PLG-OH (Db-PLG), 2,5-dihydroxybenzoic acid-LG-OH (Db-LG), 2,5-dihydroxybenzoic acid-PG-OH (Db-PG) and 2,5-dihydroxybenzoic acid-GL-OH (Db-GL) was quantified in cosmetic samples using LC-ESI-MS/MS method with positive ion mode. The method was validated using quality parameters like linearity, calibration, correlation of determination, detection limit, precision and, recovery.

Results: Retention times for peptides were following: 18.29 min for Db-PLG, 22.3 min for Db-LG, 22.56 min for Db-GL and 6.74 for Db-PG. The calibration curves were found to be linear with an average correlation of determination R² to 0.9926 for Db-PLG, 0.9903 for Db-LG, 0.9986 for Db-PG and 0.996 for Db-GL.

Detection of peptides was performed with an AB SCIEX 3200 triple quadrupole system in the MRM and positive electrospray modes. MRM transitions for Db-PLG, Db-LG, Db-PG, and Db-GL were m/z 422/234, 325.1/250, 309.1/234 and 325.1/194.0, respectively.

Limits of quantification was established for a signal to noise ratio equal to 10. This corresponds to 40 ng for 2,5-dihydroxybenzoic acid-PLG-OH, 10 ng for 2,5-dihydroxybenzoic acid-LG-OH, 50 ng for 2,5-dihydroxybenzoic acid-PG-OH and 10 ng for 2,5-dihydroxybenzoic acid-GL-OH.

Recoveries were checked at three different concentrations and it was varied from 99.3% to 101.8%.

The method was applied to detect and quantitate tri- and di-peptides in different cosmetic formulations like skin, lotion, and gel.

Conclusions LC-ESI-MS/MS method was developed for the quantification of tri- and dipeptides with anti-aging properties: Db-PLG, Db-LG, Db-PG, and Db-GL. The method was validated with the International Conference on Harmonization of Technical Requirements for Registration of Pharmaceutical for Human Use guidance note represents validation procedure of analytical Methods: The method was applied to determine short chain peptides in cosmetic formulations.

Novel Aspect: newly synthesized short chain peptides in different cosmetic formulas were quantified by using LC-ESI-MS/MS method.

Keywords: pyrrolizidine alkaloid crotalaria N-oxide monocrotaline

Introduction:

Many chickens died because their food used sorghum contaminated with *Crotalaria retusa* (Fabaceae) seeds with high concentration of pyrrolizidine alkaloids (PAs), highly toxic substances. We determined the PAs and their N-oxides (PANOs), in *Crotalaria* genus plants growing in Colombia. Alkaloid distribution was determined in root, stem, leaves, flowers, and seeds of six *Crotalaria* species and in *Utethesia ornatrix* eggs, larvae and moths, in relation to herbivory.

Methods:

U. ornatrix larvae consumed leaves of *C. retusa*, *C. pallida*, *C. spectabilis*, *C. incana*, *C. maypurensis*, and *C. nitens* maintained in an experimental garden. Solvent extraction, matrix solid-phase dispersion were used with plant material and insect parts. Pyrrolizidine alkaloids (PA) were determined both free and as their N-oxides. GC-MS analysis of PANOs required their previous reduction with Zn. Extracts were analyzed on an Exactive Plus orbitrap LC-MS system.

Results:

High-resolution mass spectrometry afforded the exact molecular masses of both pyrrolizidine alkaloids and their N-oxides (PANO). Monocrotaline, creatonotine B, crispatine, integerrimine and their N-oxides were found both in plant material (0.01 – 21 mg/g) and insect specimens (0.01 – 1 mg/g). *U. ornatrix* eggs contained callimorphine N-oxide additionally. PA + PANO content in *Crotalaria* spp. plant parts varied according to the species, but was highest in seeds, followed by flowers, leaves, and roots. *C. retusa* showed the largest PA+PANO content among the species studied. *U. ornatrix* larvae preferred *Crotalaria* spp. unripe seeds (2 mg PA+PANO/g) and apical leaves (0.3 mg PA+PANO/g). They accumulate PA and PANO, which are transferred to moth and eggs. Alkaloid content was higher in eggs (6 mg/g) than in other *U. ornatrix* stages. PA/PANO ratios of 1200 were determined in larvae fed with *C. retusa* leaves. PA and PANO content in various *Crotalaria* spp. parts did not change significantly in response to herbivory by *U. ornatrix* or mechanical cutting.

Conclusions

PAs and PANOs were simultaneously determined with LC-MS. MSPD permitted alkaloid isolation from small sample amounts. *U. ornatrix* and *Crotalaria* spp. exemplify co-evolutionary adaptation. Pyrrolizidine alkaloids produced by the plant as a defense measure are used by *U. ornatrix* as a protection from predators. *Crotalaria* spp. seeds (29 mg/g) and *U. ornatrix* eggs (5 mg/g) showed the largest alkaloid content, in which the N-oxide form was prevalent (PANO/PA ~ 1200).

Novel Aspect:

With good reproducibility, matrix solid-phase dispersion afforded plant and insect extracts with high alkaloid recovery.

1331 - GC-MS/MS DETERMINATION OF CIS AND TRANS- Δ 9-THC ISOMERS IN CANNABIS SATIVA L

STEFANO VALERA (1) - GIANNA ALLEGRONE (2) - FEDERICA POLLASTRO (2)

UNIVERSITA PIEMONTE ORIENTALE, Dipartimento di Scienze del Farmaco, NOVARA, Italy (1) - UNIVERSITA' PIEMONTE ORIENTALE, Dipartimento di Scienze del Farmaco, NOVARA, Italy (2)

Keywords: Cannabis sativa L., cis- Δ 9-THC, hemp, GC-MS/MS.

Introduction: Hemp (*Cannabis sativa* L.) is a complex plant able to produce many chemical entities. Its biomedical relevance has been focused on Δ 9-tetrahydrocannabinol (Δ 9-THC). Anyway Δ 9-THC exists in two geometrical isomers: cis and trans. The trans- Δ 9-THC is the active compound responsible for the narcotic action of hemp. The existence and the distribution of the cis isomer in cannabis is still unclear.

Aim of this study was the determination of the cis and trans- Δ 9-THC in cultivar of Cannabis belonging to different chemotypes.

Methods: A gas chromatography–tandem mass spectrometry (GC-MS/MS) method was developed for the characterization and quantification of cis and trans isomers of Δ 9-THC. Calibration curves, with internal standard (IS), were prepared from standard solutions of both molecules. Linearity, LOD and LOQ were evaluated.

Aerial parts (leaves and inflorescences) of 31 hemp varieties were extracted in acetone. The dry extracts, added of IS, were analyzed by the developed method.

Results: The method developed resulted suitable for the determination of both Δ 9-THC isomers.

The calibration curves were linear in the range 5–200 μ g/mL, LOD and LOQ were assessed respectively 0.3 and 1.0 μ g/mL.

The study demonstrated the presence of cis- Δ 9-THC in all the varieties analyzed in a range of concentration of 0.003 mg/g and 1.41 mg/g. The trans- Δ 9-THC isomer, always present in higher concentration of the cis isomer, was assessed in the range of concentration of 0.004 mg/g and 15.50 mg/g.

Conclusions: The cis- Δ 9-THC was detected in all samples analysed and its amount evaluated in comparison with the more known trans- Δ 9-THC isomer. The cis/trans rate is always less than 1 and decrease with the increment of the total amount of Δ 9-THC present in the plant.

Novel Aspect: For the first time the cis- Δ 9-THC isomer was characterized and determined in different cultivar of *Cannabis sativa* L..

1076 - CHARACTERIZATION OF ENVIRONMENTAL MICROORGANISMS BY PROTEINS AND LIPIDS MALDI-TOF FINGERPRINTS

Guérineau Vincent (1) - Barthélemy Morgane (1) - Eparvier Véronique (1) - Touboul David (1)

CNRS-ICSN, Université Paris Saclay, Gif sur Yvette (1)

Keywords: MALDI-TOF, microorganism, protein, lipid, database

Introduction

MALDI-TOF MS is an emerging technique for microbial identification, characterization and typing that has been successfully used in the clinical field. Though, studies related to the characterization of remain scarce. In order to fill this gap, protein profiles of various environmental microorganisms have been acquired and classified. Moreover lipid profiles have been obtained and are expected to be complementary to protein profiles for rapid classification.

Methods

The lipids of each strain are extracted after maceration in an MTBE / MeOH mixture and then recovery of the organic phase and evaporation of the solvent. These lipid extracts are solubilized in a CHCl₃ / MeOH mixture (2/1) and then analyzed by MALDI TOF in positive mode (DHB matrix at 20 mg/mL in THF) and negative (9-AA matrix at 10 mg/mL in MeOH). Protein extraction: (CH₃CN / H₂O / HCOOH: 50/15/35) then MALDI-TOF analysis (α -CHCA matrix at 10 mg/mL).

Results

We were able to confirm that the spectral fingerprint of a protein extract is dependent on the species of environmental microorganism, whether for a bacterium or a fungus. For example, 16S sequencing of strains belonging to genera such as Bacillus is not sufficiently discriminating for identification at the species level. On the other hand, clusters within the same genus appear well defined when observing the spectral imprints of these same strains. Unlike protein extracts, lipid fingerprints do not seem to depend on the species but only on the genus in most cases. Only data on fungi of the genus Fusarium allow discrimination at the species level. The study related to lipid fingerprints has shown that strain classification can be performed even though genetic sequencing has not been performed or if the protein fingerprint is too specific to be related to a known species.

Conclusions

In our study we observed a perfect concordance of "clustering" between genetics and spectral fingerprints. We have therefore been able to provide a proof of concept concerning the possible identification of the different environmental microorganisms by comparison of protein and / or lipid fingerprints and to show the important potential of MALDI-TOF mass spectrometry for the identification of these environmental microorganisms.

Novel Aspect

New MALDI-TOF methodology for the identification of environmental strains (phytopathogens, mutualist microorganisms, endophytes, etc.)

335 - MASS SPECTROMETRY TECHNIQUE FOR STUDYING THE PEPTIDES CYCLISATION BY NATIVE CHEMICAL LIGATION

Magdalena Wierzbicka (1) - Piotr Stefanowicz (1)

Faculty of Chemistry, University of Wrocław, Wrocław (1)

Keywords: Cyclopeptides, Native Chemical Ligation, SPPS, LC-MS, HR-MS

Introduction:

Cyclopeptides, widely spread natural products, exhibit various biological activities. The recent reports indicate that the native chemical ligation allows the synthesis of cyclic peptides [v]. However, this process has complex mechanism and optimization of this synthetic method needs extensive analytical characterization of reacting system including mass spectrometric Methods:

Methods:

The precursors of cyclopeptides susceptible to transamidation reaction were synthesized according to the solid phase peptide synthesis procedure. The synthesis and cyclization progress were monitored in microscale by Triple Quadruple LC-MS, and FT-ICR MS and MS/MS. The structure of protected cysteamine derivatives applied as substrates in this synthesis were confirmed by NMR spectroscopy, FT-ICR MS and MS/MS all with ESI ion source.

Results:

The new cysteamine derivative protected with Mmt was synthesized according to the procedure developed by Barlos et al. [vi], purified by LC and analyzed by ESI-FT-ICR-MS with MS/MS and NMR. During MS experiment the fragmentation in source was observed and highly stable Mmt⁺ ion appeared. Model peptides as well as natural ones were synthesized on solid phase. Then the N,S-transfer of acyl group, followed by transthioesterification was performed, which allowed the transformation of peptide into the form of MESNa thioester. The interaction of thioester moiety with N-terminal Cys results in cyclization of a peptide. The intermediates of this reactions were monitored by Triple Quadruple HPLC-MS as well as FT-ICR-MS and MS/MS. The application of proposed method for the synthesis of biologically active peptides will be discussed in presented poster.

Conclusions:

The presented LC-MS techniques allows the monitoring of peptides metathesis including the formation of intermediates. The developed method will allow highly efficient cyclopeptides synthesis combined with their liberation from the solid support during SPPS. The combination of the native chemical ligation with N,S-acyl shift and transthioesterification will allow the synthesis of any desired cyclopeptide containing cysteine residue.

Novel Aspect:

The novel aspect is an application of the mass spectrometric methods for real time monitoring and optimization of the complex, biologically important chemical reactions.

566 - STRUCTURAL INVESTIGATION OF NATURAL ORGANIC MATTER USING DIRECT FRACTIONATION AND SELECTIVE ISOTOPIC LABELING COUPLED TO FTICR MS

Alexander Zhrebker (1) - Yury Kostyukevich (1) - Evgeny Shirshin (2) - Oleg Kharybin (1) - Alexey Kononikhin (3) - Irina V Perminova (4) - Eugene Nikolaev (1)

Skolkovo Institute of Science and Technology, Translational medicine, Moscow (1) - Lomonosov Moscow State University, Physics, Moscow (2) - Institute for Energy Problems of Chemical Physics of RAS, Mass-spectrometry, Moscow (3) - Lomonosov Moscow State University, Chemistry, Moscow (4)

Keywords: FT ICR, natural organic matter, isotopic exchange, fractionation, structure

Introduction

FTICR MS is an exclusive method, which enables exploration of extremely complex natural organic matter (NOM). Routine analysis resolves thousands of C_xH_yO_zN_nS_s molecular compositions in NOM sample [1]. However, FTICR MS is tolerant to structural isomers. Here we show determination of specific structural sites in individual NOM molecules and isomers in different samples using selective labeling reactions and direct fractionation in combination with FTICR MS.

Methods

NOM samples were sealed with NaOD or DCl for skeletal HDX [2]. Deuteromethylation was performed by CD₃OD/SOCl₂ reaction of NOM. All samples were desalted [3] and fractionated using SPE on ppl cartridges operated at different pH. HDX of mobile protons was performed by incubation in D₂O. All samples were analysed using 7T FT MS Bruker Apex Ultra with harmonized cell (Bruker Daltonics). The FTICR MS data were processed using the lab-made "Transhumus" software.

Results

Catalytic HDX coupled to FTICR MS was applied to determine structural fragments of individual molecules of NOM and its synthetic analog. Application of HDX showed isomeric lignin-like components, which differ by aromatic ring substitution pattern. Combination of skeletal HDX provides the reliable identification of isomers in various NOM samples isolated even from similar sources. In case of models obtained by oxidative condensation of phenols, the exact structure of components was suggested.

Deuteromethylation enabled determination of COOH-groups carried by individual molecules in NOM. This allowed for mapping compounds with close elemental compositions but different protolytic properties on conventional Van Krevelen diagram. The number of COOH-groups matched model structures suggested for major NOM components. Based on this result we performed direct fractionation of NOM on hydrophobic resin performed at different pH. We observe distinct shift of molecular composition from COOH-depleted molecules to polycarboxylic compounds.

Conclusions

We found that shared molecular compositions identified in different NOM samples correspond to structural isomers. By visualization of labeling results, we discovered relationships between compartments of NOM – oxidation, decarboxylation, condensation, etc, including transformation of CHOS compounds. Due to distinct separation of carboxylic acids according to molecular compositions, the deeper fractionation of hydrophobic components of NOM was performed.

Novel Aspect

The developed approaches enabled for the first time mapping of NOM components with respect to their structural pattern, and prediction of their chemical properties

442 - DEVELOPMENT OF ISOLATION TECHNIQUES AND CAPILLARY ELECTROPHORESIS MASS SPECTROMETRY (CESI-MS) METHODS FOR THE CHARACTERISATION OF NANOMATERIAL PROTEIN CORONAS

Klaus Faserl (1) - Andrew Chetwynd (2) - Iseult Lynch (3) - James Thorn (2) - Herbert Lindner (1)

University of Innsbruck, Department of Medical Chemistry and Biochemistry, Innsbruck (1) - AB Sciex UK Ltd, Separations, Warrington (2) - University of Birmingham, 3. School of Geography Earth and Environmental Sciences, Birmingham (3)

Keywords: CE-MS, Protein-corona, nanoparticle, proteomics

Introduction:

Since the nanoparticle corona rose to eminence a decade ago, it has been investigated by a wide range of researchers trying to characterise and derive its significance [1]. To date, LC-MS is the instrument of choice for the analysis of the protein corona [1,2]. However, CESI-MS offers an exciting prospect to increase sample throughput and separate and detect highly polar and very large peptides which may be missed by conventional nLC-MS platforms [3].

Methods:

Silica nanoparticles were incubated for 1 hr at 37 °C in plasma. The on-particle digest particles were washed followed immediately by digest. In the case of the off particle digest, NP-corona complexes were boiled in SDS buffer and run on an SDS-PAGE gel prior to in-gel digestion. A Sciex CESI 8000 equipped with a 90cm neutral capillary with 30 kV separation voltage and 2 PSI pressure was used for peptide separation, detection was with a Thermo QExactive HF mass spectrometer.

Results:

This investigation began by developing a sample preparation method to isolate the corona prior to CESI-MS analysis. Here the off-particle digest method enabled the detection of 1581 peptides which correlated to 134 protein groups. Initial on-particle digest methods were limited to 1270 peptides and 147 proteins due to peptides adsorbing to the NP surface to reform a corona. To ameliorate this, the addition of urea and/or rapigest to the digest solution were investigated as potential methods to keep the digested peptides solubilised. The addition of 1.5M urea with and without 0.1% rapigest improved both peptide and protein coverage. However, the addition of 0.1% Rapigest only enabled the detection of 2215 peptides and >200 protein groups. Furthermore, this method resulted in the least number of missed cleavages whereas any addition of urea increased the number of missed cleaves compared to the initial ammonium bicarbonate digest buffer solution.

Conclusions:

The finalized sample preparation and CESI-MS methods enabled a much higher throughput analysis than a conventional nLC-MS method, 50 minutes versus 140 minutes injection to injection. This was achieved by using an on-particle digest (<12hrs) instead of an off-particle in gel digest (1.5 days). In addition, this study introduced CESI-MS to the field of nanoparticle protein corona analysis.

Novel Aspect:

This is the first example of CESI-MS being applied to the nanoparticle protein corona and the first to comprehensively compare on and off particle corona isolation Methods:

452 - RADICALS GENERATED BY NANOPARTICLES IN CONTACT WITH LIQUID WATER USING SPIN TRAPPING AND MASS SPECTROMETRY

Per Axel Clausen (1) - Vivi Kofoed-Sørensen (1) - Asger W. Nørgaard (2) - Nicklas R. Jacobsen (1) - Keld A. Jensen (1)

National Research Centre for the Working Environment, New Technologies, Copenhagen Ø (1) - Novo Nordisk, Analytical Department, Bagsvaerd (2)

Keywords: Nanoparticles, radical generation, spin trapping, MS

Introduction:

Inhalation of particles may cause airway inflammation induced by reactive oxygen species (ROS) generated by the particles. ROS are often measured by non-specific methods e.g. using 2',7'-dichlorodihydrofluorescein (DCFH₂) and comprises both radicals (hydroxyl, superoxide) and non-radicals (hydrogen peroxide) which both contribute to the response of DCFH₂. The aim of the study [1] was to measure specific radicals formed by nanoparticles in contact with water.

Methods:

The method is based on spin trapping using diethoxyphosphoryl-5-methyl-1-pyrroline (DEPMPO) that traps radicals right after their formation. In short, nanoparticles (NPs) were dispersed in pure water with added spin trap, incubated over-night, and centrifuged. The supernatant was analysed with LC-MS and the "pellet" consisting of the NPs was analysed with MALDI-TOF-MS to directly measure the spin trap radical products adsorbed to the surface of the NPs.

Results:

It turned out that the major part of the spin trap radical products was adsorbed to the particle surfaces. Carbon black (Printex 90) showed by far the strongest radical generation as compared to silica NP (NM-200), with carbon nanotubes (NM-400) in between. The preliminary results showed that the Printex 90 produced mainly the hydroxyl radical ($\cdot\text{OH}$) but also the hydroperoxyl radical ($\cdot\text{OOH}$). NM-400 produced only $\cdot\text{OH}$ and NM-203 produced no radicals. The total radical formation potential (sum of $\cdot\text{OH}$ and $\cdot\text{OOH}$ from both supernatant and "pellet") of Printex 90 was 13-46 nmol/mg NP and 8-20 nmol/mg NP of NM-400 depending on the amount of NP dispersed in the water.

Conclusions

When studying the specific radical formation of NPs using spin traps and MS techniques it is necessary to be aware, that a substantial part of the spin trap radical products may be adsorbed to the surface of the NPs and has to be measured independently. The preliminary results show that radical formation by different types of NP may range from no radical formation of silica NP and up to about 50 nmol/mg NP of carbon black. All mechanisms behind ROS production are not known.

Novel Aspect:

Quantitation of radicals formed by nanoparticles in their dispersion media and on their surface using spin trapping and MS has to our knowledge not been reported previously.

1. The present study was part of the Danish NanoSafety Centre.

714 - A NOVEL NANOCOMPOSITE COATING BASED ON SOL-GEL TITANIA/HYDROXYAPATITE FOR SOLID-PHASE MICROEXTRACTION COUPLED TO GC-MS

Fereidoon Rahmani (1) - Ali Es-haghi (2) - Mohammad-Reza Milani Hosseini (1) - Afsaneh Mollahosseini (1)

Iran University of Science and Technology, Department of Analytical Chemistry, Tehran (1) - Razi Vaccine & Serum Research Institute, Agricultural Research, Education and Extension Organization (AREEO), Department of Physico Chemistry, Karaj (2)

Keywords: Solid-phase microextraction; Sol-gel technology; Hydroxyapatite; Titania; GC-MS.

Introduction:

The underlying principle of SPME technique is based on the analyte distribution between the sample matrix and the extraction phase[1,]. Titania and hydroxyapatite (HAP) have received great interest in analytical chemistry due to very good physical and chemical properties [2]. HAP can improve the surface area, grain size and thermal stability of TiO₂. Addition of TiO₂ changes the surface morphology as well as an increase of the mechanical and chemical stability of HAP [3].

Methods:

A non-aqueous organic/inorganic sol-gel route was applied for synthesis of HAP sol and then a transparent stable titania sol was prepared. After repeating steps including; dipping, drying and sintering, a sol-gel coating was formed on the modified stainless steel (SS) wire. Finally, applicability of the prepared fiber was assessed for the HS-SPME of BTEX as model analytes from water samples followed by GC-MS.

Results:

The thickness, morphology and composition of the prepared sol-gel coatings; TiO₂, HAP and HAP/TiO₂, was investigated and analyzed by using of FESEM and EDX. The coating thickness was estimated below 1 μm when the coating process was performed 5 times. This is much less than the thickness of the thinnest conventional coating. The FESEM images showed a fully cracked and quite non-uniform coatings in terms of porosity and particle size by use of pure TiO₂ or HAP. Addition of HAP sol to the pure TiO₂ sol, considerably changes the morphology of HAP/TiO₂ coating; the coating is perfectly uniform and the size of the particles in HAP/TiO₂ nanostructure is increased compared to the pure TiO₂ coating. Nanoparticles (<50 nm) and pores (less than 100 nm) have been spread uniformly throughout the wire, providing a high surface area and a high sample loading capacity. The obtained chromatograms of BTEX after HS-SPME by prepared TiO₂, HAP and HAP/TiO₂ coatings in optimum extraction conditions testify that HAP/TiO₂ coating exhibited high extraction capacity and have better peak shapes.

Conclusions:

The proposed sol-gel method for the synthesis of HAP/TiO₂ and the coating process on SS wire are very cost-effective, simple, fast and structurally controllable. The obtained chromatograms of BTEX after HS-SPME showed that HAP/TiO₂ coating exhibited high extraction capacity. Very LOD and LOQ values were obtained for BTEX.

Novel Aspect:

A novel titania/hydroxyapatite nanocomposite coating fiber was prepared for first time through a relatively fast sol-gel technique.

Keywords: Immobilization, Mannich reaction, Phenol-containing molecules, Self-assembled monolayers, Surface chemistry

Introduction

To construct applicable materials incorporated with biologically active phenol-containing molecules, strategies for immobilization of phenolic molecules on materials are required [1]. Although a number of immobilization methods have been accomplished and reported - mostly harnessing the phenol functionality, the practical use as a general immobilization method has been hampered due to their complicated chemical reactions and low reaction yield on surfaces [2-3].

Methods

Chemical functional groups, carboxylic acid, thiol, and azide, were introduced to phenolic molecules using Mannich reaction followed by immobilization to self-assembled monolayers on gold via various surface chemistries, carbodiimide coupling reaction, Michael addition, and 'click' reaction. As a practical application, we performed sulfotransferase enzyme assay on immobilized 2-naphthol [4]. The surface reactions were analyzed by MALDI-TOF MS and XPS.

Results

Naphthol, tyrosine, and hydroxyflavone were modified by Mannich reaction to possess carboxylic acid, thiol, and azide group, which were confirmed by MALDI-TOF MS. These functionalized phenolic molecules were then immobilized to the monolayers on gold that presented amine, maleimide, and alkyne via carbodiimide coupling reaction, Michael addition, and 'click' reaction, respectively. The immobilization of the synthesized molecules to the monolayers were analyzed by MALDI-TOF MS and XPS. The mass spectra clearly showed that all the surface conjugation reactions proceeded as expected, although the fragmented final products were observed. In addition, comparison of C1s XPS indicated that the molecules were immobilized on the SAMs successfully. As a practical application, the 2-naphthol immobilized monolayers were exposed to sulfotransferase SULT1A1 and 3'-phosphoadenosine 5'-phosphosulfate, which yielded 2-naphthol sulfate.

Conclusions

We describe a simple, fast, and reliable method for the surface immobilization of phenol-containing molecules such as flavonoids by introducing chemical functional groups using Mannich reaction while maintaining the hydroxyl functionality so that their biological activities were not compromised.

Novel Aspect

Our method can be a general and practical platform for the immobilization method of various phenol-containing molecules on surfaces of various materials.

1090 - BIOIMAGING OF NANOPARTICLES IN CELLS AND TISSUE BY LASER ABLATION INDUCTIVELY COUPLED PLASMA MASS SPECTROMETRY

Norbert Jakubowski (1) - Heike Traub (2)

Bundesanstalt für Materialforschung und -prüfung (BAM), Inorganic Trace Analysis, Berlin (1) - Bundesanstalt für Materialforschung und -prüfung, Inorganic Trace Analysis, Berlin (2)

Keywords: metallicnanoparticles, imaging, biologicalcells, tissues, inorganic mass spectrometry

Introduction

The interaction of nanoparticles (NPs) with cells and tissues has become a growing field of interest in consumer care and safety, nanotoxicology and medical applications e.g. as theranostic or diagnostic agents. It will be shown that laser ablation inductively coupled plasma mass spectrometry (ICP-MS) is a new analytical tool which can visualize the distribution of NP and which provides quantitative data at cellular levels.

Methods:

In our work we have used laser ablation coupled to ICP-MS in a differential line scanning mode to study and image the up-take and distribution of metallic nanoparticles (Au, Ag, TiO₂) in single cells. Different types of adherent cells have been grown on microscopic slides and were incubated with different types of metallic nanoparticles at different time frames and concentration.

Results:

We have studied the effect of concentration, incubation time, nanoparticle diameter and surface coatings in fibroblast cells. After development of a calibration strategy using nanoparticle suspensions of known particle concentrations we could convert integrated intensities measured for a cell into the number of particles per cell. A similar strategy has been applied to convert measured intensities in tissue samples for Fe₂O₃-nanoparticles applied as contrast agents for magnetic resonance imaging (MRI) to enhance the signals in atherosclerotic plaques. By doping the oxide particles during synthesis by lanthanide elements we could easily differentiate and quantify natural (endogenous) from exogenous iron in the tissue.

Conclusion:

We have optimized a laser ablation system coupled to ICP-MS to achieve sub-cellular resolution. By application of a matrix matched calibration method we can convert the measured intensities of NPs directly into the number of particles up taken by cells. The sensitivity is sufficient to detect medium sized NP as single particle or smaller once (<20 nm) as agglomerates in cells and tissue.

Novel Aspect:

We discuss the concept and present the technical features of a novel quantitative elemental microscope based on inorganic mass spectrometry.

Keywords: Supramolecular chemistry, catalysis, nanoreactors, ion mobility mass spectrometry, CID

Introduction:

Cucurbiturils (CB[n]) are pumpkin shaped macrocycles of glycouril [1]. They are water soluble compounds which can host small molecules in their cavity and operate as nanoreactors [2]. Inclusion complex formation and catalytic activity of CB[n]s in dissociation reactions of azoalkanes have been studied using MS/MS and ion mobility MS experiments.

Methods:

Complex formation and MS/MS have been studied by ESI-Q-TOF MS (QSTAR from ABSciex) and Agilent 6560. Azoalkane inclusion inside nanoreactors have been followed by DTIM-MS using Agilent 6560 and modified Waters Synapt. Collision cross sections (CCS) have been compared to DFT calculated structures.

Results:

Complex formation between CB[n] (n=6, 7 or 8) and azoalkanes was followed by ESI-MS. The inclusion (endo) complex formation was verified by DTIM-MS and it mainly depended on steric factors. Instead of endo complexation, formation of exocomplexes was observed with smaller CBs. Size of CB[n] (n=6, 7 or 8), size of azoalkane and protonation state of the formed complex greatly affected the products formed during thermal activation of isolated complexes. In fact, different reaction pathway resulting in different end-products was observed for azoalkane complexed in nanoreactor on +1 and +2 charge states and for uncomplexed azoalkane.

Conclusions

CB[n] based nanoreactors are not only catalyzing reactions, but change substrate reactivity and enable formation of new reaction products. DTIM-MS is a valuable tool in analysis of structural features and especially endo-complexation in nanoreactors.

Novel Aspect

We have recently discovered that nanoreactors don't only catalyse reactions, but also enable formation of completely new products. DTIM-MS used for structural analysis of nanoreactors.

Keywords: Supramolecular chemistry, Pyridine[4]arenes, Ion mobility mass spectrometry, IRMPD

Introduction

Pyridine[4]arenes [1] are macrocycles, which form dimeric and hexameric capsules via hydrogen bonding [2]. This type of capsules are widely studied in supramolecular chemistry as hosts, which can bind guest molecules inside the capsular cavity. We have recently discovered new binding properties of pyridinearene capsule, which was previously assumed to encapsulate only anionic guests [3-5]. The structures of new complexes have been studied using IRMPD and IM-MS.

Methods

Complexation of pyridine[4]arene with cationic guests was studied by ESI-Q-TOF MS (QSTAR from ABSciex). The structural features of observed complexes were studied in IRMPD experiments (performed with Varian FT-ICR) and DTIM-MS. DFT calculations have been used to visualize the gas phase structures.

Results

Complexation properties of pyridinearene were tested with different alkyl ammonium guests. In (+)ESIMS experiments, complexation was observed only with tetramethylammonium cation (TMA). In (-)ESI-MS spectra ternary complexes with TMA cation and two anions were observed to bound to pyridinearene dimer. These ternary complexes were studied in infrared multiphoton dissociation (IRMPD) and drift tube ion mobility experiments. Gained results supported the encapsulation of cationic guest while two anions were bound outside the capsule. The gas phase structures were visualized by DFT calculations.

Conclusions

New type of supramolecular ternary complexes have been observed in gas phase. Different mass spectrometric techniques have been utilized to study their structure. Results were consistent and supported the encapsulation of cationic guest, while anions were bound outside the capsular cavity.

Novel Aspect

New type of supramolecular ternary complexes observed in gas phase. The structural features of these complexes were studied using IRMPD experiments and IM-MS.

Keywords: Boronic acid-functionalized particles (BAPs), Enrichment, Flavonoid, Matrix-assisted laser desorption/ionization time of flight mass spectrometry (MALDI-TOF MS)

Introduction

Detection and quantification of flavonoids which exhibit broad biological and pharmacological activity with little toxicity [1] has been hampered by their bad water-solubility and rapid metabolic elimination from human body [2]. This study concerns the development of an efficient enrichment method for facilitating the analysis of vicinal diol-containing flavonoid molecules using boronic acid-functionalized particles (BAPs) and MALDI-TOF MS.

Methods

Boronic acids on BAPs bind to vicinal diols to form boronate monoesters at basic pH. This complex remains intact during the enrichment process, and the vicinal diol-containing flavonoids are easily separated by centrifugation and subsequent acidic treatment. The selectivity and the limit of detection of our strategy were confirmed by MS analysis, and the validity was assessed by performing the detection and quantification of a model molecule quercetin in mouse organs.

Results

The selectivity of BAPs towards vicinal diol-containing flavonoids was evaluated in the presence of other flavonoids which have multiple hydroxyl groups and carbonyl groups that potentially interact with boronic acids. Next, we observed excellent enrichment feasibility for vicinal diol-containing flavonoids of our method in the presence of other flavonoids in highly excess amount. A calibration curve for quantification was constructed with various amounts of quercetin in the presence of an internal standard, and the limit of detection for quercetin was 75 pmol. The practical applicability was confirmed by quantifying quercetin spiked in fetal bovine serum with excellent accuracy and precision. Furthermore, we showed that our method can effectively enrich vicinal diol-containing flavonoids and facilitate the quantification of the targets present in animal tissues in low abundance. Finally, excellent recyclability of the BAPs with good reproducibility was confirmed indicating the practical usability and cost saving of our method.

Conclusions

We validated the selectivity and efficiency of BAPs towards vicinal diol-containing flavonoid molecules and constructed a calibration curve for quantifying quercetin. The feasibility and applicability of our method were assessed via the quantification of quercetin spiked in FBS and animal tissues. Furthermore, the recyclability of BAPs was confirmed. Taken together, this method is promising from the viewpoint of cost saving and practical applications.

Novel Aspect

Boronic acid functionality was harnessed for the analysis of flavonoids in spite of its low water-solubility and interference of other vicinal diol-containing biomolecules[3].

Keywords: MIMS, energy, hydrogen, light rare gases, real-time analysis

Introduction:

Direct measurement of gases formed in hydrogen reactors based on nanomaterials [1] is often challenging as many molecules may be of interest, rapid response is necessary and small volumes are involved. We propose an instrument, based on mass spectrometry, for small inorganic gases analysis (H₂, CO₂, O₂, NO, Ar,...) specifically adapted to the hydrogen production applications.

Methods:

Gas analysis in the reactor is processed by a membrane interface (MIMS) and a quadrupole mass spectrometer. As water from the permeate may interfere with the hydrogen signal [2], we added a cryotrap at -100°C before the vacuum cell. The pumping system was modified to increase compressibility of hydrogen. Calibration of H₂ signal is managed by a gas diluter. The apparatus was tested in a H₂ formation reactor.

Results:

The apparatus was tested in dry and in-water conditions. Headspace analysis was not possible as signal was not stable due to droplet formation on the membrane. For in-water analysis stirring of the solution is necessary to maintain constant signal.

The modifications we made on the instrument improved the detection and stability of the H₂⁺ (m/z 2) signal. Signal had a linear response to increasing concentrations. Detection limit was 2 ppm. First, use of specific material for the vacuum cell decreased hydrogen and water adsorption and ultimately lowered detection limit. Second, memory effect due to low compressibility of hydrogen was solved by the use of a second turbopump. Blanks were constant before and after introduction of high quantity of H₂ for a long period. Finally, addition of a cryotrap decreased drastically (more than 99%) water amount in the permeate, and therefore detection limit of hydrogen was greatly improved in particular in wet conditions.

Conclusions

The constructed prototype allowed for improved H₂ detection in mass spectrometer. Signal is more stable and detection is made possible directly in the water solution, with no headspace required. Concomitant analysis of O₂ and CO₂ was produced in a hydrogen formation reactor.

Novel Aspect:

New instrument specifically adapted to analysis in real-time of H₂ and different other gases directly connected to a reactor to monitor hydrogen production from nanomaterials.

Keywords: single particle ICP-MS; arsenic nanoparticles; spectral interferences

Introduction:

Analysis of nanoparticles (NPs) using single particle inductively coupled plasma mass spectrometry (sp-ICP-MS) is able to provide information on the size of NPs and their number concentration. However, the determination of some elements via ICP-MS is strongly hampered by spectral overlap from polyatomic species. Overcoming interferences of polyatomic ions, which can compromise results, is one of the challenges with ICP-MS.

Methods:

The use of ICP-MS with reaction cell enables interference-free conditions to be obtained, even in the most demanding applications. This approach has also been proven to allow analysis of NPs in matrices containing interference precursors [1]. This work is focused on the determination of arsenic NPs in biological matrices because the arsenic suffers a polyatomic interference from ArCl^+ .

Results:

The As NPs were prepared by borohydride-reduction of sodium arsenite according to previously published paper [2]. The use of NH_3 in reaction cell mode ($\text{FNH}_3=0.3$ mL/min) was demonstrated to be the most suitable to overcome the interference affecting trace As determination up to chloride concentration of 5.46 g/L, which corresponds to physiological saline solution. By using reaction cell, As NPs >50 nm can be detected. Because the sensitivity of signal was reduced not only by the reaction gas but also by salt content in sample, it was possible to provide accurate results only for As NPs >70 nm in at least 10 times diluted saline samples. In the case of <70 nm NPs, the histograms show incomplete distributions as result of the presence of the background signal.

Conclusions:

sp-ICP-MS method utilizing reaction cell that allows determination of As NPs in presence of high chloride concentrations was introduced. Despite the reduction of sensitivity and therefore increased particle size detection limit, this method promises possibility of determining As NPs in biological matrices (e.g. blood serum).

Novel Aspect:

sp-ICP-MS offers fast determination and characterization of As NPs. The applicability to biological matrices may have interesting uses in medicine.

92 - NANOSTRUCTURED TUNGSTEN OXIDE SUBSTRATE WITH OXYGEN VACANCIES FOR EFFICIENT SURFACE-ASSISTED LASER DESORPTION/IONIZATION MASS SPECTROMETRY ANALYSIS

Qiang Ma (1)

Chinese Academy of Inspection and Quarantine, Chinese Academy of Inspection and Quarantine, Beijing (1)

Nanostructured Tungsten Oxide Substrate with Oxygen Vacancies for Efficient Surface-Assisted Laser Desorption/Ionization Mass Spectrometry Analysis

Keywords: Surface-Assisted Laser Desorption/Ionization Mass Spectrometry; Nanostructured Tungsten Oxide Substrate with Oxygen Vacancies

Introduction: (Limit of 400 characters)

The development of matrix-assisted laser desorption/ionization mass spectrometry (MALDI-MS) for characterizing molecules was a significant breakthrough that build upon the 2002 Nobel-prize winning studies of Tanaka on soft desorption ionization methods for mass spectrometric analysis. While the vacuum environment and matrix preparation make the method time-consuming and laborious, ambient ionization mass spectrometry is becoming increasingly attractive because of its simple sample pretreatment process. More than 40 ambient ionization methods have been developed since 2004 and surface-assisted laser desorption/ionization mass spectrometry (SALDI-MS) is a very important branch in the ambient MS analysis. The search for more sensitive, versatile, and robust substrate for SALDI-MS becomes particularly important.

Methods: (Limit of 400 characters)

Sea urchin-like W18O49 nanoparticles was synthesized as follows: WCl₆ dissolved in ethanol followed by hydrothermal reaction at 180 °C for 24h, and a blue flocculent precipitate was collected and diluted with ethanol to obtain the suspension. All MS analysis were performed using a home-made SALDI-MS system, and capillary nanoESI was used as a post-ionization method. For each analysis, drop a spot of W18O49 suspension on the aluminum plate as substrate, and then 5 μL of sample solutions. The laser used was a 980 nm continuous-wave laser without lens for focusing. The relative distance and angel between components undertook a systematic optimization to acquire satisfactory MS signals.

Results: (Limit 900 characters)

Sea urchin-like W18O49 nanoparticles have been successfully prepared via hydrothermal process. A very large absorption tail present in the visible and near infrared regions of the absorption spectrum gives clear evidence that the W18O49 nanoparticles contain a large number of oxygen vacancies, which become less for W17O47 and even be missing for WO₃. The characteristic structure showed that compared with other nanomaterials, this substrate has a maximum energy absorption from 980 nm laser and function as “energy converter”, realizing efficient desorption of analyte. For MS analysis, the “pulse” form total ion chromatogram signal profile occurred since the power of the laser came to 4 W/cm². This characteristic property gives much higher MS response and better S/N than paper spray (PS) and nanoESI analysis of 5 μL, 20 ppb diethylhexyl phthalate (DEHP) solution in positive mode and perfluorooctane sulphonate (PFOS) in negative mode, respectively. We also noticed that there was about a 60-s delay between the signal excitation and laser irradiation, and it became shorter as the laser power increased. When the power came to 7 W/cm², the delay was less than 10 s. The photothermal analysis of the W18O49 substrate dropped on the aluminum plate showed that the temperature increased faster and had a higher final value as the laser power increased. We propose that there would be a positive correlation between the signal excitation and heat accumulation but it is not a decisive factor, since the highest final temperature was about 120 °C during testing, and such a low temperature was not enough for the thermal desorption. We compared WO₃ as substrate for MS analysis and the results showed that neither oxygen vacancy nor instrumental signal. Also, for 60 min irradiation at 6 W/cm²,

the Raman spectrum showed a certain degree of oxidation for W18O49. Corresponding MS signal for W18O49 decreased.

Figure 1 SEM images of sea urchin-like W18O49 nanoparticles a) 500 nm and b) 5.0 μm ; c) UV/Vis absorption spectrum of W18O49, W17O47 and WO3; d) TIC signal profile at different laser power; e) The photothermal analysis of the W18O49 substrate at different laser power; f) Comparison of the MS response for ESI, PS, nanoESI and this method; g) Raman spectrum of W18O49 during 60 min irradiation; h) The MS response and absorbance at 808 nm of W18O49 substrate during 60 min test..

Novel Aspect: (Limit of 150 characters)

Novel sea urchin-like W18O49 nanoparticles with oxygen vacancies was applied for SALDI-MS analysis with significantly increased desorption/ionization efficiency.

Keywords: MALDI-TOF, mass spectrometry, nanomaterials, functionalized silica nanoparticles

Introduction:

Nanomaterials have been widely used in laser desorption/ionization time-of-flight mass spectrometry as an alternative for matrix (LDI-MS) and as well for improving signal intensities in MALDI-TOF-MS [1]. In this regard, bare silica nanoparticles (SiO₂NPs) have been successfully utilized for the signal enhancement of peptides [2]. Here, we report influence of the two types of functionalized silica NPs in the development of MALDI-MS signals intensity of peptides.

Methods:

The sulfobetainesilicaNPs(SB-SiO₂-NPs) and amino propane sulfonate silicaNPs (APS-SiO₂-NPs) were prepared according to the published procedure [3].MALDI experiments were done by using the AB SCIEX4800 time-of-flight (TOF/TOF) mass spectrometer in reflectron positive mode, which is equipped with a 355 nm Nd:YAG laser. Typically, to acquire a single spectrum 800 laser shots were fired at a frequency of 200 Hz at 25% of the full laser power for samples.

Results:

Among the different methods for sample preparation, two methods were selected for MALDI-TOF-MS experiment. In this regard, 1 μ L of functionalized SiO₂-NPs was deposited onto the MALDI plate. Following that 1 μ L mixture of sample solution, including peptide and matrix, was spotted on the top of dried silica NPs. In a parallel way we mixed 1 μ L of functionalized SiO₂-NPs with 1 μ L mixture of sample solution and after 3 min vortex, 1 μ L of NPs/sample solution was directly spotted on to the MALDI plate and air dried for MALDI-MS analysis. In all analyses, the concentration of peptides in MALDI samples was maintaining constant. The maximum signal intensity for peptides was obtained when we used NPs as additive to the sample solution. SB-SiO₂-NPs had the most influence on analyte signal enhancement. Alteration the ratio of matrix and NPs in sample solution had a positive effect on signal enhancement. As well, concentrating sample with the coffee-ring effect during sample preparation, improved signals intensity.

Conclusions:

This work demonstrates that functionalized SiO₂ NPs can be used for enhancement of ion signals in MALDI-TOF-MS analysis of peptides. This improvement on signals intensity is possibly related to the electrostatic interaction between NPs and peptides. Furthermore, alteration NPs surface charge have influence on this electrostatic interaction and change the amount of peptides ionization.

Novel Aspect:

New functionalized silica nanoparticles have been utilized for the first time, since improving signals intensity of peptides in MALDI-MS analysis.

Keywords: Laser Ablation, Nanoparticles, LA-ICP-MS

Introduction

A preliminary study of nanoparticles-enhanced LA-ICP-MS is presented. It represents an analytical strategy to improve the analytical performance of the LA-ICP-MS in terms of sensitivity and LOD, preserving its excellent characteristics (simplicity, rapidity, etc.), without any changes in the experimental set-up.

Methods

Some drops of Gold Nanoparticles (AuNPs) colloidal dispersion were deposited on the sample's surface, the solvent evaporated before the analysis. Spherical AuNPs dispersions in aqueous citrate buffer (Sigma Aldrich Co.) or naked PLAL (Pulse Laser Ablation in Liquid) [1] AuNPs of different size were used on certified standard target (Copper, Titanium, Bronze, Brass, Silicon and Glass).

Results

A considerable increase of the measured signal intensity was observed in the presence of AuNPs.

By analogy with results already obtained with Laser Induced Breakdown Spectroscopy [2,3], when a critical number of NPs are deposited on the target surface, the laser pulse electromagnetic field induces the collective oscillation of the conduction electrons of the NPs that in turn results in a strong enhancement of the field. The improvement is probably induced by the best quality of the nanoparticles' agglomerate generated during the laser ablation.

Metallic elements show enhancement also in non-conductive matrices. Different metallic elements show different enhancement in the same matrix, as well as the same element shows different enhancement in different matrices. It should be noted the AuNPs can be completely removed after the analysis.

Conclusions

The existence of an improvement of sensitivity in LA-ICP-MS signal via AuNPs allows to identify and quantify elements without damaging significantly the sample's surface unlike conventional LA-ICP-MS.

Novel Aspect:

The AuNPs allow to improve the sensitivity of LA-ICP-MS technique almost in a nondestructive mode, which can be extremely useful in many fields as forensic sciences and cultural heritage.

Keywords: LDI-ToF MS, Graphene, Porphyrin, Covalent Functionalization, Nanohybrid

Introduction:

To characterize covalently functionalized graphene, several analytical methods are commonly applied.[1] Raman spectroscopy, for example, allows to detect the conversion of sp²-hybridized carbon from the graphene lattice to sp³-hybridized carbon, giving insight in the degree of functionalization of the nanomaterial. However, it cannot provide any information about the molecule bound to the graphene, making it hard to conclude if the target molecule is attached or not.

Methods:

The nanohybrid was characterized by laser desorption/ionization time-of-flight mass spectrometry (LDI-ToF MS) using a Bruker Reflex IV mass spectrometer equipped with a N₂-laser ($\lambda = 337$ nm). Further, the hybrid was washed with trifluoroacetic acid in DCM:MeOH (1:2, V:V) five times and each of the green filtrates was analyzed via electrospray ionization (ESI) quadrupole ion trap (QIT) MS (esquire6000, Bruker).

Results:

In this study, graphene was covalently functionalized with 5,10,15,20-tetraphenylporphyrin (TPP) via a diazonium salt intermediate.[2] For the first time our investigation employed LDI-ToF MS. LDI revealed the presence of several interesting species on the graphene sample. The molecular-ion peak of the TPP was observed together with other TPP-related signals occurring from side reactions, such as a TPP dimer. Washing the hybrid system several times yielded green filtrates with the color fading from the first to the last washing cycle. ESI MS of the filtrates resulted in signals of TPP together with the byproducts already detected in LDI, decreasing in intensity after each washing cycle. The precipitates from the washing cycles were then investigated again by LDI to check whether TPP is still present on the graphene or not. TPP was still observable in the LDI mass spectrum whereas the signals for the byproducts were significantly reduced, supplying strong evidence that the TPP is indeed covalently attached to the graphene lattice.

Conclusions:

LDI-ToF MS was successfully introduced as a new analytic method for the study of covalently functionalized graphene. LDI-ToF MS allowed for the first time the identification of large molecules on a graphene lattice, enabling the detection of products and byproducts, which is not possible with currently applied methods, such as Raman spectroscopy. Furthermore, a combination of ESI-QIT and LDI-ToF MS gave strong evidence that the TPP is indeed covalently attached to the graphene lattice.

Novel Aspect:

LDI-ToF MS was introduced as a new analytic method for covalent graphene samples and provided insight into the composition and chemistry of the molecules on the surface.

220 - THE MEASUREMENT OF THE OXIDATION REACTION OF FERROCENES USING LC-MS WITH ESI

Yutaka Okada (1) - Masako Tsuchida (1)

Ritsumeikan University, Department of Applied Chemistry, Kusatsu (1)

Keywords: ESI, LC-MS, ferrocene, oxidation, picrate

Introduction:

The oxidation reaction of ferrocenes is one of the typical reactions of ferrocenes. Ferrocene is readily oxidized to the ferrocenium ion under acidic conditions. The oxidation reaction of ferrocene derivatives by air under acidic conditions has been investigated by several researchers. However, the formed ferrocenium ions is not recognized by NMR due to its paramagnetic property. In this paper, LC-MS with ESI was used to detect and quantify the ferrocenium ions.

Methods:

The LC-MS was measured using a Shimadzu LCMS-QP8000A. The electric potential was 4.5 kV for positive mode, and -3.0V for negative mode. An OOS column was used under MeOH-H₂O eluent conditions.

The oxidation reaction was proceeded by air in 1,2-dichloroethane in the presence of trichloroacetic acid [1]. After the reaction, the solution was washed by water to remove the acid. Picric acid was added to the solution as anion source.

Results:

The ESI(+)-MS of ferrocene showed molecular ion peak ($m/z=186$) as base peak, and a fragment ion peak of $m/z=121$. After the oxidation reaction, the mass chromatogram showed two peaks; one is for the unreacted ferrocene, and another is a new peak. The ESI(+)-MS for the new peak showed only molecular ion peak ($m/z=186$). The ESI(-)-MS showed only one peak for picrate anion ($m/z=228$). Therefore, this chromatogram's new peak would be assigned as ferrocenium picrate.

The ESI(+)-MS of ethylferrocene showed molecular ion peak ($m/z=214$) as base peak, and a stable fragment ion peak of $m/z=199$. After the oxidation reaction, the mass chromatogram showed only one peak. The peak was assigned as the oxidized form by ESI(+)-MS and ESI(-)-MS. This is attributed to the high oxidation reactivity of ethylferrocene. For acetylferrocene, which has low reactivity, small peak was found in the mass chromatogram. The peak was assigned as the oxidized form by ESI(-)-MS.

Conclusions:

Based on the LC-MS with ESI, the oxidation reaction of ferrocenes was measured. The oxidized forms were assigned by the ESI(+)-MS, and the picrate ion as the counter anion by ESI(-)-MS. This ESI(-)-MS measurement is useful for the low oxidation reactive ferrocenes such as acetylferrocene.

Novel Aspect:

The LC-MS with ESI using picrate ion as the counter anion was an effective method for the measurement of the oxidation reaction of ferrocenes.

863 - MASS SPECTROMETRY-BASED METHODS AS A TOOL FOR MONITORING THE MICRO SCALE CHEMOENZYMATIC PEPTIDE SYNTHESIS ON SOLID SUPPORT.

Halina Płóciennik (1) - Piotr Stefanowicz (1)

University of Wrocław, Faculty of Chemistry, Wrocław (1)

Keywords: chemo-enzymatic ligation, omniligase, solid phase, LC-MS

Introduction:

Synthetic polypeptides and proteins are a particularly useful tools in biochemical research. The synthesis on solid support is limited to only relatively short sequences, while the method of producing recombinant proteins' main restriction lies in incorporating post-translational modifications and unnatural amino acids [1]. A native ligation approach requires cysteine residues in peptide chains and therefore limits the choice of synthetic strategy [2].

Methods:

Substrates for the ligation reactions were synthesized on the solid support. Products of synthesis were analyzed using ESI-MS and MS/MS Methods: Ligation reactions were performed on the solid support and in solution. Products of ligation were investigated by LC-ESI-MS analysis.

Results:

Omniligase is characterized by its unspecific activity. It allows coupling almost without any limitation (except Pro in active center) peptides [3]. Our results show that it is possible to performed ligation on the solid support. One of the most important factor to achieved a product of ligation is chosen appropriate resin. We tested selected solid supports, swellable in water, such as ChemMatrix resin, PEGA resin and TentaGel. The best results were obtained for PEGA resin which was used to the further experiments. Preliminary results indicate the relatively high efficiency of solid phase enzymatic ligation.

Conclusions:

In my poster I will compare the results of Omniligase ligation on the solid support and in solution. I will also discuss the factors influencing the efficiency ligation under various conditions.

Novel Aspect:

Evaluation of mass spectrometric methods (LC-MS, MS/MS) as a tool for monitoring the micro scale chemoenzymatic peptide synthesis on solid support.

690 - LC-MS CHARACTERIZATION OF DYNAMIC COMBINATORIAL LIBRARIES OF TASP MOLECULES WITH NOVEL SCAFFOLD

Grzegorz Wolczanski (1) - Maciej Modzel (2) - Piotr Stefanowicz (3) - Marek Lisowski (3)

Faculty of Chemistry, University of Wrocław, Wrocław (1) - Department of Biochemistry and Molecular Biology, Department of Biochemistry and Molecular Biology,, Odense (2) - Faculty of Chemistry, University of Wrocław, Wrocław (3)

Keywords: TASP, Dynamic combinatorial libraries, LC-MS, synthetic helical proteins

Introduction:

TASP molecules are artificial protein models formed by attaching peptide chains to a cyclic scaffold[1]. We present preparation of TASP dynamic combinatorial libraries (DCLs) basing on a new scaffolds, which are created by formation of disulfide bonds between N-(2,6-dimercapto-1,3,5-triazin-4-yl)peptides. DCLs were analyzed by LC-MS.

Methods:

We synthesized our peptide conjugates using the standard SPPS protocol. Libraries of TASP molecules have been created from N-(2,6-dimercapto-1,3,5-triazin-4-yl)peptides (or their dimers with a disulfide bridge) via oxidation by atmospheric oxygen or CuCl₂ in 2-propanol. Selective formation of a cystine residue has been performed by adding I₂. We used LC-MS and IM-MS to characterize TASP libraries. Identity of the isolated compounds has been confirmed by HR-MS.

Results:

Oxidation of N-(2,6-dimercapto-1,3,5-triazin-4-yl)peptides by atmospheric oxygen in aqueous solution does not occur. The peptides incubated in a more hydrophobic environment of 2-propanol produced TASP molecules by formation of disulfide bridges between 2,6-dimercapto-1,3,5-triazine moieties. Subsequent oxidation of the peptide conjugates containing an N-terminal Cys residue with an attached dimercaptotriazine moiety allows controlling the size of the macrocyclic scaffold. Similarly to systems proposed by Otto et al. [2], our peptide conjugates gave mainly trimers and tetramers. Formation of disulfide bond between Cys residues attached to triazine ring affects the size of oligomers. Used peptide sequence were designed as amphipathic α -helices. Dynamic combinatorial libraries of the oligo helical bundles were analyzed by LC-ESI-MS and IM-MS. Some of them were purified and analyzed by CD spectroscopy, showing stabilization of α -helical structures by intra-chain interactions.

Conclusions

We developed a new type of scaffold based on triazine moieties connected by disulfide bonds into cyclooligomers. Our method is useful in designing dynamic combinatorial libraries of TASP. The libraries of synthetic proteins may be simply characterized using LC-MS and IM-MS. Fixing of the relative positions of the two triazine rings by subsequent formation of disulfide bonds between attached Cys residues affects the size of the macrocyclic scaffold.

Novel Aspect:

We developed first dynamic combinatorial libraries of TASP molecules with scaffolds based on oligo triazine disulfides, which were fully characterized by LC-MS and IM-MS.

672 - FAST ANALYSIS OF MODERN OIL PAINTINGS AND DYES IN TEXTILES BY SURFACE ACOUSTIC WAVE NEBULIZATION-MASS SPECTROMETRY (SAWN-MS)

Alina Astefanei (1) - Maarten van Bommel (2) - Klaas Jan van den Berg (3) - Garry Corthals (1)

University of Amsterdam, HIMS, Analytical Chemistry, Amsterdam (1) - Cultural Heritage Agency of the Netherlands, and HIMS, Analytical Chemistry, University of Amsterdam, Amsterdam (2) - Cultural Heritage Agency of the Netherlands (RCE), and University of Amsterdam, Amsterdam (3)

Keywords: SAWN-MS, oil paintings, dyes, textiles

Introduction:

GC-MS and LC-PDA are the methods of choice to study the binding media of paintings and dyes in textiles [1,2]. Relatively large samples are needed and long sample preparation and analysis time. In GC-MS, limited information is obtained due to the hydrolysis and derivatization steps, the high temperatures and ionization energies used. SAWN-MS maintains the integrity of fragile molecules due to mild ionization, greatly reduces the sample sizes and the analysis time.

Methods:

The SAWN device was placed in front of the API inlet of a triple-TOF 5600+ MS (Sciex) and operated through a connection with a frequency and power controller. 1 μ L of liquid sample was loaded on the chip and the SAW regulated by applying a power to the electrodes (\approx 5 W). This step was repeated if needed (up to 1 min) and the data accumulated into a single file. The interface heater temperature was 150 $^{\circ}$ C, the inlet/outlet and curtain gasses were 0 psi and 10 psi respectively.

Results:

Herein, we describe the SAWN-MS technique and optimised experimental procedures for the analysis of modern oil paints and dyes in textiles for conservation studies.

SAWN-MS analysis revealed a rich representation of molecular ions that were used for the identification of mixtures of colourants present in dyed textiles [3] providing information on the colouring procedure and the state of degradation.

The technique was also applied to study levels of oxidation and hydrolysis of 20th century oil paints, by monitoring the extracted free fatty acids and diacids, both as glycerides and in the free form. The formation of diacid functionalities play a significant role in the development of water sensitivity and paint instability/failure [4]. A correlation with the pigment type and additives used in paint formulations was obtained. SAWN-MS also enabled the detection of short chain fatty acids, which cannot be easily detected by GC-MS.

Conclusions:

SAWN-MS is an excellent analytical tool for conservation studies on oil paintings and textiles. It offers unique advantages in terms of ease of implementation, simplifies the sample extraction procedures, significantly reduces the required sample sizes and overall analysis times are typically few minutes. Moreover, due to the new mechanisms and efficiency of ionization it provides additional molecular information compared to other ionization techniques.

Novel Aspect:

Novel ionization technique for fast MS analysis of organic components in paintings and dyes in textiles.

Monika Cechová (1) - Lukáš Kučera (1) - Petr Bednář (1)

RCPTM, Palacký University, Olomouc (1)

Keywords: mass spectrometry, archaeological findings, SERJs, medieval jewellery

Introduction:

The history of jewellery is long and goes back many centuries. Slavic women had worn characteristic metallic S-shaped-end ringjewels (SERJs) and those jewels were usually found near their temple skull bones. Laser desorption/ionization mass spectrometry (LDI-MS) allows to effectively study organic compounds profile on the SERJs surface and helps us to understand the way they were used - whether as a part of a headdress or knitted directly into braids of hair.

Methods:

Synapt G2-S high resolution tandem mass spectrometer (Waters, USA) equipped with vacuum MALDI ion source was used for all experiments. Organic matter of unknown origin adhered to SERJ surface (from Dětkovice archaeological locality, Moravia region, Czech Republic) was analyzed directly on SERJs surface. LDI-MS and mass spectrometry imaging experiments were done without application of matrix.

Results:

MSI of fiber residues and fiber-like imprints present on SERJs surface revealed the saccharide chains in the form of sodium adducts. Strong signals at m/z 201.0024, 363.0647, 525.1129, 687.1681, 849.2052, 1011.2562 and 1173.2977 were found in positive ionization mode and ascribed to cellulose. Besides, signals at m/z 437.0921, 599.2493 and 761.1912 were observed with lower intensity. The latter can be explained by a cross link cleavage of glucopyranose ring[1] in sugar chain and further confirm the presence of polysaccharides. On the other hand, no signal of animal origin was observed on SERJs surface.

A distinct group of signals (i.e. m/z 242.0504, 445.1452, 648.2383, 851.3283, 1054.4178) corresponding well with N-acetyl-glucosamine chains was found in MS spectra obtained from a small piece of organic matter hidden in corroded surface of another SERJ. N-acetyl-glucosamine is a common part of chitin present also in beetle elytron. We hypothesize that those signals correspond with remains of a corpse-eating insect.

Conclusions:

SERJs were attached to a headdress by a plant thread (morphology and MS data)

N-acetylglucosamine signals revealed presence of insect body remains

systematic analysis is now focused on characterization of fibers with animal origin (e.g. residues of animal skin)

Acknowledgement: Czech Science Foundation (17-17346S), Ministry of Education Youth and Sports, Czech Republic (CZ.1.05/2.1.00/19.0377; LO1305), Palacký University Olomouc (IGA_PrF_2018_027).

Novel Aspect:

Laser desorption ionization mass spectrometry allowed characterization of the organic residues deposited in corroded surface of medieval metallic jewels.

Keywords: Archeology, Ceramics, organic residues, GC/MS, molecular markers,

Introduction: The organic residues of the ceramic objects contain biomarkers produced by biochemical transformations of their original content [1-4]. The characterization of the lipid fraction in archaeological material is of great importance to obtain information on uses and dietary of people who used this material. For obtaining precise results it is important to identify presence of molecular markers in ancient materials. The aim of this study is to analyze archaeological materials with sensitive and selective methodology involving also optimal extraction Methods: The method of this study allows the identification of markers of food, wine and resins.

Methods: The identification of the organic residues in archaeological materials was performed following few stages: a) extraction of lipid; b) compounds derivatization and c) instrumental analysis. The lipids were extracted using chloroform– methanol (2:1) mixture and then the extracts were derivatised by N, O-bis (trimethylsilyl) trifluoroacetamide (BSTFA). The analysis of the samples was carried out using a GC/MS system. The mass spectrometer was operated in the electron ionisation mode (70 eV). The mass range was scanned in the range of m/z 50-650.

Results: A robust analytical method for determination of markers of wine, food and resins from archeological materials has been developed. The mass spectra of molecular markers are registered and discussed. The method proposed here will allow that the technique GC/MS to can be used extensively for the identification of lipids and wine markers, understanding the structure of the residues preserved in the samples.

Conclusions: Chemical characterization of the organic residues of ceramic vessels, contributes to a better understanding of their uses of the ancient people. Identification of chemical markers, in conjunction with a traditional study of the ceramics, plays a relevant role in establishing what the original content of a specific vessel was.

Novel aspect: The method was used for characterization of ceramic samples from centre of Transylvania, near city Turda which was built by Romans under name Potaissa. The samples are originated from Roman period. This investigation is made for first time in Transylvania region. The analyses allowed us to differentiate between archaeological material devoted to the production or preservation of wine and those used to store the vegetable oil or animal food.

Keywords:

Stable carbon and oxygen isotopes, aragonitic shell, Central Sudan, Holocene

Introduction

Rapid Climate Changes (RCC) that occurred during the Holocene are very important to understand climate changes currently underway (1). The characterization of these abrupt events allows the evaluation of ecosystems and ancient populations from a resilience point of view.

Methods

Here we investigate variations in $\delta^{18}\text{O}$ and $\delta^{13}\text{C}$ of Mesolithic archaeo-malacofauna (*Pila* sp.) found in Central Sudan (2) at high-resolution intervals along the growth axis of shell. Furthermore, in order to correctly interpret the data on the fossil specimens and validate the use of the molluscs in paleoclimate studies, modern molluscs were collected from two locations along the White Nile valley.

Results

Comparison of $\delta^{18}\text{O}$ and $\delta^{13}\text{C}$ in archaeological shell and in modern specimens revealed significant differences. The $\delta^{18}\text{O}$ Archaeo ranges from $-10,97\text{‰}$ to $-6,23\text{‰}$ whereas $\delta^{18}\text{O}$ modern ranges from $-1,17\text{‰}$ to $+5,13\text{‰}$ suggesting climate change. Moreover, the lower $\delta^{13}\text{C}$ values for modern shells suggest a variation of carbon source in the aquatic system.

Conclusions

This study demonstrates that a drying process occurred over time along the Nilotic area. The low oxygen isotope values of Mesolithic samples indicate significantly less evaporation of the Nile water and/or a different rainfall amount and seasonal distribution in comparison to the current river. (3)

Novel Aspect:

This study provides the first application of the use of *Pila* sp. as a proxy for paleo-climatic information.

Keywords: cultural heritage, restoration, extraction, separation, mass spectrometry

Introduction:

The molecular characterization of historical artifacts is becoming an increasingly important aspect for cultural heritage [1]. Nowadays all the developments in extraction, separation and analytical methodologies can be helpful for challenging tasks, such as the chemical reconstruction of the natural compounds used by artists [2]. Any of the informations about the chemical composition of binders, oils, varnishes, etc., play a fundamental role both for restoration purposes and for the reconstruction of historical informations.

Methods:

The first step of our workflow is represented by an ammonia extraction of chemical compounds from two micro samples from the preparative layers and two microsamples from external layers of a wooden sarcophagus, which can be dated towards beginning of the XXIIInd Dynasty.

The methodology used for the characterization of extracted molecules are GC-MS (for monosaccharides and lipids analysis) and high-resolution MS (for proteins identification).

Results:

According to extraction procedure, we divided analytes in three categories: monosaccharides, lipids and proteins. Monosaccharides analysis led to the identification of binders extracted from all the layers. We identified Galactose, Glucuronic Acid, Ramnose and Arabinose, which are the main constituents of Arabic gum.

We could identify palmitic, stearic and oleic acid. The relative ratio of identified fatty acid is for sure affected by aging; their co-presence though is compatible with the putative presence of egg [3]. This hypothesis is strengthened by proteins identification. We could in fact identify in the external layers (the ones connected with the decoration of the sarcophagus) Lysozyme, one of the most abundant protein in egg.

Altogether, our data suggest that the painting techniques adopted was tempera.

Moreover, in the preparative layers, we could unambiguously identify Collagen; the presence of this protein can be related to the technique used for the building of the sarcophagus itself.

Conclusions

Numerous approaches are focused on single classes of compounds; some others [4] suggest the possibility of using a single extraction procedure followed by different analytical strategies. The rationale at the basis of our approach starts from the latter assumption. However, the interesting aspect of our approach is represented by the heterogeneity of unambiguously identified molecules, which led to the characterization of the different layers sarcophagus.

Novel Aspect:

The ingenuity of our methodology relies in the use of powerful analytical methodologies (i.e. high resolution MS) in the workflow thus improving the quality of obtained results.

Keywords: Theriac, composition, analysis, mass spectrometry

Introduction

Theriac, a thick sticky liquid medicine, until the mid 18th century was regarded as a universal panacea and was used to treat infectious diseases or poisonings. Theriac contained up to seventy different often exotic ingredients. The production of a proper Theriac took months and it was supposed to be left to mature for years [1] [2]!

Here the first approach to study the composition of an ancient Theriac sample from the "Spezieria di Santa Maria della Scala" (Rome) is presented.

Methods

Different chromatographic methods principally based on mass spectrometry techniques have been used to achieve a comprehensive Theriac characterization. The organic polar compounds were analyzed by UHPLC-qTOF-MS, in high resolution (2GHz). The volatile organic compounds were analyzed by means of GC-TQ-MS, using Head Space sampling or direct injection after sample derivatization with BSTFA/Pyridine. The metal part of inorganic compounds was analyzed by means of ICP-MS, the anionic part by IC-ConD.

Results

Very sharp chromatographic fingerprints of the Theriac sample have been taken. After having studied molecular mass characteristic and the fragmentation pattern of the various molecular species, by matching data with a "in-house" specific library, different compounds have been identified. In several cases high resolution accurate mass has been crucial. Obviously, the identification step has been very intriguing! Some marker compounds specific of medicinal plants have been correctly identified but many others are very difficult to recognize, as a consequence of the transformations due to Theriac preparation as well as to the aging of the sample. Afterwards, using external standard regression curves, the identified compounds have been quantified. Glucose and fructose, typically should be from honey, are the most abundant compounds, followed by glycyrrhizin, and salicylic acid. Atypical flavonoid liquiritin has also been detected, confirming the presence of liquorice. Calcium, potassium, sulfur and iron at concentrations of 0.1-0.5% (w/w) have been found, while chloride has been found at a low value.

Conclusions

More than thirty organic compounds and twenty elements have been identified, but further studies have to be done to better elucidate the composition of Theriac. The preliminary results showed how potent is the analytical approach used. By means of data obtained from a comprehensive characterization it is possible to suggest the presence of interesting ingredients in the old Theriac sample. The rational study of Theriac is a challenge but can be convenient to suggest new solutions for the modern human beings health care.

Novel Aspect

For the first time the composition of Theriac has been investigated at a molecular level using different mass spectrometry techniques, including HR-MS.

Keywords: Paleoproteomics, Mass Spectrometry, Cultural heritage, Protein Degradation, Ancient proteins

Introduction:

In search of markers for protein aging, we use the singular case of collagen from human bones from the excavations sites in Pompei, Herculaneum, Oplonti, S.Paolo Belsito, and Scalandrone Bay as control reference site. Deamidation of glutamine and asparagine is considered as aging molecular marker [1]. Moreover, other chemical modifications that are a likely signature of diagenetically derived alterations were considered.

Methods:

Specific proteomic protocols and different sample preparation were adapted to improve protein extraction and sequence coverage yields. The analyses were performed with the use of LC-MSMS. The exploitation of bioinformatic tools such as the error tolerant search in the Mascot suite [2] or the open mass modification utility in the Protein Prospector database search [3] were used for data processing in search of unexpected chemical modifications.

Results:

Ancient human bones (100) have been analyzed by proteomic approach following an adapted protocol based on the already developed one reported in [4]. From the raw LC-MSMS data and the use of Mascot platform, COL1 α 1 and COL1 α 2 were detected with a protein sequence coverage up to 80% in all the samples. All the deamidation sites were listed and their occurrence and deamidation state were statistically evaluated. The statistical analysis is suggestive of the most detected positions, that were considered the best candidates for the quantification of the deamidation level as protein's aging biomarkers in ancient human bones. Similar approach was used to evaluate also other chemical modifications.

Conclusions:

The analysis of the deamidation in the different samples suggests that the deamidation level in the samples from Pompei is low in respect to an extensive deamidation observed in the samples from Herculaneum and Scalandrone (our control reference). Our preliminary results seem to suggest that the low deamidation level could be linked to the peculiar burial conditions and to the "lower" temperature experienced by Pompei inhabitants in comparison to Herculaneum ones.

Novel Aspect:

This set of samples constitutes an extraordinary test case to evaluate deamidation and other chemical modifications as molecular signatures of protein aging.

Keywords: organic residue analysis, tartaric acid, wine, gas chromatography – mass spectrometry

Introduction:

Wine was an important product in the Western Mediterranean. Organic residue analysis was carried out on samples from pottery and a production structure in four pre - Roman archaeological sites in Italy and Spain, aimed at identifying the presence of wine. At most of the sites the production and consumption of wine is compatible with other archaeological evidence (mainly botanical evidence).

Methods:

Samples were recovered both from the archaeological materials and the earth of the stratigraphic unit to which it belonged, in order to check possible contamination.

The samples were mechanically cleaned in the laboratory and powdered.

Samples were extracted following the extraction method proposed by Pecci et al. [1], derivatized and analysed by gas chromatography coupled with mass spectrometry.

Results:

The analyses indicate the presence of tartaric acid in some of the analysed pottery samples from the different sites in Italy and in a sample from an Iberian production structure at Coll del Moro (Catalunya, North East Iberian Peninsula).

Although other fruits, for example tamarind, may contain tartaric acid [2], on the basis of the residues identified [1,3,4], and the presence of grape pips or pollen in the area it is possible to suggest that wine or its derivatives was in contact with the sampled materials.

The fact that no tartaric acid was identified in control samples, nor in some of the archaeological samples indicates that it does not derive from post depositional contamination.

In some of the samples also other acids such as succinic, fumaric, isocitric, malic and maleic acids, are present. Although they are not exclusive markers of wine, they are present in the beverage.

Conclusions

The data in our possess allow to confirm the hypothesis on the production of wine in the Iberian structure at Coll del Moro where abundant grape pips had been identified and the storage and/or consumption of wine or its derivatives at Etruscan and Bronze Age sites in Italy.

Novel Aspect:

Investigation on wine production and consumption, not only in ceramic vessels, but also in a pre-Roman production structure.

Keywords: LC-ESI-Q-ToF, Triarylmethane dyes, accelerated ageing, photo-oxidation, degradation pathways

Introduction:

Since mid-19th century, triarylmethane dyes were widely used for ink production and dyeing textiles [1]. These dyes, characterized by bright hues, are one of the first classes of synthetic dyes produced and marketed [2]. Nevertheless, their analysis is highly complicated due to their poor light fastness and their complex composition constituted by homologous species, often differing only for the presence or position of the same substituent on the aromatic rings.

Methods:

Liquid Chromatography coupled with tandem high-resolution mass spectrometry (LC-ESI-Q-ToF) or Diode Array and Fluorescence detectors (HPLC-DAD-FD) were used to separate and identify the several miscellaneous components contained in standard triarylmethane dyes, unaged and aged wool yarns and historical samples of dyed specimens. The samples were pre-treated using an oxalic acid solution to obtain the highest extraction yields for all the components.

Results:

The analysis of standards and reference materials by LC-ESI-Q-ToF allowed us to identify specific fragmentation pathways for several triarylmethane dyes such as Fuchsine, Crystal/Methyl Violets, Methyl Blue and Diamond Green. Both positive and negative modes and collision energies were tested to optimize the MS conditions for each dye and to obtain complementary information on fragmentation pathways.

The analysis of wool yarns dyed with triarylmethane compounds, artificially aged for different time intervals, allowed us to investigate and highlight different degradation pathways, through the identification of kinetic trends of different compounds in relation to the accelerated aging times. HPLC-DAD-FD was fundamental to provide further information on the minor compounds. Analysis of selected historical samples from 19th C dyeing manuals from Glasgow's 'Dye-versity' project [3] highlighted the compositional complexity of early synthetic dyes, and revealed several isomers and different profiles depending on desired hues.

Conclusions:

The proposed analytical method, integrating HPLC-ESI-Q-ToF and HPLC-DAD-FD analyses, allowed the full characterization of the references and historical samples under study and to hypothesize the degradation pathway of several triarylmethane compounds. The detection of specific fragmentation patterns enabled distinction between different classes of compounds, while that of specific fragment ions distinguished isobaric species belonging to the same series.

Novel Aspect:

We used for the first time a solid silica core analytical column coupled with HRMS to fully characterize minor and degradation components in reference and historical samples.

University of Lille (1)

Keywords: Cultural Heritage, Top down proteomics, Lipidomics, Metabolomics, Crosslinkings

Introduction:

Natural organic polymers represent the main organic components of the most of the historic samples. However Cultural Heritage material is challenging to study[1]: (i) The sample size typically obtained from a museum- or archaeological artefact is on the order of tens of micrograms. (ii) Most pieces are made of more than one material, each containing many organic/inorganic components. (iii) The material is constantly evolving due to ageing or external conditions.

Methods:

Top down experiments are used for protein studies; particular focus is given to sample preparation fitted to handle trace compounds. Soft depolymerization and HRMS analysis of multimers are used for lipids; Kendrick and Van Krevlen plotshelp to decipher the high complexity of spectra. Polysaccharide analysis combines filter aided sample preparation and nanoLC-HRMS analysis of fingerprints; methods are fitted both to linear and highly branched structures

Results:

This conference will show how organic chemistry combined with HRMS(orbitrap, FT-ICR) address the current challenges for analysis of trace amounts of Cultural Heritage samples. For example structural elucidation of biopolymers of unknown structures and/or their chemical modifications will be shown (e.g. historic art paintings and watercolors [2]). Focus on protein crosslinkings inside paintings will be done. Another example is the combination of soft depolymerization experiments and HRMS to unravel the 3D networks formed by insoluble lipidic films (e.g. oil-paintings). The very first application of top down approach to the study of protein remains in archaeological ceramics will show impressive results both in terms of protein sequence coverage (up to 100% coverage) and identified sequences that show particular degradation patterns. The conference will be illustrated by the study of various outstanding samples from art but also from archaeological and paleontological sciences from the most famous museums and institutes of the world.

Conclusions:

Applied to the study of artworks, the chemical decoding of the organic molecular network has a major impact on the understanding of painting formulation, biopolymers degradation and it helps in the survey of preservation conditions. Considering archaeological samples, the information obtained by the proposed methods provide new historical insights; for example it points out ancient methods for food processing.

Novel Aspect:

Deciphering Art and Cultural Heritage natural polymers using unexplored developments in chemistry and top down approaches to chemically decode the organic molecular network

421 - A COMBINATION OF FAIMS SEPARATION WITH SYNCHROTRON UV-PHOTO ACTIVATION FOR THE TANDEM MS ANALYSIS OF SYNTHETIC POLYMERS

Véronique Legros (1) - Ines Aloui (1) - Alexandre Giuliani (2) - William Buchmann (1)

LAMBE (CNRS-UEVE-CEA-UCP, UMR8587), Université Paris-Saclay (Univ Evry), Evry (1) - Synchrotron SOLEIL, UAR1008, CEPIA, INRA, Saint-Aubin (2)

Keywords: synthetic polymers, electrospray, tandem mass spectrometry, UV photo-activation, field asymmetric waveform ion mobility

Introduction:

Mass spectrometry (MS) of synthetic polymers most often uses single stage MS alone but characterization of polymers can remain ambiguous without complimentary tandem MS experiments [1,2]. UV-photo-activation creates new opportunities for the characterization of polymers [3,4]. The goal of this work was to evaluate the performances of wavelength-tunable UV photo-activation of synthetic polymers, combined or not with field asymmetric waveform ion mobility.

Methods:

Precursor ions produced by ESI (positive mode) from a variety of commercial polymers (polyethylene glycol (PEG), polymethylmetacrylate (PMMA), and polysiloxane (PDMS), Sigma-Aldrich), have been stored in a linear ion trap (LTQ Thermo), and then submitted to UV synchrotron irradiation during a variable time period and over a range of wavelengths. For the highest mass polymers, UV activation was combined with field asymmetric waveform ion mobility spectrometry.

Results:

By applying suitable compensation voltages in FAIMS, it was possible to specifically isolate certain $(M+n\text{Cation})^n+$ adducts produced by ESI and to avoid the overlapping problems. The selected ions could be trapped in a linear ion trap, and then submitted to UV synchrotron irradiation during a variable time period, at different photon energies. For example, the activation of $[\text{PEG}95+4\text{Na}]4+$, produced different effects as a function of the activation method (low energy CID vs UV-Photoactivation 16eV, 10s). As low energy CID only led to the loss of one sodium cation according to the equation $[\text{PEG}95+4\text{Na}]4+ \rightarrow [\text{PEG}95+3\text{Na}]3+$, the UV irradiation $[\text{PEG}95+4\text{Na}]4+$ led to a wide series of fragment ions. Polydimethylsiloxanes also gave net differences. Series of UV-photoactivation mass spectra, recorded with variable photon energies (6 to 24eV), showed that the fragmentation started with photon energies slightly above the supposed ionization potential of the oligomer. Important fragmentations were observed at 16eV.

Conclusions:

In this work, we demonstrated the potential of UV photo-activation of ions, produced from polymers and stored in a linear ion trap. The most useful UV wavelengths were identified. The use of FAIMS made it possible the selection of certain precursor ions that were difficult to isolate (particularly useful for highly charged ions). UV photo-activation could lead to different and useful fragmentations compared to the low energy CID of the same precursors.

Novel Aspect:

The use of synchrotron UV beam for tandem MS experiments from polymers and the combined use of ion mobility for multiply charged precursor ions selection.

268 - "ADVANCED KENDRICK MASS DEFECT ANALYSIS": A TOOLKIT

Thierry Fouquet (1) - Robert B. Cody (2) - Takaya Satoh (3) - Hiroaki Sato (1)

National Institute of Advanced Industrial Science and Technology (AIST), Research Institute for Sustainable Chemistry (ISC), Tsukuba (1) - JEOL USA, JEOL USA, Peabody (2) - JEOL, JEOL, Akishima (3)

Keywords: Data processing, Kendrick mass defect, resolution-enhanced analysis, high-resolution mass spectrometry, polymers

Introduction:

Developed in the eighties from a founding change of mass scale proposed by Kendrick fifty years ago, the Kendrick mass defect (KMD) analysis has been advantageously used for an easy graphical interpretation of high-resolution mass spectra from carbonaceous samples. Recently extended to the processing of data from polymers [1], the traditional KMD analysis is now enjoying a new lease of life with the introduction of several concepts for an unprecedented visualization experience.

Methods:

Regular Kendrick masses (KMs) are $KM(R) = m/z * \text{round}(R)/R$ with m/z the accurate mass-to-charge ratio and R the exact mass of a repeating unit (IUPAC scale). "Advanced" KMs compiling a "resolution-enhancement" [2-4] and a "charge-dependence" [5] are $KM(R,Z,n) = Z * m/z * (\text{round}(R) + n)/R$ with n and Z being positive/negative integers (calculations using spreadsheet or dedicated programs). KMDs and the "remainders of KMs" [6] are $KMD = \text{round}(KM) - KM$ and $RKM(R) = KM / \text{round}(R) - \text{floor}(KM / \text{round}(R))$.

Results:

Beyond the simplest KMD plot (KMDs. vs. m/z) from the mass spectrum of a singly charged homopolymer, a regular KMD plot from multiply charged (co)polymer ions displays the charge state distribution instantly via an isotopic split. To overcome possible isotopic misalignments, a new "charge-dependent" KMD plot clusters the ion series at a chosen charge state into a single cloud facilitating their filtering and assignment.

The new resolution-enhanced KMD plot strikingly improves the separation of ion series taking full advantage of the spectral width. Using well-fitted parameters, mass spectra of copolymers become a set of elliptic clusters discriminating ions by their end-groups and co-monomeric content. Terpolymers are also easily turned into a series of copolymeric clusters in a first resolution-enhanced plot, further filtered and re-analyzed via a second resolution-enhanced KMD plot or a "degree of polymerization" plot.

The new "remainders of KMs" allow mass spectral data of low mass accuracy such as MALDI-TOF/TOF spectra to be turned into informative plots (RKMs. vs. m/z).

Conclusions

The "Advanced KMD analysis" broadens the scope of applications of a very simple data processing tool to low or high mass accuracy data, to singly or multiply charged ions and to homo- / co- / terpolymer ions with one appropriate KMD plot in every case. With a rationalized approach to help users choosing the well-fitted parameters, it may be now routinely used for a graphical and highly visual exploration of mass spectral data.

Novel Aspect:

From the historical definition of a Kendrick mass ($KM = m/z * 14/14.0157$) to a resolution-enhanced and charge-dependent KM, we propose a deeply rejuvenated KMD analysis.

327 - POTENTIAL OF LIQUID EXTRACTION SURFACE ANALYSIS FOR MASS SPECTROMETRIC EVALUATION OF SAFETY AND FUNCTIONALIZATION OF POLYMER FOOD PACKING MATERIALS.

Ambre Issart (1) - Simon Godin (1) - Hugues Preud'homme (1) - Ahmed Allal (1) - Joanna Szpunar (1)

IPREM, UMR 5254 CNRS- UPPA, Pau (1)

Ambre Issart, Simon Godin, Hugues Preud'homme, Ahmed Allal and Joanna Szpunar
IPREM- UMR 5254 CNRS- UPPA – Université de Pau et des Pays de l'Adour – Hélio parc – 2 av. du président, Angot
64053 Pau Cedex, France.

Keywords: Surface analysis, liquid extraction surface analysis, polymers additives, degradation products, food packaging.

Introduction:

The migration of constituents of polymer packaging into food has two aspects. Additives, post-polymerization or degradation residues, Non-Intentionally Added species (NIAS) are a risk for the consumers but, at the same time, “intelligent” packaging releasing natural antioxidants improve food shelf life. Hence, it is essential to develop methods to evaluate the safety and functionalization of polymer food packaging.

Methods:

LESA-MS (liquid extraction surface analysis mass spectrometry) combined with nanoESI ionisation was optimized for the direct analysis of polymer packing materials. The method does not require any sample preparation, is fast, eco-friendly and highly reproducible. It appears to have many advantages over other direct analysis techniques and is well adapted to the polymer analysis.

Results:

The method was successfully applied to follow the release of oligomers from additive-free low-density polyethylene (LDPE) during recycling. The increasing number of cycles resulted in the gradual appearance of clusters of species with m/z separated by 14 Da (the monomer) thus proving polymer degradation. LESA-MS analysis also allowed the detection of a series of species corresponding to residual polyethylene oxide - a plasticizing additive used for PET synthesis or recycling. The efficiency of the natural antioxidants (vitamin E and C) on the polymer stabilisation was proven by the comparison of the LESA-MS spectra of pure and functionalized LDPE. Moreover, the release of these additives (meant to protect food packed using this “intelligent” material) could be quantified using laboratory prepared solid state standards.

Conclusions

LESA-MS was optimized to study the release of low molecular species from polymer food packing films and the monitoring of degradation products during recycling of additive-free LDPE and migration of antioxidants from functionalized LDPE. The use of solid state standards made possible quantitative monitoring of the antioxidant release and thus quality control of “intelligent” packaging.

Novel Aspect:

LESA-MS is a fast and reliable ecological tool with a high potential for the evaluation of safety and functionalization of polymer food packing films.

Keywords: ESI-MS, polyisobutylenes, adduct ions, broadband MS/MS, survival yield

Introduction:

Polyisobutylenes (PIBs) is an important class of non-polar hydrocarbon polymers produced by cationic polymerization of isobutylene [1]. Owing to their outstanding chemical resistance and biocompatibility, PIBs can be applied in many fields spanning from coatings to various biomaterials [1]. In this lecture, we present a method based on the adduct ion formation of PIBs with anions [2], called anion-attachment method [3] for the characterization of low molecular weight PIBs using electrospray ionization mass spectrometry (ESI-MS).

Methods:

Polyisobutylenes with different molecular weights and end-groups were synthesized by living cationic polymerization. Measurements were performed with a MicroTOF-Q type Qq-TOF MS instrument (Bruker Daltonics, Bremen, Germany). The critical (activation) energies for the dissociation of [PIB+anion]⁻ into PIB + anion were determined by means of broadband MS/MS measurements using the survival yield (SY) method and supported by high-level quantum chemical calculations (DFT).

Results:

The [PIB+anion]⁻ adducts were generated using electrospray ionization (ESI) by adding the corresponding salts to the PIB solution. It was found that independently of the end-groups, presence or absence of aromatic initiator moiety, the PIB derivatives investigated in this study were capable of forming adduct ions with various anions such as NO₃⁻ and Cl⁻ ions, thus allowing the characterization of these compounds using the negative ion mode of ESI-MS. The dissociation of the [PIB+anion]⁻ adduct was shown to yield neutral PIB and charged anion and that the collision energy necessary to obtain 50 % dissociation of the precursor ion (CE50) changed linearly with the number of isobutylene units. Furthermore, it was found that the binding enthalpies of the halide ions to PIB, determined by using broadband MS/MS and the SY methods, increased in the order of I⁻ < Br⁻ < Cl⁻ < F⁻. This order is in line with that obtained by DFT calculations and correlate with the size of the halide ion.

Conclusions:

The anion-attachment under ESI conditions proved to be an appropriate method for ionizing the non-polar polyisobutylene derivatives. Furthermore, applying broadband MS/MS and the SY method information on the strength of the interaction between the respective anion and the non-polar polymer chain can be gained.

Novel Aspect:

Our work has revealed that polymers even with high hydrophobicity can be effectively characterized by ESI-MS which is known to be mainly capable of investigations of polar compounds.

1128 - STUDY ON THE SYNTHESIS AND CHARACTERIZATION OF SURFACE ACTIVITIES OF HYDROPHILIC DERIVATIVES OF β -SITOSTEROL

JongChoo Lim (1)

Dongguk University, Department of Chemical and Biochemical Engineering, Seoul (1)

Keywords: β -Sitosterol, Hydrophilic derivatives, Poly(ethylene glycol), Surface activity

Introduction

Phytosterol means all the alcohol compounds with steroid moiety found in higher plant life and at least 44 sterols have been identified [1]. The most abundant phytosterol is β -sitosterol (24-ethyl-5-cholestene-3-ol) which has the greatest potential for the production of steroidal drugs, cosmetics for healing effects on damaged skin and anti-inflammatory effects, and food ingredients that function as cholesterol-lowering agents. However, hydrophobic and lipophobic properties of β -sitosterol have prevented its widespread application.

Methods

A hydrophilic phytosterol derivative (HPS) was prepared by coupling a hydrophilic matrixcarboxyethyl- β -sitosterol (CES) to poly(ethylene glycol) (PEG), where CES was prepared by reacting β -sitosterol with succinic anhydride. The chemical structure and the distribution of isomers of HPSs were investigated by H-NMR and Maldi-Tof respectively. Surface activities of HPSs were also measured and discussed as a function of molecular weight of the parent PEG.

Results

DS (degree of substitution) was calculated from $^1\text{H-NMR}$ data and the DS values of HPSs (product having one sterol moiety at one end of PEG) were close to 1.0 and 2.0 for Di (product having two sterol moieties at both ends of PEG). From the Maldi-Tof spectra of PEG, HPS and Di with different chain lengths, each peak has intervals of 44, which is equivalent to the mass of monomeric unit of PEG, and all spectra shows a narrow range in molecular weight. Spectra of HPSs displays identical pattern with those of corresponding PEGs, except that the molecular weight (m/z) of HPS shifts to the higher m/z to the extent of approximately 500 m/z compared to that of PEG. Spectra of Di also displays a displacement to the higher m/z to the extent of approximately 1,000 m/z compared to that of PEG. These results strongly indicate that the HPSs prepared are pure mono-type derivatives. The solubility of HPS in water increased as the molecular weight of the parent PEG increased. However, based on the β -sitosterol moiety in HPS, HPS-1000 prepared from PEG 1000 showed the highest solubility.

Conclusions

Three kinds of HPSs were synthesized from PEG by reacting CES with 5 molar excess of corresponding PEG and removing unreacted PEG by extraction. All HPSs were soluble in water and found to have excellent surface activity and the same cholesterol-lowering effect as β -sitosterol. Thus, the potential application of HPS as a surface active material with biological activities of β -sitosterol such as healing effects on damaged skin or anti-inflammatory effects is expected.

Novel Aspect

New types of HPSs having cholesterol-lowering effects was synthesized by coupling β -sitosterol with a hydrophilic matrix to improve water solubility of β -sitosterol.

755 - MASS-REMAINDER ANALYSIS (MARA): TO UNDERSTAND MASS SPECTRA OF COPOLYMERS

Tibor Nagy (1) - Ákos Kuki (1) - György Deák (1) - Lajos Nagy (1) - Miklós Zsuga (1) - Sándor Kéki (1)

University of Debrecen, Department of Applied Chemistry, Debrecen (1)

Keywords: Mass Remainder Analysis (MARA), copolymer, compositional drift, end group

Introduction:

The characterization and the assignment of individual peaks of copolymers are great challenges in the mass spectrometry owing to the huge number of m/z peaks. The Kendrick mass defect (KMD) analysis [1-2] partly solved this issue with limitations such as the high resolution and high accuracy. However, our developed method that is based on the mass remainder after dividing by the exact mass of one of the repeating unit works with less limitations.

Methods:

Measurements were carried out with an Autoflex type MALDI-TOF MS instruments (Bruker Daltonics, Bremen, Germany). DHB (2, 5-dihydroxybenzoic acid) and dithranol (1,8,9-anthracenetriol) were used as matrix, while ionizing agents were sodium trifluoroacetate and silver trifluoroacetate (solvents: MeOH, THF). Ethylene oxide- propylene oxide triblock copolymers were investigated. Thioester type agent was used for the RAFT polymerization of polystyrene [3].

Results:

A new data handling method, the Mass-Remainder Analysis (MARA), was developed that use the mass remainder values for the identification of the peaks in copolymer mass spectra and correct the intensities with the defects originated overlaps and isotopic peaks. The mass remainder (MR) values are calculated by division of the measured m/z values by the exact mass of one of the monomer unit. The polymer chains differ only in the number of monomer unit (used for division) have the same MR values. Therefore, these are suitable for grouping, classifying and identifying the copolymers with different composition. For the assignation a defined mass list is used therefore, the deisotoping of the spectrum is also done during the assignation step.

Then in the next step the intensities are corrected. The intensities for the assigned peaks and their isotopologues are calculated and subtracted from the measured ones if it is necessary. Furthermore, the intensities of the identified peaks are corrected with the intensity of corresponding isotopologues.

Conclusions

It was demonstrated that our method was capable of characterizing ethylene oxide- propylene oxide copolymers with higher molecular weight, to determine the number average-, weight average molecular weights, the bivariate distribution and the composition drift [4].

Furthermore, polystyrene was identified to investigate the polymerization mechanism of reversible addition-fragmentation chain-transfer (RAFT) polymerization.

Novel Aspect:

The Mass Remainder Analysis (MARA) is a new method which capable of characterizing higher molecular weight copolymers with higher efficiency than previously used Methods:

359 - COMPOSITIONAL ANALYSIS OF HIGH MOLECULAR WEIGHT BIODEGRADABLE POLYMERS BY HIGH-RESOLUTION MALDI-TOFMS COMBINING ON-PLATE DEGRADATION WITH RESOLUTION-ENHANCED KMD ANALYSIS

Sayaka Nakamura (1) - Thierry Fouquet (1) - Hiroaki Sato (1)

National Institute of Advanced Industrial Science and Technology, Research Institute for Sustainable Chemistry, Tsukuba (1)

Keywords: on-plate degradation, resolution-enhanced KMD analysis, high-resolution MALDI-TOFMS, copolymer, polymer characterization

Introduction:

High-resolution mass spectrometry is notoriously limited to the low mass range (<3 kDa) while industrially important polymers are of high molecular weight (typically >10 kDa). We propose a “on-plate degradation” as an in situ sample preparation to reduce the molecular weight of polyesters using an alkaline solution. The low molecular weight degradation products are then amenable to a mass-analysis taking full advantage of the resolving power of the analyzer.

Methods:

Poly(3-hydroxybutyrate-co-3-hydroxyvalerate) (P(3HB-co-3HV)) with >100 kDa has been chosen as a reference aliphatic polyester. A sample solution is deposited on the MALDI target plate followed by a drop of the isotope labeled NaOH-CD₃OD. Removing the excess of alkaline solution with water, the matrix solution is finally added to make co-crystal. MALDI mass spectra are recorded using a high-resolution JMS-S3000 spiral TOF mass spectrometer (JEOL, Japan).

Results:

Following the on-plate degradation, the mass analysis of P(3HB-co-3HV) reveals a complex fingerprint in the low mass range (<3 kDa) hence validating the degradation procedure. However, the mass difference between HB / HV repeating units and between carboxyl/methyl ester chain-ends are identical at 14 Da (CH₂ moiety). To distinguish the variation of HB/HV composition from the variation of end-groups, the peaks associated with the methyl ester termination are shifted of 3 Da via the on-plate degradation using the isotope labeled NaOH-CD₃OD solution. Instead of a time-consuming peak-picking and manual assignment of data, ion series are conveniently filtered in a KMD plot computed from the complex mass spectrum using our innovative resolution-enhanced KMD analysis [1]. Peak lists are finally turned into a “degree of polymerization plot” [2] displaying the discrete co-monomeric composition at first glance. The average HV/HB content also computed from the plot is eventually in good agreement with the reference value provided by the supplier.

Novel Aspect:

The compositional analysis of a high-molecular weight polyester is made possible by combining in situ isotope labeled degradation with an innovative data processing.

301 - MS/MS READING OF POLYURETHANE BARCODES USED AS TAGGANTS IN POLYMERIC MATERIALS

Salomé Poyer (1) - Supansa Chimjarn (1) - Denise Karamessini (2) - Jean-François Lutz (2) - Laurence Charles (1)

Institut de Chimie Radicalaire, Aix-Marseille Université, Marseille (1) - Institut Charles Sadron, Université de Strasbourg, Strasbourg (2)

Keywords: Sequence-defined polymers, tandem mass spectrometry, molecular barcodes

Introduction:

Advanced polymerization techniques allow production of synthetic chains with a perfect control of the molecular structure and of the comonomeric sequence [1]. One key application of such sequence-defined polymers is information storage: a message can be chemically encoded in the chain by using a set of two comonomers and can be read using tandem mass spectrometry (MS/MS)[2]. These polymers can be used as molecular barcodes in anti-counterfeiting applications [3].

Methods:

Polyurethane (PU) oligomers were synthesized as previously described [2]. Reading of different sequence-defined polyurethanes was evaluated in electrospray tandem mass spectrometry from deprotonated ions using a Q-TOF instrument. Extraction procedures of PUs were optimized as a function of the nature of the membrane.

Results:

Sequence-defined polyurethanes (PU) are composed of carbamate-based comonomers in which the coded moiety is a small alkyl segment that contains (1-bit) or not (0-bit) methyl substituents. These are extremely easy to read in the negative mode due to i) single cleavage of the carbamate bond in each monomer and ii) unique location of the negative charge at the α chain-end. As a result, the message coded in these PU chains can easily be read by MS/MS as the distance between two fragment ions corresponds to the mass of one or the other comonomer. Due to such a high MS/MS readability, PUs were tested as molecular barcodes for the labeling of different membranes made of PS, PVC, PET and PVA. Optimization of the PU extraction step for each polymeric substrate permitted to reach detection limits in the ppm range for MS/MS sequencing. Moreover, the tagging homogeneity of membranes was evaluated from ESI-MS experiments.

Conclusions:

Sequence-defined PUs were used as molecular taggants for the labeling of various polymeric materials. Thanks to the renowned high specificity and sensitivity of MS/MS, taggants were recovered and identified even at very low concentration levels. Selectivity of taggant extraction from the membranes prevented any matrix effects during the electrospray ionization step, allowing direct sample introduction and hence fast reading of the molecular code.

Novel Aspect:

PU barcodes were successfully recovered and identified by MS/MS from polymeric materials in which they were used as anti-counterfeiting labels

Keywords: SALD ICP MS, dried droplet, polymer treatment, cold plasma, DCSBD

Introduction

Substrate-assisted laser desorption inductively coupled plasma mass spectrometry (SALD ICP MS) is a technique for inorganic analysis of liquid samples of sub-microliter volumes in the form of dried droplets on suitable polymer substrates.[1] Here we study influence of substrate surface aging effects on analysis of cadmium and indium in samples prepared on polymer substrates treated by diffuse coplanar surface barrier discharge (DCSBD)[2].

Methods

A DCSBD device (RPS400-Roplass plasma system 400 W, Roplass, Czech Republic) was used for treatment of polymer substrates at 400 W. Contact angle of the deposited droplet with Cd and In was measured using See System E, Advex Instruments, Czech Republic. Samples were desorbed in ablation cell (UP213, New Wave Research, USA) with a 213-nm laser, and content of ¹¹¹Cd and ¹¹⁵In analyzed by a quadrupole ICP mass spectrometer (7500ce ICP-MS, Agilent, USA).

Results

Four polymer substrates (polyethylene terephthalate glycol, polyethylene terephthalate, polycarbonate and styrene-acrylonitrile) were exposed to cold plasma for 1, 5 and 10 s. Droplets of Cd and In solutions in citrate, biological culture medium and cell lysate were deposited in five replicates immediately, 1, 3, 6 days, 1, 3 or 6 months after the treatment on the polymer substrates. Contact angles of droplets as well as size of the generated stains were characterized. Typically, a longer treatment of surface substrate resulted in lower contact angle. The stain diameter gradually decreased with time after treatment, sometimes showing a maximum at deposition 1 – 6 days after the treatment. Also, the longer the surface treatment was, the slower return to the original state (high value of contact angle) was observed. Citrate concentrations above 5 mM resulted in significant drop of ¹¹¹Cd intensity. Using In as an internal standard for determination of Cd alleviated the observed matrix and surface related phenomena and reduced RSD by a factor of ~2.

Conclusions

Aging of surface treated by DCSBD has been monitored using physical methods and related to SALD ICP MS response of samples prepared on the surface. The initial experiments show significant changes in contact angle, stain size and SALD ICP MS response. Using an internal standard, RSD values were reduced to <10 %. A half-year monitoring is under progress; a procedure for surface treatment and sample preparation will be recommended after completing the entire set of analysis.

Novel Aspect

Substrate surface treatment by DCSBD for dried droplet preparation. Systematic characterization of surface aging and its consequences for SALD ICP MS reproducibility.

350 - REMAINDERS OF KENDRICK MASS: KEEPING THE BEST OF A KENDRICK MASS DEFECT ANALYSIS FOR LOW-ACCURACY MASS SPECTRA OF POLYMERS

Hiroaki Sato (1) - Thierry Fouquet (1)

National Institute of Advanced Industrial Science and Technology (AIST), Research Institute for Sustainable Chemistry, Tsukuba (1)

Keywords: low mass accuracy, Kendrick mass defect, Reminders, MALDI-TOF/TOF, polymers

Introduction:

The traditional Kendrick mass defect (KMD) analysis [1] is restricted to high-resolution mass spectrometry (low mass range, high-accuracy analyzers) as it evaluates the difference between rounded and exact m/z of polymer ions. The new resolution-enhanced KMD analysis [2,3] makes data in the high mass range or recorded with low-accuracy analyzers interpretable in a KMD plot but point alignment remains of low quality. The "Reminders of KM" (RKMs) overcome this issue.

Methods:

Data were recorded using a JMS-S3000 MALDI mass spectrometer (JEOL, Japan) equipped with a high-resolution spiral TOF, a linear TOF with oligomeric resolution and a TOF/TOF device (unitary resolution). A Kendrick mass (KM) is $KM = m/z * (\text{round}(R) + n) / R$ with R the exact mass of the repeating unit and n an integer ($n=0$ for a regular analysis, $n = \pm 1, 2, 3, \dots$ for a resolution-enhanced analysis). KMDs and RKMs are $KMD = \text{round}(KM) - KM$ and $RKM(R) = KM / \text{round}(R)$ or $(KM / \text{round}(R))$.

Results:

The RKM has been found to consist in the difference between a regular KMD and a resolution-enhanced KMD [4]. In other words, RKMs take advantage of the improved separation of ion series from the resolution-enhanced analysis while errors are cancelled from the subtraction to the regular analysis. Point alignments of homologous species in a new RKM plot (RKMs vs m/z) are perfectly horizontal with an unrivalled separation power. A RKM plot is compatible with a great variety of mass spectral data, starting from single stage mass spectrometry using a high-accuracy analyzer in the high mass range with isotopic resolution. Despite a decrease of the mass accuracy via a loss of resolving power, tandem mass spectra recorded using a TOF/TOF device with unitary resolution down to oligomerically resolved data recorded with a linear TOF are turned into clear RKM plots separating product ion series and distributions via horizontal alignments, respectively [5]. It greatly facilitates the visualization and assignment as well as any subsequent data processing.

Conclusions

The Reminders of Kendrick masses (RKMs) fit onto any sort of mass spectral data from polymeric samples as long as a minimal oligomeric resolution is reached. RKMs also greatly simplify the data processing of copolymeric data [6] and are totally compatible with multiple charging [4]. Linked to the Kendrick mass defects (KMDs) in a unified theory, they are now part of an "Advanced KMD analysis" available in commercial programs computing mass defect plots.

Novel Aspect:

Data from low-accuracy analyzers or in the high mass range are turned into informative compositional maps for an easy assignment of polymeric ion series.

Gabriella Francesca Schirinzi (1) - Marta Llorca (1) - Marinella Farré (1) - Damià Barcelò (1)

CSIC, IDAEA, Barcelona (1)

Keywords: polystyrene, microplastics, seawater, HPLC-APPI/HRMS

Introduction:

Marine anthropogenic litter is a severe environmental problem[1]. One of the main issues is the extreme stability of plastic wastes[2], which can generate nanoplastics (NPLs) and microplastics (MPLs)[3]. The analysis of these plastic particles should consider a combination of different analytical tools for the quantitative/qualitative analysis of MPLs/NPLs. These studies have been carried out using polystyrene (PS) as a representative polymer.

Methods:

A standard of PS (MW~1.2kDa) was solubilized in toluene at room temperature. For the mass spectrometric analysis, the performance of different ionisation sources (ESI, APCI, APPI, DART, MALDI) were optimized and assessed under negative and positive conditions. The chromatographic separation was achieved by size-exclusion with a GPC-column and using toluene as mobile phase. Mass spectrometric analyses were carried out using a QExactive mass spectrometer.

Results:

The optimal results were obtained by HPLC-HRMS equipped with atmospheric pressure photoionization (APPI) source operating in negative mode. The ionisation of PS resulted in a characteristic profile of signals, each of them separated by 104 m/z. The addition of a chromatographic separation with GPC column showed a good performance for qualitative and semi quantitative measurements in complex extracts. The APPI source was by far the most efficient ionisation source for this polymer in comparison with ESI and APCI.

Additionally, the potential of ambient air mass spectrometry techniques, such as DART, for the detection and identification of PS was assessed. The results suggested that MALDI and ambient air ionization techniques result in low ionisation efficiencies in comparison with APPI.

These results were combined with other different techniques such as TGA and FT-IR which are useful tools for the characterisation and identification of polymers but not to quantify them.

Conclusions:

GPC-LC coupled to APPI-QExactive is a suitable approach for the analysis of low molecular weight PS (< 4000Da) and applies to real seawater samples. However, the use of LC-APPI-HRMS should be complemented by other techniques such as TGA, DSC and FT-IR, which allow obtaining qualitative and semi-quantitative information about high-molecular weight polymers, which may also be present in the environment.

Novel Aspect:

The environmental analysis of polymers should rely on a protocol, which combines different types of techniques for the complete characterization of polymers.

47 - ANALYSIS OF DEGRADED POLYBUTYLENETEREPHTHALATE (PBT) PRODUCTS BY THERMAL DESORPTION AND PYROLYSIS COMBINED WITH DART-MS (TDP/DART-MS)

CHIKAKO TAKEI (1) - KENICHI YOSHIZAWA (1)

BioChromato, Application support, Fujisawa (1)

Keywords: Polybutylene terephthalate(PBT), evaluation of degradation degree, TDP/DART-MS

Introduction:(356 /400 characters)

Polybutylene terephthalate(PBT), a thermoplastic engineering elastomer, is widely used in a variety of industrial fields. Due to its industrial applications, it is important to evaluate its degradation degree to facilitate the product development process. The purpose of this work is to evaluate the degradation degree during the initial degradation stage which hasn't been detected by FT-IR, directly and rapidly.

Methods: (394 /400 characters)

A new and degraded product made by PBT were used as the samples. Thermal desorption and pyrolysis combined with DART-MS (TDP/DART-MS) was composed of a compact (Bruker) Q-TOF mass spectrometer equipped with a DART ion source (IonSense) and an ionRocket TDP device (BioChromato). The samples were cut to ~1 square millimeter and put into the sample pot. Mass spectra were measured as the samples were gradient heated from room temperature to 600 °C at a rate of 100 °C/min.

Results: (764 /900 characters)

Regarding from the total ion current gram(TIC), as adding the temperature gradient heating by TDP device, thermal desorption and pyrolysis reactions were detected, as shown by the change in intensity. Mass spectra of samples at ca. 220 °C (ca. the PBT melting point) were detected the pyrolysis products, monomer and dimer units of PBT. Comparing the extracted ion current gram(EIC) of the PBT monomers (m/z 221.08, $[C_{12}H_{12}O_4+H]^+$) between new and degraded product, there was a difference in the detected temperature and in the amount of PBT monomer. For the degraded sample, the PBT monomer was detected at a temperature much lower than the new sample. Moreover, for the degraded sample, it was detected at much lower than the pyrolysis temperature of the PBT (ca. 400 °C). Thus, the PBT monomer that was detected at much lower than the pyrolysis temperature of PBT was presumed a one of the degradation products.

Conclusions: (263 /400 characters)

TDP/DART-MS enables detection the initial degradation state which hasn't been detected by FT-IR. Moreover, TDP/DART-MS can be a useful method to evaluate the degradation degree using PBT monomer as a marker. Thus, this method is expected to be applicable to polymer failure analysis, quality control and so on.

Novel Aspect: (87 /150 characters)

TDP/DART-MS is useful failure analysis method for thermoplastic engineering elastomers such as PBT.

36 - EVALUATION OF THERMAL HISTORY OF THERMOPLASTIC RESINS BY THERMAL DESORPTION AND PYROLYSIS COMBINED WITH DART-MS (TDP/DART-MS)

CHIKAKO TAKEI (1) - KENICHI YOSHIZAWA (1)

BioChromato, Inc., Application support, Fujisawa (1)

Keywords: Polypropylene, Irgafos168, recycle, degradation, TDP/DART-MS

Introduction:(325 /400 characters)

Recycled thermoplastic resins are regarded as important materials for realizing sustainable society. Therefore, it is important to control and grasp the thermal history of polymer recycle, because recycled thermoplastic resins are weakened in physical properties by thermal history added. Thus, the purpose of this work was to evaluate the thermal history, directly and rapidly.

Methods: (384 /400 characters)

Polypropylene(PP) virgin pellet and 3× recycled pellet were used. Thermal desorption and pyrolysis(TDP) combined with DART-MS was composed of a compact (Bruker) Q-TOF mass spec. equipped with a DART ion source (IonSense) and an ionRocket TDP device (BioChromato). The samples were cut to ~1 square millimeter and put into the sample pot. Mass spectra were measured as the samples were gradient heated from room temperature to 600 °C at a rate of 100 °C/min.

Results: (832 /900 characters)

Regarding the total ion current gram of the virgin pellet and 3× recycled pellet from room temperature to 600 °C, no significant difference was detected, and similar thermal decomposition patterns were observed. However, regarding the mass spectra, the thermal decomposition reaction of polypropylene seemed to begin at 260 °C. An antioxidant additive (Irgafos168) and its oxidized compound (tris(2,4-di-tert-butylphenyl) phosphoric acid) were detected at this point, with differences observed between samples. In comparing the intensity ratios of the oxidized and pure between samples, the ratio of the 3× recycled pellet was higher than that of the virgin pellet. This confirmed that the 3× recycled pellet possessed increased oxidized Irgafos168 because of recycle. In addition, in comparing the extracted ion current grams for Irgafos168 between samples, the 3× recycled pellet showed less than the virgin pellet. This confirmed that Irgafos168 was consumed by recycle.

Conclusions: (384 /400 characters)

Using TDP/DART-MS, additives contained in PP and PP polymer matrix were detected independently and directly by gradient thermal heating. TDP/DART-MS can be a useful way to evaluate the thermal history of recycled thermoplastic resins quickly and easily, using the antioxidants contained in the thermoplastic resins as markers. Moreover, this method could be applied to quality control for thermoplastic resin products, such as containers and parts.

Novel Aspect: (111 /150 characters)

TDP/DART-MS is useful evaluation method of thermal history for thermoplastic resins using the additive marker contained in them.

1261 - MALDI-LID-TOF/TOF ANALYSIS OF STATISTICAL AND DIBLOCK POLYACRYLATE COPOLYMERS

James Town (1) - Glen Jones (2) - David Haddleton (3)

University of Warwick, Chemistry, Coventry, United Kingdom (1) - University of Warwick, Department of Chemistry, Coventry, United Kingdom (2) - University of Warwick, Chemistry, COVENTRY, United Kingdom (3)

Keywords: MALDI-LID-ToF/ToF, Polymers, MALDI-ToF, Tandem, Fragmentation

Introduction:

MALDI-LID-ToF/ToF mass spectrometry is a technique used to aid in the characterization of proteins¹. While MALDI tandem mass spectrometry techniques have been applied extensively to homopolymer compounds², with some application to block copolymers³. Herein we report on MALDI-LID-ToF/ToF as a powerful tool to give information of monomer distributions, and microstructural information, for both block copolymers and statistical copolymers.

Methods:

MALDI-ToF and MALDI-LID-ToF/ToF experiments were performed using an UltrafleXtreme MALDI-ToF/ToF analyser (Bruker, Coventry, UK). The MALDI-ToF experiments were performed in reflectron positive ion mode, with an acceleration voltage of 19 kV. MALDI-LID-ToF/ToF experiments were carried out in reflectron positive mode, with an ion source voltage of 8 kV, and a post fragmentation cell acceleration voltage of 19 kV. Polymers were synthesized using photo-RDRP⁴.

Results:

MALDI-LID-ToF/ToF results for the homopolymers revealed that the lability of the bromine end group led to a fragmentation pattern heavily dependent upon a radical backbiting process. This in turn led to the MALDI-LID-ToF/ToF spectra only containing a single dominant fragment structure, which had both the alpha end group and an addition CH₂ vinyl, as well as some smaller secondary fragments from the radical backbiting process. This was seen for both the methyl and ethyl acrylate homopolymers.

It is this simplification of the fragmentation pathway to a single fragment that sequencing the copolymers became much less complicated. Simply observing the overall makeup of the spectra granted simple confirmation of the diblock and statistical copolymer structure, as the diblock retained two distinct regions of monomer separation while the statistical copolymer kept a random structure throughout. Evidence of mixing in the diblock also showed the microstructure resolution the technique can obtain.

Conclusions:

MALDI-ToF and MALDI-LID-ToF/ToF can provide simple screening of polymer and copolymer compounds, as the techniques use the same sample spot to produce both results, full analysis can be carried out in under an hour. There are clear differences between the diblock copolymer and the statistical copolymer spectra, and, despite the techniques simplicity, determining the co-monomer arrangement of a copolymer is fully within the reach of MALDI-LID-ToF/ToF.

Novel Aspect:

Utilizing a technique for copolymer analysis, previously only used for proteins, for fast screening of microstructure determination.

Keywords:

Ion Mobility Spectrometry; Branched Polymers

Introduction:

Synthetic polymers have many uses due to their large variety of potential properties. As alterations of the molecular structure, e.g. branching, result in significantly different solid-state properties, it is essential to characterize the architecture of produced polymers. We demonstrate trapped ion-mobility spectrometry with quadrupole time-of-flight mass spectrometry (TIMS-QTOFMS) for structural elucidation of branched isomeric polyester oligomers.

Methods:

Polyesters of terephthalic acid (TPA) and propylene glycol (PG) with trimethylolpropane (TMP; branching agent) were synthesized. Polymer solutions (20 ppm) in THF were analysed using a Bruker timsTOF instrument allowing recording of mobilograms while continuously gathering high-resolution MS/MS data. Supercharging was realized by adding m-nitrobenzyl alcohol. ¹H/¹³C-NMR was used to verify polymer branching.

Results:

Analysis under optimized TIMS conditions resulted in observation of multiple conformers per polymer mass. Mobility separation was achieved as branched polymers exhibit a reduced rotationally averaged 3D-projection. Tandem MS of mobility-separated isomeric polymer species allowed their structural assignment. However, more peaks than possible structures were observed implying influence of the adduct-ion location on the respective mobilities. In verification of the latter, localization of charge by a trivalent ion, i.e. lanthanum, was achieved. For comparison, supercharging by m-nitrobenzyl alcohol was used to achieve multiple sodium adduct formation. Supercharging also allowed simultaneous low and high mass monitoring, showing potential towards increasing separation power. The latter provided a more accurate evaluation of the peak areas in the mobilograms, providing a semi-quantitative tool for assessment of the branching content of the polymer samples.

Conclusions:

The complex and diverse properties of industrially relevant polyesters provided an ideal sample to show the added value of TIMS for polymer characterization. Structural elucidation of the multitude of isomers is realized by combining mobility traces and MS/MS data. Supercharging allowed assessing the branching content semi-quantitatively, and enabled mass observation of three times the number average molecular mass.

Novel Aspect:

Use of TIMS on supercharged polyesters allows assessment of the branching content, structure and adduct location of polyester oligomers.

Introduction

Functional materials comprise synthetic macromolecules with well-defined structures, optimized to impart properties needed for specific biomedical, technological, or environmental applications. Multidimensional mass spectrometry (MS) methods can provide accurate and sensitive information about the molecular-level composition, structure, and architecture of such materials, a requirement for understanding and optimizing their applications.

Methods

MALDI- and ESI-MS interfaced with tandem mass spectrometry (MS²), liquid chromatography (LC) fractionation, and/or ion mobility (IM) separation were utilized to elucidate sequence and architecture. Mild thermal degradation with an atmospheric solids analysis probe (ASAP) was used to analyze crosslinked materials. Conversely, surface-layer (SL) MALDI-MS was employed to characterize and image the molecular composition and defects of solid film surfaces.

Results

MS² via collision-activated dissociation and/or electron transfer dissociation has been successfully used to determine the sequence of poly(N-isopropyl amide-methacrylic acid) copolymers, read the sequence of monodisperse copolyesters, and elucidate the architecture of multi-arm polyethers. For more complex systems, such as branched polyglycerol conjugates, adding LC and IM separation was essential for deciphering branching architecture and degree of conjugation. Crosslinked hydrogels required mild thermal degradation via ASAP-MS; this method mainly breaks weak junctions in the polymer network leading to signature ions for both the crosslinks as well as defects such as unreacted ends. On the other hand, molecular information on the surface composition of solid films (<2 nm depth) could be gained by SL-MALDI-MS; this solvent-free technique allowed to image surface defects from foreign materials, material absence, mechanical scribing, and solvent perturbation on thin films made of poly(methyl methacrylate) and polystyrene.

Conclusions

Multidimensional mass spectrometry methods encompassing different combinations of mass analysis, tandem mass spectrometry, and orthogonal separation by polarity and/or shape enable sensitive and precise analysis of the microstructures of synthetic functional materials that are widely used in industrial, biomedical, and technological applications, but challenging to characterize by other analytical techniques due to their complexity, size, or topology.

Novel Aspect

Complete molecular-level analysis of functional materials for meaningful structure/property correlations and continuous improvement of their macroscopic properties.

185 - ULTRASOUND ASSISTED EXTRACTION PARAMETERS OPTIMIZATION BY EXPERIMENTAL DESIGN FOR STEROIDAL SAPONINS FROM PLANT MATERIAL AND CELL CULTURES OF DIOSCOREA DELTOIDEA

Boris Sarvin (1) - Timur Baygildiev (1) - Dmitry Kochkin (2) - Andrey Stavrianidi (1) - Igor Rodin (1)

Lomonosov Moscow State University, Department of Chemistry, Moscow (1) - Lomonosov Moscow State University, Faculty of Biology, Moscow (2)

Keywords: ultrasound assisted extraction, steroidal saponins, Dioscorea deltoidea plant cell culture, Latin square experimental design, HPLC-MS

Introduction

Many of steroidal saponins have anticancer potential and may be used for treatment of cardiovascular diseases. Cell biomass grown in bioreactors can be used to produce steroidal saponins. Dioscorea deltoidea plant cell culture contain an extremely complicated mixture of furostanol steroidal saponins. Therefore, it is critical to control the composition of cell cultures for medical use.

Methods

For the extraction of steroidal saponins ultrasound assisted extraction (UAE), multiple successive extraction (MSEM) and reflux extraction (RE) methods were used. LC separation was performed on a reversed phase C18 column in gradient elution mode. MS detection was conducted in the positive electrospray ionization mode (SIM mode).

Results

Optimization of the UAE parameters was performed with use of Latin square experimental design [1]. The following parameters have been optimized: extraction time, organic solvent concentration in extraction solution and the ratio of solvent to sample. Optimal conditions for the extraction of steroidal saponins by the UAE method were: extraction time, 60 min; acetonitrile (water) concentration in extraction solution, 50% (50%); the ratio of solvent to sample, 400 mL/g. As a result, high degree of the extraction of steroidal saponins from the D. deltoidea plant cell suspension culture was achieved. The obtained results were confirmed by MSEM and RE. It was also shown that the UAE method is not suitable for isolation of steroidal glycosides from the D. deltoidea plant material.

Conclusions

For the determination of steroidal saponins from D. deltoidea cell culture comprehensive and representative pre-LC-MS extraction procedure was proposed. Low degree of the steroidal saponins extraction from the plant material is most likely due to the lack of mechanical tissues in the cell culture, in contrast to plant material. The UAE method was tested on a series of 18 cell culture samples of different inoculation date, growing condition and growth period.

Acknowledgements

This work was supported by Russian Science Foundation (Grant No. 17-13-01146) for Moscow State University.

Novel Aspect

Comparison of the different approaches performance characteristics have been carried out with respect to finding an optimal pre-LC-MS treatment of D. deltoidea cell culture.

981 - ANALYSIS OF PESTICIDE RESIDUES IN CANNABIS REGULATED BY CALIFORNIA AND OREGON STATE USING LC/MS/MS WITH DUAL ELECTROSPRAY AND APCI SOURCE

Thomas Becker (1) - Avinash Dalmia (2) - Erasmus Cudjoe (3) - T. Ruthenberg (4) - Josh Ye (3) - M. Murphy (4) - Feng Qin (3) - David Welkie (2)

PerkinElmer (LAS) Germany GmbH, BLL/FAS-Group, Rodgau-Jügesheim (1) - PerkinElmer Inc., BU, Shelton, CT (2) - PerkinElmer Inc., BU, Woodbridge, ON (3) - SC Labs, Lab, Santa Ana, CA (4)

Keywords:

Pesticides in Cannabis by LC-MS/MS
Nonpolar and chlorinated pesticides
Dual ESI/APCI laminar flow source
heated self-cleaning interface

Introduction:

Over 20 states in the U.S. have legalized the use of recreational or medical cannabis because of therapeutic benefits for ailments such as cancer, multiple sclerosis, and ALS. Since chronic exposure to pesticides in cannabis pose serious health risks, pesticide analysis in cannabis is important. Apart from Oregon state regulatory limits for about 65 pesticides in cannabis, the state of California has issued more stringent regulatory limits for 72 pesticides residues in cannabis flower and edibles. We analyzed all 72 pesticides (including very hydrophobic and chlorinated pesticides generally analyzed by GC/MS) spiked in cannabis flower extracts using LC-MS/MS with ESI and APCI source well below the action limits specified by both Oregon and California State.

Methods:

Ground cannabis flower (1 gm) was extracted with acetonitrile (5 mL). The extract was spiked with different levels of 72 pesticides and 10 deuterated internal standards. After that, extract was further diluted 1:1 with acetonitrile containing 0.1 % formic acid. The diluted extract was analyzed directly using LC-MS/MS triple quad with electrospray and APCI source. A 20 min LC-MS/MS method using LX-50 LC, C18 Column and PerkinElmer Qsight 220 MS with electrospray source was used to detect 70 out of 72 pesticides regulated by California state. A 7.5 min LC-MS/MS method using APCI source and C18 column was used to analyze rest of 2 out of 72 pesticides controlled in cannabis by California state.

Results:

Normally pesticide analysis in cannabis and other food matrices is done by both GC/MS and LC/MS since some nonpolar and chlorinated pesticides are difficult to ionize with electrospray and APCI ion source used in LC/MS systems. Two different LC-MS/MS methods with electrospray and APCI source were used for low level analysis of all 72 pesticides (including the very hydrophobic and chlorinated pesticides analyzed by GC/MS) in cannabis. The overall sensitivity for most of the pesticides, including those that are normally analyzed by GC/MS was between 1-300 ppb in cannabis, well below regulatory limits set by the state of Oregon and California. The ability to screen and

quantitate all 72 pesticides, including the very hydrophobic and chlorinated GC/MS amenable, in cannabis with LC-MS/MS only with dual ESI/APCI source makes this a novel way of screening and quantitation of pesticides in cannabis and different matrices with a single instrument. The ionization mechanism for analysis of chlorinated pesticides in cannabis using LC-MS/MS system with APCI source would also be presented. The recoveries of majority of the 72 pesticides spiked in grounded cannabis flower were estimated to be between 60-120% with RSD less than 20%.

Long term stability data for pesticide analysis in cannabis was collected using a triple quadrupole mass spectrometer fitted with dual electrospray ionization source and atmospheric chemical ionization source (APCI) and combined with a heated and self cleaning laminar flow interface. Long term stability data for pesticide analysis in cannabis showed that response RSD over 1 week for majority of pesticides was between 2 to 10%.

Conclusions

The results demonstrate the successful approach to screen and quantify pesticides in Cannabis well below the governmental action limits. Very hydrophobic and chlorinated species are also amenable, eliminating the need for further (GC/MS) instrumentation. In addition to this, the maintenance needs of the system are substantially reduced by the heated self-cleaning/laminar flow interface, despite of the presence of challenging matrices such as cannabis.

Novel Aspect:

Analysis of GCMS and LCMS amenable pesticides in cannabis using a LCMSMS system with dual ESI/APCI ion source.

1284 - ENERGY RESOLVED TANDEM MASS SPECTROMETRY EXPERIMENTS FOR RESOLUTION OF ISOBARIC COMPOUNDS: A CASE OF CIS/TRANS ISOMERISM

Laura Braconi (1) - Marta Menicatti (1) - Silvia Dei (1) - Elisabetta Teodori (1) - Gianluca Bartolucci (1)

Università degli Studi di Firenze, Department of Neurofarba, Sesto Fiorentino, Italy (1)

Keywords: linear equations of deconvolution analysis, LEDA, energy resolved mass spectrometry, isomers characterization, multi-drug resistance

Introduction:

A series of cis/trans esterisomers, that showed high efficacy to reverse the acquired resistance of cancer cells during chemotherapeutic therapy was studied as candidate drugs [1]. In order to evaluate their stability in human plasma, a liquid chromatography tandem mass spectrometry (LC-MS/MS) method was developed together with a mathematical algorithm, that is able to identify the isomers present in analyzed samples, without their chromatographic separation.

Methods:

The LC-MS/MS analyses were carried out using a triple quadrupole system equipped with an electrospray source (ESI), operating in positive ion mode. The employed chromatographic parameters were finely tuned to minimize the run time. Therefore, a short C18 Column (3 cm) and fast elution gradient were used. Furthermore, a matrix of linear equations (LEDA), based on abundance ratios of product vs precursor ions, was applied to allow the isomers distinction[2-3].

Results:

Using the reported conditions, a co-elution of the studied isomers was observed. Analysis of isobaric molecules, and especially isomers, by tandem mass spectrometry is often complicated by the similarity between their fragmentation patterns and it is common that the same MS/MS product ions are present in the spectra of all the isomers. Hence, to find some differences among cis/trans isomers, a series of experiments based on energy resolved MS/MS (ERMS) was carried out. Knowing the characteristic ratios of pure isomer, LEDA algorithm elaborates each MS/MS acquired spectra, assigning the correct abundance to the identified isomer. Therefore, in case of an isomers' mixture, LEDA is able to resolve the co-eluting peak determining the relative concentration of each isomer eventually present.

The LEDA reliability was checked during stability studies. The results proved the effectiveness of correct assignment of the isomer present in the sample. This ability was essential to verify the behavior of the studied isomers during stability tests.

Conclusions:

The proposed approach, combining a LC-MS/MS method with a post-processing mathematical algorithm (LEDA), was able to deconvolute a mixture of isomers from chromatographically unresolved peaks. The results demonstrated that this combination was suitable for the evaluation of isomers' degradation profiles in human plasma samples. Indeed, the stability experiments have highlighted a different behavior between cis/trans isomers.

Novel Aspect:

The LEDA approach has the advantage that isomers can be quantified without the need of LC separation or additional specialized ion mobility instrumentation.

SILVIA BUA (1)

UNIVERSITÀ, NEUROFARBA, FIRENZE, Italy (1)

Keywords: Stability, NSAID, Carbonic Anhydrase, Hybrids

Introduction:

We reported a series of amide-based hybrid compounds incorporating 6- and 7-substituted coumarins and some NSAIDs as agents for the management of RA.[1] These derivatives were proved to exert remarkable anti-inflammatory action in spite of non-significant amide-bond cleavage in vivo. [1-3]

As a rational development, we report herein all such derivatives ester bioisosters to investigate the contribution of a more cleavable linker in terms of plasma stability.

Methods:

The kinetic studies were carried out through a stopped-flow assay. [4] The LC-MS/MS analysis were carried out using a triple quadrupole system equipped with an electrospray source (ESI), operating in positive-ion mode. The employed chromatographic parameters were finely tuned to minimize the run time. Furthermore, a matrix of linear equations (LEDA), based on abundance ratios of product vs precursor ions, was applied to allow the isomers distinction [3].

Results:

The ester hybrids were shown to inhibit the target human CA isoforms more efficiently than the corresponding amides. Using the LC reported conditions, a co-elution of the studied isomers were observed. Knowing the characteristic ratios of pure isomer, LEDA algorithm elaborates each MS/MS spectra acquired, assigning the correct abundance to the identified isomer. Therefore, in case of a isomers mixture, LEDA is able to resolve the co-eluting peak determining the relative concentration of each isomer eventually present. The LEDA reliability was checked during stability studies. The results proved the effectiveness of correct assignment of the isomer present in the sample. The drug stability studies demonstrate that the amides derivatives resulted to be stable in both human and rat plasma. Likewise, most esters derivatives exhibited human plasma stability, with the exception of Ketoprofen and Diclofenac derivatives, showing that the ester bond can undergo hydrolytic cleavage in human plasma depending on the NSAID fragment.

Conclusions:

Docking studies displayed the capability of the overall hybrid to bind to COX-1 and COX-2. Unlike amides, the ester bond can undergo hydrolytic cleavage in human plasma depending on the NSAID fragment. In vitro functional investigations and in vivo studies are currently ongoing to finally determine the mechanism of action of such derivatives.

The proposed LC-MS/MS approach with LEDA tool, was able to separate the isomers eventually present from LC unresolved peaks.

Novel Aspect:

Introduction of ester/amide-linked NSAIDs-coumarins hybrids for the management of RA. The use of LEDA tool to isomers analysis without LC or ion mobility separation.

1222 - IDENTIFICATION OF A NOVEL METABOLITE ORIGINATING FROM JWH-015 USING LCMS-IT-TOF

Ozgun Devrim Can (1) - Umide Demir Ozkay (1) - Serkan Levent (2) - Nazli Turan Yucel (1) - Fayza Alyu Tekes (1) - Yusuf Ozturk (1)

Anadolu University, Faculty of Pharmacy, Department of Pharmacology, Eskisehir, Turkey (1) - Anadolu University, Faculty of Pharmacy, Department of Pharmaceutical Chemistry, Eskisehir, Turkey (2)

Keywords: Narcotic Cannabinoid, JWH-015, Metabolite, LCMS-IT-TOF

Introduction

Despite regulatory efforts; use of "Bonzai" or "Spice" has increased in Turkey due to psychiatric, medical and social features. JWH-015, a narcotic cannabinoid, is one of the active components of Bonzai. Intensive literature survey indicates that studies on the metabolites of JWH-015 are limited to in vitro experiments only [1, 2]. Thus, screening of probable in vivo metabolites of JWH-015 via a non-targeted analysis were aimed in the present study.

Methods

Female Wistar rats of the same age (n=6, ~200-250 g) were used in the experiments. JWH-015 was administered via i.p. route at the dose of 5 mg/kg [2]. Urine samples were collected at varying time points within a 24-hour period and subjected to analysis by using a liquid chromatography mass spectrometry-ion trap-time of flight (LCMS-IT-TOF) instrument (Shimadzu, Japan). Molecular weights of the probable metabolites were calculated and their chemical structures were identified.

Results

In order to determine the pharmacokinetic properties of JWH-015, the analysis of the biotransformation products by LCMS-IT-TOF system were performed. As a result of analyses, a novel in vivo metabolite of JWH-015 was identified for the first time. The novel compound was a glucuronide metabolite of JWH-015, with a chemical name of hydroxy-JWH-015-O-glucuronide. Seven other metabolites with the previously reported chemical structures [1, 2] were also determined in the LCMS-IT-TOF analyses.

Conclusions

Although in vitro metabolism studies give highly accurate results for prediction of possible metabolism pathways and metabolites, in vivo verification of the results is crucial to reveal the real-time reflection of non-living based experiments. Therefore, time dependent determination of novel metabolite, hydroxy-JWH-015-O-glucuronide is very important in terms of pharmacokinetic profile of Bonzai.

Novel Aspect

Discovery of a novel metabolite of JWH-015 gives valuable information about biotransformation pathway of cannabinoid type of compounds.

Anadolu University, Faculty of Pharmacy, Department of Analytical Chemistry, Eskisehir, Turkey (1) - Anadolu University, Faculty of Pharmacy, Department of Pharmaceutical Chemistry, Eskisehir, Turkey (2)

Keywords: Ergosterol Quantification, *C.albicans*, Antifungal, LC-MS/MS

Introduction

Ergosterol is the major fungal membrane sterol that regulates membrane fluidity, plasma membrane biogenesis and functions [1]. The inhibition of ergosterol biosynthesis causes a damage in cell membrane of fungi. Hence, quantification of ergosterol level in fungi is essential for development of novel inhibitor candidates [2]. Thus, in the present work, we synthesized new benzimidazole-derivative compounds and developed an LC-MS/MS method for assessment of their effect on ergosterol content of *C. albicans*.

Methods

Sterol extract was prepared from *C. albicans*, incubated with/without inhibitor for 24h [3], and injected (1 µL) to LC-MS/MS system. The mass spectrometric analyses were achieved by employing Nexera XR UFLC system coupled to an LCMS-8040 triple quadrupole mass spectrometer (All from Shimadzu, Japan). MRM was optimized using ergosterol standard, and Labsolutions LC-MS software (Version 5.86, Shimadzu) was used to process the data.

Results

Ergosterol standard was used for quantification of ergosterol in both inhibitor-free (negative control) and inhibitor containing samples. Benzimidazole compounds and reference drugs (ketoconazole and fluconazole) were used at 0.78 µg/mL, 1.56 µg/mL, and, 3.12 µg/mL concentrations. Ergosterol quantity in negative control samples was regarded as 100%. All concentrations were analyzed in quadruplicate, and the results were expressed as mean ± standard deviation. Ergosterol quantification studies indicated that compounds 5i, 5s and reference drugs significantly reduced ergosterol levels at all tested concentrations. Compound 5i displayed 61.74%, 85.41%, and 93.71 % inhibitions at 0.78 µg/mL, 1.56 µg/mL, and, 3.12 µg/mL concentrations, respectively. An inhibitions ratio of 62.05%, 84.48%, and 93.12% were observed for compound 5s at the same concentrations. Reference drugs indicated similar inhibition potencies to those of compounds 5i and 5s in the range of 63.71% to 94.46%.

Conclusions

We achieved highly acceptable results via developed LC-MS/MS method. Ergosterol quantification studies using *C. albicans* indicated that compounds 5i and 5s and reference agents cause a concentration dependent decrease in the level of ergosterol. Hence, it can be obviously suggested that compounds 5i and 5s have a role in the ergosterol biosynthesis pathway.

Novel Aspect

The developed LC-MS/MS method may hopefully be beneficial for researchers who study on novel antifungal agents as ergosterol biosynthesis inhibitors.

Introduction

The identification of unknown small molecules, such as impurities, metabolites, degradants, extractables and leachables remains one of the most challenging workflows. Mass spectrometry-based chemical and structural characterization of small molecules greatly benefits from multi stage fragmentation (MSn) coupled with high resolution and high mass accuracy analysis. However, the use of these tools during the untargeted analysis of complex samples is often challenging, owing to the slow precursor interrogation rate and the large number of potential precursors. Here, we describe new data acquisition approaches for the characterization of small molecule extractable and leachable compounds. Building upon sophisticated methods that employ multistage Orbitrap analysis (FTMSn), we dynamically update inclusion and exclusion lists between LC analyses to enable efficient and deep interrogation.

Methods

All experiments were run on a modified Thermo Scientific™ Orbitrap tribrid mass spectrometer. Liquid chromatography separations were carried out on a Thermo Scientific™ Vanquish™ LC system using mobile phases composed of: A: H₂O/0.1% formic acid, and B: ACN/0.1% formic acid with gradient on a Thermo Scientific™ Accucore™ C18 LC column (2.1X100 mm particle size: 2.6µm). A mixture of common plastic and elastomer additives was spiked into matrix and analyzed using LCMS to demonstrate the methodology. This was followed by IPA/water extracts of representative elastomeric components used in biopharmaceutical process. The data was processed using Thermo Scientific™ Mass Frontier™ 8.0 and Thermo Scientific™ Compound Discoverer™ 3.0 software.

Preliminary Data

In this study, a mixture of known additive standards was used to verify the data acquisition features. The IPA/water extract of representative elastomeric components used in pharmaceutical process demonstrates that using the new features significantly enhances unknown extractable chemical entity identification in a representative solvent extract of an elastomeric component used in pharmaceutical process. The instrument control and data acquisition software for the mass spectrometer was modified to enable automatic generation of inter-run inclusion and exclusion lists based upon the real time component detection in the LC-MS data. Using these inter-run inclusion and exclusion lists, the instrument can selectively trigger MSn scans on features detected in the sample of interest while excluding any distracting background ions. Samples are automatically re-injected to allow for exhaustive MSn data generation for the detected features of interest.

Within each data-dependent LC-MS analysis, we employed sophisticated mass spectrometer methods that are comprised of multiple levels of MSn fragmentation coupled with both high-resolution Orbitrap and low-resolution ion trap analyses. The initial workflow was tested on commercially available standards comprising of plastic and elastomer additives such as antioxidants, slip agents, plasticizers, UV protectants and processing aids. Structure elucidation was conducted based on a newly implemented substructure similarity searching algorithm in Compound Discoverer. Additionally, the MSn data generated for the small molecule compounds of interest was used for generation of a custom spectral library using Mass Frontier 8.0. In the next steps, we will apply this workflow for data analysis of complex unknown small molecule samples.

Novel Aspect

Intelligent data acquisition, processing and interpretation strategy to enable rapid MSn characterization of small molecule unknowns

1258 - IDENTIFICATION OF DIPROPYLAMINOPRETADALAFIL USING HIGH RESOLUTION MASS SPECTROMETRY UNDER MULTI-STAGE FRAGMENTATION PATHWAYS

Agnes Chin (1) - Chee Leong Kee (2)

Health Sciences Authority, Pharmaceutical Laboratory, Singapore, Singapore (1) - Health Sciences Authority, Pharmaceutical Laboratory, Singapore, Singapore (2)

Keywords: Dipropylaminopretadalafil, Diethylaminopretadalafil, HRMS, multistage fragmentation

Introduction:

Phosphodiesterase type 5 (PDE-5) inhibitors and their analogues are commonly detected in illegal health products used to treat erectile dysfunction in men. The emerging health risks have become prominent with the first fatal case associated with intoxication by desmethylcarbodenafil reported in 2017 [1]. Therefore, it is crucial that the laboratory is equipped with the necessary equipment and knowledge to structural elucidate the structure of new analogues. In this study, a new tadalafil analogue was detected in a routine analysis in the laboratory. The structure of this unknown was compared to that of a known tadalafil analogue, diethylaminopretadalafil, using liquid chromatography mass spectroscopy (LC-MS) and high-resolution mass spectroscopy (HRMS).

Methods:

The unknown PDE-5 inhibitor analogue was isolated by liquid-liquid extraction and purified by recrystallization process. The isolated compound was then dissolved in acetonitrile for Liquid Chromatography-Mass spectroscopy (LC-MS). The sample solution was further diluted with 0.1% formic acid in water: 0.1% formic acid in acetonitrile = 4:1 for direct infusion using a Thermo Fischer Scientific LTQ Orbitrap XL FTMS. The infusion flow rate was 10 μ L per minute. The MS₂ fragmentation pattern under High energy Collision Dissolution (HCD) was acquired using the optimized normalized collision energy (NCE). The multistage fragmentation pathways MS_n (n= 2,3) were acquired by selecting ions of interest under Collision Induced Dissolution (CID). The fragmentation patterns obtained from both modes were compared to a known standard, diethylaminopretadalafil. The accurate mass measurement of each product ion was determined with the aid of Mass Frontier 7.0 software. Mass error of all product ion has been limited to within \pm 5.0 ppm tolerance.

Results:

The fragmentation patterns for both unknown compound and diethylaminopretadalafil were compared. Under MS₂ experiment in HCD mode, the unknown compound showed an intense signal at m/z 492, which is more than diethylpropylaminopretadalafil at m/z 464 by 28 Dalton, indicating the presence of -C₂H₄- to the known standard structure. Similarly, the difference has been observed for the fragment ion at m/z 393 of the unknown compound and the fragment ion at m/z 379 of diethylaminopretadalafil. The common ion at m/z 334 is a result of the cleavage of C-1, C-3 and nitrogen [2]. Under CID mode, the MS₂ spectrum of the unknown compounds showed fragmentations at m/z 393 and 292, both were 28 Dalton higher than the fragment ions at m/z 379 and 278 derived from diethylaminopretadalafil. The most intense ions at m/z 393 and 379 for both compounds can be formed from the cleavage of amido bridge via N-C bond and followed by the new N-C bond formation with a propyl and ethyl respectively. This is a good indication to rule out the possibility of having asymmetrical dialkyl groups linked to terminal amine. Two common ions have been observed at m/z 336 and 264. The first one can be due to the loss of the labile N-propyl and N-ethyl for the unknown compound and diethylaminopretadalafil respectively. Meanwhile, the

smaller ion at m/z 264, consisting of indole- benzodioxole substructure can be formed from the loss of the ethylmethyl ester-N-alkyl linked moiety.

Under MS3 experiment, the precursor ion at m/z 393 produced three major ions at m/z 336, 292 and 264. Similar fragmentation pattern had also been observed for ion at m/z 279 derived from diethylaminopretadalafil to yield fragments ions at m/z 336, 278 and 264. The difference of 12 Dalton between ions at m/z 292 and 278 supports the formation of N-C(alkyl) bond as explained above. The common fragmentation pathways for ions at m/z 336 and 264 had been observed in both MS3 experiments. The former produced an intense signal at m/z 130 due to cleavage of the ethyl methyl ester and benzodioxole from the precursor, forming the stable methylated indole. Lastly, the precursor ion at m/z 264 gave rise to ion at m/z 234 as a result of the removal of HCHO from the benzodioxole group. Subsequent neutral loss of one CO resulted in the ion at m/z 206.

Conclusions

Dipropylaminopretadalafil has been characterized by a series of comparison studies with the known diethylaminopretadalafil under High energy Collision Dissolution (HCD) and Collision Induced Dissolution (CID). The similarities and differences observed by these two compounds have been explained through their fragmentation pathways with the aids of reference ions.

Novel Aspect:

In the absence of NMR facility and limited sample amount, the application of HRMS with MS_n capability is able to provide important information on the fragmentation pathways through comparison with a suitable known reference compound.

Keywords: maytansinoid, anti-tumor, metabolites, microsomes, tandem MS.

Title:

Comprehensive metabolite identification of DM4, a maytansinoid anti-tumor agent, in S100 fractions of Human Liver microsomes, by UPLC-QToF Mass Spectrometry

Authors:

E. Ciuti*, F. Tavani*, V. Chirulli', C. Carboni', A Triolo*

* Laboratory of Analytical Chemistry for Development, Menarini Ricerche Spa, via F. Rismondo 12A, 50131 Firenze (Italy)

' Department of Pharmacokinetics and Metabolism, Menarini Ricerche Spa, via .T. Speri 10, 00040 Pomezia (RM, Italy).

Introduction:

Maytansinoids are highly cytotoxic molecules; several of them are investigated in cancer therapy, as conjugates with antibodies (ADCs) targeting specific cells. This study describes the identification of the metabolites of the maytansinoid DM4, after incubation with S100 fractions of human liver microsomes (HLM) [1]. Particularly, we wanted to gain better understanding of truly metabolic processes from chemical degradation of the molecule.

Methods:

After 1-h incubation, the samples were injected onto a RP C18 UPLC column, and the mass spectrometer was operated in positive ESI alternating low- and high-energy full-scans. Molecular masses of all the DM4-related molecules were obtained by extraction of the masses of typical fragment ions from the high-energy scans (Product Ion Filtration, PIF), and mass defect filtering (MDF) from the low-energy scans. Fragment masses were used for structural elucidation.

Results:

Given the reactivity of DM4, the drug-related molecules in HLM incubates were matched with those occurring in control experiments, i.e. HLM incubates without the NADPH activator and DM4 incubates in incubation buffer only. The results are as follows.

Incubation in buffer only: DM4 underwent side-chain hydrolysis (N-methylglycyl maytansinol), degradation of 1,3-oxazinan-2-one ring of the core structure, SH oxidation to sulphinic and sulphonic acid, hydroxylation of the core ring.

S100 incubation without NADPH: besides the above molecules, the DM4 conjugates with cysteine and, at trace level, with glutathione, were observed.

S100 incubation with NADPH: Sulphinic and sulphonic acid were more abundant. In addition to the above, a metabolite with the side chain SH group replaced by an OH was observed, and a pair of products from Michael reaction of DM4 with 1,4-dihydropyridine-3-carboxamide, resulting from interaction with NADPH or one of its impurities.

Investigations are ongoing to ascertain the nature of the Michael adducts.

Conclusions:

The experiments performed on DM4 HLM incubates allowed to distinguish true DM4 metabolites from products arising from merely degradative processes. To the first category belong a sulphinic and sulphonic acid, also partly generated by spontaneous oxidation, cysteine and glutathione conjugation, and side chain SH to OH substitution.

Novel Aspect:

Observation of novel DM4 metabolites, first discrimination of P450-dependent processes from other biotransformations and chemical degradation.

63 - IMPACT OF CENTROIDING AND DIFFERENCES IN DATA PROCESSING ON QUANTIFICATION USING HIGH-RESOLUTION MASS SPECTROMETRY

Liesbeth Vereyken (1) - Lieve Dillen (1) - Rob Vreeken (1) - Filip Cuyckens (1)

Janssen R&D, Discovery Sciences, Beerse (1)

Keywords: High-Resolution MS, quantification, data processing, mass extraction window

Introduction:

The improved performance of High-Resolution MS (HRMS) systems triggers more (bio)analysts to switch from triple quad MS to HRMS for quantitative analysis. The impact of differences in data handling by different software packages, the impact of centroid or continuum data as well as the use of theoretical or measured accurate mass on the selection of the optimal narrow mass extraction window was studied.

Methods:

Calibration curves of 8 pharmaceutical drugs in plasma were analyzed in 5-fold on a Synapt G2-S QToF system. Data were acquired in continuum mode and processed in four different ways: as centroid data, as individual profile data points and as full profile data using 2D and 3D processing. One compound was analyzed on 2 QTofs and one Orbitrap system and processed in six different software packages.

Results:

Centroid data provided advanced selectivity resulting in cleaner XICs for qualitative analyses but with a limited to no effect on quantitative performance (LOQ, precision, linearity). The optimal mass extraction window (MEW) selection showed to be solely defined by the mass accuracy of the system used. For profile data, the improved selectivity provided by narrower MEWs is counterbalanced by a loss in MS peak area affecting signal-to-noise. Therefore, the full width half maximum (FWHM) of the peak showed to be the ideal starting point for MEW selection in addition to mass accuracy that becomes gradually more important with increasing MS resolving power. 3D peak processing can overcome the challenges of MEW selection but comes with different challenges such as the difficulty in reviewing and adjusting bad peak integrations.

Conclusions:

The impact of centroid or profile data and different software approaches on the extraction of MS data to generate XICs were investigated. While there is an effect on the optimal MEW selection for which guidelines are given, the effect on quantitative performance was minimal.

Novel Aspect:

The impact of differences in data treatment by software packages
Optimization of processing parameters for quantitative HRMS performance

1221 - INVESTIGATION OF MONOAMINE OXIDASE INHIBITORY ACTIVITIES OF NEW CHALCONE DERIVATIVES: COMPARISON OF LC-MS/MS AND FLUOROMETRIC METHODS

Ümide Özkay (1) - Nafiz Öncü Can (2) - Serkan Levent (3) - Yusuf Özkay (3) - Özgür Devrim Can (1)

Anadolu University, Faculty of Pharmacy, Department of Pharmacology, Eskisehir, Turkey (1) - Anadolu University, Faculty of Pharmacy, Department of Analytical Chemistry, Eskisehir, Turkey (2) - Anadolu University, Faculty of Pharmacy, Department of Pharmaceutical Chemistry, Eskisehir, Turkey (3)

Keywords: Monoamine Oxidase, Inhibition, Chalcone, LC-MS/MS

Introduction

Monoamine oxidase (MAO), is a key enzyme that metabolizes monoamine neurotransmitters in peripheral tissues and in the central nervous system [1]. MAO involves two isoforms, i.e. MAO-A and MAO-B. MAO-A inhibitors constitute a well-known class of antidepressant drugs, whereas MAO-B inhibitors have importance towards age-related disorders such as Alzheimer's and Parkinson's diseases [2]. In the present work, we applied both fluorometric and LC-MS/MS assay to observe MAO inhibitory potency of new chalcone derivatives.

Methods

MAO enzyme inhibitory effects of newly synthesized chalcone derivatives (2a-2i) [3] were tested in the concentration range of 10^{-3} to 10^{-9} M via a fluorometric method using MAO-A/B Inhibitor Screening Kit (BioVision, CA, USA) according to the manufacturer's guidelines [4]; in addition, a new LC-MS/MS assay method was also developed based on the measurement of tyramine and both methods were compared statistically with each other.

Results

In the fluorometric microplate method, a non-significant inhibition was determined against hMAO-A. In contrast, all compounds indicated higher inhibition profile towards hMAO-B isoform. Compounds 2c, 2e and 2i displayed good inhibition against hMAO-B with lower IC_{50} values than $1 \mu\text{M}$. In order to support the results of enzyme inhibition assay, quantification of substrate (tyramine) level was performed using LC-MS/MS via MRM. Effects of the compounds 2c, 2e and 2i on tyramine level were in agreement with those of compounds observed in fluorometric assay. It was observed that lower inhibitor concentration causes a decrease in the substrate level.

Conclusions

Inhibitors usually react with the enzyme and change it chemically. Hence, in the presence of an inhibitor, the enzyme-substrate complex does not form routinely. Thus, the quantification of tyramine level was performed by an LC-MS/MS method. It was found out that tyramine level increases in the higher concentrations of compounds 2c, 2i and 2f. Consequently, the results of fluorometric kit assay was supported/verified by a more sensitive LC-MS/MS method.

Novel Aspect

Newly reported LC-MS/MS method is very helpful to quantify substrate level in MAO-substrate reaction and to compare results with those of known fluorometric assay.

518 - LC-ICP-MS AS AN ALTERNATIVE TO RADIOACTIVITY IN PHARMACOLOGY

Christine Enjalbal (1) - Emmanuelle Cordeau (1) - Gilles Subra (1) - Didier Gagne (1) - Nolween Prache (1) - Carine Arnaudguilhem (2) - Brice Bouyssiere (2)

IBMM, University of Montpellier, Montpellier (1) - IPREM, UPPA, Pau (2)

Keywords: ICP-MS; Peptide; Quantification; Pharmacology; Labeling

Introduction

Measuring the affinity of a ligand for its target is an issue of central importance in drug development. At present, radiolabeling is the reference method in pharmacology, allowing a highly sensitive detection of the molecule of interest but with many drawbacks (user safety, environmental issue). In this context, we developed an alternative methodology using mass spectrometry due to its intrinsic capabilities in terms of specificity and sensitivity of analysis.

Method

The cornerstone of this analytical methodology relies on the production of very abundant signals related exclusively to the peptide ligand of interest to be quantified by a generic mass spectrometry method, applicable to all receptor/ligand systems, while demonstrating performance equal to radioactivity. Among all techniques investigated [1-3], LC-ICP-MS associated with peptide selenium labeling provided extreme efficacy and robustness of quantification.

Results

This strategy was applied to quantify peptide ligands at very low concentrations from cell cultures in pharmacological experiments (saturation and competitive binding assays). Noteworthy, we developed a straightforward protocol that can be performed with a standard macrobore LC-ICP-MS system without any sample treatment or special instrumental set-up, while allowing efficient suppression of all mass interferences to reach the targeted sensitivity. Significantly, a quantification limit of 50 ng Se L-1 (50 ppt/63 fmol of injected Se) was achieved, the samples issued from the pharmacological assays being directly introduced into the LC-ICP-MS system. The proof of concept was illustrated on the vasopressin/AVP pharmacological model. The methodology was then successfully applied to a second ligand/receptor system (CCK-4/CCK) proving the generic aspect of the protocol. A very good correlation of all experimental data for the determination of K_i , K_d and IC_{50} by both ICP-MS and radioactivity demonstrated the reliability of the strategy.

Conclusions

We aimed to obtain a generic mass spectrometry method, applicable to all receptor/ligand systems, while demonstrating performance equal to radioactivity in order to convince pharmacologists to modify their practices by the eradication of the use of radioactive substances. The gathered results with two different ligand/receptor systems indicate clearly that the LC-ICP-MS-based developed method represents a viable alternative to radiolabeling.

Novel Aspect

LC-ICP-MS equaled radioactivity for peptide quantification from cell cultures which should convince pharmacologists to modify their practices.

1018 - LONG TERM STABILITY OF CANDESARTAN CILEXETIL AFTER MICRONIZATION

Anna Maria Alves de Piloto Fernandes (1) - Marcel Menezes (2) - Phellipe Honório Amaral (3) - Marcos Nogueira Eberlin (4) - Nelci Fenalti Höehr (2)

Labmass Laboratory, State University of Campinas/ Thomson Mass Spectrometry Laboratory, Campinas (1) - none, University of Campinas/Department of Clinical Pathology, Campinas (2) - Labmass Laboratory, University of Campinas/Department of Clinical Pathology, Campinas (3) - none, University of Campinas/Thomson Mass Spectrometry Laboratory, Campinas (4)

Keywords: candesartan, micronization, HRMS, long term stability, degradation products

Introduction:

Water solubility is a rate-limiting factor for drug bioavailability. Micronization is the reference technique to increase solubility [1]. In spite of being an old technology, there is little published data about the degradation of pharmaceuticals during this process. Here, ESI-HRMS was used to identify degradation products (DP) of candesartan cilexetil (CC) micronized by milling and stocked for a long time period.

Methods:

CC samples was milled for 0.25, 2, 48 or 170 hours. Micronized CC was analyzed 24 months after milling using a ThermoQ-Exactivemassspectrometer at a resolution of 70,000 (@m/z 400). The formation of the DP was evaluated by plotting the ratio of the absolute intensity of the (DP) to that of the CC (IDP/ICC) versus time.

Results:

Different times of milling were applied in order to better correlates the micronization process and the formation of the DP of CC. The HRMS analysis of samples 24 months after the micronization process revealed the presence of O-Desethyl Candesartan Cilexetil (Impurity B) and 2-Ethyl-Candesartan Cilexetil (Impurity F). These impurities were identified both in positive (as Na adducts) and negative ion modes. It was verified two different profiles along the long term degradation study: for Impurity B, the ratio IDP/ICC increased seven folds after 48 hours of micronization and remained stable until the end of the experiment. Impurity F, however, showed a continuous growing of the IDP/ICC ratio revealing a close relation between the time of milling during the micronization process and its formation during storage.

Conclusions:

Our data indicates a strong correlation between the time of milling and the formation of DP. The kinetic energy transferred to the particles during the process, produces the DP in different extents according to their stability and kinetics of formation. For the first time, the profile of formation of these CCimpurities, especially impurity F, were described after a long term storage study.

Novel Aspect:

Original HRMS information about the long term stability of candesartan cilexetil after micronization by milling.

1021 - MASS SPECTROMETRIC CHARACTERIZATION OF A POLYMERIC DEGRADATION PRODUCT FORMED FROM THE ANTIBIOTIC CEFTAZIDIME

Anna Maria Alves de Piloto Fernandes (1) - Nilton Soares Camilo (2) - Elias Paulo Tessaro (3) - Marcos Nogueira Eberlin (4)

Labmass Laboratory, University of Campinas/ Thomson Mass Spectrometry Laboratory, Campinas (1) - none, University of Campinas/Institute of Chemistry, Campinas (2) - Labmass Laboratory, University of Campinas/Thomson Mass Spectrometry Laboratory, Campinas (3) - none, University of Campinas/Thomson Mass Spectrometry Laboratory, Campinas (4)

Keywords: ceftazidime, Anti-HIV-1 activity, degradation products, β -lactam antibiotic

Introduction:

Degradation products in pharmaceuticals may cause harmful side effects but the new substances generated may have different therapeutic activities. Ceftazidime is a β -lactam antibiotic, which polymerizes during normal storage conditions [1]. Ceftazidime polymer showed a high inhibitory effect on HIV-1 reverse transcriptase [2,3]. In this study mass spectrometry is applied with the objective of revealing the chemical structure of a ceftazidime polymer.

Methods:

Ceftazidime (5 g) was heated to 60°C for 210 h in a covered container [2]. A methanolic solution of this polymerized material (1 μ g/mL) was analyzed by direct infusion in a QExactive™ Hybrid Quadrupole-Orbitrap coupled to an HESI II source. MS and MS/MS spectra were acquired at a resolution of 70,000 (@ m/z 400) in the positive ionization mode. MALDI analysis was performed in an Autoflex III Smartbeam MALDI-TOF/TOF instrument using 2,5-DHB as matrix doped with NaCl.

Results:

The HRMS showed a distribution of chain length typical of a polymeric material, with ions distributed along 300 - 1700 Da mass range. The calculated average molecular weight from the HRMS result was 911.7500 Da. The ions were equally spaced at 74.018 Da units apart. For each oligomeric unit, three different isotopic patterns with mass differences of 5 and 14 Da were observed. MALDI spectra presented the ion clusters between 600 and 1300 Da splitted by a difference of 23 Da suggesting the presence of sodium cationized oligomers.

Conclusions:

For the first time, a mass spectrometry based study of ceftazidime polymer has been published. Our mass spectra data, together with other techniques, allows the complete characterization of this interesting degradation product.

Novel Aspect:

First mass spectrometry study of a ceftazidime polymeric degradation product.

1067 - FULL VALIDATION OF METFORMIN IN HUMAN BLOODS USING VOLUMETRIC ABSORPTIVE MICROSAMPLING

Na Ha (1) - Kyungho Jang (1) - Song-Hee Han (1) - Seon eui Lee (1) - Min-Gul Kim (2)

Center for Clinical Pharmacology and Biomedical Research Institute, Chonbuk National University Hospital, Jeonju (1)
- Department of Pharmacology, School of Medicine, Chonbuk National University, Jeonju (2)

Keywords: Microsampling, Volumetric absorptive microsampling, Metformin, LC-MS/MS, Validation

Introduction:

Volumetric absorptive microsampling (VAMS) is a novel sampling technique that allows the collection of an accurate volume of blood by dipping an microsampler tip. The purpose of this study is to validated the concentration of metformin using LC-MS/MS in VAMS. We demonstrate full validation to ensure that this method is accurate, precise, and stable in metformin.

Methods:

A high-performance liquid chromatography with mass spectrometry (LC-MS/MS) was developed and validated for the accurate determination of metformin in human using VAMS. The method was validated for accuracy, precision, sensitivity, recovery, matrix effect, specificity, linearity and stability according to the KFDA guideline.

Results:

Validation the selectivity of the optimized method was assessed to determine any interfering peak around the retention times of metformin. The calibration curve was calculated by using the linear regression equation of $y=ax+b$, which is the weight ratio of metformin to the peak area of the internal reference material. Calculations of deviations between the measured and theoretical values for the six standard concentrations used in the calibration using the back-calculation method showed that at least 85% of the standard concentrations were within the standard (within 20% of the lowest limit of quantitation, Concentration was within 15%). For standard concentrations that did not meet the acceptance criteria, they were excluded from the calibration curve. The coefficient of determination (r) was higher than metformin 0.9990.

Conclusions:

The LC-MS/MS method was used to establish the analytical method for analyzing the concentration of metformin in human blood, and the validity of the established method was verified. In the concentration range of 2 - 100 ng/mL, it showed good linearity and no interference from human blood. The fully validated LC-MS/MS method showed applied to clinical trials such as bioavailability, bioequivalence and pharmacokinetic evaluation of metformin.

Novel Aspect:

This is the first paper analyzed metformin by LC-MS/MS using VAMS, a novel technology of microsampling.

1095 - DETERMINATION OF AN ISONICOTINOHYDRAZIDE DERIVATIVE, A NOVEL POSITIVE INOTROPIC COMPOUND, IN MOUSE PLASMA BY LC-MS/MS AND ITS APPLICATION TO A PHARMACOKINETICS STUDY

Renjie Hui (1) - Jingyi Liu (1) - Bainian Feng (1)

School of Pharmaceutical Science, Jiangnan University, Wuxi (1)

Keywords: isonicotinohydrazide derivative, LC-MS/MS, pharmacokinetics, mice

Introduction:

Heart failure (HF) is a growing public health problem with high mortality and morbidity [1-2]. The development of HF drugs is a pressing problem [3-5]. In previous works, we presented a new positive inotropic compound, an isonicotinohydrazide derivative (AF-HF001), which can directly effect on the myofibril and has a significant effect in the treatment of HF [6-8]. In this study, we employed LC-MS/MS for the qualitative and quantitative analysis of AF-HF001.

Methods:

Samples were prepared by one step precipitation with ethyl acetate and stored in acetonitrile. Chromatographic analysis was carried out on a Hypersil Gold C18 column with a gradient mobile phase consisting of acetonitrile and 0.1% aqueous formic acid. The analyte was detected by selective reaction monitoring (SRM) mode with target quantitative ion pair of m/z 292.1 \rightarrow 148.2, using praziquantel as the internal standard (IS) m/z 313.1 \rightarrow 203.2.

Results:

AF-HF001 is a novel positive inotropic compound, which has been reported very recently. The analysis of AF-HF001 in biological matrices is never published. We developed and validated this LC-MS/MS method for the quantitative analysis of AF-HF001 in ICR mice plasma. The one step extraction of ethyl acetate accomplished both drug extraction and protein precipitation, and provided better recovery, stability and simplicity. Then the chromatographic condition with both the composition of mobile phase and the column was also ameliorated to get good sensitivity and selectivity of drug in plasma. With the chosen ion pairs of drug and internal standard, we achieves the quantitative analysis with better precision and sensitivity of AF-HF001 in biological sample. Good linearity ($r=0.995$) was observed over a wide concentration range. The validation of method shows that this bioanalytical method we have developed is sufficient for the analysis of AF-HF001 in mice plasma and will be very essential for the further PK-PD studies of the drug.

Conclusions

A specific and sensitive LC-MS/MS method was developed for the determination of AF-HF001 in mice plasma for the first time. After a full method validation, it was successfully applied in the preliminary pharmacokinetic studies of AF-HF001 in mice after a single i.p. dose of 45mg/kg. The analyte was proved as a competitive candidate for the treatment of acute heart failure. Further pre-clinical and clinical pharmacological studies of AF-HF001 are also needed.

Novel Aspect:

A full validated LC-MS/MS method of AF-HF001 is described for the first time. It was successfully applied to a very first pharmacokinetics study of AF-HF001 in mice plasma.

292 - LC-MS/MS CHIRAL METHOD FOR SIMULTANEOUS DETERMINATION OF R,S-KETAMINE AND ITS METABOLITES IN RAT PLASMA AND BRAIN SAMPLES FROM PHARMACOKINETIC STUDIES.

Monika Janicka (1) - Mikołaj Matfoka (1) - Ewa Tratkiewicz (1) - Maciej Wieczorek (1)

Celon Pharma S.A., R&D, Łomianki (1)

Keywords: ketamine, metabolites, chiral chromatography, LC-MS/MS

Introduction:

Ketamine is a well-known agent used in anesthesiology since 1960s. The analgesic properties of ketamine were discovered in 1990s. Surprisingly, quite recently this agent also was shown to display unique antidepressive properties. Researchers from Celon Pharma S.A. have conducted comparative analyses of antidepressive effects exerted by R- and S-enantiomers of ketamine and its metabolites in dry powder inhalation as a delivery method.

Methods:

Samples (rat plasma and brain) were purified by protein precipitation and centrifugation. Analytes separation was achieved on a chiral Lux® 3 µm Amylose-2 column with a mobile phase consisting of 10 mM ammonium acetate, acetonitrile and 2-propanol. The flow rate was set at 0.5 mL/min. Mass spectrometric detection was performed with use of Agilent 6460 mass spectrometer in positive ionization mode. Ketamine-d4 was used as an internal standard (IS).

Results:

The aim of this study was to develop and validate LC-MS/MS assays for stereoselective quantification of R,S-ketamine and its metabolites, R,S-norketamine, (2S,6S)-hydroxynorketamine, (2R,6R)-hydroxynorketamine and R,S-dehydronorketamine in rat plasma and brain samples enabling the characterization of the ketamine pharmacokinetics after administration of a low intravenous (i.v.) or intratracheal (i.t.) dose. Due to very low volume (50 µL) of samples collected during preclinical studies only protein precipitation could be used as a sample preparation. As a result lower limit of quantitation (LLOQ) for all of compounds was determined to be 25 ng/mL. Analytes were separated in one 45 minutes run. Quantitation was performed using at least two MRM transitions per analyte and IS. The quadratic calibration curves for all analytes were obtained over the concentration range 25–5000 ng/mL. The intra- and inter-day precisions were <7.9% and the accuracy (relative error) was within ±5.3%.

Conclusions:

The study describes the development and validation of an easy, selective and reliable LC-MS/MS method for simultaneous determination of ketamine enantiomers and its metabolites in low-volume rat plasma and brain samples. The importance of the method is demonstrated by its ability to compare the ketamine metabolites concentrations in these matrices to healthy rats.

Novel Aspect:

LC-MS/MS method can differentiate enantiomers of ketamine and its three major metabolites in 45 min run using low volume complex matrix sample.

1153 - PHARMACEUTICAL INDUSTRY CHALLENGES WITH MASS SPECTROMETRY SOLUTIONS: FROM MICROSAMPLING TO MONOCLONAL ANTIBODIES

Walter Korfmacher (1)

Sanofi (1)

Keywords: Pharmaceuticals, Biologicals, Microsampling, HRMS, LC-MS

Introduction: (Limit of 400 characters)

The pharmaceutical industry is undergoing many changes. One challenge is to follow the 3R's by reducing the number of laboratory animals needed in the new drug discovery process. One solution is to take smaller blood samples (microsampling) so fewer laboratory animals are needed [1]. Another challenge is the shift toward biologicals. Biologicals are more difficult to assay than small molecules.

Methods: (Limit of 400 characters)

For blood microsampling, either capillary microsampling (CMS) tubes or a volumetric absorptive microsampling (VAMS) device was used. For mass spectrometry imaging (MSI), various high resolution mass spectrometer (HRMS) systems are discussed. For biological assays, various MS systems are described including triple quadrupole systems and HRMS systems.

Results: (Limit 900 characters)

In one study, we used the 8- μ L CMS blood sampling method [2]. In another study, we demonstrated the utility of both blood CMS and VAMS for getting samples from rat PK studies [3]. MSI has now become an important tool for understanding the distribution of a drug as well as its metabolites in laboratory animals. MSI can also be utilized for identifying disease and toxicity biomarkers as part of new drug discovery. Various strategies have been developed to measure therapeutic biological compounds, including monoclonal antibodies, in serum from mouse or monkey PK studies. One strategy is the "surrogate peptide approach", where the large biological compound is cut into smaller pieces (typically by using trypsin digestion). Then one or more of the peptides is selected to serve as the analyte that is quantified (typically by LC-MS/MS) in order to then calculate the concentration of the large biological molecule. Another approach is to use LC-HRMS to measure the intact biological compound directly.

Conclusions (Limit of 400 characters)

Overall, these studies provide additional data that blood CMS is a valuable approach for serial blood sampling from discovery rat PK studies. Mass spectrometry continues to be a key system that is used throughout all stages of the pharmaceutical industry research paradigm, from early drug discovery to clinical studies. As MS systems continue to improve, then new applications become possible.

Novel Aspect: (Limit of 150 characters)

The talk will describe how MS has been utilized to provide solutions for the pharmaceutical industry during new drug discovery and development.

1256 - EVALUATION OF SMALL MOLECULE DRUGS RETENTION IN FLUORINATED SILICA NANOPARTICLE STABILIZED PICKERING EMULSION USING ESI_MINE(TM) PLATFORM

Xin Li (1) - Jo Francis (2) - Colin Pilkington (1) - Alex Clay (1) - Clive Smith (1)

Sphere Fluidics Limited, R&D, Cambridge, United Kingdom (1) - GlaxoSmithKline (GSK), R&D, Stevenage, United Kingdom (2)

Keywords: ESI-Mine™, Pickering emulsion, Picodroplet, Microfluidics

Introduction:

Microfluidic Water-in-Oil (W/O) picodroplet technology has been emerging as a useful tool for single cell and biological macromolecule characterizations. However, poor retention in polymeric surfactant stabilized picodroplets has limited its applications in small molecules related analyses.

Methods:

ESI-Mine™ is a novel, high-throughput, mass spectrometry (MS) based platform developed for analyzing the contents of microfluidic picodroplets. Fluorinated silica nanoparticle (f-SiNP) stabilized W/O Pickering emulsion is reported capable of retaining a hydrophobic fluorescent dye (resorufin) in picodroplets. Here, we profiled the retention potency of non-fluorescent small molecules with a logP range from -2 to 4 in Pickering picodroplets using ESI-Mine™.

Results:

Pickering emulsion picodroplets (600-700 pL) were generated on a flow focusing 60X60 Pico-Gen™ biochip. f-SiNP (50 nm diameter) suspension in Novec™ 7500 (5%, w/w), prepared following Stöber's [1] and Pan's approaches [2], was used as the continuous phase, and an aqueous solution with/without 10 μM selected small molecule as the breaking phase. 'Occupied' picodroplets contain the selected small molecule, but 'Empty' do not. Picodroplet mixture of 'Occupied' and 'Empty' were reinjected onto a MS emitter microfluidic biochip interfacing with a Perkin Elmer Axlon 2 mass spectrometer, i.e. ESI-Mine™. Total ion current (TIC) signal of the picodroplets were recorded as a series of peaks. Extracted ion current (EIC) signal only shows 'Occupied' picodroplet peaks if the selected small molecule is retained inside 'Occupied' picodroplets, but in both 'Occupied' and 'Empty' if the selected small molecule cannot be retained. Eight small molecules of a logP range from -2 to 4 were selected, and analyzed on ESI-Mine™ platform.

Conclusions

We employed and demonstrated ESI-Mine™ platform as a useful tool to evaluate the retention potency of non-fluorescent small molecules inside f-SiNP stabilized Pickering emulsion picodroplets. Improved retention potency of small molecules inside f-SiNP stabilized Pickering emulsion picodroplets was observed compared to conventional polymeric surfactant stabilized picodroplets.

Novel Aspect:

Novel aspects include MS analysis of Pickering emulsion picodroplets, and evaluating retention potency of non-fluorescent small molecules inside Pickering picodroplets.

894 - CHARACTERIZATION OF A NOVEL ZETAMICIN IMPURITY BY LC-MS AND NMR: AN ORTHOGONAL TECHNIQUES APPROACH FOR THE STRUCTURAL ELUCIDATION OF LOW-LEVEL BYPRODUCTS

Elisa Libralesso (1) - Elisa Ciuti (1) - Antonio Triolo (1) - Fabio Lamonaca (2) - Matteo Gentili (3)

Menarini Ricerche spa, Preclinical Development, Firenze (1) - A. Menarini MLS, Analytical Research, Firenze (2) - Giotto Biotech, Organic synthesis, Firenze (3)

Keywords: antibiotics, impurities, LC-MS, NMR

Introduction:

Zetamicin is a wide spectrum antibiotic belonging to the aminoglycoside family. Its active principle Netilmicin is made up of a di-aminosaccharide unit (N-ethylgaramine) bound to an aminopyran moiety (6-(aminomethyl)-3,4-dihydro-2H-pyran-3-amine). A novel impurity was found in API Zetamicin, while performing a screening for potential related impurities; hence the need to fully characterize it in order to assess its potential toxicity.

Methods:

LC-MS analysis provided information on the m/z ratio, elemental composition and UV absorption maxima. The isolated impurity was then characterized by mono and bidimensional ¹H NMR, thus refining the structure and assigning the correct isomer among the possible ones. Following the structural determination, the compound was synthetically produced.

Results:

Perfect correspondence of the ¹H NMR traces, of MS and MS/MS spectra, and of LC retention times between the process and the synthetic impurities allowed to confirm the assignment to the correct isomer.

Conclusions:

This synergic teamwork between orthogonal techniques, such as LC-MS and NMR, was tailored to exploit their unique strengths. In fact, the high sensitivity and separation capabilities of LC-MS allowed to detect and isolate the low-level impurity, and to sketch out of its general structure, while NMR characterization performed on the isolated compound succeeded in the punctual assignment of its structure.

Novel Aspect:

Combination of LC-MS and NMR proved effective in the case study, sensibly easing data interpretations, for the strengths of each technique covers the weaknesses of the other.

1259 - GENERIC METHOD FOR PARALLEL ARTIFICIAL LIQUID MEMBRANE EXTRACTION OF NONPOLAR BASIC DRUGS FROM HUMAN PLASMA

Marthe Lid (1) - Astrid Gjelstad (1) - Stig Pedersen-Bjergaard (1)

Pharmaceutical Institute, University of Oslo, Oslo, Norway (1)

Keywords: Drug analysis, liquid phase microextraction (LPME), sample preparation, automation, green chemistry.

Introduction:

Through parallel artificial liquid membrane extraction (PALME) it is possible to perform miniaturized liquid-liquid extraction in a 96-well platesystem without the need for solvent evaporation and sample reconstitution prior to LC-MS [1-3]. Thus, with PALME, liquid-liquid extraction can be downscaled, simplified and automated. The aim of this project was to propose, develop, and test a generic method for PALME of monobasic drugs from human blood plasma with $\log P > 2$.

Methods:

The setup consists of a commercially available 96-well sample plate and filter plate. Samples of human blood plasma were mixed with carbonate buffer and methanol (total volume 250 μ l) and were pipetted into wells in the sample plate. Liquid membranes of 3 μ l organic solvent (1 % trioctylamine in dodecylacetate) were established by pipetting the mixture on filters in the filter plate. Acceptor solutions of 50 μ l aqueous formic acid (20 mM) were pipetted in the filter plate. The two plates were clamped together and agitated for 45 minutes at 900 rpm. Acceptor solutions were analyzed by UHPLC-MS/MS.

Results:

Data on extraction of 46 analytes have shown recoveries >40% for most analytes. Preliminary work on linearity, precision and accuracy on a selected number of analytes complied with the requirements of international guidelines for bioanalytical method validation, and a full validation is currently in progress.

Conclusions

A generic PALME method was proposed for monobasic drugs with $\log P > 2$, and tested for extraction from human blood plasma. The preliminary results show potential and complies with international guidelines for bioanalytical method validation. The generic PALME method provided a simple workflow (with potential for automation), efficient sample cleanup for LC-MS analysis [1], and reduced the consumption of organic solvent to 3 μ l per sample.

Novel Aspect:

This study is the first attempt to develop generic methods for parallel artificial liquid membrane extraction (miniaturized liquid-liquid extraction in 96-well format).

Keywords: ionisation efficiency, electrospray ionisation, metabolites, biological matrices

Introduction:

Ionisation efficiency depends on the structure of the compound as well as solvent and setup used. Presently, the relative abundance is evaluated based on the peak area. We demonstrate that the accuracy of such analyses in biological matrices can be significantly improved by predicting ionisation efficiencies.

Methods:

All measurements were carried out in ESI negative mode. The logarithm of ionisation efficiencies ($\log I_E$) of 10, predominantly pharmaceutical, compounds were predicted in 6 biological matrices (blood, plasma, cerebrospinal fluid, urine, brain and kidney tissue). Charge delocalisation parameter WAPS and degree of ionisation α calculated via COSMO-RS were used as input parameters.

Results:

The $\log I_E$ values in different biological matrices were in good correlation with the $\log I_E$ values in a solvent. This good correlation suggests that ionisation efficiencies can be predicted in the matrices similarly to the procedure previously proposed for the solvent. To test this, WAPS and α were used to fit the models for predicting $\log I_E$ values in biological matrices.

The best predictive power of the model was observed in liver tissue homogenate (the root mean square error of the models, sRMSE = 0.49) and the lowest predictive power in urine (sRMSE = 0.80). The correlation between measured and predicted $\log I_E$ values over all matrices is high, $R^2 = 0.83$ and sRMSE = 0.67 $\log I_E$ units. Therefore, on average, the mismatch between the predicted and measured ionisation efficiencies is lower than 8 times. This enables semi-quantitative LC/ESI/MS analysis by using a set of calibration compounds to adjust model coefficients for the biological matrix of interest.

Conclusions:

Until now equal ionisation efficiencies of all compounds in all matrices are assumed if authentic standards are lacking. For the compounds used in this study, this approach would lead to a mismatch of 660 times with reality. Correcting signals with predicted ionisation efficiencies improves accuracy by almost two orders of magnitude. Additionally, we demonstrate that ionisation efficiencies can be predicted in biological matrices.

Novel Aspect:

We present an accurate approach to predict ionisation efficiencies in ESI negative mode for complex biological matrices.

840 - A NOVEL GC-MS METHOD FOR SIMULTANEOUS DETERMINATION OF SEVEN PARABEN DERIVATIVES IN PHARMACEUTICAL AND COSMETIC PRODUCTS CONSUMED IN TURKEY

Saniye Ozcan (1) - Serkan Levent (2) - Aysun Geven (3) - Nafiz Oncu Can (1)

Anadolu University, Anadolu University/ Faculty of Pharmacy/Department of Analytical Chemistry/Doping and Narcotic Compounds Analysis Laboratory, Eskisehir (1) - Anadolu University, Anadolu University/ Faculty of Pharmacy/Department of Pharmaceutical Chemistry/Doping and Narcotic Compounds Analysis Laboratory, Eskisehir (2) - Anadolu University, Anadolu University/ Faculty of Pharmacy/Department of Analytical Chemistry, Eskisehir (3)

Keywords: GC-MS, parabens, isomers, pharmaceuticals, cosmetics

Introduction:

Due to official regulations on the use of Alkyl esters of p-hydroxybenzoic acid (parabens) [1], the presented study was developed for quantitative determination of methylparaben (MP), ethylparaben (EP), n-propylparaben (NPP), i-propylparaben (IPP), n-butylparaben (NBP), i-butyl paraben (IBP) and benzylparaben (BP) in some pharmaceutical and cosmetic products consumed in Turkey using gas chromatography-mass spectrometry (GC-MS) - isotope dilution method.

Methods:

GC was carried out using a highly inert 95% dimethylpolysiloxane, 5% diethylpolysiloxane phase column (Rxi®-5ms, 30 m × 0.25 mm × 0.25 µm film thickness, Restek, USA). The ion trap mass spectrometer was operated in the electron impact - positive ionization mode (+70 eV) using an external ionization configuration. In the full scan mode the mass range was varied from 35 to 500 m/z at 0.6 s scan⁻¹.

Results:

Analyte concentrations were determined by isotope dilution method using ¹³C¹³-MP-EP-PP-BP solutions as an internal standard to quantitative the unlabeled paraben derivatives. The obtained results for linearity, precision, and accuracy of the proposed method support their potential use for simultaneous identification and quantitative determination of the MP, EP, NPP, IPP, NBP, IBP and BP in samples. The method was validated according to ICH Q2(R)1 regulations [2], and system suitability parameters were checked according to the USP.

The amount of each of paraben was calculated using the calibration equations in 17 pharmaceutical and cosmetic products. Among the samples, none of the above-mentioned parabens were found in 11 of the analyzed products; both MP and NPP were detected in 4 of the products.

Conclusions:

A simple, selective and highly accurate isotope dilution - GC-MS method was developed and applied to analyze the MP, EP, NPP, IPP, NBP, IBP and BP in cosmetics and pharmaceutical products. Further studies with more products of different compositions and different manufacturers have to be conducted to make a better assessment overall possible hazard from originating from pharmaceutical and cosmetic products.

Novel Aspect:

To the best of our knowledge, this is the first study in which pharmaceutical or cosmetics products from Turkish market were analyzed for parabens content using GC-MS.

1223 - ANTICANCER ACTIVITY EVALUATION OF NEW PHORTRESS ANALOGUES AND IDENTIFICATION OF BIOACTIVE METABOLISM PRODUCTS USING LCMS-IT-TOF

Yusuf Özkay (1) - Derya Osmaniye (1) - Begüm Nurpelin Sağlık (1) - Serkan Levent (1) - Sinem Iğın (2) - Zafer Asım Kaplanıklı (1)

Anadolu University, Faculty of Pharmacy, Department of Pharmaceutical Chemistry, Eskisehir, Turkey (1) - Anadolu University, Faculty of Pharmacy, Department of Pharmaceutical Toxicology, Eskisehir, Turkey (2)

Keywords: Phortress, Benzoxazole, Anticancer, Active Metabolite, LCMS-IT-TOF

Introduction

Phortress, including benzothiazole moiety, is a prodrug displaying anticancer activity. The active metabolite of phortress is a potent agonist of the aryl hydrocarbon receptor and switches on cytochrome P450 CYP1A1 gene expression [1]. In the present study, new analogues of phortress were synthesized and investigated for anticancer activity. In order to identify a probable active metabolite, biotransformation studies were conducted and results were examined by mass spectroscopic analyses.

Methods

Target benzoxazole derivatives (3a-3p) were synthesized [2], and anticancer activity tests were performed on colon (HT-29), breast (MCF7), lung (A549), liver (HepG2) and brain (C6) carcinoma cell types [3]. Induction potential of the compounds 3m and 3n on CYP1A1/2 enzymes was additionally investigated. Biotransformation studies for 3m and 3n were evaluated by LCMS-IT-TOF instrument (Shimadzu, Japan). Moreover, molecular docking studies for compound 3n and its some metabolites were performed.

Results

Anticancer potentials of phortress analogs 3a-3p were assessed by cytotoxicity, DNA synthesis inhibition, and apoptosis induction assays. Compounds 3m and 3n were the most cytotoxic agents, which inhibited DNA synthesis of carcinogenic cell lines, significantly. It was also determined that these compounds have an effect to induce apoptotic cell death. In the biotransformation studies, compounds 3m and 3n were incubated with HepG2 cell line for 24 h. Metabolite identification studies were performed using LCMS-IT-TOF system. Proposed biotransformation pathway displayed that there are metabolites (3mM1, 3mM2, 3nM1, and 3nM1), which undergo the same metabolic reactions as active metabolites of phortress. CYP1A1/2 enzyme induction and molecular docking studies gave similar results to those of phortress.

Conclusions

As synthesized compounds thought to be prodrugs, their metabolic pathways were evaluated by applying biotransformation studies. Identification of very similar metabolites to active metabolites of phortress recommended that 3m and 3n have same mechanism of action with that of phortress. Furthermore, results of CYP1A1/2 enzyme induction and molecular docking studies also supported this suggestion.

Novel Aspect

Two novel anticancer drug candidates, which have stronger activity than phortress, were developed along with their active metabolites determined by LCMS-IT-TOF analyses.

University of Picardie Jules Verne (UPJV), Analytical Platform (PFA), Amiens (1) - University of Picardie Jules Verne (UPJV), BIOPI-EA3900, Amiens (2) - Technologie Servier, Synthesis, Orléans (3) - Technologie Servier, A.S.M.P., Orléans (4)

Keywords: Biotransformation; Position of substitution; MS/MS; Ion mobility; Chemometrics.

Introduction:

Biotransformation is used to build molecules, similar to active principal ingredient, in the drug discovery program [1]. The structural identification of metabolites remains challenging when isomeric substituted molecules are involved. In this work, we present a methodology which combines, travelling-wave ion mobility separations (TWIMS) [2], MS/MS fingerprints and chemometrics [3], to successfully assign a number of isomeric hydroxylated metabolites.

Methods:

A model molecule bearing an aza-bicyclo moiety and 6 of its hydroxylated metabolites, previously isolated, were used for our methodology development. Retention times (t_R) from UPLC/HRMS separation, instrument measured drift times (t_D) from TWIM separation of the protonated molecules, accurate m/z and intensity measurements of fragment ions from MS/MS spectra, were collected.

Results:

The t_R, drift times and MS/MS data set of our standard molecules led to coherent information regarding hydroxylated metabolites substitution position, shape, polarity and stereochemistry. Statistical processing of MS/MS fragment ions intensities, using multivariate analysis (SIMCA-P), enabled a fast and unambiguous assignment of the metabolites structures, which could allow the transposition of our approach to investigate complex bioconversion mixtures.

Conclusions:

To validate our workflow, the UPLC/HRMS screening of 12 fungi stains followed by a principal component analysis (PCA) were performed. After the selection of the best candidate, the hydroxylated metabolites content was quickly elucidated with the previously described tools.

Novel Aspect:

Investigation of isomeric compounds using a combination of ion mobility, MS/MS and chemometrics.

186 - COMPLEX APPROACH FOR ISOLATION AND HPLC-MS DETERMINATION OF STEROIDAL GLYCOSIDES FROM PLANT MATERIAL AND SUSPENSION CELL CULTURE.

Igor Rodin (1) - Boris Sarvin (1) - Andrey Stavrianidi (1) - Timur Baygildiev (1)

Lomonosov Moscow State University, Department of Chemistry, Moscow (1)

Keywords: extraction, HPLC-MS, steroidal saponins, experimental design

Introduction

For thousands of years, herbal medicines made from terrestrial plants were used by humans to prevent and treat diseases. Extraction is the crucial first step in the analysis of medical plants. Researches have shown that most of the therapeutic properties of *D. deltoidea* and *T. terrestris* are due to the presence of steroidal glycosides. The main objectives of this study were to develop a complete strategy of isolation and HPLC-MS determination of steroidal glycosides.

Methods

The HPLC separation was conducted on a C18 column. The separation was carried out in a gradient elution mode. Detection were performed by MS in positive ion (SIM mode). Ultrasound-assisted (UAE), refluxing (RE), low pressure refluxing (LPRE) and Soxhlet (SE) extraction techniques were developed for determination steroidal saponin content. The results were confirmed using the multiple successive extraction method and spiking with standards before extraction.

Results

Extraction parameters for UAE, RE, LPRE and SE methods were optimized by single-factor-experiment for isolation of steroidal glycosides from *T. terrestris* [1]. Extraction parameters for UAE method were optimized by Latin Square experimental design at 4 levels for 4 factors for isolation of steroidal glycosides from *D. deltoidea* plant material and cell culture [2]. Thermal decomposition of protodioscin was observed after long term high temperature extraction process. The accuracy for all studied extraction techniques was confirmed by spiking of the plant material with standards before extraction and HPLC-MS analysis and the analytical method was validated for linearity, limits of detection, limit of quantification, precision and accuracy. Also, a high degree of extraction was confirmed by multiple successive extraction method (MSEM) and RE Methods: At the same time, it was shown that the UAE method is completely inappropriate for a similar task when working with plant material. This may be due to the lack of mechanical tissues in the cell culture, in contrast to plant material.

Conclusions

In the course of the work cycle, a study was made of the patterns and features of extraction, chromatographic separation followed by mass spectrometric determination of the steroidal glycosides from plant material and cell cultures. The impossibility of using the UAE extraction method for working with plant material was also shown.

Acknowledgements

This work was supported by Russian Science Foundation (Grant No. 17-13-01146) for Moscow State University.

Novel Aspect

The method for HPLC-MS determination of steroid glycosides was developed and validated. The optimization and comparison of extraction techniques were performed.

175 - USE OF HIGH RESOLUTION MASS SPECTROMETRY FOR TROPANE ALKALOIDS DETERMINATION AND UNTARGETED ANALYSIS IN DRUGS AND HOMEOPATHIC PRODUCTS FROM ATROPA BELLADONNA SEED EXTRACTS

Roberto Romero González (1) - Jesús Marín Sáez (1) - Antonia Garrido Frenich (1)

University of Almería, Almería/Dept. Chemistry and Physics, Almería (1)

Use of high resolution mass spectrometry for tropane alkaloids determination and untargeted analysis in drugs and homeopathic products from Atropa Belladonna seed extracts

Roberto Romero González*, Jesús Marín-Sáez, Antonia Garrido Frenich

Research Group "Analytical Chemistry of Contaminants", Department of Chemistry and Physics, Research Centre for Agricultural and Food Biotechnology (BITAL), University of Almería, Agrifood Campus of International Excellence, ceiA3, E-04120 Almería, Spain. Email: rromero@ual.es

Keywords: Homeopathic products, tropane alkaloids, Atropa belladonna, Orbitrap-MS, untargeted analysis.

Introduction:

Tropane alkaloids are compounds with therapeutic properties naturally obtained from Solanaceae plants as Atropa Belladonna, which has been used in drugs and homeopathic products. The main concern related to homeopathic products is the scarce information about their composition as well as recent cases of secondary effects [1]. New methods are necessary to control these products, including untargeted analysis.

Methods:

The extraction method was based on solid phase extraction (SPE) for homeopathic products and then, the recomposed extract was analyzed by liquid chromatography coupled to high resolution mass spectrometry (Exactive-Orbitrap). For drugs (ointment) and Atropa Belladonna seeds only dilution was used prior injection. A homemade database with 41 tropane alkaloids was created and applied. Compound Discover 2.1 was used to search untargeted compounds.

Results:

The method was optimized using a SPE procedure to concentrate the compounds present in homeopathic products, as well as the dilution step for drugs and Atropa Belladonna seeds. The method was validated evaluating parameters as specificity, linearity, accuracy, precision and limits of detection (LOD) and quantification (LOQ). The proposed method allows the determination of a large range of tropane alkaloids in Belladonna seeds and ointment from Belladonna extract at concentration up to 337.5 mg/kg for atropine, while in homeopathic products only atropine, scopolamine, tropine and apoatropine were detected. When untargeted analysis was performed, other tropane alkaloids (benzoylecgonine) found in related plants [2] were also detected. In addition to tropane alkaloids, amino acids, considered as precursors of tropane alkaloids (phenylalanine and ornithine), were confirmed in the seeds as well as sugars (glucose, fructose and lactose) in the homeopathic drugs.

Conclusions

The developed method provides the quantification of a large range of tropane alkaloids. High resolution mass spectrometry allows the retrospective analysis of the samples and the available software makes possible untargeted analysis, detecting other tropane alkaloids, precursors as amino acids and other compounds present in the drugs.

Novel Aspect:

A suitable methodology for the comprehensive characterization of homeopathic products from Atropa Belladonna applying targeted and nontargeted approaches is provided.

Keywords: linear equations of deconvolution analysis, LEDA, energy resolved mass spectrometry, isomers resolution, ion trap

Introduction:

The separation of a mixtures of isomers by chromatography generally requires lot of time and it is isomers pair-specific. To overcome this issue, LC-MS/MS methods, together with a mathematical algorithm that is able to identify the isomers present in the sample without their chromatographic separation, were developed [1-2]. This approach was applied to MS/MS acquisitions obtained with both triple quadrupole and ion trap mass analyzers.

Methods:

The LC-MS/MS analysis were performed using both triple quadrupole (QqQ) and ion trap (IT) systems, either equipped with ESI source, operating in positive-ion mode. The chromatographic parameters employed to analyze the samples were finely tuned to minimize the run time. Moreover, a matrix of linear equations (LEDA), based on abundance ratios of product vs precursor ions, was used. This approach was verified to 6 isomers pairs of NSAID-coumarin hybrid inhibitors [3].

Results:

The study was carried out on standard solutions of analytes and their mixtures in the concentration range of 10 to 100 ng mL⁻¹. Using the reported conditions, a co-elution of the studied isomers were observed. Therefore, in case of a isomers mixture, LEDA must be able to resolve the co-eluting peak determining the relative concentration of each isomer eventually present. However, some issues were occur in the QqQ results, that showed in some cases lack of precision. These problems were mainly due to the difficult evaluation of the abundance of the precursor ion before its decomposition. To avoid the early decay of the precursor ion, the MS/MS experiments in IT were carried out. The fragmentation mechanism in IT allows a better management of the ions (precursor/products) ensuring their correct abundance rating. Indeed, the different energy transfer during collision process, lead to the formation of product ions directly by precursor ion. However, this characteristic often produce a poor number of product ions, which contrasts the LEDA application.

Conclusions:

The quali-quantitative data obtained from both tested MS analyzer demonstrated the LEDA reliability in the isomers speciation.

Novel Aspect:

The LEDA approach has the advantage that isomers can be quantified without the need of LC separation or additional specialized ion mobility instrumentation.

Laboratory of Analytical Chemistry for Development, Menarini Ricerche, via Francesco Rismondo 12A, 50131 Firenze (Italy)

Keywords: Polysorbate, quantification, characterization, tandem MS, all-in-one method

Introduction:

Polysorbate (PS) is a polyoxyethylene (POE) type non-ionic surfactant derived from esterification of sorbitan, made from a very complicated mixture of polymers, widely used as excipient.

Analytical challenges are: structural heterogeneity caused by different sorbitan core structures esterified in different positions with a mix of fatty acids; small amount in formulations, potential interferences from excess of drug substance and excipients; no UV absorbance.

Methods:

All the information is obtained in one HPLC-MS run using a Q-ToF instrument. The method includes a low-energy survey MS scan, to obtain information on the intact components and the molecular weight distributions of the involved species; a data-independent MS/MS scan to detect characteristic fatty acids marker ions; a data-dependent MS/MS of selected precursor ions, triggered by detection of a given fatty acid marker in the data-independent scan.

Results:

We developed and validated an analytical method for simultaneous profiling and quantification of polysorbate 80 (having oleic acid as the main fatty acid component) either as neat excipient or contained in pharmaceutical and biopharmaceutical formulations.

The method provides identification of components, their apparent percentages, the fatty acids profile, the absolute quantification of this excipient in formulations, the detection and identification of its degradants.

The developed method finds different application in quality control, comparison of suppliers, monitoring batch-to-batch consistency, regulatory documentation, understanding preformulation and stability issues.

Conclusions:

The developed method is suitable for rapid characterization and quantification of neat polysorbate and polysorbate in pharma and biopharma formulations, yielding simultaneously components identity, their apparent percentages, the fatty acids profile and its absolute quantification in different kinds of solid and liquid formulations.

Novel Aspect:

First description of a suitable quali/quantitative method for comprehensive characterization of PS.

961 - RAPID HPLC-MS/MS EVALUATION OF THE BATCH-TO-BATCH CONSISTENCY OF THE PAYLOADS SUBSTITUTION OF A LYSINE ANTIBODY-DRUG-CONJUGATES (ADCS).

Fabiana Tavani (1) - Antonio Triolo (1)

Menarini Ricerche SpA, Analytical Chemistry for the Development, Florence (1)

Keywords: ADC; Conjugation site analysis; Lysine conjugation; Data-independent acquisition; Batch-to-batch consistency

Introduction:

The aim of this work is the determination of the drug substitution sites of a lysine antibody-drug conjugate (ADC) by a very specific LC-MS analysis of its peptide digests [1][2]. Conjugated peptides were detected with high sensitivity and specificity by monitoring the characteristic reporter fragment ions of the cytotoxic molecule. Moreover, the batch-to-batch consistency of the conjugation was studied to evaluate the reproducibility of the production process.

Methods:

The ADC was denatured and digested with a Trypsin/Lys-C mix (E/P ratio 1:25). The instrument was a Synapt G2 HDMS mass spectrometer interfaced with a Waters ACQUITY UPLC H-Class System, using an Acquity Peptide CSH UPLC column. The data acquisition was in MSE mode. Conjugated peptides were detected by extracting the payload fragment ions from the high energy trace. The results were elaborated by UNIFI software (Waters).

Results:

From the automatic data processing with UNIFI software, about 30 payload-substituted peptide were detected, which were then visually inspected to confirm their identity. The conjugated peptides were characterized by their accurate masses, retention times and by their MS/MS sequence, allowing unambiguous detection of the substituted residues [3].

Subsequently, eight batches of ADC were treated with the same experimental method and the extracted ion chromatograms of the payload reporter ions were compared: in this way it was possible to highlight similarities and differences among the obtained chromatographic profiles, and hence the similarity degree of the substitution sites among all batches. The evaluation of the obtained chromatograms showed that they were practically superimposable, demonstrating excellent batch-to-batch consistency of the payload substitution.

Conclusions:

The payload-substituted peptides in the digestion mixture were detected with high specificity, allowing substitution site determination based on sequence information from the MS/MS data. Moreover, the comparison of the profiles of the extracted chromatograms of the payload fragment ions allows to evaluate the reproducibility of the production process and to identify any differences, in the substitution sites, among several batches.

Novel Aspect:

Description of a quick and simple method to assess batch-to-batch reproducibility of the conjugation process in an ADC.

818 - SUB-PPM DETECTION AND IDENTIFICATION OF IN-VIVO METABOLITES OF AN ANTIBODY-DRUG CONJUGATE BY DATA-INDEPENDENT HPLC - HIGH-RESOLUTION TANDEM MS

Antonio Triolo (1) - Elisa Ciuti (1) - Chiara Carboni (2) - Vera Chirulli (2)

Menarini Ricerche, Analytical Chemistry for Development, Firenze (1) - Menarini Ricerche, Pharmacokinetics and Metabolism, Pomezia (2)

Keywords: antibody-drug conjugates, anti-tumor, metabolites, data-independent, tandem MS

Introduction:

The activity of an Antibody-drug conjugate (ADC) is exerted after drug release from the ADC inside the cancer cells. Drug and its cellular metabolites are further transformed *in vivo*, generating a series of highly cytotoxic drug-related molecules which must be identified as a first step for their pharmacological and toxicological evaluation. Here we describe identification of the payload metabolites in serum of cynomolgus administered intravenously with an ADC.

Methods:

The deproteinized sera were analyzed by LC-MS/MS with a 100 x 1.0 mm RP column, using a Q Exactive mass spectrometer operated in positive ESI. Data acquisition consisted of a full-scan MS at FWHM resolution = 70000, alternated with a series of 30 MS/MS scans, at resolution = 17500 and HCD collision energy 20 V, acquired with precursors ranging sequentially from m/z 610 to 1161 in steps of 19 m/z units, and 20 m/z units quadrupole isolation windows. Scan time was 2.8 secs.

Results:

The above described method afforded full-scan sensitivity to sub-ng/mL levels, and sufficient selectivity to distinguish the metabolites signals in the presence of coeluting matrix peaks up to 3 degrees of magnitude higher in abundance. The payload-related metabolites were detected by extracting the accurate masses of selected fragment ions from the entire MS/MS data set, whereas their precursors were visually searched at the corresponding retention times in the MS data set, inside the 20 m/z -wide interval from which the fragment ions were generated. The method selectivity was verified by analyzing blank serum, and the capability of detecting unknown payload-related compounds by spiking blank serum with 5% v/v drug incubates in human liver microsomes. Cynomolgus sera treated with 5 and 1 mg/kg ADC showed the presence of the free drug, its cysteine conjugate, and the drug plus linker adduct. Each metabolite was characterized by the accurate masses of the precursor and its main diagnostic fragment ions.

Conclusions:

High-resolution MS and data-independent analysis with sequential windows MS/MS acquisition of a series of precursors spanning an about m/z 600 mass interval, allowed successful detection and identification of the payload-related metabolites in cynomolgus serum after treatment with an ADC at 5 and 1 mg/kg dose. The method features high specificity and full-scan sensitivity in the sub-ng/mL range, with mass accuracy typically below 2 ppm.

Novel Aspect:

First data-independent scanning application to the detection and identification of *in vivo* ADC metabolites.

375 - MALDI TOF MASS SPECTROMETRY FOR THE CHARACTERIZATION OF ANTITUMOUR RUTHENIUM(II) POLYPYRIDYL COMPLEXES

Romana Masnikosa (1) - Filip Veljkovic (1) - Boris Rajcic (1) - Ana Rilak (2) - Suzana Velickovic (1)

Vinča Institute of Nuclear Sciences, University of Belgrade, Belgrade (1) - Faculty of Science, University of Kragujevac, Kragujevac (2)

Keywords:

MALDI-TOF-MS

ruthenium(II) complexes

instrumental parameters

Introduction

Ruthenium(II) polypyridyl compounds, such as Ru(II) terpyridine complexes, are among lead compounds in anticancer drug discovery [1]. Their characterization after synthesis is, thus, necessary, but also presents a challenge. To this end we used matrix-assisted laser desorption/ionization time of flight mass spectrometry (MALDI-TOF-MS). Our main goal was to find how instrumental parameters affect the mass spectra of $[\text{Ru}(\text{Cl-Ph-terpy})(\text{N-N})\text{Cl}]^+$ complex ions.

Methods

Experiments were performed on the MALDI TOF Voyager-DE PRO (Sciex, USA) instrument, equipped with a delayed ion-extraction device and a pulsed nitrogen laser (337 nm 3 ns pulse width) operating at 20.0 Hz laser repetition rate. Solution of dithranol in tetrahydrofuran was employed as a matrix. A 0.5 μL of the matrix was placed onto a stainless steel target plate and laid over by 0.5 μL of a sample solution.

Results

MALDI MS has been successfully applied for identification and characterization of transition metal compounds and organometallics [2-5]. In spite of this, data regarding the effect of matrix, laser intensity and analysis mode on mass spectra of transition metal complexes is limited [6]. In the study presented herein we optimised the values of input variables: the laser intensity, the extraction delay time, the accelerating voltage, the grid voltage and the number of laser shots for the characterization of the three complexes. The complexes have a general formula $\text{mer-}[\text{Ru}(4'\text{-chlorophenyl-}2,2':6',2''\text{-terpyridine})(\text{N-N})\text{Cl}]\text{Cl}$, where N-N is a bidentate ligand: 1) 1,2-diaminoethane (en), 2) 1,2-diaminocyclohexane (dach) or 3) 2,2'-bipyridine (bpy). The fact that Ru possesses seven stable isotopes aggravated the analysis of mass spectra of its compounds. Since the studied complexes contain an inner chloride, the isotopic distribution of Cl must also be taken into an account.

Conclusions

In the mass spectra of the studied Ru(II) complexes the peaks of molecular (nonfragmented) ions were visible only upon the careful selection of the instrumental parameters. Otherwise fragment ions dominated the mass spectra, which precluded the determination of the precise molecular masses of the complexes. The accelerating voltage, the grid voltage and the extraction delay time had the greatest influence on the mass spectra and isotopic resolution of the peaks.

Novel Aspect

Tuning of instrumental parameters of the MALDI TOF mass spectrometer for characterization of novel anticancer Ru(II) terpyridine compounds.

334 - NEW QC IDENTITY TESTING FOR ACELLULAR PERTUSSIS COMBINATION VACCINES USING LC-MS

Hong Zhang (1) - Rob Maharajh (1) - Seeven Vydelingum (1) - Lois Yin (1)

Sanofi Pasteur, Analytical Process and Technology, Toronto (1)

Keywords: LC-MS, Vaccine, Quality Control, Identity Testing, Regulation

Introduction

A Liquid Chromatography-Mass Spectrometry method (LC-MS) was developed, validated, and implemented in Quality Control (QC) for the identity testing of acellular pertussis combination vaccines. QC activities represent around 70% of product cycle time and are often considered as bottle necks. A single LC-MS method is able to replace several antibody based identity tests to enhance quality, increase efficiency, and reduce cost and cycle-time.

Methods

The vaccine samples are digested to generate peptides. The peptide mixtures are then separated using liquid chromatography and analyzed in real-time by the mass spectrometer. The mass spectrometer detects the antigen specific peptides or signature peptides using accurate mass and retention time.

Results

The LC-MS identity assay is able to not only detect the presence of each of the antigen specific peptides derived from Diphtheria Toxoid (D), Tetanus Toxoid (TT), Pertussis Toxoid (PT), Fimbriae (FIM), Pertactin (PRN), Filamentous Haemagglutinin (FHA), Inactivated Poliomyelitis Vaccine (IPV) but also the dosage of the vaccines for the identification and differentiation of the products with different formulations. The specificity of the method is validated by the positive detection of the antigen specific peptides in samples/products where the corresponding antigen is present and their lack of detection in samples/products where the corresponding antigen is absent. Robustness tests were performed to examine the potential sources of variation. This was done by selecting factors expected to affect method responses, and the effect of the factors were examined and statistically analyzed.

Conclusions

The identity testing for pertussis and related combination vaccines using LC-MS is specific and robust. The test method is validated and accepted by the Regulatory Agencies, such as FDA, Health Canada, and EU. Implementation of LC-MS ID test in QC replaces identity tests using traditional Western Blot, Dot Blot, Agar Immunodiffusion, and ELISAs, eliminates the use of more than 18 antibody reagents, and reduces the cost and cycle time.

Novel Aspect

Implementation of a LC-MS release test for vaccine identification in QC and obtaining regulatory approval represent breakthroughs in the vaccine industry.

291 - ISOTOPIC VARIABILITY OF BIRDS FEATHERS IN THE ALPS: EFFECT OF ENVIRONMENTAL AND ECOLOGICAL CHARACTERISTICS ON A REGIONAL SCALE

Alessandro Franzoi (1) - Federica Camin (2) - Paolo Pedrini (1) - Luana Bontempo (2)

MUSE, Sezione Vertebrati, Trento (1) - Fondazione Edmund Mach, Food Quality and Nutrition Department, San Michele all'Adige (2)

Keywords: stable isotope ratios, Passerines, Alps, isotopic niche

Introduction:

Stable isotopes are a practical tool used to define animal movements and to delineate trophic structures in animal communities [1, 2]. A crucial aspect of spatial ecology is the definition of the degree of isotopic variability that can be measured locally in animal tissues, in order to carry out the correct probabilistic assignments to a geographic location, calibrating the isotopic discrimination between stable isotopes in trophic sources and animal tissues [3].

Methods:

Stable isotope ratios of bio-elements ($\delta^2\text{H}$, $\delta^{18}\text{O}$, $\delta^{13}\text{C}$, $\delta^{15}\text{N}$, $\delta^{34}\text{S}$) were determined in feathers of Passerines from the Italian Alps. The feathers were sampled on an altitudinal gradient in a restricted region from juvenile and post-breeding generations. Stable isotope ratios were determined by Isotope Ratio Mass Spectrometry after preparation of the feathers according to Bontempo et al. (2014) [4].

Results:

Isotopic variations can be mainly related to species feeding habits [5], seasonal effect of regional climatic conditions [6], geographic and topographic patterns [7, 8], natural or anthropogenic inputs which perturbate the local isoscapes [9, 10]. Through this study we assessed the probable variability sources, taking into account the distinct stable isotope ratios separately. In particular, the local variability in the sampling sites within a specific area of Italian Alps was measured, comparing the isotopic composition in feathers of several common Passerine species sampled from different moult generations in moulting and fattening sites within or close to the breeding locations. Using the derived information it was possible to determine the specific regional multi-isotopic variability, as well as to define seasonal isotopic variability related to trophic and habitat niches.

Conclusions

The local variability of the isotopic composition within the sampling sites, comparing different species and different feathers generations was measured. In particular, the regional multi-isotopic variability for Passerines according to trophic sources and animal tissues was defined. This information is crucial in depicting the isotopic niche in local birds of Central Alps, deepening the knowledge about isotopic variability related to topographic, environmental and seasonal perturbations.

Novel Aspect:

Isotopic variability in avian keratinous tissues was estimated with a multi-isotopic approach in a narrow Alpine region. The concept of isotopic niche was deepened.

1125 - POTENTIAL USE OF THE STABLE ISOTOPE RATIOS OF BIOELEMENTS AND ELEMENTAL COMPOSITION TO TRACE THE ORIGIN OF DAIRY PRODUCTS

Luana Bontempo (1) - Federica Camin (1)

Department of Food Quality and Nutrition, Research and Innovation Centre, Fondazione Edmund Mach (FEM), Via E. Mach 1, 38010, San Michele all'Adige (TN), Italy (1)

Keywords: stable isotope ratios, elemental composition, traceability, dairy products

Introduction:

There is an increasing demand for reliable analytical methods to verify the authenticity of the food we eat. This is also important for PDO dairy products, which can command significantly higher prices than their non-PDO competitors. Stable isotope ratios and elemental composition have been used for discrimination and can be used to verify the authenticity of marketed products. An overview of the use of this approach to trace dairy products is presented here.

Methods:

Isotope Ratio Mass Spectrometry and Inductively Coupled Plasma Mass Spectrometry methods were developed to characterise and determine the authenticity of different types of dairy products. In particular, the stable isotope ratios (SIRs) of five bioelements- hydrogen, carbon, nitrogen, oxygen and sulphur - were determined in defatted dairy products, whereas elemental composition was determined in the raw product after acid microwave digestion.

Results:

Geo-climatic and pedo-geological factors affect SIRs in nature and the isotopic variations are ultimately incorporated into animal tissue through eating, drinking, breathing and exchanges with the environment, and are memorised in the resulting dairy products. Similarly, the elemental composition of dairy products is affected by different factors related to the place of origin (e.g. geology and soil characteristics) and animal diet, but also depends closely on the conditions in which such products are made and processed. The combination of these two approaches has led to the development of models able to trace the origin of high premium products. The developed method was applied to test the traceability of PDO cheeses: Italian alpine cheeses (e.g. Fontina, Montasio and Toma) [1, 2], as well as buffalo Mozzarella from the Campania region, Grana Padano and Parmigiano Reggiano [3, 4, 5].

Conclusions:

This work considers a robust and effective method that can be used to guarantee the authenticity of dairy products to consumers, focusing particularly on cheese. The method is based on determination of stable isotope ratios and the elemental composition of products. Specifically, in the case of PDO Grana Padano and Parmigiano Reggiano cheese, the model has been officially adopted as a reference method for assessing the authenticity of grated and shredded products on the market. Furthermore, this method was recently officially validated and adopted by UNI (Italian Standardisation Body, UNI Regulation 11692:2017).

Novel Aspect:

The method applied and described has been officially validated and can be used before the courts in legal cases.

1318 - DEVELOPMENT OF NOVEL COMPACT CARBON DATING INSTRUMENT BASED ON COLLINEAR RESONANCE IONISATION SPECTROSCOPY (CRIS)

Giles Edwards (1) - Kieran Flanagan (1) - Ben Cooper (1) - Sultan Alsufyani (1) - Christopher Ricketts (1) - Cory Binnersley (1)

The University of Manchester, School of Physics and Astronomy, Manchester, United Kingdom (1)

Development of novel compact carbon dating instrument based on Collinear Resonance Ionisation Spectroscopy (CRIS).

Traditional carbon dating techniques based on isotope ratio accelerator mass spectrometry are expensive, experimentally complex and access to instrumentation is often associated with excessive lead times. The use of CRIS as an alternative method affords unparalleled interference suppression when compared to RIMS for example. This is achieved by effectively decoupling the inlet electron cyclotron resonance ion source from the resonance ionisation spectroscopy by means of a charge exchange cell. The instrument employs a variety of ion optics including initial multi-collector magnetic sector mass selection and a linear ion trap to increase duty cycle; the sample inlet is a flash GC nitrogen/carbon elemental analyser.

The CRIS technique was initially developed at CERN in the ISOLDE facility for the analysis of exotic nuclei. The instrument at the University of Manchester is configured for the analysis of carbon isotopes but can easily be tuned for other nuclei and offers a state-of-the-art alternative technique for various forensic, dating and food security applications.

Giles completed his Ph.D last year at the University of Manchester, advancing the field of Laser post-ionisation Sputtered Neutral Mass Spectrometry (L-SNMS) which also included some RIMS of organometallic biological agents.

He is an analytical chemist and works as a consultant for HPLC & LC/MS method development and also as a freelance mass spectrometer service engineer.

More recently Giles joined the Nuclear Physics group at Manchester as a part-time post doc working on the compact carbon dating system.

Gary M. Hieftje (1)

Department of Chemistry - A150 Chemistry Building, Indiana University, Bloomington (1)

Keywords: metallomics, speciation, plasma source MS, Isotope ratio, instrumentation

Introduction:

Most ion sources for mass spectrometry are tailored for specific species such as molecules, atoms, or biomolecules, requiring instruments to be designed and constructed with limited flexibility. What would be desirable is a source that can ionize a broad range of species and sample types, including solids, liquids, or vapors. Such a source, termed the Solution-Cathode Glow Discharge (SCGD) is now being evaluated and will be described and evaluated

Methods:

The Solution-Cathode Glow Discharge (SCGD) is a relatively low-power (~70W) ionization source that operates in the open atmosphere. Sample solution flows from a small glass capillary and serves as the cathode of a discharge that strikes to a metallic anode pin just above it. The electric field at the cathode surface is high enough that electrical spraying takes place. Thermal fragmentation or even complete atomization of incoming analyte species is also possible.

Results:

A broad range of sample types has been investigated with the SCGD. Metallic species in solution can be either fully atomized or partially fragmented, yielding alternatively atomic mass spectra or spectra reflecting original solution composition. Thus, the SCGD is useful for either elemental or chemical-speciation analysis. Further, sensitivity is sufficient that isotope ratios can be measured at precision levels dictated by the IAEA International Target Values for natural uranium (0.28% *rsd*), with an integration time of only 150 s. For somewhat labile molecules, fragmentation can be controlled merely by adjusting the operating current and voltage of the SCGD. For triethyl phosphate, for example, the survival yield can be varied from at least 25-80%. Under conditions that favor electrical spraying, the SCGD can be fed directly with a peptide-containing solution and yields fragmentation mass spectra that are unlike those from other ionization sources and are surprisingly easy to interpret.

Conclusions:

Although originally developed as an emission source for elemental analysis, the SCGD has proven to be an extremely versatile ionization source for mass spectrometry. It is simple to construct, operates on a low-power supply, requires no gas supply, and is simple to set up and employ. Most work to date has been with an Orbitrap[®] spectrometer; ongoing work will employ alternative mass spectrometers, some suitable for field use.

Novel Aspect:

A new, highly versatile but simple ion source has been developed and is being tested. It is useful for samples ranging from biomolecules to atoms.

High-resolution and tandem mass spectrometry techniques contribute to the discovery of new arsenic metabolites of toxicological importance

Qingqing Liu, Xiufen Lu, Hanyong Peng, Elaine Leslie, Martin Zuidhof, Xing-Fang Li, X. Chris Le*

Keywords: Arsenic speciation; protein binding; toxicology; biotransformation; LC/MS/ICPMS

Introduction: Nearly 100 arsenic species, with diverse toxicities (1,2), are present in the environment and in biological systems. There is a tremendous analytical challenge in the identification and quantification of trace amounts of individual arsenic species present in complex biological sample matrix. This presentation will highlight our recent development of mass spectrometry techniques for studying arsenic species, including the oxygenated and thiolated, trivalent and pentavalent, and inorganic and organic arsenic species.

Methods:

Hybrid quadrupole time-of-flight, linear ion trap, and triple quadrupole mass spectrometers were used to conduct high-resolution and tandem mass spectrometry experiments. Effluent from high performance liquid chromatography (HPLC) separation was split 80% to inductively coupled plasma mass spectrometry (ICPMS) and 20% to electrospray ionization tandem mass spectrometry (ESI-MS/MS). Human primary hepatocytes and hepatocellular carcinoma HepG2 cells were treated with 0, 20, or 100 μM Roxarsone (3-nitro-4-hydroxyphenylarsonic acid).

Results:

The combined techniques enabled identification and quantitation of individual arsenic species present in a variety of environmental and biological samples. Roxarsone was metabolized to more than 10 arsenic species in human hepatic cells. Several new metabolites were identified (3,4). The 24-hour IC₅₀ values of thiolated Roxarsone for A549 lung cancer cells and T24 bladder cancer cells were 380 ± 80 and 42 ± 10 μM , respectively. This thiolated arsenic metabolite was more toxic than Roxarsone, whose 24-hour IC₅₀ values for A549 and T24 cells were 9300 ± 1600 and 6800 ± 740 μM , respectively.

Conclusions:

We have characterized the metabolism of Roxarsone in human liver cells and successfully identified the new phenylarsenical metabolites. The identification and toxicological studies of the new arsenic metabolites are useful for understanding the fate of arsenic species and assessing the potential impact of human exposure to Roxarsone.

Novel Aspect:

The complementary techniques enabled the discovery of new arsenic metabolites that have important toxicological implications. The study improved mechanistic understanding of arsenic biotransformation.

1123 - ISOTOPIC TECHNIQUES FOR STUDYING THE SOURCES AND PROCESSES OF POLLUTANTS IN THE ENVIRONMENT

Nives Ogrinc (1)

Jožef Stefan Institute Department of Environmental Sciences Ljubljana (1)

Keywords: isotopic techniques, sources, mercury, organic pollutants, environment

Introduction:

The use of isotopic techniques is in the midst of a remarkable period of innovation and discovery; the last decade has seen the emergence of stable isotopes of metals and new capabilities for measurements of organic compounds. These advances hold the potential to reveal new insights into the nature, sources and transformation processes of pollutants in the environment. The selected examples will include: polycyclic aromatic hydrocarbons (PAH), atrazine and mercury.

Methods:

The sources of PAHs were determined in lake sediments using isotopic composition of carbon, while isotopic composition of nitrogen and carbon in atrazine was used to characterize degradation processes. These measurements were performed by gas chromatography coupled to isotope ratio mass spectrometry through combustion unit (GC-C-IRMS). Stable isotopes of Hg determined by MC-ICP MS were applied to determine the Hg sources in Mediterranean deep-sea sediments.

Results:

The dominant PAHs signatures identified in sediments of Lake Bled were mainly attributed to a coal/wood burning source, but PAH from carsoot could also contribute. Retene (Re) and Perylene (Per) exhibit profiles and isotopic composition that are distinct from those of other PAHs suggesting their natural origin. However $\delta^{13}\text{C}$ values of Re determined in anoxic part linked Re to both natural and pyrolytic origin [1]. Stable isotope analysis of atrazine brings forward two additional lines of evidence to assess the degradation state of atrazine and desethylatrazine in natural samples: (i) to distinguish different degradation pathways of atrazine and (ii) to detect further degradation of DEA [2]. Both mass-dependent and mass-independent fractionation processes influence the isotopic composition of Hg in the Mediterranean Sea. Positive $\Delta^{199}\text{Hg}$ values are likely the result of enhanced Hg^{2+} photoreduction in the Mediterranean water column, while mass-dependent fractionation decreases $\delta^{202}\text{Hg}$ values due to kinetic isotope fractionation during deposition and mobilization. At least three primary Hg sources of atmospheric deposition could be defined: urban, industrial and global precipitation-derived.

Conclusions

The results indicate that together molecular and isotope composition of PAHs are useful tools for obtaining more detailed identification about sources of PAH inputs into lacustrine sedimentary environments, while trends in multi-element isotope data of atrazine may decipher different degradation pathways. Stable isotopes of Hg provide new insights into the sources and geochemistry of Hg in deep-sea sediments.

Novel Aspect:

Isotopic techniques such as GC-C-IRMS and MC-ICP-MS open new avenues for studying sources, fate and impact of contaminants in the environment.

272 - EXPERIMENTAL EVALUATION OF TIMS-BASED DETECTION METHODS FOR ISOTOPIC ANALYSIS OF URANIUM AT ULTRA-TRACE LEVEL

Jong-Ho Park (1) - Kahee Jeong (2)

Korea Atomic Energy Research Institute, Nuclear Chemistry Research Division, Daejeon (1) - Central Research Institute of Korea Hydro & Nuclear Power, Chemistry & Environmental Group, Daejeon (2)

Experimental evaluation of TIMS-based detection methods for isotopic analysis of uranium at ultra-trace level

Keywords: TIMS, Isotopic Analysis, Uranium, Detection Method, Nuclear Safeguards

Introduction:

Thermal ionization mass spectrometry (TIMS) is one of the most accurate and precise techniques for isotopic analysis, and suitable for monitoring undeclared nuclear activities[1-3]. The analytical performance of the three TIMS-based detection methods was experimentally evaluated for isotopic analysis of uranium at ultra-trace levels, in terms of analytical accuracy, precision, and measurement uncertainty.

Methods:

Isotopic measurement of uranium at 1 ng, 100 pg, 30 pg, 5 pg, and 1 pg levels were performed by TIMS (TRITON Plus, Thermo.) using three detection methods; Dynamic, multi-dynamic, and static Methods: Analytical performance, such as accuracy, precision, and measurement uncertainty, was experimentally evaluated depending on the detection Methods:

Results:

The TIMS analysis for the ten replicated U samples with amounts of 1 ng and 100 pg showed no significant improvement in analytical performance irrespective of the detection method adopted, whereas slight improvement was observed for the analysis of 30 pg uranium using the multi-dynamic and static detection Methods: Considering the analytical performance and the easiness of detector calibration, the preferred detection methods for 1 ng and 100 pg U is the multi-dynamic method, while that for 30 pg U is the dynamic method. The static detection method offers the greatest accuracy and precision, and the smallest uncertainty for TIMS measurements of 5 pg and 1 pg of U due to the greater detection sensitivity of ion counters than faraday cups, the elimination of ion signal drift, and the large number of valid data sets in a measurement.

Conclusions:

This study deals with the evaluation of three detection methods (multi-dynamic, dynamic, and static) in the isotopic analysis of ultra-trace amounts of uranium using thermal ionization mass spectrometry. For samples containing 5 pg and 1 pg uranium, the static detection method provided the best results in terms of accuracy, precision, and measurement uncertainty.

Novel Aspect: (Limit of 150 characters)

This study shows that the static detection method of TIMS can be applied to particle analysis of environmental samples for nuclear safeguards.

C and H stable isotope ratio analysis using GC-IRMS for vanillin authentication

Matteo Perini, Silvia Pianezze, Federica Camin

Fondazione Edmund Mach (FEM), Via E. Mach 1, 38010 San Michele all'Adige, Italy

Keywords: stable isotope ratios, vanillin, authentication, gas chromatography

Introduction:

Vanilla extracts are widely used as flavouring ingredients in foods and beverages and as aromatic compounds in perfumes and pharmaceuticals. Due to the high production cost of high-quality natural extracts from *Vanilla planifolia*, synthetic or natural identical biosynthetic vanillin (which derives from natural precursors such as guaiacol, ferulic acid, eugenol and lignin) are often used as a substitute for authentic natural vanillin [1].

Methods:

We combined analysis of $^{13}\text{C}/^{12}\text{C}$ (expressed as $\delta^{13}\text{C}$) values and $^2\text{H}/^1\text{H}$ (expressed as $\delta^2\text{H}$) ones using gas chromatography coupled to isotope ratio mass spectrometry (GC-IRMS) [2]. 16 authentic samples of *Vanilla planifolia*, 16 natural identical, 5 synthetic vanillin and 20 commercial extracts were considered.

Results:

The carbon isotope ratio values allow discriminating between natural and natural identical or synthetic vanillin (averagely -19‰ vs -30‰). Authentic natural vanillin from *Vanilla planifolia* and natural identical vanillin are characterised by $\delta^2\text{H}$ values much lower than synthetic vanillinones (averagely -50‰ vs $+73\text{‰}$). The isotopic values of all the commercial extracts declared to be from *Vanilla planifolia* ($N=20$), had $\delta^{13}\text{C}$ values within the typical range of natural vanillin, but $\delta^2\text{H}$ values outside the range and more similar to that of synthetic vanillin. Our results show how the stable isotope ratio analysis (SIRA) of $^{13}\text{C}/^{12}\text{C}$ is no longer sufficient to discover vanillin adulteration, due to the practice of adding ^{13}C to the methyl site of synthetic vanillin [3], and the new analysis of $\delta^2\text{H}$ is mandatory.

Conclusions:

The combination of $\delta^{13}\text{C}$ with $\delta^2\text{H}$ GC-IRMS analysis of vanillin can therefore be proposed as a suitable tool to improve the detection of vanilla extract adulteration.

Novel Aspect:

Stable isotope analysis of $^2\text{H}/^1\text{H}$ can be a rapid and effective method to identify the natural or synthetic origin of vanillin.

1183 - STABLE ISOTOPE RATIO ANALYSIS FOR AUTHENTICATION OF CHITOSAN

MATTEO PERINI (1) - Tiziana Nardin (1) - Matteo Venturelli (1) - Silvia Pianezze (1) - Roberto Larcher (1)

Fondazione Mach, Technology Transfer Centre, Experiment and Technological Services Department, S. Michele all'Adige (TN), Italy (1)

Stable isotope ratio analysis for authentication of chitosan

Matteo Perini, Matteo Venturelli, Tiziana Nardin, Silvia Pianezze, Roberto Larcher
Experiment and Technological Services Department, Technology Transfer Centre, Fondazione Edmund Mach (FEM),
Via E. Mach 1, 38010 San Michele all'Adige, Italy

Keywords: stable isotope ratios, chitosan, authentication, animal or fungi origin

Introduction:

Chitosan is a linear polysaccharide with a number of possible uses (e.g. in medicine). It is produced by deacetylation of chitin, which is the structural element of exoskeleton of crustaceans. Due to the presence of allergens in seafood, its production from fungi has gained increasing attention. To identify its origin, residual glucans, viscosity and settled density are used, but often not effective. This calls to the development of new methods, such as the stable isotope ratio analysis.

Methods:

Following the prescription of OIV International Oenological Codex [1], residual glucans, viscosity and settled density were measured to identify the crustacean or fungi origin of 20 chitosan samples. Moreover, the stable isotope ratios (SIRs) of four bioelements - hydrogen, carbon, nitrogen, oxygen - were analysed in the raw product using Isotope Ratio Mass Spectrometry.

Results:

The biosynthetic pathway of the chitosan's precursor chitin affects its isotopic composition. The samples identified by the OIV official methods as from crustaceans showed lower $\delta^{13}\text{C}$ (averagely -20.8‰) and higher $\delta^{15}\text{N}$ values (-2‰). This fits with the marine origin of the font (the exoskeleton of crustaceans) characterized by low $\delta^{13}\text{C}$ value (around -20‰) and high positive $\delta^{15}\text{N}$ value (around $+7\text{‰}$) [2]. The low $\delta^{15}\text{N}$ values here found are probably due to the addition to the yeast broth of nitrogen synthetic sources such as urea with low $\delta^{15}\text{N}$ values [3]. The samples identified of fungi origin based on the OIV prescriptions, are characterized by higher $\delta^{13}\text{C}$ (-13.8‰) and lower $\delta^{15}\text{N}$ values (-4.1‰). The higher $\delta^{13}\text{C}$ values of these chitosan samples are explained on the basis of the fact that sugar cane juice and molasses with typical $\delta^{13}\text{C}$ around -11‰ [4] are used as economic substrates in fungi chitosan production [3]. D/H and $\delta^{18}\text{O}$ are lower in chitosan from fungi probably due to the lower value of the fermentation water.

Conclusions:

This work considers a robust and effective method, based on the determination of stable isotope ratios of bioelement, that can be used to identify the origin of chitosan.

Novel Aspect:

Stable isotope analysis could be a rapid method to identify the crustaceans or fungi origin of chitosan.

Keywords:

Laser ablation/ionization mass spectrometry, collisional cooling, ion funnel, fs-laser, CD-nozzle

Introduction:

Laser ablation/ionization mass spectrometry is becoming again an attractive analytical technique for element composition determination of solids [1,2,3,4]. It offers several advantages: little sample preparation, high sample throughput, high spatial resolution and the possibility to analyze any kind of solid sample. We present a novel strategy using fs-LA at elevated pressure in combination with CD nozzle and Rf-only ion funnel for element imaging in solids.

Methods:

The laser ablation ion funnel ion source, described in this work, employs an Rf only ion funnel in combination with a convergent-divergent nozzle for collisional cooling of laser generated ions and their separation from the buffer gas. This configuration achieves a sufficient pressure drop between ion source and mass spectrometer while allowing for multiple collisions and consequent focusing. The "LAFU" source was coupled to a TOF-MS and different laser were employed.

Results:

The first results obtained with the coupling of ns-LAFU (3 ns, 532 nm) source with time of flight mass spectrometry (LAFUMA), showed that also low m/Q ions (12C, 27Al) can be successfully focused in the Rf-only ion funnel. The ion signal intensities could be increased by up to 300 times in comparison with ablation in high vacuum. Still the ion transmission through the ion funnel was found to have a pronounced dependence on m/Q , as a result of the pseudo-stationary fields created near the ion funnel electrodes. Compared to the previously used ns laser ablation, the fs laser (150 fs, 400 nm) ablation exhibits significantly smaller mass ablation rates and generally more comparable sensitivities. Transient evolution of the pulsed ion signals was longer than for ns LA regime and less affected by buffer gas pressure., indicating that a fraction of high energetic ions could not be thermalized completely in this case.

Conclusions

An ion funnel has been successfully combined with laser ablation for ion generation at elevated pressure, achieving a significant enhancement of ion transmission. The combination of the ion funnel with a CD nozzle for differential pumping shows promising features for the further development of laser ionization/ablation mass spectrometry in element and isotope analyses of solids.

Novel Aspect:

Collisional cooling of laser generated ions at elevated pressure in combination with an Rf only ion funnel for fast element image acquisition was successfully realized.

¹ Université de Corse, UMR CNRS 6134, Laboratoire Chimie des Produits Naturels, BP 52, 20250 Corte, France

² Aix Marseille Univ, CNRS, Institut de Chimie Radicalaire, UMR 7273, 13397 Marseille, France

Keywords: *Scapania undulata*, essential oil, hydrosol, SPME

Introduction: (Limit of 400 characters)

S. undulata is a liverwort living wild on the rocks of deciduous broadleaved forests of Corsica [1]. To our knowledge, four studies deal with the chemical composition of *S. undulata* essential oil from Europe [2–5]. Some sesquiterpenes such as longiborane and himachalane derivatives were identified as main components. The aim of the present work was to determine and characterize the volatile compounds of *S. undulata* from Corsica using hyphenated Methods:

Methods: (Limit of 400 characters)

Plant material was collected in several Corsican forests and dried at room temperature. Essential oils and hydrosols were prepared by hydrodistillation as well as the volatile fraction was extracted by HS-SPME (HeadSpace - Solid Phase MicroExtraction) under optimized conditions. Et₂O extract was prepared by maceration from powdered plant material. The plant volatiles were investigated using an analytical procedure including LC, LLE, GC-FID, GC-MS, ESI-MS, tandem MS and NMR.

Results: (Limit 900 characters)

The present study focuses on the volatile components of *S. undulata* from Corsica. The chemical investigations of the four extraction matrices allow determining different chemical profiles. Essential oil (EO), hydrosol (HY) and Et₂O extract (EXT) was dominated by oxygenated sesquiterpenes (EO 63.5%; HY 82.0% and EXT 63.9%) while the volatile fraction (VF) extract by HS-SPME was dominated by hydrocarbon compounds (VF 61.2%). The main components of essential oil and hydrosol of *S. undulata* were respectively epicubenol (49.0% and 64.5%), β -Muurolol (5.0% and 7.2%) and longiborneol (3.0% and 7.2%) while epicubenol (44.4%) with longipinanol (11.9%) were the main components of Et₂O extract. As previously reported, longipinanol is rather labile and was almost completely degraded during hydrodistillation, but was detected in considerable amounts in the ether extract [3]. In addition, epicubenol (27%), calarene (9.6%), were the main components of the volatile fraction sampled by HS-SMPE. As epicubenol, himachalol, longiborneol and longipinanol were absent to our spectral library, their identifications were ensured by NMR and ESI-MS experiments.

Conclusions (Limit of 400 characters)

The study provides an overview of the volatile components of *S. undulata*. Sesquiterpene compounds were the dominant natural products of the plant extracts obtained by hydrodistillation, HS-SPME and Et₂O maceration. Oxygenated compounds characterized essential oil, hydrosol and Et₂O extract while the volatiles emitted by the plant were largely hydrocarbons. The study confirms the necessity to use different sample preparation methods in order to study the complete chemical diversity of the plant.

Novel Aspect: (Limit of 150 characters)

The study reports for the first time the volatile components of *S. undulata* from Corsica. To our knowledge, the report of epicubenol as main essential oil component was original, as well as, the study of the volatile components emitted by *S. undulata*. HS-SPME analysis allows approaching of chemicals emitted by the plant and the identification provides information concerning the allelopathic properties of the liverwort.

1201 - EXPLORING FOOD AROMA RELEASE AND PERCEPTION USING DIRECT-INJECTION MASS SPECTROMETRY

Jonathan Beauchamp (1)

Fraunhofer Institute for Process Engineering and Packaging IVV, Department of Sensory Analytics, Freising, Germany (1)

Keywords: DIMS, aroma, nosespace, olfaction, perception

Introduction:

Direct-injection mass spectrometry (DIMS) –in the forms of proton-transfer-reaction MS (PTR-MS), atmospheric pressure chemical ionization MS (APCI-MS), and selected ion flow tube MS (SIFT-MS) – has been increasingly implemented over the past two decades to explore food flavor release and perception. This keynote lecture will review novel food flavor insights that have been achieved using on-line DIMS techniques, focusing on applications in *in vivo* analysis.

Methods:

Food flavor perception is a complex process that depends on manifold parameters, including the physicochemical properties of the flavor compound, the food matrix, saliva, oral and nasal anatomies, as well as the mucosa lining the airways, amongst other factors [1]. The real-time analytical capability of DIMS techniques has opened up new opportunities for characterizing the fast dynamics of flavor release and relating this to perceived sensory impressions.

Results:

In vivo analyses using DIMS was pioneered around two decades ago by Taylor and Linforth using APCI-MS [2,3,4] and offers an opportunity to explore parameters affecting flavor release and perception systematically. Analyses involve sampling exhaled breath via the nose – termed nosespace analysis – to capture volatile aroma compounds that are released from the food (or beverage) matrix during oral processing and enter the nasal cavity during swallowing, eliciting perceived flavor impressions. This approach has been used, for example, to assess aroma perception in relation to taste attributes [5] and textural and physiological parameters [6], or olfactory acuity in general [7]. DIMS has also been applied to generate sensory profiles of food products based on non-destructive headspace analysis, as a means to characterize a product's sensory attributes without the (explicit) need of a trained human sensory panel [8]. New developments and peripheral equipment have extended the range and versatility of DIMS systems in food flavor research [9,10].

Conclusions:

Nosespace analyses via DIMS techniques has provided many insights into flavor perception that would not have been achievable using conventional mass spectrometry in combination with classical gas chromatography (GC-MS). The shortcomings of DIMS techniques tend to be their lack of unequivocal identification, but this requirement is obviated when using a targeted approach to monitor fast processes of individual flavor compounds that are known *a priori*.

Novel Aspect:

On-line direct-injection mass spectrometry is a versatile and powerful tool for investigating the dynamic processes involved in flavor release and perception.

97 - EFFECT OF GERMINATION TIME, ROASTING LEVEL AND ALTITUDE IN THE AROMA RELEASED BY COFFEE POWDER MONITORED BY PROTON TRANSFER REACTION MASS SPECTROMETRY AND GAS CHROMATOGRAPHY MASS SPECTROMETRY

Martina Bodner (1) - Ksenia Morozova (1) - Prapaijit Kruathongsri (2) - Prodpran Thakeow (2) - Sergio Angeli (1) - Matteo Scampicchio (1)

Free University of Bolzano-Bozen, Faculty of Science and Technology, Bolzano (1) - Chiang Mai University, Department of Product Development Technology, Chiang Mai (2)

Keywords: PTR-QMS; GC-MS; coffee powder; aroma; volatile organic compounds

Introduction

Coffee is one of the most consumed beverages all over the world, as well as in Thailand especially in recent years. Two species of coffee are harvested in Thailand, *Coffea arabica* in the northern part and *Coffea canephora* var. *robusta* in the southern part. Arabica coffee plantation in the north of Thailand cover about 9000 hectares, distributed in eight provinces. Arabica coffee is mainly grown in the cooler highlands, wet processed in order to obtain high quality green bean and used in roasted coffee for domestic use[1].

Wet-processed beans are characterized by more fruity and acidic notes and less bitter and burnt attributes, compared with dry-processed beans. Moreover, the wet method allows the preservation of intrinsic properties of the beans, leading to coffees with a more desirable aroma[2].

Coffee aroma is the main responsible for organoleptic properties and therefore appeal of coffee. It is developed during the roasting process and depends on operative conditions such as temperature and time, but also on variety, origin and composition in terms of aroma precursors in green beans. In particular, caramelization of sugars leads to the production of furans (responsible for burnt and caramel notes), Maillard reaction of sugars develops pyrazines (characterized by roasty notes, mainly responsible for the coffee aroma), trigonellines are the precursors of pyridines (which confer smoky notes to the coffee) and lipids metabolism leads to the production of carbonyls [2, 3, 4, 5].

The effect of three different factors, such as altitude of harvesting (900 and 1500 meters above sea level), germination time (0, 24, 28 and 72 hours) and roasting level (light, medium and dark) on the volatile profile found in 24 different types of coffee were analyzed by Proton Transfer Reaction Quadropole-Mass Spectrometry (PTR-QMS) and by Gas Chromatography Mass Spectrometry (GC-MS). The best conditions to minimize undesirable odor and maximize the desirable ones were evaluated by Design Expert®.

Methods

Coffee beans (*C. arabica*) were harvested at 900 and 1500 meters above sea level in the Thai province of Chiang Rai in Doi Chang by Waweecoffee Co., Ltd. 1 Kg of green coffee beans, harvested at each altitude, was placed in boxes, soaked with 5 liters of water in a growth chamber at 28 °C, in dark, and let germinate for 24, 48 and 72 hours. 300 gr of green coffee beans harvested at 900 and 1500 meters were not induced to germinate. Germinated and not germinated coffee beans were roasted at 200 °C by Waweecoffee Co., Ltd. Three different roasting profile were achieved: light, medium and dark. Light-roasted coffee beans were roasted for 6 minutes, show 1-5% of weight loss and a light brown color; medium-roasted coffee beans were treated for 8 minutes, show 5-8% of weight loss and a medium brown color; dark-roasted coffee beans were roasted for 10 minutes, show 8-10% of weight loss and a dark brown color.

The headspace of coffee powders was measured by PTR-QMS. 35 mg of coffee powder were placed to equilibrate in 40-mL glass vials at 30 °C for 15 min. Five replicates for each sample were analyzed. Four empty vials were analyzed and considered as blanks. The measurement order was randomized to avoid possible memory effect. The instrumental conditions were the following: drift voltage 600 V, drift temperature 75 oC, drift pressure 2.10 mbar, affording an E/N value of 149 Td (1 Td = 10⁻¹⁷cm² V⁻¹ s⁻¹).

SPME analysis was carried out with a Gas Chromatography-Mass Spectrometer. 2 g of coffee powder were weighted in a 20-mL septum-sealed gas vial and sampled through the SPME fiber for 30 min at 60 °C. Chromatographic conditions were the following: 40 °C for 3 min, from 40 °C to 200 °C (0 min) at 3 °C/min, then to 240 °C (1.2 min) at 16 °C/min.

Multivariate data analysis methods were applied to visualize data and the optimization of factors was performed using Design Expert®.

Results

2 g of coffee powder from eight different samples (L900, D900, L924, D924, L1500, D1500, L1524 and D1524) were analyzed by SPME-GC-MS. 27 compounds were tentatively identified and five of them were found only in the high-altitude samples. Acetic acid and 2-furanmethanol were high in L900 and L1500 samples and decreased with roasting and germination. 2-ethyl-6-methyl-pyrazine is found to be more abundant in low-altitude samples compared to the high-altitude ones and show no significant changes related to roasting level and germination time. Dodecane undergoes a reduction in both low- and high-altitude samples after 24 hours of germination

The volatile profile of all 24 types of coffee was monitored by PTR-QMS. The 181 mass peaks obtained by each of these analyses were subjected to one-way ANOVA ($p < 0.01$); subsequently 89 masses were found at significantly different concentration between the three factors. Among these 89 masses, only the ones also found in GC-MS and tentatively identified (14 masses) were used in the optimization of the conditions.

A 3-level factorial design was used to study the effect of altitude, germination time and roasting level in the composition of desirable and undesirable volatile compounds in coffee. The 14 masses found both in GC-MS and in PTR-MS were used in the model and the optimum conditions were found minimizing undesirable odor (m/z 61, 80, 99 and 101), and maximizing the desirable ones (m/z 95, 97, 109, 111, 117, 123, 131, 135, 137 and 148). The software proposed 23 solutions, with an index of desirability between 0.537 (best solution) and 0.256 (worst one). The two best solutions were the samples M924 (low-altitude, 24h-germination and a medium level of roasting) with an index of desirability of 0.537 and M1524 (high-altitude, 24h-germination and a medium level of roasting), with an index of desirability of 0.517.

Conclusions

Altitude of harvesting, germination time and roasting level have different impact in the volatile profile of coffee powder. Altitude of harvesting seems to be the factor contributing the less, while germination time and roasting level have a more important role in the development of aroma. The tentative identification of mass peaks identified by PTR-QMS and GC-MS allows the determination of desirable and undesirable odor and therefore the optimization of the three factors responsible for the volatile profile of coffee powder.

Novel Aspect

PTR-QMS and GC-MS has been used for the first to evaluate the effect of altitude of harvesting, germination time and roasting level in the development of aroma profile in coffee powder. Moreover, it is the first time in which data from PTR-QMS and GC-MS has been used coupled with Design Expert® to optimize growing conditions and treatments of coffee beans to obtain a more desirable aroma in coffee powder.

Keywords: Selected Ion flow tube mass spectrometry, Breath, Real-time analysis, Volatile organic compounds, Cancer.

Introduction: The VOCs in the exhaled breath represent promising biomarkers able to give useful information on the physio-pathological status of the individual [1]. Real-time breath analysis of VOCs is an attractive non-invasive approach for cancer disease diagnosis and monitoring. Here we report the feasibility study of the use of selected ion flow tube mass spectrometry (SIFT-MS) to measure targeted breath VOCs suitable to monitoring cancer patients in a clinical setting.

Methods: The analysis of 32 targeted VOCs has been performed by Voice 200UltraTM. The instrumental VOCs panel included: ammonia, acetone, isoprene, acetonitrile, dimethyl ether, aliphatic alcohols (n=5, C1-C5), cyanuric acid, low chain aliphatic acids and their corresponding aldehydes (n=12, C1-C6) including benzaldehyde, ether compounds (n=5) and phenol compounds (n=3). The study involved (n=12) healthy controls and (n=17) metastatic cancer patients.

Results: Twenty two (72%) out of 32 VOCs targeted VOCs panel were detectable by SIFT-MS under the analytical conditions used. As compared to healthy group cancer patients present significant lower breath level of ammonia ($p<0.001$), acetone ($p<0.05$), carbon disulfide ($p<0.01$) and phenol ($p<0.05$) evaluated by t-test. Within the series investigated was possible to recognize qualitative and quantitative individual VOCs signatures for both cancer patients and healthy individuals. Specific VOCs signature associated with the disease progression was observed in a case of a patient with sarcoma.

Conclusions: The use of SIFT-MS in clinical setting is a feasible and appropriate approach for the qualitative and quantitative analysis of a discrete number of exhaled VOCs. The study underlines the potential of the real-time VOCs profile analysis to identify specific patient pharmacological phenotype and supports the use of such breath metabolomics approach for longitudinal monitoring of cancer patients.

Novel Aspect: The SIFT-MS analytical instrumentation can be effectively applied for the real-time breath VOCs profile analysis in a clinical setting

Keywords: Process monitoring;volatile organic compounds;headspace solid-phase microextraction;GC-MS;C.tetani.

Introduction

Vaccines are one of the most important products of biological processes which are generally less controllable and more susceptible to variation [1]. HS-SPME-GC-MS method, allows determination of biogenic volatile organic compounds(BVOCs) emerged from microorganism [2]. The identified volatiles can be considered as biomarkers for the identification and classification of organisms as well as for monitoring the bioreactor [3-5].

Methods

HS-SPME sampling was applied for extraction of VOCs, emerged from *C. tetani* in different culture media, followed by GC-MS analysis for identification and quantitation of BVOCs. Then, a portable dynamic air sampling (PDAS) device was constructed and used for sampling biomarker VOCs from the exhaust gas flow of bioreactor by the SPME fiber at the optimum condition. Other cultivation parameters such as pH and optical density were measured during the sampling time.

Results

About fifty volatile compounds released from *C. tetani* in different media were identified by the proposed method. The main detected compounds were sulfur compounds such as dimethyl trisulfide, dimethyl tetrasulfide, and Butanethioic acid S-methyl ester which specified as a biomarker for monitoring bacterial growth in a bioreactor. In the second step, sampling condition was optimized and the exhaust gas flow rate of 1 mL^s-1 and sampling time of SPME fiber in PDAS of 20 minutes were obtained. Sampling of bioreactor was performed 6 times per day during the incubation period. The results showed good correlation between conventionally control parameters of bioreactor and quantitated VOCs.

Conclusions

Dynamic sampling from off-gas of bioreactor by SPME fibers was used for sampling bacterial VOCs from bioreactor and analysis was done by GC-MS. Reliability of proposed method was performed using pH and optical density of the *C. tetani* cultivation as the conventional monitoring parameters. Results showed that, the proposed method can be used as a novel process monitoring method for microorganism cultivation.

Novel Aspect

HS-SPME followed by GC-MS method was developed for monitoring bacteria growth in bioreactor.

Keywords: chocolate – nosespace – PTR-ToF-MS – Temporal Dominance of Sensations (TDS)

Introduction:

Aroma of dark chocolate depends on process and cocoa origin and variety. A sensory analysis of 206 standardized chocolates produced from various cocoa beans classified them in four sensory categories. These categories were confirmed in a PTR-MS analysis of the chocolates volatilome [1]. The objective here was to study the nosespace of a subset of chocolates simultaneously with their temporal profile to better explain the sensory categorization at a perception level.

Methods:

A Temporal Dominance of Sensations (TDS) evaluation of 8 chocolates (2 selected per category) was done in triplicate by 12 subjects while the aroma released in their nose were simultaneously collected and injected into a PTR-ToF-MS. The two sets of data were analyzed conjointly by defining an index of abundance of each detected aroma compound while a given attribute was dominant: the Abundance While Dominance (AWD) index [2].

Results:

TDS is able to dynamically capture multidimensionality of perception. The obtained TDS curves clearly differentiated the chocolates that were regrouped by sensory category as revealed by a principal component analysis (PCA). The dynamics of perception have been considered only scarcely in comparison to simultaneous in vivo aroma release over time measured by on-line mass spectrometry (nosespace). Computation of the AWD indices at individual level allowed to statistically assess the differences between the products over subjects and replicates and assessed statistically the relationships between the two sets of data. Through correspondence analyses (CA) some relationships between certain aroma compounds and the sensory attributes expected to be related to them were found. Although in previous studies pairing nosespace and TDS various temporal links could be proposed [3], no clear relationships could be safely established due to the fact that the conclusions were mainly based on a descriptive analysis of the data conducted at panel level.

Conclusions:

Pairing nosespace with Temporal Dominance of Sensations evaluation of dark chocolates categorized in four sensory groups provides meaningful data that can be analyzed at individual level thanks to the AWD indices. Descriptive multivariate analyses of these AWD indices gave interesting clues on the relationships between the aroma compounds released in mouth and their expected perceived sensory attributes.

Novel Aspect:

Pairing nosespace PTR-ToF-MS with Temporal Dominance of Sensations allows assessing the relationships between aroma compounds released in vivo and their perception.

High-pressure photoionization time-of-flight mass spectrometry combined with dynamic purge-injection for rapid analysis of volatile metabolites in urine

Keywords: high-pressure photoionization mass spectrometry, dynamic purge-injection, urine analysis, volatile organic metabolites

Introduction:

Small molecule metabolites are widely used as biomarkers in the research field of metabolomics for disease diagnosis and exposure assessment. As a readily available biofluid containing plenty of volatile organic metabolites (VOMs), urine is ideal for non-invasive metabolomics analysis.[1] However, there is still lack of rapid analysis method for VOMs in urine.

Methods:

A dynamic purge-injection apparatus was designed by coupling of a thermostated water bath and a bubbling bottle. The urines were firstly acidized or alkalized by simply adding a small amount of H₂SO₄ or NaOH. The VOMs were released into the gaseous phase by bubbles bursting at the gas-liquid interface, which were taken into the high-pressure photoionization (HPPI) mass spectrometer for analysis.[2]

Results:

Various types of metabolites, such as ketones, alcohols, acids, sulfides, pyrroles and amines were detected directly by simple acidification or alkalization of urines. Nitrogen-containing compounds, especially polar amines, could be ultra-sensitively measured without any derivatization. Interestingly, a new biomarker 2,5-dimethylpyrrole was exclusively found in the smoker's urine sample besides toluene. Five valuable metabolites, trimethylamine, toluene, styrene, p-xylene, and 2,5-dimethylpyrrole, were well quantified with the limits of detection down to 0.02–0.1 $\mu\text{g L}^{-1}$, and the relative standard deviation (R.S.D.) ranged from 0.42% to 14.4%. Being highly sensitive and humidity-friendly, the whole analytical procedure was easily operated in less than 6 min.

Conclusions:

The coupling of HPPI-TOFMS with dynamic purge-injection was demonstrated as a novel tool for rapid nontarget disease biomarkers screening or target monitoring of specific compounds through the investigation of volatile metabolites in urine. The highly sensitive and humidity-friendly system might aid in clinical diagnosis for development of diagnostic tools for disease identification.

Novel Aspect:

A powerful and sensitive direct mass spectrometric technique for high-throughput analysis of volatile organic metabolites in urine.

Keywords: volatile compounds, SPME, GC-MOX sensor system, human semen

Introduction:

The most used method for determining the volatile compounds of biological matrices is headspace solid-phase microextraction gas chromatography (HS-SPME-GC). Usually, the detector is mass spectrometer (MS) [1]. In this work, we propose a new technique based on the application of a MOX sensor [2], as additional detector after GC separation, to evaluate metabolome profile of human semen applied to infertility study.

Methods:

First, semen samples motility was assessed by standard semen analysis (SA). Next, volatile organic compounds (VOCs) of human semen were extracted by SPME technique and separated by gas chromatograph. The two detectors, MS and MOX sensor, work in parallel by a two-way splitter. The MOX sensor traces (resistance vs time) and physiological parameters of semen analysis were used for data analysis. Partial least-squares discriminant analysis (PLS-DA) was applied to the preprocessed sensorgram to evaluate the ability of the GC/MOX sensor to discriminate sperm samples with different motility.

Results:

Seminograms allowed us to classify the 57 samples in two motility groups: 16 asthenozoospermic samples with sperm progressive motility <32% and 41 normozoospermic ones. Forty-nine total VOCs were detected by GC/MOX sensor system.

Overlapping of a chromatogram and the corresponding sensorgram (as function of run time) for each sample group showed that background contamination, such as column bleed, is not perceived by VOC sensor.

2D- and 3D- PLS-DA results obtained from sensor data were compared with data obtained by seminograms, considering 2 groups (asthenozoospermic and high motility samples). 2D-PLS-DA based on SA showed an accuracy of 85% in the discrimination in two groups. In three dimensions, accuracy increases up to 92%. Using exclusively sensor resistance profiles, accuracy is of 77% (in 2D) and 78% (in 3D) for discrimination in asthenozoospermic and normozoospermic samples.

VOC sensor has different affinity to organic compound classes, having a higher reactivity with aldehydes, ketones and acetamides.

Conclusions:

GC/MOX sensor system allowed us to develop a reproducible and novel method to detect human semen headspace VOCs. We have shown that the never-explored seminal VOC fingerprinting is a valid basis for discriminating samples with different motility. PLS-DA based on VOCs analysis by sensorgrams provided good classification between asthenozoospermic from normozoospermic samples, compared to PLS-DA based on sperm motility measured by sem

Novel Aspect:

Setup of a dual system of volatile compound detection that allow to outline resistance profile that can discriminate asthenozoospermic from normozoospermic samples.

1099 - METHODOLOGY FOR QUALITATIVE AND QUANTITATIVE ANALYSIS OF VOLATILE COMPOUNDS FROM COMPOSITE MATERIALS AT ELEVATED TEMPERATURES

Célia Lourenço (1) - Sarah Bergin (1) - Daniel Francis (1) - Stephen Staines (1) - Jane Hodgkinson (1) - Chris Walton (2) - John Saffell (3) - Ralph P. Tatam (1)

Cranfield University, Cranfield University/Engineering Photonics, Cranfield, Bedfordshire (1) - Cranfield University, Cranfield University/Centre for Environmental and Agricultural Informatics, Cranfield, Bedfordshire (2) - Alphasense, Alphasense, Essex (3)

Keywords: Volatile organic compounds, composites, gas sensors, TD-GC-MS.

Introduction:

The increasing use of composite materials on the aircraft structure led to the need to investigate their performance under on-board operating conditions and non-standard conditions such as the onset of fire [1]. The investigation of possible effects on the on-board air quality arising from the introduction of new composite materials on the aircraft structure, particularly at elevated temperatures where Volatile Organic Compounds (VOCs) may be released is evaluated here.

Methods:

The described methodology allowed the characterisation of composite materials inside an air-tight tube furnace operated up to 250°C. The real-time detection of released gases was accomplished using commercial off-the-shelf (COTS) gas sensors, in addition, stainless steel thermal desorption (TD) tubes were used and analysed by gas chromatography-mass spectrometry (GC-MS) combined with thermal desorption (TD-GC-MS) for both qualitative and quantitative analysis.

Results:

Real-time detection of released gases (CO, NO, SO₂, NO₂, CO₂, O₂) and volatiles was performed over a temperature ramp from 22 °C with dwell points at 70 °C, 150 °C, 200 °C and 250°C. The volatile thermal degradation products yielded by the chemical breakdown of carbon fibre based epoxy composite at the glass transition temperature were measured, where a mixture of aromatic compounds and unsaturated compounds were identified and quantified.

Conclusions:

The sensors have demonstrated a good performance to real-time detection of gases, although cross-response of sensors to a range of volatiles might occur. It is important to accurately determine the characteristics of these compounds in aircraft cabins, and modelling is needed to link the emission rate in such tests with a possible concentration in the cabin.

Novel Aspect:

A methodology combining real-time data information and GC-MS data was set to investigate further on potential emissions of volatiles. To the authors knowledge, this work has not been previously reported.

Keywords: Volatile organic compounds, metabolomics, gut microbiome, SIFT-MS, TD-GC-MS.

Introduction:

Increasing evidence suggests that the host-gut microbiota interactions and gut microbiota composition impacts strongly on the metabolic phenotypes of the host, although the underlying mechanisms are poorly understood [1]. Dysbiosis of the gut bacteria influences the production of the volatile fermentation products resulting on an altered metabolome and contributing to the onset of metabolic diseases [2].

Methods:

This research aimed to investigate longitudinal changes in volatile organic compounds (VOCs) present in the faecal headspace of Cushing's syndrome mouse model of type 2 diabetes and once compared to their wild-type littermates. The volatile faecal metabolome was analysed using Selected Ion Flow Tube Mass Spectrometry (SIFT-MS) and Gas Chromatography-Mass Spectrometry (GC-MS) combined with thermal desorption (TD).

Results:

Univariate and multivariate data analysis revealed statistically significant differences in volatile metabolites between wild-type littermates and diabetic animals. Cushing's mice developed obesity and showed significantly higher blood glucose concentrations and plasma insulin concentrations, supporting the hypothesis that Cushing's mice develop a diabetic phenotype related to a gut microbiota interaction.

Conclusions:

The gut microbiota of Cushing's diabetic mice seem to have a different composition once compared to wild-type littermates, and the statistical analysis revealed statistically significant differences in volatile faecal metabolites. Overall, the predictive model provided information on whether the volatile metabolome is able to discriminate groups according to the phenotype.

Novel Aspect:

The use of animal models can aid in the interpretation of metabolic pathways under controlled conditions. This work has never been done before.

440 - INVESTIGATIONS OF VOCs PRESENT IN BREATH USING PTR-MS: PRELIMINARY STUDIES OF KETONES AND ANAESTHETICS

Michaela Malásková (1) - David Olivanza Leon (2) - Felix Piel (3) - Pawel Mochalski (1) - Martin Klieber (1) - Christopher Mayhew (1)

Institute for breath research, University of Innsbruck, Innsbruck (1) - School of Physics and Astronomy, University of Birmingham, Birmingham (2) - Ionicon Analytik Gesellschaft m.b.H., Eduard-Bodem-Gasse 3, Innsbruck (3)

Keywords: breath, volatiles, proton transfer reaction mass spectrometry

Introduction:

The need for a non-invasive clinical diagnostics has grown over the past years. Breath research is gaining an important role in this field. More than 500 volatile organic compounds (VOCs) in breath can provide us with a wide variety of biomarkers. Most of these compounds are present in very low concentrations (sub parts per billion), therefore finding a sensitive instrument for analysing breath samples is crucial.

Methods:

Proton transfer reaction mass spectrometry (PTR-MS) has proven its qualities in many research fields including breath research.^{1,2} Its high sensitivity for VOCs, easy or usually no sample preparation and if used correctly, high selectivity, provide us with a strong analytical tool. Although PTR-MS usually uses H₃O⁺ as a reagent ion (RI), it can also be used in modes to produce different RIs, e.g. O₂⁺ and NO⁺, which react with VOCs of interest providing the reactions are exothermic.³

Results:

The investigation with the ketones is a major collaborative project involving 3 ESRs from 3 organisations. We measured and analysed fragmentation patterns while changing the reduced electric field for 21 compounds.⁴ A fast GC was coupled to the PTR-MS in order to separate isobaric compounds, which can have often completely different origins in the human body and therefore can be found in the breath. Some of these substances were measured also with different RIs and different humidity conditions, to provide us with an even wider database to allow ease of identification under different conditions.

In addition to investigating endogenous breath compounds, we have begun to investigate important exogenous compounds in breath. To date we have focused on the anaesthetics, isoflurane, sevoflurane, desflurane and enflurane. Initial studies have been undertaken to determine the product ions following reaction with H₃O⁺, in order to determine which ions should be monitored. Detailed studies of product ions as a function of reduced electric field will be presented.

Conclusions:

We demonstrate that changing the reduced electric field aids in the identification of VOCs. This pre-study has generated a useful database of fragment product ions resulting from the ketones and anaesthetics for various reagent ions and under various conditions, which will be presented.

Novel Aspect:

In our work we are aiming to create a database of VOCs present in breath and their reactions with RIs, the product ions of which could serve as biomarkers for diseases.

51 - AN INNOVATIVE ANALYSIS METHOD FOR FRAGRANCE OF SAKE USING AN INTRODUCING DEVICE FOR VOLATILE COMPOUNDS COMBINED WITH DART-MS

CHIKAKO TAKEI (1) - YUKIKO OTAKE (1) - KENICHI YOSHIKAWA (1) - HARUKA NISHIMOTO (2) - TAKAHIRO AKASHI (2)

BioChromato, Application support, Fujisawa (1) - HAKUTSURU SAKE Brewing Co., Ltd., Research & Development, Kobe (2)

Keywords: Sake, Fragrance, DART-MS

Introduction:(345 /400 characters)

Sake is a Japanese national liquor, and many kinds are brewed for different flavor notes such as fruits, flowers, herbs, and spices. Additionally, sake can be served in a variety of vessels (cups): a choko, a Masu, a sakazuki, and a wineglass, allowing one to enjoy different scents, depending on the cup. The purpose of this work is to visualize the differences of sake fragrance depending on cups.

Methods: (399 /400 characters)

Hakutsuru Daiginjo (sake) and cups (Choko, Daichoko, wineglass, and Champagne glass) were used. Analytical system was composed of compact (Bruker) mass spec equipped with DART ion source (IonSense) and Volatimeship introducing device for volatile compounds (BioChromato). Data acquisition via the mass spectrometer were began, the cup added in sake were placed at the introducing tube of the Volatimeship, where the position of human nose, when the human is drinking.

Results: (652 /900 characters)

Ethyl caproate (i.e., ethyl hexanoate) provides one of the characteristic fragrances of sake. As the cup of sake was placed at the introducing tube of the Volatimeship, ethyl caproate was immediately detected by mass spectrometer. The volatilization behavior of ethyl caproate for each cup were measured. The wineglass not only showed higher intensity at the moment of placing the cup, but it also showed better sustainability. These analysis results supported the results of organoleptic evaluation. Moreover, the detected compounds from sake was different depend on cups. As for wineglass and champagne glass, there were some compounds that were not detected from Choko. These analysis results also supported the results of organoleptic evaluation, too.

Conclusions: (387 /400 characters)

An introducing device for volatile compounds combined with DART-MS enabled continuous detection of the change in fragrance intensity directly from the sake vessel. Therefore, this method can be useful for objective evaluation of the duration and change of scent. Additionally, this method can be useful for visualizing the sensory evaluation, because it enabled visualization of the varying intensity, or quality, of the fragrance of sake depend on cups.

Novel Aspect: (117 /150 characters)

An introducing device for volatile compounds combined with DART-MS enables objectively evaluation the sensual sensation of fragrance.

Keywords: nose-space analysis, in vivo flavor analysis, SIFT-MS, population screening

Introduction: (Limit of 400 characters)

Selected-Ion Flow-Tube Mass Spectrometry (SIFT-MS) allows on line accurate quantification of several volatile organic compounds down to the ppb range [1]. The technique has been applied to different cases of breath analysis [2]–[5] but to the authors knowledge it has not been applied to monitor in nose flavor release during food consumption for a large population.

In this work we describe a SIFT-MS based approach to measure in-vivo nose-space VOCs concentration during consumption of strawberry flavored candies on a large healthy population with the aim to investigate the inter-individual variability in flavor release: nose space analysis might disclose new information regarding the interaction between products and consumers [6].

Methods: (Limit of 400 characters)

In this study the effect of gender, age and BMI on flavor release was investigated. Ninety-two volunteers (60.9 % female) between 22 to 68 years old (mean= 40.9; SD= 11.9) participated in the study. Each subject, after filling in a socio-demographic questionnaire, consumed a strawberry candy following a specific bite-based procedure supported by a video tool. Simultaneously nose-space analysis with a SIFT-MS machine was carried out (SYFT VOICE 200 ultra, Syft Ltd, New Zealand). Each subject performed at least 3 replicates of the same sample.

Results: (Limit 900 characters)

With the set up used it was possible to monitor in real time 7 different aroma compounds released by the candy (ethyl maltol, 3-hexen-1-ol, ethyl 2-methylbutanoate, (Z)-3-hexenyl acetate, ethyl butanoate, ethyl hexanoate, 2-methylbutanoic acid) and acetone as marker of the participant breathing cycle. Principal Component Analysis (PCA) showed a possible effect of age and BMI on the flavor release signals. Both age and BMI were found to have a slightly negative correlation with in-nose aroma release for three of the monitored compounds (Pearson correlation, $p < 0.05$). Significant differences were found in hexenyl acetate and acetone levels (Welch t-test $p < 0.01$) between males and females: in both cases females presented higher in-nose levels. The study is part of a broader investigation that aims to evaluate the Italian olfactory function (COLFIT PROJECT) and here some preliminary results of the explorative data analysis are presented.

Conclusions (Limit of 400 characters)

Real time mass spectrometry analysis by SIFT-MS can detect and monitor in-vivo volatile organic compounds release during candies consumption. For the first time the analysis was applied to a large sample of the population with the aim to characterize how physiological factors like age, gender, BMI and eating behaviors affect in nose aroma release. The results suggest an effect of age on aroma release and an effect of BMI that might be used to study some aspects underlying the retronasal perception mechanisms in more detail.

Novel Aspect: (Limit of 150 characters)

Real time direct injection mass spectrometric analysis through SIFT-MS is a powerful tool to realize population screening and investigate flavor release mechanisms.

297 - IN NOSE-SPACE ANALYSIS THROUGH PROTON TRANSFER REACTION MASS SPECTROMETRY: INVESTIGATING VARIABILITY IN FLAVOR RELEASE AND PERCEPTION DURING CHEWING GUM CONSUMPTION

Michele Pedrotti (1) - Iulia Khomenko (2) - Vincenzo Fogliano (3) - Franco Biasioli (2)

Foundation Edmund Mach, Wageningen University FQD, Wageningen (1) - Foundation Edmund Mach, DQAN, San Michele all'Adige (2) - Wageningen University, FQD, Wageningen (3)

Keywords: nose-space analysis, chewing gum, in vivo flavor analysis, PTR-MS

Introduction: (Limit of 400 characters)

Proton Transfer Reaction Mass Spectrometry has been described as particularly suited to provide "in vivo" on-line flavor monitoring during food consumption [1]. In the last years, the technique has been applied to different food matrixes [2-4]. Due to analysis rapidity and high sensitivity, the technique has become a reference tool for the investigation of the complex phenomena related to flavor perception [5].

In this work we describe a PTR-MS based approach to measure in-vivo nose-space VOCs concentration during chewing gum consumption coupled to discontinuous time intensity sensory evaluation.

Methods: (Limit of 400 characters)

Two different studies were conducted on chewing gums to monitor respectively differences in aroma release due to two different gum ingredients formulations and the effect of physiological parameters (oral cavity volume, salivary flow and papillary count), gender and ethnicity in flavor perception. Sensory evaluation on flavor intensity and sweetness was performed simultaneously with nose-space analysis with two different PTR-MS machines (PTR-ToF-MS and PTR-QiTOF-MS, Ionicon Analytik, Austria). A total of 40 panelists participated in the two studies.

Results: (Limit 900 characters)

In the first study, a significant difference in total aroma release (p .value < 0.05 ANOVA) was observed between the different chewing gum formulations. In particular, it was observed that these differences were compound dependent and that PTR-MS signals are associated to a high variability reflecting panelists' physiological differences. In the second study, ethnicity was found to have a significant effect on both in nose-space concentration and sensory perception. For different mass peaks associated to mint flavor compounds, Chinese panelists exhibited higher levels than European ones (p .value < 0.05 Welch's t-test) generally after 90 seconds of consumption and after the gum was removed from the mouth. The same trend was found in sensory perception both for flavor and sweetness attributes. No differences were found between panelists of different gender in both flavor release and perception.

Conclusions (Limit of 400 characters)

Real time mass spectrometry analysis by PTR-MS can detect and monitor in-vivo volatile organic compounds release during food consumption.

The results of the studies suggest a multimodal effect of aroma release on both flavour and sweetness intensity. Individual differences due to physiological, biochemical and physiocochemical phenomena may have a relevant effect in aroma perception and thus in sensory flavor perception. Although, it cannot be excluded a cultural bias due to an ethnocentric experimental environment, results suggest that higher in-nose concentration in Chinese judges may explain their higher flavor and sweetness perception.

Novel Aspect: (Limit of 150 characters)

Real time direct injection mass spectrometric analysis coupled with dynamic sensory methods is a powerful tool to investigate flavor perception mechanisms and highlight physiological and cultural biases.

237 - WASTEWATER-BASED EPIDEMIOLOGY: USE OF ADULTERANTS TO ESTIMATE COCAINE CONSUMPTION PATTERNS IN BRASÍLIA, BRAZIL BY LC-QTOF-MS

Katyeny Manuela Da Silva (1) - Adriano Otávio Maldaner (2) - Fernando Fabríz Sodr  (3)

University of Bras lia, Chemistry Institute/Faculty of Technology, Bras lia (1) - Federal Police, Federal Police, Bras lia (2) - University of Bras lia, Chemistry Institute, Bras lia (3)

Wastewater-based epidemiology: Use of Adulterants to Estimate Cocaine Consumption Patterns in Bras lia, Brazil by LC-QTOF-MS

Katyeny M. da Silva; Adriano O. Maldaner; Fernando F. Sodr 

Keywords: wastewater epidemiology, drugs of abuse, forensic toxicology, cocaine, adulterants

Introduction: Illicit drugs are a major public safety problem in Brazil. Findings of the Brazilian Federal Police concerning drug seizures show that levamisole (LEV) is the main adulterant in cocaine hydrochloride (mean of 13.2%), while phenacetin (PHE) is the mainly found in freebase cocaine – crack (mean of 15.2%).^{1,2} Thus, strategies based on quantification of LEV and PHE, together with the major cocaine metabolite, benzoylecgonine (BE), in wastewater may contribute to identify different forms of the consumed cocaine.³

Methods: Composite (24 h) raw sewage samples were collected at the entry of the two main wastewater treatment plants (NW-WWTP and SW-WWTP) in the Brazilian Capital, Bras lia. Aliquots of 50 mL (pH 2) were passed through solid phase extraction cartridges (StrataX) previously conditioned with MeOH:ACN (60:40) and H₂O (pH 2).³ Analytes were recovered with 6 mL of MeOH, the extracts were spiked with isotopically labeled standards (BE-d₃ and COC-d₃) and concentrated to 0.2 mL. Analyses were carried out using a liquid chromatography system coupled to a quadrupole-time-of-flight mass spectrometry (LC-QTOF).

Results: Results revealed a cocaine consumption varying from 750±120 to 2470±410 mg/day/1000 inhab in weekdays and 2340±1190 to 4580±750 mg/day/1000 inhab in weekends. In terms of load, considering cocaine purity in Brazilian seizures (49 ± 29 %)², we estimate an annual consumption of 2 tons of cocaine, in the region. PHE/LEV ratios found in seized cocaine street samples varies from 0.18 in hydrochloride cocaine to 15.2 in freebase samples, indicating the prevalence of crack consumption as PHE/LEV ratios becomes higher. Relationships between both adulterants in the sample evidenced a higher use of crack cocaine in the NW-WWTP region (PHE/LEV = 3.0±1.5) compared to SW-WWTP. The PHE/LEV ratio was the same in the SW-WWTP region (PHE/LEV = 1.5 ± 1.0) when compared to 2014 data,³ while the ratio for NW-WWTP region doubled suggesting an increase of crack users in this region.

Conclusions: The LC-QTOF-MS system allows the identification based on accurate mass measurements and quantification with multiple reaction monitoring. Regarding the forensic field, it is very important to know how a drug is consumed. The use of adulterants, such as PHE and LEV may be useful to provide novel information concerning cocaine consumption patterns and poliuse of drugs.

Novel Aspect: Alternative approach to differentiate crack and hydrochloride cocaine consumption based on the quantification of adulterants in wastewater samples.

218 - DUAL MICROPROBE CE-ESI-HRMS FOR THE CHARACTERIZATION OF PROTEINS AND METABOLITES IN SINGLE EMBRYONIC CELLS OF LIVE FROG EMBRYOS

Camille Lombard-Banek (1) - Rosemary Onjiko (2) - Sally Moody (3) - Peter Nemes (1)

University of Maryland, Chemistry & Biochemistry, College Park (1) - University of Maryland, Chemistry and biochemistry, College Park (2) - The George Washington University, Anatomy and Regenerative Biology, Washington (3)

Keywords: Single-cell, CE-ESI-HRMS, Systems biology, Proteomics, Metabolomics

Introduction:

Establishment of cell-to-cell heterogeneity is critical to the normal formation of different tissues in vertebrates. A system biology understanding of this heterogeneity with single cell resolution could provide important insights on how cell fate is established. We thereby developed a dual-microprobe sampling approach hyphenated to CE-ESI-HRMS to measure proteins and metabolites from the same identified single embryonic cells in the 8-cell frog embryo.

Methods:

A 10 nL volume was withdrawn from identified cells of the 8-cell *X. laevis* embryo using capillary microsampling. Metabolites were extracted in 40% acetonitrile/40% methanol solution. Proteins were delivered into 50 mM ammonium bicarbonate and trypsin-digested. All extracts were measured using our custom-built CE-ESI-HRMS platforms. Metabolites were quantified by using peak-area under the curve as a proxy of relative concentration. Proteins were quantified using MaxLFQ approach integrated in MaxQuant.

Results:

To advance the systems biology understanding of cell heterogeneity during embryonic development, we developed dual-microprobe sampling to collect two different portions of the cytoplasm from the same cell to measure metabolites and proteins. We used this approach on the D1 and V1 cells in the same 8-cell embryo. These cells are situated across the dorsal/ventral axis of the embryo. The approach is based on our previous microprobe-CE-ESI-HRMS protocol, whereby an ~10 nL volume of the cell cytoplasm is extracted, leaving the embryo essentially intact. We consistently quantified 335 proteins and 150 metabolite features. The different cells separated using PLS-DA analysis based on protein and metabolites profiles. Overall, 6 proteins and 5 metabolite features were differentially expressed. Using these quantitative data, we performed pathway enrichment analysis. We identified the arginine and proline metabolism pathway as one of the most statistically significantly enriched, which suggests its importance in early embryonic development.

Conclusions:

We have developed a dual sampling approach enabling the analysis of proteins and metabolites from the same cell. The collected data represent the first example of proteomic and metabolomic analyses from the same single-cell in a live embryo, providing new information on cell heterogeneity in the 8-cell frog embryo. Moreover, the technology promises to deepen our understanding of the mechanisms involved in embryo patterning during embryonic development.

Novel Aspect:

Dual microprobe-CE-ESI-HRMS enabled proteomic and metabolomic analyses in the same single-cell of live frog embryos.

34 - HISTOLOGY-DIRECTED PROTEOMICS: COMBINING AUTOFLUORESCENCE GUIDED MICRO-DIGESTIONS WITH LIQUID SURFACE EXTRACTIONS

Daniel Ryan (1) - Nathan Patterson (2) - Jessica Moore (2) - Jeffrey Spraggins (3) - Richard Caprioli (3)

Vanderbilt University, Department of Chemistry, Nashville (1) - Vanderbilt University, Mass Spectrometry Resource Center, Nashville (2) - Vanderbilt University, Department of Biochemistry, Nashville (3)

Title: Histology-Directed Proteomics: Combining Autofluorescence Guided Micro-Digestions with Liquid Surface Extractions

Authors: Daniel Ryan, Heath Patterson, Jessica Moore, Jeffrey Spraggins, Richard Caprioli

Keywords: Autofluorescence, LESA, Bottom-Up Proteomics

Introduction: (Character Count 400)

Liquid extraction surface analysis (LESA) has proven to be an effective approach for generating spatially-targeted, proteomics data from tissue.^{1,2} Current approaches enzymatically digest the whole tissue surface prior to extraction. When foci are smaller than the LESA spot size, signal from the area of interest is diluted. Herein, we demonstrate proteomic analyses of foci using histology-directed micro-digestions guided by autofluorescence (AF) microscopy.

Methods: (Character Count: 400)

Rat kidney tissue was sectioned and mounted on microscope slides. AF (fluorescence of endogenous molecules) microscopy images of a section was used to guide trypsin spotting onto foci of interest using a piezoelectric spotter. LESA samples from the individually digested foci were pooled and analyzed by LC-MS/MS on a Q Exactive Orbitrap mass spectrometer. Adjacent sections were digested using robotically sprayed trypsin to compare to traditional LESA approaches.

Results: (Character Count: 899)

Proof-of-concept experiments were completed using LESA to extract from undigested control sections, sections that were robotically sprayed with a homogenous coating of trypsin, and sections with trypsin spotted on foci guided by autofluorescence microscopy. The control experiments resulted in ~10 protein IDs per extract. Robotically sprayed tissue sections contained on average 250 protein identifications per mm² sampled by LESA. The robotic spraying approach also suffers from some analyte delocalization during the spray process, as monitored by AF microscopy of the tissue following digestion. This approach is poorly suited for targeting foci smaller than the size of the LESA extraction. LESA samples from micro-digested kidney using AF-guided trypsin spotting provided upwards of 1500 protein ID's per mm² sampled by LESA, a 5-fold increase compared to the robotic spray method. The diameter of the trypsin spots approach 100 μ m at its smallest, providing a 3-4 fold improvement of spatial resolution when compared to extracting via LESA alone.

Conclusions: (Character Count: 286)

LESA is limited to relatively large droplet diameters and is inadequate for studying small, discrete foci (< 400 μ m) often of interest in biological tissues. The combination of tryptic micro-digestions guided by AF microscopy and LESA circumvents LESA's spot size limitations by only producing digested peptides from the targeted foci.

Novel Aspect: (Character Count: 126)

Autofluorescence-guided tryptic micro-digestions combined with LESA allows for targeted proteomic analysis of small biological foci in tissue.

60 - COMBINING BIO-CONJUGATION AND MATRIX-ASSISTED LASER DESORPTION IONISATION MASS SPECTROMETRY FOR BIOMOLECULE DETECTION AND LOCALISATION IN TISSUES

Katherine Stevens (1) - Parul Mittal (2) - Andrew Abell (1) - Tara Pukala (1)

University of Adelaide, Physical Sciences, Adelaide (1) - University of Adelaide, Biological Sciences, Adelaide (2)

Keywords: MALDI, imaging, glycoprotein, cross-linking, bioconjugation

Introduction:

Membrane proteins are central nodes in the networks that allow cells to receive and transmit signals between themselves and their environment. These proteins comprise 30% of the proteome and their diversity is enhanced by post-translational modifications, such as glycosylation [1]. These proteins are involved in a range of diseases, including various cancers and inflammatory diseases [2,3].

Methods:

We have developed a matrix-assisted laser desorption ionisation (MALDI)-mass spectrometry (MS) approach that combines cross-linkers capable of targeting intact proteins within tissues, to enable their detection via MALDI imaging. This approach uses a novel photocleavable cross-linker that is released by excitation with a MALDI laser to produce a signature mass signal in the resulting spectra.

Results:

We have demonstrated a simple and versatile synthetic route for developing MALDI imaging cross-linkers, which contain a photocleavable moiety that is released by excitation using a MALDI laser and produces a signature mass signal in the resulting spectra. The mass signal can be easily modified as the design allows for a one-step addition of peptides of various lengths at the site of photocleavage within the cross-linker. Furthermore, the specificity of this probe can be modified to enable detection of different target biomolecules. The practical application of these cross-linkers has been confirmed by MALDI and electrospray ionisation (ESI)-MS experiments. We have found using MALDI experiments that we are able to detect the desired mass signal, which corresponds to the release of the expected photocleavage product.

Conclusions:

Based on our initial findings, we aim to apply this method for the detection of multiple glycoprotein targets simultaneously in tissue sections, as a potential new approach to cancer diagnosis. Additional ongoing research is focussed on optimising this technique for glycoprotein detection and developing similar approaches for targeting DNA oligos and glycan-binding proteins within tissues.

Novel Aspect:

This approach provides a method for detecting intact biomolecules using MALDI-MS. It has the potential for multiplexing by modifying the length of the peptide mass signal.

ETH Zürich, Chemistry and Applied Biosciences, Zürich (1)

Keywords: Target plate material, MALDI, anion formation

Introduction:

In MALDI mass spectrometry, initial charge separation and charge transfer processes remain elusive. To improve analyte anion signal intensity, enhance sensitivity, and gain more insight in the roles of the target plate material and matrix in MALDI anion formation, a systematic study was carried out. The influence of 21 different metals and alloy substrates, and a range of matrices, in the absence and presence of diphenyl phosphate (DPP), on anion yield, was studied.

Methods:

Molecular anion signal intensities were systematically analyzed and compared by varying laser fluence for substrates with varying melting points, thermal conductivity, electrical resistivity and work function. A comparison of DPP molecular anion signal intensity was made, based on the matrix UV-absorption (λ : 337.1 nm), electron affinity and crystallization. As many factors as possible were considered to explain observed anion signal intensity differences.

Results:

Metals with oxide layers that, upon surface ablation, show an intrinsically high anion formation in absence of a deposited sample, provide the highest DPP anion signal intensity. Using Ag as target plate material generally increases the analyte signal intensity 10-fold relative to the conventionally used stainless steel. Metals with high melting points (such as Cr, W, Mo, Ta) tend to underperform. For most metals, the homogeneously deposited fullerene-C60 performed best as a matrix, though anthraquinone and 9-cyanoanthracene performed best on Ag at the highest tested laser fluence.

Conclusions:

We conclude that when matrix and target plate material are chosen carefully, this can significantly enhance the ion signal intensity of an added analyte in MALDI. Hence, the commonly used stainless-steel target plates should be reconsidered. The target plate material acting as a catalyst, resulting in different anion signal intensities, should be considered, along with the potential of MALDI to predict catalysts for (photo-)chemical reactions.

Novel Aspect:

Target plate material strongly affects the outcome of the ionization process and a proper choice enhances ion yields significantly.

PLENARY LECTURE

1411 - LITHOGRAPHICALLY PATTERNED ELECTRODES FOR MINIATURIZED ION TRAP MASS SPECTROMETERS AND OTHER ION OPTICS DEVICES

Daniel E. Austin (1) - Stephen A. Lammert (1) - Aaron R. Hawkins (1) - Yuan Tian (1) - Ailin Li (1) - Trevor Decker (2) - Brett Hansen (1) - Qinghao Wu (1)

(2)

Lithographically Patterned Electrodes for Miniaturized Ion Trap Mass Spectrometers and Other Ion Optics Devices

Keywords: microfabrication, ion trap, planar electrode, charge detection

Introduction:

All mass and mobility analyzers rely on carefully shaped electric fields (sometimes combined with magnetic fields) to separate ions. These electric fields are traditionally established using shaped metal electrodes. We have demonstrated several types of devices in which electrodes are patterned onto circuitboard or onto rigid substrates (ceramic, glass). Advantages include miniaturization, novel devices, and complex electrode arrangements.

Methods:

We have developed quadrupole and linear ion traps, concentric dual ion traps, multi-stage image-charge detectors, charge detection mass analyzers, and electrostatic ion beam traps. Recent studies have focused on substrate misalignment effects, modeling the electric field, and microparticle analysis.

Results:

We have demonstrated the operation of a sub-mm linear ion trap with better than unit mass resolution for small organic molecules. We have also observed the effect of misalignment between electrodes in several degrees of freedom (corresponding to the possible orientations of the substrates), and compared the measurements to simulations of misalignment. Using angled electrodes printed on circuitboard material, we can measure the trajectory of microparticles passing through a vacuum system, such as the divergence from an aerodynamic lens or microparticle-surface impact and rebound. We are also developing a microparticle analyzer (mass, charge) for a future mission to study aerosols on Mars.

Conclusions:

These devices demonstrate the utility and flexibility of creating complex and miniaturized devices for ion analysis using electrode printing on substrates. Electrode alignment, which is critical for many applications, is easily explored using alignment between plates. Charge detection with printed electrodes has the same sensitivity as conventional metal electrodes.

Novel Aspect:

Novel approach to making ion optics devices including ion traps and charge detection analyzers. First study of misalignment effects in ion traps in multiple degrees of freedom.

1407 - ADVANCES IN MALDI IMAGING MASS SPECTROMETRY: MOLECULAR MICROSCOPY IN THE NEW AGE OF BIOLOGY AND MEDICINE

Richard Caprioli (1)

Depts. of Biochemistry, Chemistry, Pharmacology and Medicine Vanderbilt University School of Medicine
(1)

Caprioli Abstract for IMSC, Florence 2018

ADVANCES IN MALDI IMAGING MASS SPECTROMETRY: MOLECULAR MICROSCOPY IN THE NEW AGE OF BIOLOGY AND MEDICINE

MALDI Imaging Mass Spectrometry (IMS) has been employed in studies of a wide variety of biologically and medically relevant research projects. This technology has seen significant advances in both the instrumentation and in the fields of basic biological investigations and medically relevant applications including patient biopsies. Several of these applications will be presented in this presentation. In addition, new technological advances will be described, including sample preparation and instrumental performance to achieve images at high spatial resolution (1-5 microns) and at high speeds in order to minimize image acquisition time. Instrumentation improvements include those developed for both MALDI FTICR MS and MALDI TOF mass spectrometers and will be demonstrated by specific applications. Finally, new biocomputational approaches will be discussed that deals with the high data dimensionality of IMS, image registration with microscopy, and our implementation of 'image fusion' in terms of predictive integration of MS images with other imaging modalities.

1345 - AT THE INTERSECTION BETWEEN CHEMISTRY AND ART: SCIENTIFIC RESEARCH FOR THE STUDY AND PRESERVATION OF CULTURAL HERITAGE.

Marco Leona (1)

Department of Scientific Research, The Metropolitan Museum of Art, 1000 Fifth Avenue, New York, NY 10028 (1)

At the Intersection between Chemistry and Art: Scientific Research for the Study and Preservation of Cultural Heritage.

Keywords: cultural heritage; art; Raman; x-ray fluorescence; mass spectrometry.

The creation of a work of art is a process often depicted as untouched by material constraints. Pure, unfettered inspiration, without the limitations imposed by physics. It should be evident, however, that only with materials having defined physical properties a certain esthetic effect can be obtained. Works of art are complex technological objects: their appearance and their performance over time are the results of a careful selection of materials and techniques. Thus, artists' choices can be interpreted not just in the classical framework of art history, but in a holistic approach encompassing esthetics and technology. In absence of direct testimony from their often anonymous creators, masterpieces of the past become key material evidence in our efforts to retrace the working practices of artists, the technical knowledge and esthetic preferences of ancient cultures, and the complex trade patterns linking distant empires.

The quest for color, for beauty is a fundamental constant in human history, as well as an economic engine, and an inspiration for art and technology alike. While we easily recognize that the desire to produce richer and more lively images is a clear driver to seek new materials, on the other side of the world, in mines or forests, or in the crucibles of the alchemist (or of his modern counterpart, the chemist), we often overlook how new materials lead to new esthetics.

Scientific investigations have expanded significantly our understanding of works of art, often upending traditional interpretations. A typical example is the rediscovery and investigation of the original polychromy of ancient Greek and Roman sculpture, once a contested topic and now an established research field. Many more cases highlight the importance of the work of cultural heritage scientists, not only in investigating works of art, but also in developing the techniques that make these studies possible. Examples include the discovery of the earliest organic pigment, in a 4,000 years old Egyptian leather fragment; new insights into the global trade of dyes in the Middle Ages; and closer to us, the introduction of synthetic pigments and dyes in the 19th centuries, from the craze for mauveine to Van Gogh's unfortunate passion for geranium lakes, passing by Hokusai's experiments with Prussian blue in the Thirty-six views of Mount Fuji, and the color revolution prompted by the arrival into Japan of the aniline dyes in the Meiji period.

Using advanced analytical chemistry, from x-ray fluorescence spectrometry to Raman and surface-enhanced Raman spectroscopy, from electron microscopy to mass spectrometry, we can build a material history of art based on physical evidence gathered from masterpieces spanning four millennia, from ancient Egypt to Modernity, demonstrating that technological developments were not only readily embraced, and often prompted by artists and their audiences, but also that they in turn created new forms of expression, in a continuous dialogue between materials and meanings.

1320 - MASS SPECTROMETRY AND THEORETICAL CHEMISTRY IN SERVICE OF CATALYSIS RESEARCH: A MÉNAGE-À-TROIS AT ITS BEST

Helmut Schwarz (1)

Mass Spectrometry and Theoretical Chemistry in Service of Catalysis Research: A Ménage-à-Trois at Its Best

Helmut Schwarz

Institut für Chemie, Technische Universität Berlin, 10623 Berlin, Germany

Helmut.Schwarz@tu-berlin.de

The ultimate goal in heterogeneous catalysis is to make use of each and every atom of supported (metal) catalysts, i.e. in the extreme to perform single-atom catalysis (SAC). While this arduous task constitutes a non-trivial, if not daunting challenge in 'real-life' chemistry, in the gas phase SAC can be achieved in a rather straightforward manner by conducting experiments with mass-selected species under (near) single-collision conditions. These mass spectrometry-based studies on isolated reactants, when complemented by state-of-the-art computational and spectroscopic work, provide an ideal arena for probing the energetics and kinetics of a chemical process in an unperturbed environment at a strictly molecular level without being obscured by ill-defined side effects. Thus, the concept of SAC can be explored or, more generally, the mechanisms of reactions and the active parts of single-site catalysts, the so-called 'aristocratic' atoms, can be identified.

Examples discussed include:

The room-temperature, cluster-oxide mediated redox reactions of the CO/N₂O couple which, arguably constitute one of the most prominent oxidation processes, and novel metal-mediated C-H bond activation and C-C coupling of methane, which are regarded as one of the holy grails in chemistry.

1408 - DRIVING INNOVATION - FROM A PROTEIN SEQUENCE TO A PROTEOME

John R. Yates (1)

The Scripps Research Institute, La Jolla (1)

Keywords: proteins, proteome, tandem mass spectrometry, informatics

Introduction:

Proteins are the workhorses of the cell. They are the molecules that catalyze the reactions for the metabolic and catabolic activities of the cell, transmit signals and transport necessary molecules and metabolites. Proteins operate in systems, which can be pathways, organelles, cells or even tissues. The development of proteomic technologies allows the study of proteins in the context of cellular systems. This lecture will trace the development of some of the methods of proteomics and demonstrate their use to understand mechanisms underlying the disease Cystic Fibrosis.
